When the curtain is rung down on this little talk of mine, I feel sure you will be convinced that there is at least some truth in the maxim that art is long and time is fleeting. Not that this is to be a studio talk. We'll leave the question of technique, mediums and kindred topics in the hands that hold the palet and ply the paint brush. We'll forget, as much as possible, the mechanical processes of the engraving shop and the printery; and we'll confine ourselves, in a general way, to the interesting art of laying out and making up a magazine. It's a long story. I can only hope to touch on it.

I called it an interesting art. I should have spoken of it as a fascinating art. In my opinion there is nothing more absorbing in the work-a-day life of an editor, nothing in connection with his job that will give him more of a "kick" than a serious application to the problems that determine the appearance of his magazine.

Every magazine, regardless of its classification, has a personality. Just as with human beings, some personalities are good, others are bad and a whole lot are just plain indifferent.

Appearance has a great deal to do with personality. You've often heard it said that clothes make the man—but before you get the clothes you've got to have the man. A skeleton in a Brooks suit and a Stetson hat wouldn't make a successful stage Johnny. Nor would a string of empty sentences and silly phrases dolled up with the finest illustrations and decorations of the period make a successful magazine. Give some real, virile copy a good suit of Sunday clothes, however, and you've got a house publication combination that can't be beat. It'll come close to hitting the bull's eye every issue.

As with all types of creative art, no rule of thumb governs the presentable appearance of a magazine. To get the right result is simply a matter of exercising good taste and common sense, after a knowledge of the possibilities and the limitations of type, engraving and printers' ink has been acquired and the amount of money to be spent has been determined.

With many, the amount of available money seems to be the most important factor. Certainly the more there is to spend, the more art work, plates and colors may be employed by the editor. That money is the keynote of success in the matter of appearances, however, is an erroneous idea.

A magazine may be elaborate; it may be plain; or it may be some-

where in between; but it can always be good. You will find there is color in ordinary black ink; and beauty in plain printing type—providing thought and care and discretion are used in their employment.

"What face and size of type shall I use in my magazine to get the best results?" you might ask me. "How many illustrations shall I use, and how much, in proportion, shall I spend on art work?" Frankly, I don't know the answers to these questions. They are matters for you to decide—and you'll not be able to decide them over night, either. To produce the best within your means requires much thought and concentration. In this business, as in everything else, the law of compensation applies. Never be satisfied with your first decisions. They may be the best, but take time and trouble to prove this to yourself.

In trying to arrive at an answer to these questions, recall to mind the purpose of your magazine. The dress of the issue is always tied up with the editorial aims and purposes.

First of all, the success of your publication depends upon its being read, and therefore your main consideration is the legibility of the type you employ. There are too many periodicals on the market for people to bother straining their eyes with mean, small and irregular type. They just won't do it. The conservation of their sight is more important than the information to be derived from the text.

There Are Many Excellent Type Faces

Now, there are a number of excellent type faces that may be selected from the hundreds of styles made. Here is where your printer can be of valuable assistance. If you feel your type is not as legible as it should be, go over the matter with him. Pore through his type books and get his opinion. He's supposed to know more about type styles than you are. It's his business. And if he's worth being called a printer he won't suggest any tricky type with queer descenders and flourishing seraphs for the body of your book. He won't advise the use of a job-lot assortment of a number of faces and combinations like they used in Victorian days before the dawn of the plant publication.

Legibility, of course, does not depend entirely upon the style of type. Once you have picked out a face that is clear, bold and well rounded you must turn your attention to its size and spacing. Five or six point type—even eight point—is too small to use for the body of a magazine. Choose a size that stands out, line for line and word for word, and yet blends into a harmonious whole. Set it in a width measure that is not too long to tire the eyes as they run across the lines. Frame it in a margin of sufficient width to make the type stand out like a picture. Then, without illustrations or decorations of any sort, you will have a page that will be both legible and attractive.

So much for type. Let's think some about dressing it up. First, illustrations.

As you know, there are many types of illustrations; many mediums in which they may be effected. I use the term illustrations in this case in its broadest aspect.

Most common of all with plant publications is the photograph. Then come the productions of artists, like pen and ink, pencil, charcoal and dry-brush drawings; oil paintings; water-colors, opaques, temper paintings, etc.

Depending on the ability and the reputation of the artists, this latter class of illustrations is expensive—at least when the circulation of a magazine is limited. Publications that run only into the hundreds can seldom afford to pay a reasonable price for art work, and regardless of circulation, no magazine can afford to buy cheap work. You get what you pay for, usually, and it doesn't pay to run poor drawings.

But photographs are different. Certainly they vary just like drawings and paintings—but the variation is not as noticeable to the layman's eye. Many photographers command as much money for their pictures as the average good commercial artist and I mean by that that one print often exceeds the hundred dollar mark in cost.

On the whole, however, photographs are comparatively cheap. Many of them can be taken by the editor, many of them are contributed by the readers, the "hard ones" can be snapped by a professional at a nominal cost. And since it is these classes of photographs that we editors mostly deal with, let's look a little closer into the interesting possibilities they present.

Amateur Photographs Are Often Commonplace

As they reach the editor's desk, photographs are often commonplace in appearance. They have a square finish. The garden variety is usually devoid of interesting composition, and oftentimes show figures with amputated feet, clipped hats, sliced arms, etc. In most of them, the background either predominates over the real center of interest or is monotonous and uninteresting. There is sometimes too much foreground; there is sometimes too much sky. In short, the perfect photograph is a rarity. So the question is: "What treatment shall I give this picture to make it interesting, attractive and effective?"

That, then, brings us to the matter of layout.

The arrangement of a printed page—which is the unit of a magazine—reflects either care or carelessness. If the type and illustrations are just thrown together, then the question is one of simple mathematics where the problem is to fill a given space with something or other—and that's that. The result will show it.

But a good looking, well balanced page is a crystallization of something that was first an idea, a creation of the mind. Where a thing is only in the mind it can be shifted around and arranged at will according to the dictates of the imagination. When it's frozen into type and engravings, and running on the press, well—that's the end of it. So, in laying out a page, I'd suggest that you spend a good deal of time in silent thought. It's no crime to stick your feet on the desk, your thumbs in your vest, puff a cigarette and let your body loaf while your mind does some high-powered thinking.

Here's the problem to work on: given a certain amount of copy and a

certain number of photographs, figure out what arrangement will lend to them the most attractiveness.

Experience is the best teacher in gauging the amount of space that will be occupied by the copy on hand when it is set in the type that you use. When this has been estimated, you will know, roughly, how much space on the pages is available for the illustrations.

Some editors have their type set in galley form before they think of placing the illustrations. In this case, the cuts are usually made in either column or page widths and are pasted in the dummy along with the galley proofs that are cut to fitting sizes. Now while that is the cheapest and the easiest method of making up a page, there is another way of doing it that will produce infinitely better results, that will add considerably to the attractiveness of the issue and that will relieve the monotony of the pages because of the variety of combinations that can be produced. This method requires the making of the engravings before the printer starts to set the type. For want of a better name, I'll call it the "run-around method." Incidentally, if you exercise care, it does not cost a great deal more than the galley method of make-up.

Planning the Attractive Page Make-up

This is how it is done!

When you have visualized the appearance of the pages to be laid out, get out your pencil and some sheets of paper. For this purpose in *The Telephone News* office we use regular layout sheets which we have our printer prepare for us in quantities. Sketch out on the paper, roughly, your idea of how you imagine the pages should look. Rough out a lot of different combinations. Remember that it's a whole lot easier to rub out a pencil line on a piece of paper than it is to look at an ugly printed page of your own making. And remember, also, that hundreds of other eyes besides your own look at the printed page. Don't be afraid to make changes and alterations. It's not wasted time. Do it a dozen different times, if necessary, until you're completely satisfied with the result. You need not be an artist to do this, any more than a man who makes blue prints need be a skillful painter. These roughed out pages, in reality, are the blue prints of your magazine.

Remember in making your layouts that, excepting the front and the back covers, no page in your magazine stands alone. Every page has a companion page opposite and the two should harmonize in balance, arrangement and "color". When you do your page planning, therefore, consider as well the page that is to go opposite it. Otherwise there will be a clash of contrast and perceptible rivalry for attention.

On determining the position of the different pages, I have found that drafting a tentative program of the contents of the coming issue is of decided helpfulness. This program is arranged so that the opposing pages are shown at a glance. The program consists of two columns, with the title of the articles listed alongside the page numbers they will occupy. Page 1 stands by itself on the right hand column. Pages 2 and

3 are opposite each other, as are pages 4 and 5, 6 and 7, etc.—just as they will appear in the bound magazine.

To get the proper composition and balance, do not run all of your photographs with a square edge. Employ curves and ovals; cut in the corners where it can be done judiciously; overlap your illustrations for the sake of variety; and sprinkle in a few vignettes and outlined figures. In using these different shapes and combinations, caution, of course, is necessary. Never try to make a page look too "tricky." Beware of outlining profiles, lest the nose, the brow or the chin be altered in the engraving. Queer, unexplainable shapes and indentures should be tabooed.

Feet that have been cut off in the photographic print can be painted in—skillfully—by your engraver at a nominal cost; likewise missing hat tops and other appendages that would spoil the picture. Where these can not be painted in, stripping another photograph over the one that is incomplete, oftentimes solves the problem. It requires actual photographs and actual conditions to determine an exact treatment.

Strive for a "swing" across the opposing pages in the arrangement of your pictures. Curves are always more pleasing than straight, angular lines. The symmetry of a Grecian urn is more graceful than the hard edges of a cubical box. A sweeping arc is more charming than the cold outlines of a pyramid. Bear these shapes in mind; they will assist you in planning your magazine.

Adapting Drawings to the Page Plan

In the event of your using drawings instead of photographs have the artist make his pictures in the shape that you think will look well in the magazine. Drawings can not be tampered with like photographs because the artist eliminates everything that is not essential to the picture, and altering its shape when it is finished will usually spoil the picture. The time to change a drawing is when the artist submits a sketch of what he intends to draw. That can be changed around as much as desired or discarded altogether.

On every hand you will find examples of good make-up. The big magazines all employ skillful, high-salaried art editors to plan the appearance of their pages. These art editors are experts and their work bears study—and imitation.

While imitation is to be recommended, the execution should be done in a professional way. The subjects involved should be of such type that they will fit harmoniously into the composition. Otherwise imitation is a dangerous and foolish thing.

And above all, when in doubt stick to simplicity in layout. Never, under any circumstances, become extravagant or tricky or foppish. Always there is safety in simplicity.

When General Lew Wallace arrived at the climax of his masterpiece, "Ben Hur," where his task was to describe that most famous of chariot races, he chose a style that was the essence of simplicity, yet that carried with it the excitement, the tumult and the thrill of the packed arena and

the speeding chariots. "The race was on," he wrote. "The souls of the racers were in it. Over them bent the myriads."

As with writing, so it is with art and magazine layout. Simplicity in appearance imparts strength and bespeaks sincerity. Consciously or unconsciously a sincere and attractive appearance will win and retain the support of the readers of your magazine. They will look forward to its delivery. They will contribute to its columns. They will heed the advice and assistance that is offered them.

After all, that is the mark that editors shoot at.

CHAIRMAN DOELLER: Mr. Herr, I want to thank you personally and officially on behalf of the Section. I will now call on Mr. Bronson B. Tufts, of the Hercules Powder Company, Wilmington, Delaware, to lead the discussion.

DISCUSSION OF MR. HERR'S PAPER

Bronson B. Tufts, Editor "The Mixer," Hercules Powder Co.,
Wilmington, Delaware

There are four elements that enter into make-up, and paper, I think, is the first one. You can get a good layout, a good photograph, and if you have poor paper, it spoils it all.

Mr. Herr said that money, to his mind, is not a deciding element in getting out a magazine. I differ with him there, because good paper and good photo-engraving cost money. I find that the printer and the photo-engraver can help you a lot, the photo-engraver especially, because he can take the poor photographs as they come to you, and he can get out of them a great deal more than is in them.

In making up the magazine, or rather the page, some of you are in the same position that I am. I can't devote all my time to the magazine. I get a whole lot of photographs in the morning mail, but I haven't the time to look them all over. I send them to the photo-engraver and tell him that I want such-and-such a photograph in the middle of the page and to build the others around it, and he makes up the page for me. Of course, I have to pay for that. You can go to a cheaper man to have it done, but he may spoil them.

Mr. Herr spoke of two ways to make-up the magazine; first, galleying your matter, having the cuts made, and the run-around method. In making up my magazine, I use these sheets. Probably a good many of you use these or ones similar to them. Our measure is two columns, each 21 picas wide. The back of the book is a three-column, 13-picas wide. We have 12 pages of this measure (indicating) and 12 pages of this measure (indicating). We have an editorial page and the balance of the magazine is for the pages of 13 pica width.

This is a two-column, 21 pica page. I have always been taught in making up a page of this kind where you want to use a large photograph, that you first should have the caption or heading, and in between your heading and the body of your story to have the picture, because it is

always much better and always more attractive. Still, I notice the *Saturday Evening Post*, for one, puts the heading, then the picture, and then the story.

Of course, in making-up I generally reserve the page opposite the editorial page for miscellaneous pictures. You may get a lot of pictures late, or you may have some that you wouldn't want to put anywhere else, so I just group them altogether on this page.

You see, our main office is in Wilmington, Delaware. We are a little differently situated than many of you people. We have approximately 20 plants, from New York to California, and from the Mississippi up into Northern Michigan. I can't get around to see them all, so I have to trust to the correspondents at the different plants to send the photographs and the information in to me.

I think I will probably be disputed on this, but I think one curse of the plant magazine is the amateur cartoonist. You probably have all had trouble with him. I know in our organization we have a fellow who is a good friend of mine, but he is a cartoonist of this kind. He comes to me and says: "Why don't you use my material?" I hate to tell him that it is no good, but it is the truth, and I will have to do it some time.

When we use a cartoon, we try as much as possible to use first-class work. We pay for it. You have to pay for it, if you want good, first-class work, but it is worth it, I think.

The Back Page Carries a Company Advertisement

This is a page that we made up for the summer number. One of the young ladies at our plant wrote this verse. I wanted to use it here, so I took one of these sheets, which I always use when I have a page like this. I tried several different ways of making it look attractive and finally I sent it to the artist and asked him to read it and to give me his ideas for a border. He did that, and this is the result. This artist, incidentally, draws for the *Country Gentleman* and other magazines of that type.

On the back page, we generally run one of our company advertisements. We want to let the employees know what kind of advertising we are doing. They don't all see the advertisements unless we do that.

Mr. Herr has said that simplicity is the keynote to success, and I agree with him. I think some of our pages may be criticized as being severe. Personally, I don't like too many curves on the photographs, and I would rather spot three photographs that may square than to make them fancy. I think they always look better.

CHAIRMAN DOELLER: Mr. Tufts, we want to thank you also for your contribution to this program.

At this time I want to interrupt just a minute before we get into the discussion of these papers, and introduce a distinguished visitor who is internationally known and who knows more about the human interest problems than any other man in the United States. I am going to ask Mr. Whiting Williams to give us a word at this time.

WHITING WILLIAMS: I feel that I am out of my element in talking on the technicalities of the magazine. On the other hand, I don't take second to anyone in my belief in the tremendous possibilities of the plant magazine in these days, especially of the approach—it might be called, the dramatic approach.

The fault I find with the ordinary magazine that I take up is that it is too aesthetic. This is not true of the plant magazine. I believe what the average reader of a plant magazine desires is the approach to any subject in terms of some specific experience. One of the great words around the plant is, "Let me tell you my experience." The worker never attempts a generalization; he don't know much of concepts, except in the terms of a definite experience. I believe if the plant magazine has that sort of approach, there is a tremendous opportunity for the plant magazine to do a much bigger job than the ordinary magazine attempts.

Educating the Employee in His Own Job

Today we are so specialized in these individual jobs, that there is no possibility of trying to do away with specialized workers. There is no possibility of getting a man to do in his work a part of the process which gives him an idea of the entire process. Just that fact, however, gives a big opportunity to the magazine to supply the frame of the picture, which gives meaning to the individual thing that he does.

I must tell you a story along that line. About the time the electric iron first came out, the men who worked in the steel plants, rounding out the steel didn't know what it was used for. I went around and asked each one of these men individually what this steel was for, and not one of them could tell me, except that you had to be damn careful. About three years later I went around again and asked the men where the stuff went to. One of the men said to me, "Can't you see it goes over to the inspection department, you damn fool." That was as far as I got.

I visited Mr. Ashe and others there at the General Electric and they asked me how I would like to see what they did to make the motors. I never will forget the thrill I got when they took me into the plant and showed me the big piles of steel, and said, "Here is where the thing starts," and then I went all through the process.

So you see, the plant magazine can help people to see what they make is used for. It is absolutely necessary that you teach them, because the average man is apt to think that all that men work for is money, and they don't care what it is all about.

There is one more story I must tell of what the foreman said to a lot of foreign workers that were supposed to be interested in money. They didn't care what they had to do as long as they got the money. The foreman said: "Dig me a hole six feet deep." About a half-hour later he said, "Dig me another hole about six feet deep." A half-hour later he said, "Dig me a hole six feet deep." Those fellows went on digging. They cared nothing about the purpose of the work, and they would go

on indefinitely if we paid them the money. One of the fellows, however, said to the foreman, "No, we quit. We damn fools for nothing. What the hell!"

The foreman said, "What, you don't understand? We have got to find a water pipe. The drawings have been lost and it is up to me to find it. I will lose my job unless I find that water pipe, and I wish you would help me."

The workmen said, "All right, we will help to find the pipe."

Now, the plant magazine's big function today in this era of specialized industry is to help to give the man a picture of the value of the work that he does by indicating what goes into it and what becomes of it, and what the meaning of the whole thing is. It will help him to realize the part that he is playing in the manufacture of that thing. That is done by means of the dramatic approach. It seems to me that the plant magazine plays a part in the industrial relations, and in the contentment and in the worthwhileness and the entire effectiveness of the organization that is secondary to no other thing I know about.

CHAIRMAN DOELLER: Thank you, Mr. Williams, for this word of advice you have given us. I know it is appreciated by all of us.

We will now proceed with the discussion of this last topic.

Queer Shapes in the Pictures May Be Overdone

G. F. CLOSE (Commonwealth Steel Company, Granite City, Illinois): I have been quite interested in the way in which the cuts are dressed up and dolled up in some magazines. In some magazines they are taking the background away, and particularly you will see the cuts rounded on the top or possibly straight on the top and rounded on the bottom and all kinds of things done to make them look different. I just wonder how far, in the experience of the editors here, is that a good thing? I am inclined to think that we can overdo it. My thought is that a page with the cuts mostly square or occasionally with a variation makes a better looking magazine than where most of the cuts are put into all kinds of different shapes.

I was just wondering what the impression of the editors here was as to whether that sort of thing does particularly appeal to the reader of the magazine or not, or whether it does not perhaps take away something from the dignity of it?

MR. TUFTS: I don't believe in having them square. A few curves at the top of the pages and sometimes an oval or a circle in a group layout are good, but I would much rather see a page severe and plain, because too many curves are bad. I don't like them.

M. L. HENDERSON (Bucyrus Company, South Milwaukee, Wis.): I have been a commercial artist for a good many years, touching up the photographs. I agree with you that a lot of severity is a good thing in a plant publication, but if the pictures that come in are donated, they generally have poor photography in them.

About a month ago, we sent our photographer to get a bunch of pictures of a picnic. One of the pictures I had in making the layout was a group of 10 or 20 girls on the grandstand, but the background was very dark. The only way to bring out the picture was to touch it up.

Other pictures that we get are construction pictures, which show long roadways, or a lot of machinery, and in order to bring out the details, it is absolutely necessary to outline it.

Last week I had a bunch of pictures of operators working in the dead of winter with shovels, and the machinery was in around the trees. The way the picture was taken, it was absolutely impossible to make out the machines, and therefore, we had to cut out part of the trees, so as to show where the machines were. So, it is absolutely necessary to cut up a lot of those pictures.

Amateur Cartoons Are Often a Problem

The question came up a while ago of using pictures at the head of the page. Many articles are headed with the main headline and then the sub-headline. If it is an important sub-head, put your main headline at the top and then cut your photograph, cut it up so as to draw attention from your main headline down to your sub-headline. Work the layout the way the advertising people do it. Use the picture with the same effect as you would an arrow, but cutting it out and leading the attention down from the headline to your sub-headline, bringing emphasis on it.

MR. AUGUSTUS: I would like to have an expression from the editors as to whether they think amateur cartoons a good thing or not. Are we putting out the magazine for ourselves or for the boys who read them? Personally, I have been running a page of them for six years. When the men receive the magazine, that is the first thing they look at. If I cut it out, they will come to me and say: "Aren't we running the cartoons any more?" Aren't we putting out the magazine for our readers and not for ourselves? If we are putting it out for the boys in the plant and they like it, shouldn't we give them what they like?

VICTOR H. KUPFERER (The Studebaker Corporation, South Bend, Indiana): All I have got to say is that Augustus is lucky to have a fellow draw a page for him every month.

G. F. CLOSE (Commonwealth Steel Company, Granite City, Ill.): We don't use cartoons very much. We have a man in the office, a photographer, who is more or less of an artist, and when we get cartoons that we want to use, we just ask the man if he has any objection to us reproducing them in a better artistic form without changing the subject, and we find he is glad to have us do that.

MR. KUPFERER: I don't think there is any way of bringing out a point stronger than by use of the cartoon. If the man will go to the man who makes the cartoons and say to him, I have a certain idea, and give it to him and ask him to make a cartoon of it, he will do so. If the editor gives this man the idea that he wants to put across, the cartoon will do it for him.

CHAIRMAN DOELLER: How many of the editors use paid service, that is, buy the cartoons or photos?

(Six raised their hands.)

CHAIRMAN DOELLER: How many use local talent?

(About 50 raised their hands.)

J. C. BETHURUM (Buick Motor Company, Flint, Mich.): I believe the argument was against the cartoon that was on the face of it so amateurish. I would like to feel the men out on whether or not it is worth the money it would cost you to have the ideas drawn by somebody who knows the business rather than by the amateur.

CHAIRMAN DOELLER: The consensus of opinion seems to be opposed to the amateur. Maybe it is a matter of economics. Let's have some discussion on that.

MR. HERR: I think a lot of people believe that the average man in a plant has no conception of beauty and that anything drawn up with a very amateurish touch is good as long as it has an idea to it, and it will get across with him. Perhaps that is right. I don't know. I do contend that everybody, regardless of their standing in life, does appreciate beautiful things, and they unconsciously or consciously realize the difference between amateur work and professional work.

Helping the Cartoonist With Various Suggestions.

A cartoon isn't necessarily a piece of art, but there is a professional touch to it that you can see and feel. I think it is much more worth while to present a good drawing that will help the appearance of your page than to present something grotesque. A cartoonist caricatures, but he does not make his subject necessarily horrid as amateurs, try as they will, can't help doing sometimes. In engraving, you will find that the amateur drawing of a cartoon with ordinary writing ink won't give you the possibilities of giving a real reproduction to his work. Sometimes it is a matter of experience, and sometimes it is a matter of keeping your crowd happy when you use these things. Personally, I think that your best solution is to get good art work when it is done, just so long as it has a good professional touch to it, and you as editors are the judges of that.

HERBERT W. ALLEN (M. Wile & Company, Inc., Buffalo, New York): I usually furnish the would-be cartoonist in the plant with a sheet of paper on which he does his cartoon work. I give him the sheet and tell him the cartoon must fill the sheet, and then when they are reduced they look very much better. I then get it done over by an artist.

FRANK CHIVERSON (Olds Motor Works, Lansing, Mich.): Being an artist as well as an editor, I can give you a solution to some of the troubles. If you have a cartoonist in the plant, furnish him with a photograph of the subject you want cartooned. Have him take his pen and simply draw over the features of this photograph, a pen-like drawing. You can get from your photographer a solution which will then simply dissolve your photograph entirely, leaving your pen-like sketch on the top, which is a good portrait of the thing you want cartooned.

HARRY D. LIVERS (Southwestern Bell Telephone Company, St. Louis, Mo.): I am not an editor, but the Hercules Powder man made some statements that I didn't like, and I just want to ask him something about them. Should an editor turn out bad copy or depend on the printer or engraver to do his job for him because he thinks he don't have enough time or should the management hunt a new editor?

MR. TUFTS: Well, it wasn't bad copy I was talking about, it was bad photographs. The editor is not responsible. If you give him a poor photo, you are not going to get good results. Many times you get out of them more than is in them.

MR. RICHARDSON (Erie, Pa.): I think I can answer the gentleman's question. I think if the management has the idea that they want to get out the plant publication, they should let the editor give his full time to the preparation of that paper, and not have him do some other duties.

MR. LIVERS: What is an editor, what does he do, and what is he for?

MR. TUFTS: One of his duties is to get the engraving done the best but at the cheapest price. If you are going to buy a good suit of clothes, you are going to a good tailor, and that is what I do with my engraving.

New Classification of Points for the Contest

G. F. CLOSE: I believe an editor ought to do all the work he can himself. There are a lot of things of a technical nature where technical assistance is very desirable, but on ordinary work, I think the editor ought to do it himself. Our paper, *The Commonwealth*, is printed by a printer whose first name is service. Anything along the line of advice or suggestions as to arrangements and cuts, he is more than glad to give. He gives us all the service we want. I think it is a good idea to take all the assistance we can.

Somebody asked, "What is an editor?" The answer is that he is a goat. "What is he for?" He gets nothing if it is good and he gets hell if it ain't.

CHAIRMAN DOELLER: For those who were not at the luncheon today, I want to announce that a new classification of points will be in vogue next year for the contest. For "Safety," 25 points instead of 40. "General interest," 20, the same as it was. "Educational features" was raised from 15 to 25. The "General Character" of the paper, the same as it was, 10. "Make-up and Art" was raised from 10 to 15. "Unusual Features" will be the same as it was, 5 points. This probably will also be announced through the NATIONAL SAFETY NEWS.

One other thing was suggested in that meeting, and that is, that we have two classifications for basis of judgment, the purely magazine type and the newspaper type. It has been rather hard to throw the two together under the same heading, so we are making two classifications next year.

Is the Resolutions Committee ready to report at this time?

VICTOR H. KUPFERER (The Studebaker Corporation, South Bend, Indiana): I want to say that Mr. Belmonte and myself were looking to

Mr. Price for some good help on the resolutions, but we found out at the last minute that Mr. Price was called away on account of illness of his father. If there are any deficiencies in the resolutions, we hope that you will charge it to Mr. Price and not to Mr. Belmonte and myself. Resolutions are hard things to get up anyway.

We present the following resolutions for this Section:

Resolutions Passed by the Section

Whereas, The officers of the Plant Publications Section of the National Safety Council, namely, Mr. G. A. Doeller, chairman; Miss Ruth E. Cade, vice-chairman, and Mr. A. G. Strickrott, secretary, have during the past year generously given of their services and efficiently directed the work of the Section, which has resulted in the considerable growth of the Plant Publications Section and culminated in one of the most interesting and best attended conferences ever held by the section; be it

RESOLVED, That the members of the Plant Publications Section extend to those officers their whole-hearted thanks in recognition of their services.

Whereas, Miss Margaret T. Stevens, Mr. S. W. Ashe and Mr. Spencer Hord, gave unstintingly of their time, thought and energy to the most stupendous and at the same time extremely delicate task of judging the publications entered in the Plant Publication contest, this being the second year of their service in this respect; be it

RESOLVED, That the members of the Plant Publications Section express their sincere gratitude for this great service and commend the judges for the highly satisfactory manner in which the judging of the publications was accomplished.

Whereas, The National Safety Council has during the last year heartily cooperated with all the efforts of the Plant Publications Section, especially in the promotion of meetings of this Section, and in giving space in the **NATIONAL SAFETY NEWS**; be it

RESOLVED, That we, the members of the Plant Publications Section, extend our appreciation to the National Safety Council, and particularly to Mr. Kershaw for his part in furthering the cooperative activities of the Section and the National Safety Council.

Whereas, Plant Publications Section members have noticed with considerable pride and have read with interest the page conducted by Miss Margaret T. Stevens, Chairman of the Publicity Committee on Plant Publications in the **NATIONAL SAFETY NEWS**; and

Whereas, we have also noted her excellent publicity work generally; be it

RESOLVED, That this body thank Miss Stevens and recommend that she be requested to continue her activities on publicity, especially in connection with her page in the **NATIONAL SAFETY NEWS** for the ensuing year.

Whereas, The General Electric Company, through Mr. S. W. Ashe, has provided excellent facilities in the form of display racks for exhibiting the plant publications entered in the contest; and

Whereas, The said racks have been presented to the Plant Publications Section as its permanent property; be it

RESOLVED, That we acknowledge with sincere appreciation this generous contribution of the General Electric Company to the work of the Plant Publications Section.

Whereas, Those in attendance at these meetings realize the value accruing from various conferences of the Plant Publications Section as well as from the interchange of ideas throughout the year, and from other activities of this Section; be it

RESOLVED, That we urge the promotion of the membership to include as many editors as can possibly be enlisted, and that each member give the officers his hearty cooperation to this end.

Signed

A. A. Belmonte,
Union Carbide Co., N. Y. C.
V. H. KUPFERER,
Studebaker, South Bend, Ind.

(Upon motion duly made and seconded, it was voted that the report be accepted as read.)

Section Committees Are Announced

CHAIRMAN DOELLER: I would like at this time to introduce to you your newly elected chairman, Mr. Boswell of the Buick Company, who will announce, I believe, the chairmen of the committees for the coming year.

CHAIRMAN ELECT BOSWELL: Mr. Chairman and Members of the Plant Publications Section: I am just beginning to appreciate more forcibly the job you hitched on to me this afternoon.

The committees for the ensuing year are as follows:

Program—G. A. Doeller, Dayton Power & Light Company, Dayton, Ohio; F. E. Heibel, Nickel Plate Railway, Cleveland, Ohio; G. E. Close, Commonwealth Steel Company, Granite City, Illinois.

Publicity—E. T. Wilkins, General Electric, Schenectady, New York; Milton B. Herr, Bell Telephone Company, Philadelphia, Pa.; C. T. Fish, National Safety Council.

Membership—N. L. Devendorf, Consumers Power Company, Jackson, Michigan; Victor H. Kupferer, Studebaker Corporation, South Bend, Indiana; Ruth E. Cade, Staley Manufacturing Company, Decatur, Illinois.

Service—Ernest Augustus, Mead Pulp and Paper Company, Chillicothe, Ohio; Albert H. Richardson, General Electric Company, Erie, Pa.; L. H. McReynolds, Jeffery Manufacturing Company, Columbus, Ohio.

Judges—S. W. Ashe, General Electric Company, Pittsfield, Mass.;

Spencer Hord, Eastman Kodak Company, Rochester, New York; Ralph H. Wheelock, Narragansett Electric Lighting Co., Providence, Rhode Island.

While I am on my feet, I wish you would indulge me for a moment. This is your Section and what we get out of it depends upon what we put into it. A year ago I prepared a paper which I read at the Cleveland conference and I am sure that I, personally, got more out of the preparation of that paper than any other person got out of my reading it.

There are a good many jobs around here. Most of you could do the jobs just as well as any of those who have been appointed or elected today for the ensuing year. It has been the policy of the committees in the past (and I think it is a good one) that the jobs be rotated from year to year so that everyone gets his or her chance to do what he can.

The officers of this Section will succeed in making the meetings next year valuable or otherwise, depending upon the cooperation which the members give to their officers. You will be asked to make contributions and I wish that everyone who is here (you have manifested your interest by your attendance) will be willing to make suggestions when called upon by the various officers and committeemen. You will have some suggestions, I am sure, to offer with reference to some of the things that are discussed here and we would like to have them. The program committee, no doubt, will be asking you for suggestions as to what you think ought to be discussed or something that we can hook in or tie in to this program that will make it worth while. It is easy enough to set up a program, but the question is, "Are we going to put enough meat into it so that the members will say it is worth while?"

I thank you for the honor you have conferred upon me in electing me your chairman. I assure you that I am not unmindful of the responsibility it carries.

A Characteristic Mark Twain Story

CHAIRMAN DOELLER: We will now proceed into the second part of our program for this afternoon. The subject is, "Getting the Most Out of Your Magazine." We have been fortunate, I think, in having all of our speakers who are on the program appear, but in the case of the next speaker, he will be unable to be present. We received a letter from him and among other things he says: "All along I have looked forward with anticipation to this meeting. I must disappoint myself. One of the members of my family must go to the hospital at that time, and I will be unable to leave Scranton." This letter is from Mr. D. C. Vandercook, director of the International Correspondence Schools. In his absence, we are asking Mr. Ashe to read the paper, which Mr. Vandercook has sent in.

S. W. ASHE: This is a job that I don't enjoy—reading somebody else's paper. I would much rather read a radio talk to you.

Mark Twain was out with a party of friends hunting. They had a cook they thought a good deal of. The cook had an accident—everyone has

accidents. He fell into the fire and was burned to a crisp. Everyone wanted to do something; they all felt badly about it. To Mark Twain was allotted the task of writing the epitaph. So, on the bottom of the Tombstone Mark Twain wrote: "Well done, good and faithful servant. Rest in peace." That is what I would rather do than read this. I will read it rather slowly so that you will be able to get it. It is a little difficult to read somebody else's paper.

GETTING THE MOST OUT OF YOUR MAGAZINE

D. C. Vandercook, Director, Business Service Department, International Correspondence Schools, Scranton, Pa.

When that fateful day arrives for balancing budgets, "Getting the Most Out of the Plant Periodical" usually is transformed into "getting enough out of it to pay to continue it."

The publisher, who foots the bill, thereupon uses his own particular yard stick to determine whether he shall say thumbs down or thumbs up. Like those who buy advertising space to reach paid circulations, he expects the overpraised "Power of the Press" to influence in his favor the potential reader public, his employees; to create in them confidence for him; to build their faith into loyalty; and to stir this loyalty into team action.

"It's for their good," he may say with sincerity. "Our interests are quite mutual." Nevertheless, this is "a business proposition," and results "must be measured"; and they are measured by the distance the printed pages have gone in changing the minds of employees, or in moving them along the highway toward the objective which he has pointed out to the editor.

Off to the other side stands the reader, and whether he is passively quiescent, mildly curious, or eagerly alert, in effect he is saying with varying degrees of intensity, "I dare you to get my attention. I dare you to change my mind!"

"Here's the medicine they ought to be given," commands or suggests the publisher, pointing to those abstract qualities of confidence, loyalty, thriftiness, team spirit and creative productivity.

"Guess we know what we want," challenges the reader. "We're interested in ourselves—our families, our homes, our pay check, a steady job, and other working conditions."

And, then, looking at the poor editor in the middle of the sandwich, they shout in unison, "Pour the gravy all over him! Let him suit us both—if he can!"

To which the editor may retort, if as quick on the trigger as was Abraham Lincoln when competing hat manufacturers brought samples of their craftsmanship, "Gentlemen, you have mutually excelled each other."

To get enough out of your personnel periodical, there must be reader receptivity: what are your readers able to take in, to hold, to contain? What are they willing to take in, to hold, to retain?

First, then, the editor must know his audience. What races are represented among his potential readers? What is the percentage of illiteracy and literacy? What per cent of them are out in the shops? In the front office? What proportion are executives and supervisors? These and other questions must be asked and answered, either in detail or in a general way, that the editor may know what his readers are able to take in, to hold, to contain?

Reader Interest—what readers are willing to take in, to digest, and retain as their own, is quite a different matter. Dry statistics may help, but they must be interpreted in light of numerous contacts, observation and experience. Interpreted in the light of each day: a changing process, for "nothing is permanent but change." Interpreted, too, by personal contact at frequent intervals. The editor's job is not merely to sit at a desk, waiting in solemn dignity for his "staff" to send in their modest contributions. He needs to go out where they live and work, to know what they say when relaxed and off the job between shifts, or en route to their work or their homes. He must know individuals in a cross-section of his audience well enough so that they will fill his ear, when he holds it close to the ground. Being a great editor is something more than filling pages with printed words and pictures: to be a great editor is to understand human wants and motives, and what will move human beings to action; it is to ride the current and the cross-currents of a torrent of thoughts; it is to look back, but only that one may look forward; it is to help to make history, as well as to write it, by participation in the world of affairs; it is not alone to report, but to interpret, to prophesy, and to stimulate. This he can only do as he gets out where "the world do move"; to learn first hand not only what his readers are able to take in and hold, but what they are willing to take in.

Points That Prove the Bacon Is On the Fire

Now, how can the editor best prove to his boss that he has brought home the bacon, that there have been undeniable demonstrations of reader receptivity and reader interest? Here are suggested a dozen units for his standard of measurement:

1. By the expressions of anticipation when an issue is due, or overdue.
2. By the reception accorded it when it appears. By the number of copies thrown away. By workers seen reading it riding home on street cars, walking away from work, or seen taking it home. What they say when handed it.
3. By the criticism, favorable and unfavorable, which each issue provokes, in letters, by telephone calls, personal interviews, etc.
4. By the enthusiasm and interest of staff contributors who are not paid for their work.
5. By the willingness and the anxiety of readers to be photographed for its pages or written up.
6. By the suggestions of editorial changes, policies, and programs volunteered. Who makes these suggestions?

7. By the expressed desire of various company or employee organizations, groups, committees, department heads, and individuals of the rank and file that the periodical shall give publicity to certain events, causes, enterprises, etc.

8. By the volunteered comments which reach the ears of the editor through the ears of the management, both favorable and unfavorable. By the general comment "behind the back" of the editor.

9. By requests for extra copies of current issues.

10. By the life of given issues. How old are the issues requested? WHO requests them: Management? Department heads? The rank and file? Members of their family? The local press? Other companies?

11. By unsolicited requests of outsiders to be put on the mailing list.

12. By a large paid subscription list, rather than a free circulation!

Here is where I suppose I shall be classed as a "*Bull-she-veekee*," and perhaps thrown out of the synagogue for being unorthodox. Have patience, my brethren, until we have thought about this matter for a moment. "Why is a paid subscription list a better criterion of reader receptivity and reader interest than a largely free circulation?"

That Which Costs Something Is Valued Most

A few weeks ago, when I visited a great industry employing close to 20,000 people, a great executive told how the company had for years operated a summer resort at a nearby lake. "At first," said he, "any employee might ask for a cottage at that lake, and enjoy it with his family for a week, without paying any rent. Our company planned great picnics, provided free transportation to and from the picnic grounds, hired a band, bought the picnic dinners—and saw but a few accept its hospitality. The lean years came, and the company decided to ask a \$10 rental fee for those cottages; it provided free coffee, cream and sugar, but left it to our employees to provide their own picnic dinners, their transportation, and their programs of amusement. Of course, the company helped, but it no longer offered to pay the bill. Now there are not enough cottages. Now, through the summer, picnic grounds are in constant use. Never have we seen such great crowds of our employees at that lake."

There may be exceptions, but as a rule that which costs something is valued above that which is given away. The so-called "plant" or "employee" publication is not much different from other obnoxious "welfare" activities, when given away. For how the upstanding, liberty-loving, flag-waving, eagle-screaming, sesqui-centennial celebrant does demand the privilege of keeping his self-respect! How he does hate to be forced to buy something he does not want. "Oh, but he isn't," say you who are giving them away. "The company foots the bill." Not in the worker's mind. He says: "If the company will spend its money for that paper, it will spend it for other things we don't need or want. Anyway, I'd rather decide for myself how I spend the money I earn." If you don't believe this, check up on it when the lean times come, when there are lay-offs, or when there is complete suspension.

Then, too, when the publication is put on a subscription basis, the attitude of the reader-worker is changed, because he is paying for it because he wants it. For brief periods men may buy that which they do not want, "just to help out," but not for long. Folks only continue to put their "good money" continuously into a subscription because it genuinely interests, satisfies, amuses, stimulates or serves them or their loved ones.

Furthermore, the attitude of the editor, or would-be editor, is changed, when a subscription price is charged for a worker's periodical. Fewer would decide today and start tomorrow with those toy balloons which so soon will be punctured, if they thought that literally they must produce a publication, so good that they could sell it to the worker-reader. Also, if the workers share the cost with the management, then the editor has good evidence that he is actually working for both, that he must keep in mind the interests of both, and that he must make good with both.

Paid Circulation a Standard of Read Interest

Again, although I have not the evidence to prove it, I believe that the life of the periodical is likely to be stabilized and prolonged. The management has a very accurate standard of measurement of reader receptivity and reader interest when there is a paid circulation.

Take, for example, the Audit Bureau of Circulation, which has 1,919 members, of which 1,482 are publishers of newspapers, magazines, farm and business papers with a circulation of single imprints of approximately 13,500,000 copies in 1925. "Over two-thirds of all newspaper and periodical advertising appropriations, amounting to many hundreds of millions of dollars, are placed with security and confidence in A. B. C. mediums." Circulations are audited because "what the advertiser wants above all else is a standard of reader interest, as determined by a statement as to those who want a publication bad enough to pay for it." Keyed advertisements have repeatedly demonstrated that the periodical with the free circulation does not get results proportionately as large as do paid circulations. Now we all know that the advertiser pays more than the subscriber toward the actual cost of putting out newspaper or magazine. And why isn't the management of an industry in a similar position? Why hasn't he the right to expect the largest returns, if his workers are permitted to pay something toward the cost of their factory paper?

Take, for instance, *The Arrow*, published at Spray, N. C., by the Carolina Cotton and Woolen Mills Company. Its editor, J. O. Thomas, says that its subscribers have always been charged for it. Until the first of the year 1926, the price was \$1.50 a year; now it is \$1 a year. Over 90 per cent of its circulation is paid for on this basis. Free copies are given to its reporters. "We count our paid circulation by the actual number of paid subscribers," says Mr. Thomas. "We have about 1,600 names on our mailing list. Nearly 85 per cent of these are employees of the company. A number of business men in our village subscribe, and a great many employees send copies to their relatives in Virginia and

other places. Our circulation is mainly in Leaksville, Spray and Draper, N. C., and in Fieldale, Virginia, at which places the plants of The Carolina Cotton and Woolen Mills Company are located.

"In 1925, our subscriptions returned about 15 per cent of the total cost of getting out the paper. The advertising returned about 25 per cent, but advertising has not been good, owing to depressed business conditions. We compete with one weekly newspaper here, which is printed by the same publishing house which prints *The Arrow*.

"Our employees seem willing to pay for *The Arrow*. We have thought of giving all of them a copy gratis, but we feel that they will appreciate the paper more to pay something for it."

And now in conclusion, how can an editor create reader interest? By filling his columns with articles of genuine human interest. Henry Albert Phillips declares that a good test of human interest, or dramatic interest, can be found in the answer to the question: "Does it produce emotion, or feeling, within the breast of its audience?"

"Contrast," he goes on to say, "is the salt of life; it is the most prolific source of human interest."

"Contrast taps the wellsprings of curiosity, wonder, amazement, surprise, incredulity, amusement, passion, anger, hatred, admiration, adoration, love, pity, pathos and sublimity. In art, they call it light and shade, or chiaroscuro."

"If the incidents, the characters, and the settings are all alike, there will be no conflict, no contrast, no drama."

Then he proceeds to point out that the sources of human nature are to be found in the extraordinary in our midst, in the novel, in the evidences of nobility about us, where we did not expect to run upon it; pathos, where we expected comedy. Human interest is to be found in expectancy, in intensity, in exciting curiosity, in the appeal to the heart of humanity.

By touching the larger proportion of its readers, potential and actual, at the most points. And every contact gets attention. Attention stirs up interest. Interest excites emotion. And emotion should lead to action.

CHAIRMAN ELECT BOSWELL: I regret that Mr. Vandercook couldn't be with us today. I am sure that those of you who have met him regret that he couldn't be here.

The discussion of this paper is to be made by Mr. H. J. Burton, of the Consumers Power Company.

DISCUSSION OF MR. VANDERCOOK'S PAPER

H. J. Burton, Consumers Power Co., Jackson, Mich.

I agree with Mr. Vandercook's paper, at least a part of it. I do especially agree with the part where he talks about the contrast:

In that part in which he talks about the paid subscription, that is, employees should be charged for a company publication, I absolutely disagree with him. Further, I disagree with the premises that he points

out for a paid circulation. I subscribe for several magazines. I pay \$1, \$2, \$3 or \$5 a year for them. I don't value the one at \$5 any more than the others. I don't remember which is the \$5 magazine until I get the bill. Furthermore, if the editor were to say to me, "You can have it for nothing for five years," I think I would still read it.

A company publication, as I said before, is to sell an idea to employees, and I don't know why we should charge them for this magazine. It isn't what they pay for it, but what is in it, what they get out of it. As I say, I absolutely disagree with the idea of paying for a plant publication.

Mr. Vandercook just gave me a synopsis of his paper, and I didn't hear it until just this moment. I made some rather hurried notes as these thoughts came to me. It is the spirit back of the paper that makes it valuable and sometimes to make it interesting, you have got to show it.

Further Discussion of a Charge for the Plant Magazine

He said (I may not quote him exactly), "If you give a magazine away, it resembles some of the other obnoxious welfare activities of a company." If your plant publication is obnoxious, it is not going to be what you are trying to put over.

As I say, in a plant publication we have got to sell an idea, we have got to instruct the readers, if you please. If you want to amuse them, why you can subscribe to *Life* for them or make them pay for it. We are getting an idea over which is a part of our organization, just as important a part as anything else.

In the synopsis of the paper he said to me, "We always value a gift according to what is paid for it." I think we value it no matter what amount the one who gave it to us put into it. I was talking to a man some years ago, in New Jersey, just after Christmas time. He showed me a little gift he had received, a little piece of pasteboard. It probably didn't cost even a cent, and it was perforated with pins. It was made by a little child. This little child for a month or so before Christmas—the child was about three or four years old—worked on this and finally it worked out a little cross. He told me that every time he went into the house, the child would run with this pasteboard to its mother and say to him, "I am making something for you for Christmas, but you can't see it now." He showed more pride and cared more for that thing than anything he had ever gotten.

I just have one more little note here that I made while Mr. Ashe was speaking. A plant publication must have an objective, and we must accomplish that objective whether an employee likes it or not. The main objective of the paper is to make him like it. If they don't like it, we should educate them to like it.

CHAIRMAN BOSWELL: This meeting is open for discussion. I think we ought to confine the discussion to one speech to a person until everyone who wants to speak has done so. Have you any questions you wish to ask?

H. P. ALLEN (Charles H. Tenney & Company, Boston, Mass.): How many of the editors here charge any rate for their paper?

MR. BELMONTE: We charge \$2 a year for our magazine. This magazine of ours is not primarily an employee's magazine, it is a club magazine, and the members of the club are the employees of the organization. The dues are \$6 a year, and \$2 of the dues are applied to the magazine.

The magazine was just for the employees in the Metropolitan district, but lately it has been sent throughout the country. We have about 40 plants and 160 sales offices. These fellows are pretty insistent that we send the magazine out to them. We simply charged them \$1 initiation fee and \$2 a year for the magazine. It now goes all over the country.

I just stepped into our Detroit office to find out how they liked it. They tell me it is great, and that they would pay \$2 alone for some of the stories that are in there. We are running a history of the subsidiaries of our company and information of that type which has never before been given to the employees, and these men out in the field especially are simply grabbing it up.

A Successful Magazine Presents Concrete Things

The men don't mind paying for it. Two years ago we started with a four-page magazine, and now we have run it up to about 20. We are getting jammed with a lot of stuff, and I think it is read fairly well. I was going to ask that same question, how many magazines are sold to the employees and how the employees like it? Personally, I don't like the idea of charging for the magazine. The corporation wants to charge for it, so there is nothing else to do.

There is another thing I would like to talk about while I am on my feet. I have read a lot of stuff on what we ought to do and what we can do, but I think what we want to know is how it should be done. When I started in this work, I was pretty new. I wrote to Mr. Ashe and a couple of others and asked them "How do you do this thing, and what is it all about?" I got some very fine ideas from these gentlemen. I think in order to make your magazine successful, you have got to make things concrete. You have got to state, "Well boys, we have got to be careful," and then cite some specific illustration. I recently purchased a book, and it contains 900 pages. The word "concrete" appeared 600 times in that book, and that is a thing I want to leave with you. Let us be concrete in our magazine work.

E. E. CRISWELL (The New River Company, Macdonald, W. Va.): When a large department store goes to sell anything to its customers, it does not make a charge for style service, it sends out bulletins. Do you think for a minute they would sell the amount of goods they do if they made a charge for those bulletins? Personally, I don't think so, and I think the employees' magazine is in much the same position as the large department store.

We have something to sell to the employees of our company. If we make a charge for that magazine, I don't think that it will reach as

many employees as it reaches now, therefore, I don't think it will make as many sales. That is my idea on the subject of subscriptions.

S. H. LIBBY (General Electric Company, Bloomfield, N. J.): A careful questioning brings out the fact that every employee does not subscribe for that magazine. Further careful examination indicates that if 60 or 75 per cent of those employees do subscribe for the magazine, it is the balance that we want to sell the thing to more than any of the others, and we have left them out of it.

I am heartily in accord with practically every one here that we should not attempt to sell the magazine to the employee. I think, as someone else has said, make it so good, give them so much good material that the matter of who pays for it will be lost entirely, and we will put the thing over that we are trying to put over, service to the men in the shop as well as service to the company.

HERBERT W. ALLEN (M. Wile & Company, Inc., Buffalo, N. Y.): We took up the matter of charging for our magazine when it first came out merely as a matter of form. We didn't believe in doing it, but we wanted to consider it. We resolved the matter by deciding that it was the employees' own magazine, published by the company for the employees and published through their cooperation. We make them believe that it is their magazine, and their part of it is to furnish the stuff that goes into. The company furnishes the money to pay for publishing only. If it is their magazine, why should they pay anything for it, except the efforts they put into it?

Employees Interested in What They Do for Themselves

ARTHUR M. COON (Dunlop Tire & Rubber Company, Buffalo, New York): I don't know anything about the actual expenses, because we have never charged for our paper. I am inclined to think it would go over better if we charged something for it. We have found in the plant that whatever we have done isn't as well appreciated as if the employees do it themselves. When we gave them the picnics in the past, the company would pay all expenses, furnish coffee and prizes and things of that sort. This year we tried having the employees run the picnic themselves, and it turned out much better than it has ever been in times past. We find that other things work out the same way.

They are fixing up at the present time a recreation room for the employees. The employees are doing a good part of the work themselves. They stay after hours at night. We have cleared out a wing of the factory. We feel that when they do it themselves, they appreciate it a good deal more. I am inclined to think that if we charged something for the paper it would be appreciated more.

MR. WILCOX (Larkin Company, Buffalo, N. Y.): I believe Mr. Coon is right. My conception of the origin of practically all plant publications is the plan of doing something for itself. If it were not, we wouldn't be here and have our jobs. If we think of a paper as a welfare item, obnoxious or otherwise, it might be all right to charge, because I think

Mr. Coon is right that along those lines anything that they get is more valuable to their paper. This is something that the company is doing, our employers are doing, and it is not something we are doing for the employees.

CHAIRMAN ELECT BOSWELL: That is a very valuable thought, and is really the crux of the whole thing.

G. A. NOXON (Ralston Purina Company, St. Louis, Mo.): I might state first that I am not an editor. I am looking at this question just from the production man's point of view. It seems to me that in art and literature we have an exception to the general rule. This is evidenced by our public libraries and our public museums. We all take an interest in art and literature; we all get something out of it even though we don't pay anything out of our own pocket when we go to these places.

I read a good many magazines. Like one of the speakers here, I pay from \$1 to \$5 for a good many of them, and others are sent free of charge. I know that some of the free magazines that I receive, such as *Business*, which is put out by the Burroughs Company, and one or two others of the like, are more valuable to me than some others which I pay for.

Good Business to Give the Magazine to the Employee

MR. LIVERS: I wonder when we are thinking of our publication and thinking of charging the employee for it, whether we are going to raise a spirit of antagonism in their hearts. Nobody yet has said anything about this, and I may be criticized for it, but I am going to say it. There is no question at all in my mind but that it is mighty good business to give to your employees the stuff that you will put in your magazine that you want them to get. It is good business, and I contend it is good business for the company to put that message across to the employee. It is mighty good business for the employee to get it. It don't cost him anything. We don't want it to cost anything. The minute you put a price on it, well, our friend here told us that 40 or 60 per cent might take it. The others have the idea that we are trying to put something over and make them pay for it, and we never reach them.

MR. ASHE: I have always been very much interested in this matter of charging. I think the whole thing comes down to a matter of economics largely, and in things of that sort if they are successful they have got to be built firmly on definite fundamental principles. If you are going to give a magazine away free to people, as so many have stressed here today, and that is going to be your medium of feeding the stuff out that you want to get over to your people, it seems to me that the proper thing to do is to give it away free.

If you are going to charge for that magazine, it seems to me that immediately it becomes the employees' magazine. The minute you charge for it you have got the situation that you are going to let the employees tell you how they want that magazine published, and what they want in it. It is their magazine. It is not the company's magazine. You have

got to choose which way you want to do it. You can't go half way on this business. You have got to be 100 per cent. You can't let them pay for it and then publish it the way you want to publish it. That is a purely economic thing. It is not going to get you any distance, because you have got everything against you, and, therefore, you have got to make up your mind, it seems to me, as to whether you are going to charge for it or not.

I think if you have something enforced that is going along 75 per cent or 80 per cent well, it is a good thing to have that the definite policy and stick to it, rather than to change and try something else. Find out what the weaknesses are and why you can't get it to go the extra 10 per cent, rather than say we will try it this way, and then the other way. The minute you make a change of policy and go from one way to another, you never get back, because the minute you have done that, you have lost all you have built up over those previous years. Those are the two ideas I have in connection with that. If you are going to make a change, you want to be awfully careful what you do.

A Third Session at the Congress Suggested

CHAIRMAN ELECT BOSWELL: The question has been asked whether we have had enough time devoted to these discussions in the program this year? How many think we ought to throw in a third session?

(All raised their hands.)

CHAIRMAN ELECT BOSWELL: That will give the Program Committee something to work on.

The members of the Executive Committee of the Plant Publications Section, (the personnel of that committee comprising the chairman of the various committees that have been appointed this afternoon, and the officers), will have a meeting on Friday morning at 9:30. We will have an announcement made in due time where it will be held. We will proceed with our discussion.

MR. CLOSE (Commonwealth Steel Company, Granite City, Ill): There is one phase of this matter of charging for magazines which I think is important and that is the type of employees. We have a steel foundry, with a great many men who are more or less ignorant, and I venture to say that if the matter of charging for the magazine were brought up, it would have to be presented to the men when they came to work probably. They would be pretty sure to get the idea then that the company wanted them to subscribe for it. If we didn't do that, we might be put in the position of seeming to force our employees to buy it, which would be very unfortunate and would spoil the whole effect. It seems to me that that sort of a proposition can't be worked out successfully. If you are going to have the right attitude toward a magazine, it is necessary, it seems to me, to give it to them.

MR. WILKINS: I think if you charge for your magazine that the reporters for your paper should be paid, or anyone else who contributes anything. If the employees' magazine is given away free, your reporters

are perfectly willing to give their services. I think you get better cooperation through a paper that is handled in that manner than you do from a paid publication. I know of one publication that charges one cent a copy. They maintain a staff of two or three girls and in order to get that one cent from the employees it costs them five cents.

I have a list of about 15 reporters. We have a meeting once a month. We have a dinner once a month. Those men sure do cooperate with me in this work. All of them are willing to give their services, and I think that is one of the vital issues in this charging. If it is a paid magazine like any other, a contributor should be paid for his services.

A Perennial Question at Every Congress

MR. RICHARDSON (General Electric Company, Erie, Pa.): This is one of the perennial questions that have always come up in any convention I have attended of the Plant Publications Section. It has been interesting to me that the preponderance of opinion has always been that it would be very unwise to charge the employees for the paper. The principal thing seems to be, in the final analysis, that when you charge you begin to compete with the immense number of periodicals that are on sale on the news stands, and the ordinary factory staff is not equipped to maintain any decent competition at all. Therefore, as has been expressed so many times this afternoon, if you have a message to get across, the best way to get it across is to hand it out to the employees, make it interesting, and you stand a very good chance that it will be read by the very people that you want to get it to.

HERBERT W. ALLEN (M. Wile & Company, Inc., Buffalo, N. Y.): Is it a fact that the magazines which charge are those published by the principal industry of a small town and that they use it as much for the town paper, you might say, as anything else? I ask this question as a matter of information.

CHAIRMAN ELECT BOSWELL: That type of magazine is put out by the sales department, I should judge, or put out by business-getters.

L. F. McREYNOLDS (The Jeffrey Manufacturing Co., Columbus, Ohio): There is another phase of this charging business that has not been brought out this afternoon. There was a time when plants, the majority of them, were so small that they didn't care whether they had a plant publication or whether they charged or gave it away. The company grew, of course, I am speaking more of mine (every company has been growing in the last 10 years) and we have been putting out *Service* since 1924. As the company grew, of course, the president or the general manager couldn't get out and get that contact. They couldn't get out and see 1,500 or 1,600 men, so they started to issue an employees' publication. I know that Mr. Jeffrey feels the same as we do, that it wouldn't do to charge for it.

In the depression in 1921, the secretary of the Jeffrey Company suggested that they discontinue *Service*, not altogether, but to make it once

every two months instead of monthly. It was taken to the president, and he said, "Absolutely not."

Jeffrey Service is purely an employees' publication. I know that Mr. Jeffrey personally gave it a lot of careful thought. It is making the Jeffrey Company one big family and we are proud of the fact in Columbus that we have the Jeffrey family. I think by charging you would lose that contact among the employees and they wouldn't feel the same about it. You can realize, of course, that in a big corporation, the president or the general manager can't go around and shake the hand of John in this department and Jack in the other, and so on. They do, however, get out once in a while. I know that we would lose the purpose of the *Jeffrey Service* if we started to charge.

FRANK L. GREENYA (Fisk Rubber Company, Cudahy, Wis.): The matter of division was discussed to some extent in the judging of the plant publications in the future. Has there been any disposition made of that particular subject? Has any provision been made for having a committee arrange to study the division or anything of that sort?

CHAIRMAN ELECT BOSWELL: I don't know whether there was any action taken at all. Have you something to offer?

MR. ALLEN: I believe they divided it into two divisions, the newspaper and the magazine type.

MR. DOELLER: It was left in the hands of the Judges Committee, whoever they may be during the coming term.

Opinions of Some of the Women Delegates

MR. GREENYA: I don't think under the present basis that the smaller magazines or the newspapers have a chance against the elaborate magazine put out by the Northwestern Bell and the others. Just as a matter of fair competition, I think something ought to be done along those lines.

CHAIRMAN ELECT BOSWELL: There are some others that agree with you.

MR. GREENYA: From the discussion back of the screens, there are plenty that agree with me on that subject.

CHAIRMAN ELECT BOSWELL: It was suggested that the ladies haven't participated in this discussion this afternoon.

Mrs. C. B. COXE (Atlantic Refining Company, Philadelphia, Pa.): In our company, our employees as a rule resent anything that shows paternalism at all. They don't like any of the things that the company does for them. They don't, however, resent the plant publication at all, because they think it is a fifty-fifty proposition. They furnish the material and the company pays the bills. The reporter is not paid. The only thing we pay for is the actual cost of the work done by the printer and the photographer and the photo-engraver. They don't consider it in any way as a paternalistic idea to have a magazine free of charge. I don't think they like to pay for it at all.

MISS BETTY C. SHORT (Barber-Colman Company, Rockford, Ill.): We have a free magazine and we have free entertainment. We have a picnic each year that the company gives to the employees. We have a 75 per cent representation at both the picnics and the parties.

We have a staff of 15 reporters on our magazine. They have three dinners a year, and they are given at cost to the reporters. The company gives us the free use of the club house for the parties and everyone seems to be very happy.

I don't think there would be that good feeling if they had to pay for the magazine. As the man across the aisle said a few minutes ago, the employees magazine is good advertising for the company; it is 95 per cent advertising for the company. I know, because I worked on a newspaper before I went into this work. I was a dramatic editor for one of the newspapers, and I know more companies through their magazines than I had ever known before. I never knew what the companies were until I started to receive the magazines. They sold themselves to me in that way. Of course, our company is small. We only issue about 3,500 copies each month. Everyone who gets one of those copies knows of the Barber-Colman Company. It does seem wrong to sell advertising to the people who give us the material for it. I agree heartily with the plan of giving the magazines away free.

ADJOURNMENT

Public Utilities Section

New Officers of the Section

CHAIRMAN: GEORGE C. A. OPP
The Detroit Edison Co., Detroit, Mich.

VICE-CHAIRMAN, ELECTRICAL INTERESTS: C. J. RUTLAND
Texas Power & Light Co., Dallas, Texas.

VICE-CHAIRMAN, GAS INTERESTS: C. HOWARD STEWART
Laclede Gas Light Co., St. Louis, Mo.

VICE-CHAIRMAN, TEL. & TEL. INTERESTS: H. L. MEADE
Ohio Bell Telephone Co., Cleveland, Ohio.

SECRETARY: HARRY M. KELLER
Northern Indiana Public Service Co., Hammond, Ind.

PAST CHAIRMAN: B. B. McCULLOCH
Bureau of Safety, Chicago, Ill.

Committees

PUBLICITY: H. F. WEBB, Chairman
West Penn Power Co., Pittsburgh, Pa.

POSTER: IVAN L. SCOTT, Chairman
Wisconsin Power & Light Co., Madison, Wis.

FIRE PROTECTION AND PREVENTION: H. B. HARMER, Chairman
The Philadelphia Electric Co., Philadelphia, Pa.

MEMBERSHIP: F. S. ARMSTRONG, Chairman
Central Illinois Public Service Co., Springfield, Ill.

ENGINEERING REPRESENTATIVE: C. R. BEARDSLEY
Brooklyn Edison Co., Inc., Brooklyn, N. Y.

COUNCILLORS:

C. B. SCOTT.
Bureau of Safety, Chicago, Ill.

H. W. MOSES
Edison Electric Illuminating Co. of Boston, Boston, Mass.

J. C. HUBBARD
Western Union Telegraph Co., New York City.

H. M. WEBBER
Illinois Bell Telephone Co., Chicago, Ill.

B. FRANK DAY
The Philadelphia Electric Co., Philadelphia, Pa.

C. E. MORRISON

Utilities Mutual Insurance Company, New York City.

HERMAN SPOEHRER

Union Electric Light & Power Co., St. Louis, Mo.

October 26, 1926

BUFORD B. McCULLOCH, Chairman
Bureau of Safety, Chicago, Ill.

THE Public Utilities Section of the National Safety Council convened in the Blue Room of the Tuller Hotel, Detroit, Michigan, Tuesday, October 26, 1926, at 9:50 o'clock, Mr. B. B. McCulloch, Bureau of Safety, Chicago, Illinois, presiding.

CHAIRMAN McCULLOCH: The first matter of business on the program this morning is the report of the officers. I will read the report of the chairman for the past year.

REPORT OF BUFORD B. McCULLOCH, CHAIRMAN

The year which closes this week has been the most successful in the history of the Public Utilities Section. To review in detail the accomplishments of the Section during the past year would, no doubt, be a repetition of the information contained in the reports of the committee chairmen which will be presented at this meeting. Only a brief statement will therefore be made in connection with the activities of each of the four committees.

Shortly after the Cleveland Convention, Mr. H. F. Webb, of the West Penn Power Company, Pittsburgh, Pennsylvania, was appointed chairman of the Publicity Committee. This was the first time that such a committee had been appointed in the Public Utilities Section and its purpose was to provide information, not only to members of the Section, but to public utility companies throughout the United States, this information to cover various phases of accident prevention in connection with the operation of public utility properties.

Through the efforts of Mr. Webb, valuable papers on accident prevention subjects have been secured and furnished to the *Bulletin* of the National Electric Light Association and to the monthly publication of the American Gas Association. These articles, which have been gratefully received by the editors and which have been credited to the publicity committee of the National Safety Council, have been the means of keeping the name of the Council before a large majority of the electric and gas companies of the country. In addition, articles have appeared regularly in the NATIONAL SAFETY NEWS. The service rendered by Mr. Webb will undoubtedly cause the Public Utilities Section to continue a publicity committee.

The Poster Committee, under the chairmanship of Mr. Harry M. Keller, of the Northern Indiana Public Service Company, Hammond, Indiana, has greatly improved the type and quality of posters reproduced monthly in the NATIONAL SAFETY NEWS. Each month, three posters have been published, one each for the gas, electric and telephone and telegraph divisions, and the demand for these posters has been an indication of their popularity and the improved quality. The Sectional Poster Catalogue, published during the last month by the National Safety Council, is the first Sectional Poster Catalogue ever to be published. The copies which are available to all members of this Section, together with the poster exhibit which has been prepared by the National Safety Council with the assistance of Mr. Keller, will undoubtedly prove of value to all members in selecting the posters most suitable to their individual needs.

To mention the work of the Program Committee, under the chairmanship of Mr. B. Frank Day of the Philadelphia Electric Company, appears to be unnecessary, as the program which you have in your hands and the papers to which you will listen during the next three days are the result of Mr. Day's efforts, covering a period of several months. Mr. Day is deserving of great credit for his part in the preparation of the program and the securing of speakers.

Remarkable Section Increase in Membership

Probably the outstanding record in connection with the activities of the Public Utilities Section during the past year, is the remarkable increase in membership. This has not been accomplished by any one person, but because of the organization which was created by Mr. Carl J. Rutland, of the Texas Power and Light Company, Dallas, Texas, who is chairman of the Membership Committee, and because of his follow-up system in connection with membership expirations, he is entitled to a large portion of the credit for our unusual record. A total of 73 companies (including subsidiaries) have been accepted as members since the Cleveland Convention, a gain of 21 per cent, while the cancellations have amounted to 16, or five per cent. It is of interest to note that 10 per cent of the new members secured by the National Safety Council during the past year have been public utility companies, and they represent over 40,000 additional employees who are receiving the services of the National Safety Council, increasing the total number of employees served by this Section to approximately 750,000.

So much for the review of the past year's service. It has been made because of a feeling on the part of your chairman that the Section is properly subject to criticism for not keeping its members better informed during the year as to its activities through monthly news letters and otherwise.

This Congress marks not only the close of a year of successful endeavor, but also the beginning of what we trust will be a greater one. The new Executive Committee which will be elected should look forward with enthusiasm to its opportunities and in the hope that this

report may contain something of value to them and something that will assist in their program of work during the coming year, the following recommendations are submitted:

1. That every effort be made to cooperate with and secure the cooperation of the Accident Prevention Committees of the Utility Associations. During the past year our Executive Committee has enjoyed a fine spirit of cooperation between the National Electric Light Association and the American Gas Association. Such cooperation was, in a measure, due to the fact that our Executive Committee contained members from each of these associations. The value of such representation lies in the fact that it avoids duplication of effort and makes available to each organization the records and reports of the other associations.

Regional Conferences Are Emphasized

2. It is recommended that, if possible, regional safety conferences be held by this Section. In planning these conferences, it may be well to take into consideration the advisability of holding joint meetings with other Sections in which are problems of mutual interest. This would apply particularly to the Electric Railway and Plant Publication Sections.

3. The supply of safe practice pamphlets on the subject "Protection of the Public," issued a number of years ago, has been exhausted, and, before reprinting, the information contained in this pamphlet should be revised in order to care for modern hazards such as those in connection with radio installation. It is recommended that a special committee be appointed for the purpose of revising the data and illustrations in this pamphlet and that this be done as soon as possible because of the requests which the National Safety Council now have for additional copies.

4. The Public Utilities Section has confined its activities almost entirely to its own Section and has thereby overlooked a broader field of education on utility safety problems within the other industrial Sections. This is a matter of policy which is of considerable importance and deserves the serious consideration of the new Executive Committee. It is possible that the engineering representative of this Section is the logical one through whom this point of contact should be established. As an example of the character of the work to be done in this connection, the revised booklet on "Electrical Equipment in Industrial Plants" should be given as much publicity as possible and an effort should be made to secure a wide distribution of this booklet among the member companies of other industrial sections. This would be a step towards educating the employees of industrial plants as to the hazards incident to electric and gas service and equipment and would tend to reduce public accidents and claims.

5. To secure any degree of success in accident prevention, it has been found necessary to concentrate activities upon one problem or subject at a time. The effectiveness of the work of this Section could undoubtedly be materially increased if such a policy were adopted in connection with the preparation of its yearly program. It is therefore recommended that a series of subjects be planned for in advance, one subject to be emphasized each month, and that this program be followed closely by the Bulletin Committee in the preparation of posters, by the Publicity Committee in the publication of papers, and by the secretary in the distribution of news letters. This would result in the efforts of the Section being confined to one subject each month, and if a series of practical and important problems in connection with the hazards of utility operation are carefully outlined at the beginning of the year, the following of such a plan will undoubtedly increase the value of the service rendered by the Section.

I will ask the Secretary to submit his report.

REPORT OF EDWIN R. DOBBIN, SECRETARY, PUBLIC UTILITIES SECTION

As secretary of the Section my report is of necessity short. During the year at the request of your chairman, his meetings of the Executive Committee were both held in New York City—one in December and one in June. Routine business, reports and discussions on the activities of the membership, publicity, bulletin and program committees, as developed in these meetings have, under the directions of your chairman, resulted in the excellent program you now have before you. The increase in membership and the excellence of the work of the bulletin committee, as shown by reports submitted, can not but make you feel that real progress is being made.

The News-letter, to which was attached a questionnaire relating to accident cost comparisons, brought in but comparatively few replies. These were routed through the chairman to headquarters for its use. The other services which your secretary rendered were negligible, it being only routine correspondence.

It is my humble opinion, if I may be allowed to express it, that your secretary should be selected from a locality near that of your chairman. This would give closer personal contact and the secretary could give better service and more of it. As it stands now your chairman has done much of the work that should have been done by your secretary—and the fact is hereby acknowledged.

CHAIRMAN McCULLOCH: I will ask Mr. H. F. Webb to submit the report of the Publicity committee.

REPORT OF H. F. WEBB, CHAIRMAN OF PUBLICITY COMMITTEE

The expansion and growth of the Public Utilities Section, National Safety Council, brought the need for an additional means of advertising the wares, and the progressive spirit of the Sectional officers caused the formation of a Publicity Committee. The function of this committee hardly needs explanation or description, since the activities were mainly confined to satisfying a normal desire of executives, engineers, foremen, and others interested in the prevention of accidents for safety information directly applicable to the public utility industry. The quest of desirable manuscripts containing substantial information directly concerning the promotion of greater safety in the electric and gas industries was not an easy task, but your committee feels that it was fairly successful, at least in supplying continuity of publication.

Altogether nine manuscripts were received, eight of which have been published in such journals as the NATIONAL SAFETY NEWS, *N. E. L. A. Bulletin*, *American Gas Association Monthly*, and *Safety Engineering*. One manuscript has been held for near future publication. As a matter of record, this report contains a brief recapitulation of published manuscripts and the names of contributors for prevention of possible duplication.

SUBJECT	CONTRIBUTOR	PUBLICATION
Public Safety Education	E. F. Tucker, Coun- ties Gas & Electric Company	NATIONAL SAFETY NEWS
Hydro Electric Acci- dent Hazards	T. C. Stabley, Penn- sylvania Water & Power Company	NATIONAL SAFETY NEWS & <i>N. E. L. A. Bulletin</i>

The Trend of Accident Prevention in the Gas Industry	M. L. Mix, Peoples Gas Light & Coke Company	NATIONAL SAFETY NEWS <i>A. G. A. Monthly</i>
Selling Safety to Gas Men	F. E. Drake, Lynn Gas & Electric Company	NATIONAL SAFETY NEWS <i>A. G. A. Monthly</i>

Your committee would like to express our appreciation of the cooperation on the part of the author contributors listed in this report.

An additional work accepted and accomplished by the Publicity Committee was the re-edition of "Personalized Safety" pamphlet, published by the NATIONAL SAFETY NEWS to more exactly fit the Sectional need. A number of the form letters contained in this pamphlet were revamped, and several were removed for replacement with other selected letters. The completed pamphlet which contained 15 form letters suitable for executive use in promoting safety interest among foremen, was accepted verbatim, and republished by the NATIONAL SAFETY NEWS for distribution to public utility members.

Your committee would recommend that the Publicity Committee be continued as a definite part of the Public Utilities Sectional activities for there is no discounting the value of continuous advertising attack.

CHAIRMAN McCULLOCK: Mr. Day, have you anything to report in connection with the program activities?

MR. DAY: Mr. Chairman, there is nothing additional to report. The program has been printed and placed in the hands of each member. I desire, however, to express my grateful appreciation of the assistance given by each member of the executive committee in the work of preparing the program, and I would like also most cordially to thank each one who has so willingly agreed to prepare a paper. Those papers involve considerable work in the life of busy individuals, and I would like to have them know that as chairman of the committee I very much appreciate their kind assistance.

CHAIRMAN McCULLOCK: I will ask Mr. Keller of the Northern Indiana Public Service Company to submit the report covering the activities of the Bulletin Committee.

REPORT OF H. M. KELLER, CHAIRMAN OF THE POSTER COMMITTEE

The present Poster Committee of the Public Utilities Section has prepared three posters per month since the last Safety Congress at Cleveland. This committee consisted of H. D. Harper, Kansas Gas & Electric Co.; W. H. Oelschewsky, Western Union Telegraph Co.; Ivan Scott, Wisconsin Power & Light Co.; W. H. Mulligan, Hydro-Electric Power Commission of Ontario, Canada, and H. M. Keller, Northern Indiana Public Service Company, as chairman.

Of the three posters issued each month, one dealt with hazards encountered in the gas industry, one in the electric, and one in the

telephone and telegraph division. Considerable time and effort has been spent in attempting to make each and every poster of this section one which would convey to the workmen such an impression that the picture would not be forgotten.

The National Safety Council recently printed a four-page catalogue containing miniature reproductions of some of the posters issued during the past year. This is the first and only sectional catalogue they have published and copies are available for everyone.

Special credit is due the Peoples Gas, Light & Coke Company for their splendid cooperation in this work, although none of their representatives were appointed as members of this committee. We also wish to express our appreciation to the Texas Power and Light Company, Western Union Telegraph Company, By-Products Coke Company, Wisconsin Power & Light Company, and the Hydro-Electric Power Commission of Ontario. All of the photographs used were supplied by these organizations, and the Northern Indiana Public Service Company.

Posters Depicting Hazards of Meter Men Needed

Your committee hoped to issue a number of posters dealing with hazards encountered by meter men, and took the matter up with the N. E. L. A. meter committee. In April suggestions for posters of this type were forwarded to them, asking for comments, but because of the delay in replying to our correspondence, only two such posters were issued. We therefore recommend that this be given consideration by the new Bulletin Committee.

A number of valuable suggestions have been received from various sources which can be used to good advantage during the coming year, but everyone here should take it upon himself to assist the new committee by sending photographs or suggestions to the chairman. If you can not send pictures, simply set down your ideas in writing and arrangements will be made elsewhere to photograph them.

This sort of cooperation is just as important as any other activity in which you may participate to aid in the prevention of accidents, and I can assure you that such assistance will be greatly appreciated by both the Poster Committee chairman, and the National Safety Council. As Mr. VanBrunt stated last year, "The Council can not get out the posters and the chairman of the Poster Committee doesn't amount to a tinker's damn, unless he has your assistance." So let's all get behind this proposition and help, not so much to save the chairman's reputation, but the reputation of the Public Utilities Section. It is the best now—and we want to keep it on top.

CHAIRMAN McCULLOCH: I am very sorry it is impossible for Mr. Carl J. Rutland, of the Texas Power & Light Company, to be present to report in person the progress made by the membership committee of this Section. I want to give you an idea of the extent of the organization which Mr. Rutland accomplished. I believe it is the best membership record ever made by any Section in one year. Mr. Rutland divided the country into 14 geographic divisions, and appointed a chairman in charge of each.

It was Mr. Rutland's intention to introduce personally the representatives of all the new companies which have been taken in since the Cleveland convention, but because of the delay in starting our program this morning, I am afraid we shall have to eliminate that. As you know, there are 73 companies on which we would have to call for representatives and it would take more time than we can allow this morning.

On the nominating committee to nominate the officers of the Section for the coming year, I am going to appoint Mr. Harry M. Webber, of the Illinois Bell Telephone Company, of Chicago, as chairman, Mr. Harry J. Burton, of the Consumers Power Company, Jackson, Michigan, and Mr. Harmer, of the Philadelphia Electric Company. This committee will submit their report at the beginning of our session tomorrow morning.

The first paper on the program this morning will be presented by Mr. C. R. Beardsley, engineer of station construction, of the Brooklyn Edison Company, Brooklyn, New York.

Mr. Beardsley has been very active on the accident prevention committee of the National Electric Light Association, has made a thorough study of this subject and is well qualified to present a paper to us this morning.

SAFEGUARDING OF WORKMEN DURING CONSTRUCTION, ALTERATION AND INSTALLATION OF POWER HOUSE EQUIPMENT

C. R. Beardsley, Electrical Construction Engineer, Brooklyn Edison Company, Inc.

It is hardly necessary to answer the question, "Why do we need to safeguard?" It is still true that in bravado the boy is father to the man. Years must elapse before the average workman can be educated so as not to feel a little ashamed to admit a fear of hazards, especially those inherent in his line of work, and with which he is contemptuously familiar. Pride in skill often leads men to incur risks that should not be taken. Caution and care of self and fellows grow with advancing years. Acquisition of family responsibilities often steadies a man into more careful work.

Study of accident records of New York State and the Province of Ontario, including more than 100,000 cases, shows that the great majority of accidents and the high frequency rates occur to men under 30 years of age, who are liable to be more careless. The progressive utilities have recognized their responsibilities and strive, with increasing interest of executives and officials, to prevent accidents. Our assignment is to answer "How?"

The responsibility for elimination of physical hazards, for selection, placing and instruction of workmen, for correct application of holdoff system in live stations or on steam lines, for enforcement of other safety rules, must be fixed.

Regardless of the nature of safety organization which obtains in any company, the man in authority in the field, to whom workmen or sub-

foremen look for direction, seems to me to be the logical selection for this responsibility. His authority over men and movements is essential in securing safe working conditions.

In power house construction and alteration, there exist some obvious hazards. The accidents they cause are so frequent and severe that only the most callous attitude of mind can ignore and permit their continued existence. Not long ago, I heard a building construction superintendent argue that railings and guards for open wells are worse than useless, because they tend to make men less careful. I may add that this man's record of accidents was frightful, and together with other causes, necessitated his being superseded, whereupon the job record was sharply improved. I believe the time is rapidly passing when a superintendent, however able and experienced, will be considered effective and thorough if he allows the continued existence of physical hazards.

Operating utilities, the larger general contractors, electrical and steam-fitting contractors and others, have recognized the value of securing reputation for low accident experience, as a builder of their own personnel and an actual saving in expense. It is to be regretted, however, that many smaller contractors and foremen, too often blinded by the immediate measurable cost of hazard removal, overlook the intangible loss of efficiency due to slowing up of work and the man power loss to industry and suffering caused by accidents. Such people selfishly rely on their compensation insurance coverage for their own protection, and fail to rise to the moral obligation of protecting their men.

Order on Job

Among the obvious hazards worthy of special mention is disorder and the confusion of a newly organized job. A careful check of accident reports on jobs aggregating several million dollars in construction expense has proved conclusively that the higher frequency of accident occurs in the early stages of the work. The blocked aisles and littered walkways, concrete form stripping and brick masonry, handling of large quantities of materials of all kinds, including heavy pieces, falling materials, density of traffic, unfamiliarity of new gangs with the job, all tend to increase frequency of accident. This dictates to a careful foreman the necessity of just as careful planning for safety as for construction progress, and he must not wait until the job is in progress, when everyone is too thoroughly engaged by other activity to worry about hazards. Good housekeeping is one of the best safeguards. Good housekeeping can be secured by planning the arrival of materials to the job on a minimum headway in advance of actual needs, and the immediate disposal of crates and packing materials.

It will therefore be sufficient merely to call attention to the following list of physical hazards, assuming that any progressive and humanely directed utility will provide inspection and necessary cost of removal.

The question then arises, having removed physical hazards—have we entirely eliminated accidents? It is a happy official who can answer in the affirmative.

If accidents continue to occur after removal of physical hazards, then we must look to the more intangible causes and devise preventive measures.

Analyses of nature of work and actual accident occurrence often disclose unsuspected danger points, but more frequently lead to the workmen themselves as a responsible contributing factor. It is therefore very productive to engage in a study of the workman, his habits, his mental processes in normal pursuit, but especially his reactions under strain and pressure incident to rush and overtime work, in emergency, under bad weather or temperature handicap, on "blue Monday," after an indigestible lunch, after a row with his mother-in-law, or a plate-throwing contest with his "storm and strife." Ridiculous and irrelevant as it may appear, we have traced some accidents in which mental aberration was the immediate cause, to some unhappy condition in the home which prevented the workman from concentrating on his work.

Ascertaining Health and Mental Condition

It is difficult to ascertain the existence of and safeguard against such conditions. Friendly, confidential relations between foremen and men, and between officials and foremen, help in bringing to light conditions that might result in confusion. I have known a man to be shifted to less hazardous work or sent home because of impending fatherhood, or because of whooping cough among his children which caused him loss of sleep.

Safeguarding against such causes must commence at time of employment when physical examination may disclose defects in eyesight, hearing, nerve and muscular control, digestion, teeth, general health, etc. Further examination in home conditions after employment, by visiting nurses, will disclose other conditions which may predispose to accident.

The Brooklyn Edison Company, of which I am an employee, makes a determined effort, at the instance of its president, Matthew S. Sloan, to eliminate overtime work. Although much of the work in our group of 750 to 1,000 employees associated in electrical construction must be scheduled over week ends or at night, for the last two years, during a tremendous construction program, we have incurred less than 2 per cent of annual overtime referred to the total normal working hours of the group. No individual is allowed to work in excess of 10 per cent annual overtime. Formerly, the group overran as high as 25 per cent, and individuals as high as 50 per cent and 100 per cent for long periods, in accumulated overtime hours.

Certainly the men now have more time for recreation and home life, and it is a fact that wives appreciate the regular hours of work. Since this reduction of overtime and a similar reduction in accidents are coincident, I am convinced that it is one of the heavily contributing causes of the improvement.

As men are hired or advance in ability to the point where they may be assigned more hazardous duty, it is not sufficient to expect them to assume the new responsibilities and immediately be cognizant of all

dangers. They should be coached and watched for a time by someone who has been through the mill and can be depended on to point out dangers.

In this training more than mere rules and obedience to them are necessary, more than mere rehearsal of mechanical moves. As an example, let me cite one feature in the test routine performed by the Electrical Construction Bureau, Brooklyn Edison Company, incident to placing cable and apparatus in service.

High voltage tests are applied by use of stationary sets in generating stations or portable trailers, containing Kenotron Test Sets capable of producing D. C. voltages as high as 250,000 volts. Standard test on 27,000 volt cables is 135,000 volts phase to phase, or 95,000 volts to ground for five minutes. On long cables when insulation is good a heavy condenser charge is built up. On completion of test it is therefore necessary to thoroughly discharge cable and dissipate stored energy by grounding, before any further connections can be safely made. The difference between mere mechanical performance and an intelligent conduct of test lies in the understanding of what constitutes thorough discharge of energy and the reasons for the routine necessary. To connect to ground for a few minutes is not sufficient, for the reason that the cable insulation "soaks up" a charge with an apparent mechanical stressing which does not relieve itself even after voltage has been reduced to zero; that is, the voltage of the charge will again build up after removal of ground, to a part of original value. It requires at least 15 minutes of grounding to relieve the stressed dielectric and dissipate energy. Therefore, a tester may safely remove test leads only while they are grounded and by use of an insulated handle.

Supervision and Esprit De Corps

Recently a large manufacturer succeeded in effecting a considerable reduction in the supervision expense in his factory by means of a higher degree of training and responsibility fixed on group foremen. Among the old New England metal and machine trades, mechanics and foremen combined manual dexterity with knowledge of craft so that less supervision was required than with the lower class employee of the present day. Largely automatic operation has succeeded the old skillful manual worker.

The analogy can be drawn in the utility field today in construction work. Does the utility group obtain high grade supervision, low turnover of skilled field labor, *esprit-de-corps*, and personal interest of executives and officials in the field man? If the work is to a large degree contracted out, it is difficult to build up these aids to safety and efficiency, as the contractor and his supervising group act as a barrier and the field man has no direct responsibility to the utility. On the other hand, if opportunity exists to maintain and train a group of utility employees, whose term of employment is reasonably continuous and turnover low, the effects of training and spirit of cooperation are evident in reduction of necessary supervision.

Contractor foremen on lump sum work have difficulty in interesting themselves in safety measures. On percentage work, they often feel precautions are at cost of progress, although experience should indicate the reverse.

Among hastily assembled groups of contractor men there is a lack of the kindred personal feeling that grows in a group of men who have worked together for some years.

Results in accident occurrence in a large group of contractor men as compared with results in similar work of equal volume performed by utility employees shows a frequency much lower in the utility group. Severity can not be compared, due to lack of data on the outcome of contractors' accident cases.

For greater safety it is necessary to limit contractors to "dead station work" and turn over work in operating stations or operating parts of stations, to utility construction forces thoroughly familiar with the system and rules, and trained for accident prevention.

Designing for Safety

With the increasing concentration of power, the results in accidents are of increasing scope and magnitude. Designs must not only be calculated to produce K. W. hours or cu. ft. of gas at low cost and with continuity of service, but must allow for safety to operating and construction forces. Mishaps, which a few years ago would have been confined to small area, may now involve adjacent busses and apparatus, due to metallic conducting vapors given off in large volume from short circuits fed by larger power units. It would be interesting to compare the number and seriousness of accidents in which the effects are due only to heat and gases, and without actual contact with current carrying parts, with accidents caused by contact and shock alone.

In my experience, by far the greater frequency and severity are due to heat effects. I would be very glad to have the comment of others in this respect.

A further consideration is that in confined spaces, unless prevented, oil vapors may mix with air in proportions such as to form explosive mixtures. Design should prevent this possibility by ventilation, or scavenging. This ventilation should also be designed so as to give quick outdoor discharge of conducting gases and vapors caused by short circuits, before they cause short circuits on other live parts. Sectionalized switch groups, phase separation, etc., have a marked effect on limiting the scope of such accidents.

The amount of expense warranted for prevention of possible accident can only be determined by estimate of probability of accident. Such estimate is often largely conjecture. Difference of opinion may readily exist between designers and those who have responsibility over men who are subject to hazard. Experience indicates it is well to err in the direction of being safe, rather than sorry, which I am happy to say is the policy of the executives in my company.

It is safe to say that there are few if any executives who are not desirous of eliminating accident. However, the desire itself is not sufficient to achieve results.

For several years the unflagging personal interest of President Sloan and his efforts as chairman of the Brooklyn Safety Council have inspired other officials of the Brooklyn Edison Company to constant care and gratifying success in reduction of accident occurrence.

Happily, few executives are so wholly engaged in pressing financial problems that all other matters assume a money complexion. Such executives must first be impressed by statistics of compensation and medical cost, consequent damage to apparatus, interruptions to service and consequent loss of prestige.

If there are any such executives who, while desiring to limit accidents, do not take personal interest in accident reports and preventive measures, these results are liable to prove unfavorable.

Progressive utility men have wider horizons. In order to protect their policies, they realize that the best medium is a contented, well-trained personnel. Properly harmonious relations with consumers, on which stability and prosperity of utilities must depend, begin with the "gang" as an integral part of the population served. Attention of executives has therefore been directed to a greater extent than heretofore to the general make-up, training, living conditions and welfare of all their employees. This closer personal interest in the men should be the means of a changed viewpoint, a much greater sense of intimate loss, when men are taken by accident.

Executives Should Have Personal Interest in Men

Too long we have received accident reports with the comment "Too bad! Jim was a good man! Now, who will get his job?"

Too little have the responsible executives taken personal interest in the results to Jim's family; how the widow will manage; what kind of education the children will receive.

It may be argued that the executive should be shielded from this sympathetic strain and loss of time. I say he should be shielded by preventing the accident; that a part of the necessary safeguarding is that he himself maintain a continual personal interest in prevention; that the best way to keep up that interest is to know intimately the tragic results.

It is at least as important that an executive check the effectiveness of his supervisors of men in their accident prevention work as in their efficiency of production. Continued executive interest is the required spur in either case.

My challenge to you men interested in safety, then is: "Does safety work in your company cease, so far as your executives are concerned, after appointment of a safety director, appropriation of a few paltry dollars, and the securing of compensation and liability insurance?" Or do your executives evince a continued interest that impels a study of each accident, suggestions for preventatives, a follow up of the men or

the families they leave, and a greater helpfulness even than the law requires, so that they continuously inspire the whole personnel to conscious safety effort?

When this spirit is general we will have the beginning of real accident prevention. The spirit of the executives will color the thought and actions of the whole personnel of the industry, and safety will be a dominating movement.

SOME HAZARDS IN POWER STATION CONSTRUCTION

- | | |
|--|--|
| 1. Caveins. | 15. Flying chips. |
| 2. Unsafe walkways or runways. | 16. Flying ashes, coal, dust. |
| 3. Unsafe or slippery floors. | 17. Operating machinery, gears, belts, chains. |
| 4. Littered floors. | 18. Upturned nails. |
| 5. Steep stairs. | 19. Projecting nails, wires, slivers. |

| 14. Falling materials (improper slings, etc.). | 28. Handling pipes, rods, lumber. |

CHAIRMAN McCULLOCH: The discussion of Mr. Beardsley's paper will be led by Mr. J. F. Connor, safety supervisor, U. G. I. Contracting Company, Philadelphia, Pennsylvania.

DISCUSSION OF MR. BEARDSLEY'S PAPER

J. F. Connor, U. G. I. Contracting Co., Philadelphia, Pa.

Mr. Beardsley used a phrase about temporary checking up. That brought to my mind a little story that I read recently in reference to an electrician and his helper running a line, and through some reason or other he forgot which end of the circuit was the positive and which was the negative, so he called to his helper: "Hey, Bill, get hold of one of those lines." Bill got hold of it. Then he said, "Do you feel anything?" "No." He said, "That is good. I forgot which line it was. Now be careful, don't get hold of the other one; it has got 6,600 on it."

Mr. Chairman, I have not prepared any paper on this discussion. Mr. Beardsley has presented his subject in such an able manner that it hardly appeared necessary to go to the trouble of preparing a paper, but

I do want to emphasize some of the points which he has brought out. Stress has been placed on having the field engineer responsible for the safety of the men.

To my mind and from my experience I feel that the greater responsibility is in getting the executive so thoroughly imbued with the safety vision that by reason of that feeling he lets it be known all down the line. Now, unless we have the executive interested, that is, the executive directly in charge of the field officer or the field engineer, we find that the field engineer is not going to take the responsibility. He feels that it is an added expense to his work. He is afraid of being jacked up, and he is not going to interest himself to any great extent. His attitude is then reflected in the foreman, and from the foreman on down the line to the workmen.

That there is a crying need for reduction in the accident frequencies in the construction end can not be gainsaid. We have felt that in Pennsylvania in our Department of Labor and Industry for a period of a couple of months. They took their inspectors from all other work and centralized them right on construction work. I will just give you a few figures. In Pennsylvania in 1925 we had 245 fatalities in the construction end, which represented 12.2 per cent of the accidents occurring in the industry. We had 20,008 non-fatal accidents in the construction work, which represented 11.5 per cent of the total industrial accidents. During the first six months of 1926 we had 106 fatalities, which represents 10.9 per cent, and 9,067 non-fatal accidents, which is 10.7 per cent of the industrial accidents.

Most Accidents Due to Minor Causes

The majority of these fatalities and non-fatal accidents are due to very minor causes: falls from scaffolds and ladders, falls from buildings, falls from runways, floors and stairs and falls from other elevations, falls through floor openings and into excavations, and falls on the level. That means congested passageways, objects lying in the passageways, causing a man to slip. Now, you can see that most of those conditions can be readily taken care of without any appreciable expense. All that it requires is that the field engineer or superintendent be so imbued with safety that he is supervising the construction all the way through.

Mr. Beardsley mentioned that it is hard to control sub-contractors where part of the contract is let out. I agree with him in that. It is very hard, but a way to overcome that, I think, can be found. In most contracts we find a clause in which the sub-contractor is to indemnify the principal contractor or purchaser, or both, in the event of any damage which the principal contractor or purchaser will be required to pay on account of any damage caused by the sub-contractor. That is a very good clause for protecting the principal contractor and the purchaser, but why not insert in the contract that the sub-contractor shall perform his part of the contract with the reasonable care for the protection, not only of his own men, but of the other workmen on the job?

That can be readily incorporated, and with that clause in the contract this will give the field engineer the authority to supervise the method in which the sub-contractor does his work. It has been our experience, the same as Mr. Beardsley's, that unless you have some means for controlling the sub-contractor, all he thinks about is getting through his end, regardless of what hazards he exposes other workmen to on the job.

Another important feature in any construction work is good "house-keeping." That is the guarding against ordinary perils, or the guarding of hazardous conditions. They can be taken care of, and I know it to be a fact that if those two features are looked after it will bring about a material reduction in the accident frequencies.

Cautious in the Employment of the Applicant

Then the field engineer must go a little bit further. He must be watchful in the employment of the men, not simply take a man on because he wants a man to work, but in talking to the prospective workman, size him up, find out how his eyesight is, whether he is subject to any fainting fits, or anything which plays an important part in accident frequencies. We have overcome that in some of our large operations to a great extent by subjecting all employees to a physical examination, not merely on entering the job, but sometimes every two weeks; or if a man comes to the doctor for treatment for some minor injury, the doctor inquires then casually as to what other conditions he might have which might lead us to believe that he was not a safe man to have on the job.

Then again, no workman should be required to go into any hazardous location without being first apprised of the hazards involved in it. I say that because only recently I saw a painter painting guard rails around live installation that was carrying 110,000 volts. Several years ago we had a painter doing a painting job around lightning arresters, and the tip of the paint brush, as he was getting along the inside of the guard rail, came close enough to form an arc across, and the man was killed. Now, we make the point that if painters are going into any live installation to do any work, a competent electrician be right on the job with those painters. It is an extra expense, but it pays.

If a man is going, say, into the purifier house of the gas works, the man should be apprised of the danger; otherwise he might strike a match or carry some other exposed flame. He might get away with it the first or second time, but he may go in there another time when there happens to be an explosive mixture in that compartment or room, and we would have an explosion that would cause a very serious interruption to service; just the same way as the short circuiting of some circuit may cause a serious interruption, and which could be guarded against by the man being properly instructed before taking up that line of work.

In spite of all of these hazards that we have found in the construction work, I dare say that if any of you men would go on any construction operation, the hazards would be self-evident to you. I am speaking of that generally, but of course I know of many instances where the safety

program is being carried through with considerable force. But unless the executive is sold on the safety movement, he can not get the field engineer to give his best interests. Therefore I say that if we are going to get the results in this prevention of accidents in construction work, or any work, we first have to get the executive so thoroughly imbued with the subject that his instructions to his subordinates will demonstrate that the safety program must be carried out to its fullest extent. Unless you have that cooperation from the head, we are not going to get the cooperation down the line, because the men below are going to be governed by the attitude of the man in charge of the work.

CHAIRMAN McCULLOCH: Mr. Beardsley's paper shows a list of hazards in connection with power station construction that I believe is worth taking the time to read. It is a list of 28 hazards, and it may help in connection with the discussion of this paper.

Now our time is limited on the discussion of this subject, but we can devote a few minutes, so let us make it snappy.

H. F. WEAS (West Penn Power Company, Pittsburgh, Pennsylvania): Mr. Beardsley brought out some very interesting things about the mental condition of the men. That certainly does produce a good many accidents among electrical workers. I think there is another thing that perhaps some of us may have overlooked, and that is that a good many accidents come perhaps from over-ambition on the part of young workers.

The Too Ambitious Man is a Dangerous Employee

Last year we built a very large outside steel substation structure. Several young men in the gang were very ambitious and they wanted to climb. They were given positive instructions that they would not be allowed to climb under any circumstances. But when the station had been cut in, and there was some power on top in the buses, especially, the foreman, who was an experienced man and a very safe worker, took his entire gang down underneath the concrete platform to do some work. He thought he had them all, but unfortunately he did not. This young ambitious boy saw a block and fall hanging up in a steel structure and he knew that had to be removed. It was a job for a trained man to remove it, but he waited his opportunity, and when this gang was under the concrete platform, he proceeded to climb that structure. When he got up on some of the diagonal lattice bracing, unfortunately it was wet, he slipped through and fell directly on a 25,000 bolt bus.

Now to add to the trouble, just as soon as the men rushed up there, a young cadet engineer who also had no business whatever climbing structures (and he knew it), in the excitement he shinned up that steel structure like a monkey and in a few seconds was on an adjacent bus that was also energized, and within a few seconds two men were dead. They could not be revived. There is a case of over-ambition, and I think that is a thing that should be watched out for with these younger fellows.

To make it brief, as Mr. McCulloch suggested, about three weeks ago down at another of our power stations in the outside structure, a young fellow was killed who had no business climbing and who had been given

definite orders that he positively could not climb, because he was inexperienced. Some men were to do some work on a dead part of the structure. It was only energized on the very top. It was perfectly safe, that is, to men who were experienced. This young man came to the foreman and said, "I would like to climb up and help those fellows there." The foreman said, "You keep down from there. You have no business there." Then he went around and started to walk to the cage, and before anybody could see that young fellow, he had climbed to the top of the structure which was charged with 66,000 volts, and you know what happened. These are two positive cases of over-ambition on the part of young workers. You have got to watch those young fellows, and not let them get too ambitious.

Many Young Men Are Over Ambitious

Mr. MOTT (Illinois Bell Telephone Company, Chicago): I wish to verify what Mr. Webb has said. He is talking, I presume, more or less about steel structures. When a young man comes before me, and is over-ambitious, and he falls from a pole, in nine cases out of 10, I get hold of him and sit down and talk to him, and he says his spur cut out. If any of you young fellows know about climbing, you know there is no such thing as a spur cutting out if you are careful. "How long have you been climbing?" "About two weeks." He tries his utmost to impress me with the idea of how fast he can get up and down a pole. A boy climbing two weeks tries to hasten it, tries to be rapid in climbing a pole! I find a vast number of cases of that. A young man has not been properly instructed, or does not know about the spurs cutting out. The young man that I have to contend with is the fellow who won't use one of our ladders or go to the trouble of getting it. He goes and borrows almost any kind of a ladder.

Mr. PACKARD (Connecticut Power Company, Middletown, Connecticut): Almost all construction accidents result from doing something which should not be done or from following an improper method. The main reason for that, in the opinion of many of us in safety work, is improper assignment. Your construction man, be he contractor or central station man, is faced with a tremendously difficult problem. Oftentimes he must build up a big organization, build it up quickly, and get it functioning quickly. The result is improper assignment of the new help that is taken on. Switchboard operators are put up climbing steel structures and vice versa. The men are doing things for which they are not fitted either mentally or physically, and that, to my mind, is one of the biggest things we have to contend with on construction work.

An interesting method has been followed by some executives. In connection with Mr. Beardsley's plea for executive attention to these things, I know of one company in the east which lost an old employee whom they valued very highly. This old employee had been very instrumental in the safety work of the company, yet he was killed in a very silly accident. In order to perpetuate his memory, the company set aside a fund of \$75,000. That fund is distributed among employees who are exposed to

electrical hazards, provided there has been no fatal accident in that group of employees during the six months immediately preceding.

This income is divided into a number of shares, depending upon the number of employees involved, and the distribution is made. An employee who is a first class lineman, for instance, would get ten shares, a ground man might get three shares. That is, the extent to which each electrical employee participates in the distribution of this money, depends upon the degree of his exposure. The result has been that every ground man watches the lineman on the pole, and if that lineman does something that the ground man knows from his safety rules and instructions is wrong, he calls the lineman's attention to it. It has practically eliminated that old spirit of bravado among electrical workers in that particular company. It has been going about three years now and the accident record looks a whole lot better. Whether there is any relationship between the improved accident record and this so-called "McCauley Foundation" nobody knows, but we think there is.

CHAIRMAN McCULLOCH: We are going to make a slight change in the program because one of our speakers is required to go into the electric railway session to take part in their program, so instead of calling on Mr. Gillette first, we are going to have Mr. James Harmon, of the Kentucky Utilities Company, Louisville, Kentucky, describe to us one way to "keep from getting old."

ONE WAY TO KEEP FROM GETTING OLD

James Harmon, Kentucky Utilities Co., Louisville, Ky.

I think the time has come when all well-regulated utilities companies have attempted to standardize on their safety work. I think most every utility company and railway company conducts its safety work along about the same line. Some man will get up and say he believes that the accidents occur to the new men. Another will say that all of their accidents have occurred to the old men. The other day an engineer in our plant, who has been there for 12 years, went out to pull a fuse on a circuit and failed to pull the disconnect and was burned up. Now, he would not have let anybody else do that in his organization, but he does it himself. I want to show you that just as a comparison. You might expect it sometimes to the old men.

Some accidents have occurred on our property recently to men who have been supervisors, who have held the position of superintendents. They go out and do things they know absolutely are wrong, and they admit they know they are wrong. They do not have any excuse for it. They could not tell you why they did it. So, I say all utility companies have standardized to a certain extent on safety work. That is the proper thing to do. But even at that, with all the energy and all the efforts that you put forth, and all the support that you have from your executives—and I think most of them have the backing of their executives—even at that there is always something happening which you wonder at.

The subject assigned to me is "How to keep from getting old." I am going to refer to an accident on one of our properties. I should have a map to show you the contour of the ground where this accident occurred. This is in the mountain district of Kentucky down near Harlan, Kentucky. Every once in a while somebody wants something done real quick. The regular construction gang is out building a transmission line and they are away off. They do not want to bring them in for this little job, a week's job, we will say, and you only send your foreman out to do that work. He gets out in the community in which he is going to do the work. Maybe he picks up one lineman or two linemen. It is not really work or energized equipment but it is work in close proximity thereto, and he picks up his own men in that territory. All he wants to know is whether they can work, usually, and in this particular case this was a very steep mountain job.

Building a Line Up the Mountainside

They had built a line this way. They go up one side, they build the line and complete it on top of the mountain. What they are doing is stringing a line under a 33,000 transmission line. They come up and get on top of the mountain and they are going down. The men working can't see one another 20 feet apart on account of the contour of the ground and the underbrush they have to work through. It was necessary to use horses and mules and men to take the slack out of the line. They were laying it on the ground getting ready to put it up on some cross arms under a 33,000 volt line.

In this particular instance they had a foreman on the job. We had a superintendent on the job, or he was supposed to be on the job. We had a general superintendent who had visited the job just previous to the accident, but at the time the accident actually occurred, none of these men was there, and there was no one there to supervise the work. The men who were doing the work were untrained men. They were qualified to do the work they were doing, but they were not experienced enough to know the danger which they were working close to.

In coming down this mountainside half way down they had a team of horses or mules which were pulling the slack out. Down a little further four men were stationed on a turn, and they were also pulling out the slack. A little further down the mountainside were a mule and two boys. What they had been doing and what their instructions were, when they were stringing this line and laying it on the ground, was that it was necessary to use block and tackle to pull the slack. It was necessary to fasten the block and tackle to the base of the pole. They did that all along until, because of the contour of the ground, they put the block and tackle up the side of the pole instead of putting it at the base of the pole. One of the men later said that the reason he put it there was that the boy who was driving the team told him to do it.

At any rate, the fellow put the block and tackle on the pole and he hollered to the boy to take up the slack. You can imagine, on account of the transmission line coming down like that, when he took the slack up,

it pulled the line right up into the 33,000 volt line. That is the thing briefly. It killed three men, injured two, and killed a couple of horses. It took all day to find out how the accident happened. Every fellow was protecting the other fellow. The real fact is that there was not any experienced men on the job. The foreman had gone away and had not left proper instructions. I said to the lineman on the job at that time, "Didn't you know better than that? Aren't you a first class lineman?" He said, "No, I am a second class lineman." I said, "What do you mean by a second class lineman?" He said, "I don't draw as much money as the other fellow."

I mention that to show you that we all sometimes feel that our safety organizations on our property are the best. We sit down comfortably and feel at ease and think that we are doing everything that we ought to do, and off in some isolated place something like this happens. We have absolutely fallen down on the job. We have not even touched the places we ought to touch.

You go ahead and hold your local meetings in towns where you can get a lot of employees who attend regularly and take an active part, but the fellow you do not attend to is the fellow out in the hills, whom you can't reach unless you have somebody go out and personally interview him. The time has come when you have to give more attention to the places where there are not so many men and not so much attention given as in meetings where we make speeches and make them all feel good.

I feel that the time has come where you have to do more personal work in your organization and not so much in a general way, because the accidents which occur on our properties are to fellows who have been employed to do work which they know nothing about. They have not been properly instructed and therefore they are not qualified to do the work which they are supposed to do. The foreman also is the fellow you have to check up pretty carefully and often not only from his conversation, but by your observation. It is a most important thing, in my opinion, because the accidents are not always occurring to the new fellow who has not been properly instructed. It is sometimes the fellow who has been properly instructed and the fellow who knows better and still goes ahead and does it.

CHAIRMAN McCULLOCH: Mr. W. F. Gillette, General Operator of the Detroit Edison Company, will give us another means, for substation operators, to keep from getting old.

A SUBSTATION ACCIDENT

**W. F. Gillette, General Operator, The Detroit Edison Company,
Detroit, Mich.**

The education and training of operators for substation work is one of the important problems confronting the modern public service corporation today and the type of employee required for this important position must possess a cool head, be able to think quickly and keep his mind on the various operating duties demanded from time to time.

The routine operating duties (or switching) which are performed day after day seem to develop a spirit of carelessness among certain types of operators and this carelessness sooner or later results in an accident or an interruption of service.

An operator's training covers a period of 18 months, during which time he is allowed a two hour study period each day, and attends the operator's school one-half day each week. During this period of training he is classified as a helper and acts directly under the supervision of a qualified operator, and in order to give him the required proficiency he is allowed to perform certain operating duties.

An operator was given the order by the system operator to change a 2,400 volt lighting circuit from one phase to another phase, and as his helper had reached the period of training where he was allowed to help in such operations, he was given permission to pull the jumpers in series with the switch.

The operator had opened the switch, killing the circuit, and the helper, being desirous of demonstrating his ability as an operator, rushed to the basement and pulled the jumpers on another circuit which was in commission before the operator could stop him. The resulting arc burned the helper about the body, face and arms, with such severity that he died the next day.

As all jumper compartments are plainly marked and this helper understood thoroughly the particular part he was to perform, this accident was the result of carelessness on his part, carelessness in checking jumper compartments before opening jumpers and disobeying orders in not waiting for the operator.

As a result of this accident a closer check is made of helpers during their period of training and the habitually careless man is dismissed from the service or transferred to a less hazardous occupation.

CHAIRMAN McCULLOCH: We will have a description of two accidents in connection with gas operation, the first of which is an employee on the consumer's premises, by Mr. H. M. Keller of the Northern Indiana Public Service Company of Hammond, Indiana.

AN EMPLOYEE ON CUSTOMER'S PREMISES

H. M. Keller, Northern Indiana Public Service Company, Hammond, Indiana

Mr. Harmon's statement of the trouble encountered in making an investigation after an accident and the men trying to cover each other up, reminds me of that story of the lady who, when her husband did not return home by midnight, picked out the names of several of his best friends and sent out telegrams and said, "Jim not home. Have you seen or heard from him?" Within an hour seven telegrams came in and said, "Jim is spending the night with me."

The fatal accident, which I am about to describe, is one which occurred before our company had adopted organized accident prevention measures.

One of our fitters was notified of a gas leak in a customer's residence at East State Street, Hammond, Indiana. He responded and was told by the lady of the house that in her opinion the combination gas fixture in the kitchen was leaking. So the fitter, accompanied by the customer, proceeded to the kitchen, where he placed a table under the fixture and then a chair on top of the table.

According to the statement of the customer, the fitter looked over the fixture with the aid of a flashlight. "Then he put the light in his pocket and struck a match—the match was of the common type. There followed immediately a terrific flash and a loud noise; the flames seemed to shoot down upon us. He jumped right toward me. His clothing was on fire and so was mine. He ran down stairs with his clothes in flames into the street, then turned and ran up stairs where one of the roomers threw a rug over him, partly extinguishing the flames."

The statement goes on to tell how violent the man was and finally that he was taken away to his home where, upon advice of a physician, he was removed to the hospital, where he died two days later from the burns he had received.

Accidents About Gas Leaks Are All Too Common

The records show that the victim had been in the employ of the company for six years and had 15 years of experience in gas fitting. A fellow employee stated that this man had been warned scores of times about using matches in his work.

What might be considered a contributory feature in this accident is disclosed in the report of an employee who was sent to the scene of the explosion soon after it occurred. He stated that gas was leaking from the fixture. He went to the basement and found the shut-off cock in a position that ordinarily would shut off the gas, but upon closer examination he found this cock worn and defective, which allowed the gas to proceed through the pipes to the fixture and appliances.

We had an accident shortly afterward (which fortunately did not end in a fatality) in which a lady handed a candle to a fitter's helper who was searching for a gas leak. He found it—and later he was also found, with a few minor bruises, under the cement blocks which had once been the foundation of the house.

Our company now has a strict ruling that all tests for leaks must be made with a soap and water solution, and we have every reason to believe this rule is being complied with, as we have not had an accident which can be attributed to this cause since the rule was made.

CHAIRMAN McCULLOCH: I have just asked our vice-chairman, Mr. J. C. Hubbard, of the Western Union Telegraph Company, if he will not introduce the next speaker who is to describe another fatal accident.

J. C. HUBBARD (Western Union Telegraph Company, New York City): When the Section asked the telegraph company or the telephone company

to produce an example, we were rather hard put to it to find something that would be of general interest. Everybody of course puts up his own problem, so after going over several hundred cases, we selected one in which a fatal accident occurred to a man who was doing some reconstruction work on a pole.

It is of special interest to telephone and telegraph companies, but also we think will be of interest to power companies, whether they use wood poles or not. A great many of you here are safety engineers. You are spending your time on this work. We selected a man from the ranks, a man who has been through the work himself, started as a ground man, became a lineman and is now supervisor of telegraph work, handling the state of Florida. I take pleasure in introducing Mr. Morgan from Atlanta.

A FATAL ACCIDENT

E. C. Morgan, Maintenance Supervisor, The Western Union Telegraph Company, Atlanta, Ga.

There is nothing that depresses the minds of those interested in safety work more than a report that a fatal accident has occurred, and we immediately begin to wonder how, with all the precautionary measures we have taken, such an accident could have crept in.

After detailed reports are reviewed we are sometimes struck with the simplicity of it all, and find it hard to realize how it could possibly get past us.

I sometimes think that if we were to purposely plan a fatal accident, our scheme would be so apparent that the victim would detect our purpose before the plan could be carried out.

Let me describe to you a fatal accident which snatched away the life of one of our men. Also let me explain to you how easily this accident might have been avoided.

For a number of years, each lineman employed by the Western Union Telegraph Co. has been served with a written notice at the time of his employment, advising and warning him of the danger in climbing poles without first inspecting them to ascertain their condition. Each employee is instructed and warned not to climb a pole if there is any doubt about it being strong enough to support him safely and any strain which he may place upon it. When there is a doubt as to the condition or strength of a pole, he is instructed to take the necessary steps to strengthen it before climbing. Poles are tested with a pike pole or rope, the tests are made by pushing or pulling the pole across the line, not with the strain in line with the wires.

Employees are warned not to untie the last wire on a defective pole until the pole is securely held by guys, braces or pike poles. It is often possible to lash an old pole to a new pole while the old pole is being dismantled.

These warnings, among others, are accepted by the linemen as part of their job, and they enter vitally into their every day work.

Picture, if you will, a small group of plant workmen carrying on under the direct supervision of a city foreman, in an average size town, where the telegraph company has, in addition to its main telegraph plant, circuits that are distributed over town in some sections on other companies' poles, in order to reach patrons with their time, messenger and other classes of subsidiary service.

The city foreman knows his men and their capabilities, each of them is skilled in his work, accident prevention methods have been discussed and the safety first thought has been absorbed by the men who get out around town and work alone. Safety first has become a feature of their every-day work and when no accidents creep in to disturb the daily routine, the foreman is apt to forego repeating instructions on safe working practices to his men, and he takes it for granted they will realize where danger lurks and will take precautions to protect themselves.

In the course of a day's work, one of the linemen notices a pole of another company from which its wires have been removed, but upon which the telegraph company has two wires used as a clock circuit. The other company has rerouted its wires and it is apparent to the lineman that the pole is to be removed. It will be a simple matter to transfer the wires so that they will clear this pole and release it. On his return to headquarters he reports to the city foreman the necessity for the work. The foreman asks how much assistance he will require, and the lineman, believing the work can be easily accomplished, replies he can use one man, and without hesitation the city foreman assigns a man to assist with the work, instructing them to take whatever material and tools are necessary.

Another Accident That Could Have Been Avoided

The first thing the next morning, the two men proceed to the scene—they will be designated as Mr. "A" and Mr. "B". No pike poles are taken and there is no evidence that the pole is tested. Mr. "A" puts on his climbing tools and climbs the pole. Mr. "B" remains on the ground. "A" reaches the crossarm, throws his leg over it, and unties the wires. "B", from his position on the ground, sees the pole start to fall, shouts a word of warning—too late, the pole catches in the limbs of the tree and its weight with its human burden tears through and strikes the ground, with Mr. "A" underneath. The pole was rotted 21 inches below the ground line. Mr. "A" was killed.

How could this accident have been avoided?

(1st) Had warnings and definite instructions been followed by the men doing the work, no accident would have happened. When Mr. "A" stood on this scene the day before and planned in his mind the work necessary, he completely overlooked the hazard there might be in a pole to be abandoned.

(2nd) The city foreman to whom the necessity for the work was reported, also failed to picture in his mind a dangerous condition and when he told the linemen to take whatever material and tools were necessary, he was not definite enough and should have sensed a dangerous

condition, even if his other work made it impossible for him to make a personal inspection.

(3rd) Both Mr. "A" and Mr. "B" failed to heed instructions and warnings that had been given them; they did not take the necessary tools and material to do the job safely; they should have taken along pike poles and ropes so that the pole might have been tested, and even if a pike pole test failed to show the defect, as a precaution, the pole could easily have been lashed to a nearby stub.

Mr. "A's" position on the pole was wrong, there was no necessity for going above the crossarm, his proper place on the pole was under the crossarm on the side of the pole, away from which wires were pulling, in a position where he could hook his leg around the pole and reach up, untying the wires. In this position he would have had a much better chance when the pole started to fall.

To prevent an accident of this character, nothing must be taken for granted, instructions must be followed, warnings must be heeded by the men actually doing the work.

Foremen and others who direct work must never let a chance go by to repeat a warning and stress the necessity for precaution. The city foreman in this case should have said, "Don't climb that pole until you have tested it with pike poles; then guy it or lash it to an adjacent pole before you climb it."

We see from this accident that despite warnings, despite instructions, despite direct supervision, accidents can creep in, and only by anticipating such an accident and taking proper steps to see that instructions and warnings are followed, can they be avoided.

Trying to Save Time in a Coal Yard

CHAIRMAN McCULLOCH: We still have about half an hour in which to discuss the subject of fatal accidents. It has been my experience that if there is any one thing a safety man likes to talk about, it is how his accidents occur. Here is your opportunity. The meeting is yours for half an hour.

W. L. ANDREWS (Dayton Power & Light Company): We recently had a case in the northern part of our city where a man had been killed in a coal yard. They were in a considerable hurry in endeavoring to move a coal conveyor. At this particular location we had a 33,000 volt line at the top of the guy wire coming down between a 6,600 volt line. The coal people did not care to take the time to lower their conveyor to pass the guy wire. They thought that they could use precaution and endeavor to steer the top part of the conveyor under the guy wire; the owner practically admitted that he appreciated the hot voltage above, but unfortunately they were not successful. The conveyor hit the guy wire, which of course was not insulated. They swung into the 6,600 volts and the workman who was operating that conveyor received 6,600 volts and was instantly killed.

This brought up a point to our company to make a survey of the

town, of the coal dealers particularly, and other construction men who are using cranes, and so forth, where they may be swinging into the 6,600 volt lines or other voltages. We have made this survey and at least we have the coal operators or dealers on the alert to guard themselves against such conditions.

MR. SPRINGER (Detroit City Gas Company, Detroit, Michigan): I want to bring out the difficulty with employees who are experienced and have become confident of their work. In this case a man had a fall which proved fatal. It was a job which was to be done in a hurry. The men who were on the job were thoroughly experienced in that class of work and capable of doing it. But owing to his perfect intimacy with that class of work on high elevations and high steel work, the workman simply neglected the possibility that an old piece of structure might have a joint which was rusted out or which might become loose under pressure. Perhaps in working around this somebody actually leaned up against this particular piece of timber or steel work when the structure was more firmly bound together and found it was tight. After removing some other pieces, this may have removed the support. This man leaned against it and it fell. This is the point I want to bring out. The older men are liable to overlook some of the things that a newer man might not become aware of.

Accidents While Unloading Heavy Poles

CHAIRMAN McCULLOCH: It is not necessary to limit ourselves to the discussion of fatal accidents. If you have any accident, serious or fatal, or otherwise that can bring out any lesson of value to the other companies, this is a good place to explain it.

MR. GREEN: (Ohio Power Company, Canton, Ohio): We had an accident about a month ago. In unloading poles, the guys had been cut. There were stakes on one side of the car track and stakes on the other side of the car track. On examination, these stakes were found to have about 60 per cent dry rot. A man was caught and crushed when the poles broke and rolled the other way.

MR. DILLON (Central Illinois Public Service Company, Springfield, Illinois): We have had several accidents unloading poles. We do not unload any poles now without going over the top of the pole. We absolutely make sure that the pole will not break and go the other way.

I want to relate an incident that occurred in the ice industry. We had recently taken over a new property at Centralia, and the C. B. & Q. railway was trying for part of the fruit business of the south, and in order to service those people we had some ice trucks that would hoist ice to the top of the car and a man could drag the ice truck into the bunkers. On the first night they shoved into the yard 13 cars to be iced. The men on the job were new. The truck was new. There were seven or eight of the Q. officials there directing the work instead of having our men direct it. They took that job upon themselves and they had our fellows all scared to death.

The fellow who was the chauffeur, or the truck driver, started to raise

his truck. He was so excited, at least that is what he says, that he could not get it to function. The foreman standing back behind the truck saw that there was something wrong and he told him, "You have got to hurry, because we can only stay here so many minutes." He grabbed the crank and started to raise the truck by hand, and by the time he got it started, the truck driver got his mechanism started, and of course this started the handle going about 50 miles an hour, and instead of turning it loose and running, he attempted to pull it off and escaped with only three ribs broken. I think this brings out that the foreman did not have control of his men, or complete control of the job.

MR. BENNETT (Northern Indiana Public Service Company, LaFayette, Indiana): Most of these accidents described have been the fault of material, or lack of supervision. I went to tell you about an accident that occurred on our property that was not the fault of supervision. We have not been able, on investigation, to lay it to faulty material. It appears to have been more an act of God than anything else.

A Peculiar Accident When a Tree Limb Interfered

There was one of our line gangs running a line just outside of town. There was a high tension line running to another town, 22 miles away, 66,000 volts. This new line was being run 12 feet below this high line which was energized. Eight phases had been run and tied in between section poles. In starting to run "C" phase, which was the outside, on the other side, the phase caught on the limb of a tree. "A" phase had been tied in at least half an hour before, and was presumably all right. The foreman sent a young lineman who was considered capable up into this tree to loosen the "C" phase. Going up into the tree, he could not reach it without putting on his belt, so he put his belt around the trunk of the tree and had to lay back. Just as he reached the wire, "A" phase snapped loose and instead of falling down, which it would do in nine cases out of 10, it flew up, wrapped itself around the 66,000 volt line and energized the tree, making a veritable electric chair out of it. The sorry part of this was that this line was being energized from this other town and it took 10 minutes to get them on the phone and get them to cut loose. In the meantime this man was burned on both shoulders and both feet.

The foreman had presence of mind. Another man in the gang grabbed an axe and started after the tree but was stopped by the foreman. You know what would have happened to him if he had got to the tree. He stated afterwards that was the last thing on God's earth he thought would occur. Just what to lay that accident to we have never fully decided.

MR. LUECK (Commonwealth Edison Company, Chicago, Illinois): During the past year we had five fatal accidents and not one of them could we attribute to a direct cause, as we analyze our accidents. We had one man who was working around a railway crane. This man was given to understand that he was not to ride on the step of that railway

crane. He did step on it one day and the crane turned around and forced his body between the body of the crane and that of the railway car.

We were building a new service building. We had got up to the fourth floor. Understand that this was a contract job. On one of the openings, (which would be a stairway later on) they had placed a platform. They were pouring concrete. The platform was built by the contractor and we had a man there to see that this concrete was not poured into the conduit; and while they were walking across this platform with a concrete bucket the platform collapsed and our man was thrown down to the basement and instantly killed. Another man on the first floor was seriously injured, but recovered.

We had a trouble man, one of the best that we have ever had in our organization. He went out one week to flash phases. It could have been done very safely in the position that had been outlined for him, or in which it was customary to do that work. However he mounted to a point where he was able to get his head against a trolley feeder and was instantly killed.

We had only very recently an oil switch repair man killed. He is the man we seldom hear about getting into trouble. In fact, it is the first one we have had. He was sent down in the reactor compartment to stand by until they killed the particular reactor that they were to work on, and when the men returned they found this man was dead, lying in front of the reactor with the door ajar. A spot was rubbed off the reactor and his finger tips were burned. The rule was a man was to touch a reactor only in the presence of another man.

Of all these fatal accidents, there was not a thing that we could do to prevent them. You can't detect the slow acting mind. You can not tell the absent minded man. They are not absent minded always, but sometimes.

ADJOURNMENT

WEDNESDAY MORNING SESSION

October 27, 1926

The Public Utilities Section of the National Safety Council convened in the General Assembly Room of the Detroit-Edison Company, 2000 Second Avenue, Detroit, Michigan, at 9:30 o'clock, Mr. B. B. McCulloch, Bureau of Safety, Chicago, Illinois presiding.

CHAIRMAN McCULLOCH: At this time we will hear the report of the nominating committee.

**REPORT OF HARRY M. WEBBER, CHAIRMAN OF THE
NOMINATING COMMITTEE**

In compliance with your request, the nominating committee has the following names to submit for consideration as the officers of this Section for the ensuing year:

For chairman, George Opp, safety engineer, Detroit Edison Company, Detroit, Michigan.

Vice-chairman, Electrical interests, Carl J. Rutland, safety engineer, Texas Power & Light Company, Dallas, Texas.

Vice-chairman, Telephone and Telegraph interests, H. L. Mead, plant supervisor, Ohio Bell Telephone Company, Cleveland, Ohio.

Vice-chairman, Gas interests, C. Howard Stewart, assistant treasurer, Laclede Gas Light Company, St. Louis, Mo.

Secretary, H. M. Keller, Northern Indiana Public Service Company, Hammond, Indiana.

Signed, H. M. Webber chairman, H. B. Harmer, H. J. Burton.

CHAIRMAN McCULLOCH: You have heard the report of the Nominating Committee. What is your pleasure?

(It was moved and properly carried that the nominations be closed, and that the Secretary be instructed to cast the ballot for the election of the officers.)

SECRETARY DOBBIN: Mr. Chairman, the secretary casts the ballot for the officers nominated.

CHAIRMAN McCULLOCH: The first number on our program this morning is an address by Mr. A. J. Van Brunt of the Public Service Corporation of New Jersey, Newark, N. J.

ACCIDENT PREVENTION IN THE GAS INDUSTRY

A. J. Van Brunt, Public Service Corporation of New Jersey, Newark, N. J.

Colonel O. H. Fogg's paper, presented at our session last year, completely and ably covered the subject of cooperation in accident prevention work as applied to the ability of the safety man to sell the thought to his executives.

Let us assume, therefore, that the safety man has sold the thought to his executives and they are willing to give him 100 per cent cooperation; that all proper safety appliances necessary for that type of gas plant have been purchased and installed; that all are in order and the mechanical guards operating efficiently. I am willing to admit right here, of course, that I am a very presumptuous fellow and that this condition as I have outlined it is not apt to exist in its entirety, but for the sake of argument we will assume that the condition is so. This is not enough. It is only a good beginning and the least important part of the completed job. In order to have efficient safety conditions prevail, we must reach the superintendents, the foremen and all of the other employees.

It has been truly said, that of the accidents in the gas industry only about four per cent are attributable to the industry; 96 per cent are of a type that occur to any industry. Also carefully worked out tabulations based on reports from a large number of gas companies appear to prove that 81 per cent of the accidents occurring in the gas industry are due to carelessness; only 19 per cent can by any possibility be attributed to defective appliances, tools or material.

Include Every Employee in the Safety Organization

So if, from a humanitarian standpoint, we wish to cut down the accidents, and if from a financial angle we desire to save the damages paid to injured employees, the wages earned by them while convalescent, and the money cost of training new employees because of their unfamiliarity with their jobs, we have got to reach way down below the executive officials and the safety man. We must include the superintendents, the foremen and absolutely all of the employees. We must sell them the safety thought, so that each of them will recognize that it is a worth while thought, not merely a measure that will benefit the company or the boss, but each of them personally; and having sold them this thought, having succeeded in getting into their understanding the conviction that the safety educational work being done is as much for their benefit as for the company—after that we have to keep everlastingly at it.

What means shall we use? All possible means. How shall we do it? In every way. No one way is best, no one way will do it all.

One safety man says bulletins, another says the spoken word, another relies on the printed word; one on safety committees, another on investigation of the accident and the posting of the result of the investigation where the employees can and will read it; still others put their faith in meetings of the employees, competitions between groups with a reward for the best results obtained, praise of individual employees, outings, suppers, entertainment, motion pictures, etc.

All efforts and every effort that can possibly be made—first the impression and then the reimpression of the desirability of considering personal safety of paramount importance to the individual—are good and all are necessary. In my estimation no single one is adequate, and

so far as our individual situation will permit we should use them all. Each man in charge of safety work must consider the conditions existing in his own territory and use every possible effort to convince those under him that the thought for safety is the first thought of self. First, convince the executive officials that it is best from all angles; next be absolutely sure you have secured the real cooperation of the minor officials, superintendents and foremen, and then in every way possible convince the employees that the safety thought is a worth while one and that it makes for their comfort, happiness and financial welfare.

I consider it unnecessary to name here even approximately in detail the many conditions in and around a gas plant which are dangerous. My presumption is that you all know as much if not more about those things than I do. But I know that the safety man is too apt to rely upon one or two, or possibly three or four types of educational safety effort, and I want to succeed in getting across to you the one thought that there is nothing you can possibly do in the way of safety educational work to all of your people all of the time that is not worth while.

If there is a person here who is not thoroughly familiar with the Schafer Prone Pressure Method of Resuscitation, you are behind the times. It is your duty to familiarize yourself with the method and see that it is taught to, and practiced by, every person over 12 years of age in every plant you have access to.

The results obtained by the Company members of the A. G. A. and the N. E. L. A. in the use of the Schafer Prone Pressure Method justify me in saying this in this way.

Discussion Following Mr. Van Brunt's Paper

CHAIRMAN McCULLOCH: Before proceeding with the discussion of Mr. Van Brunt's paper, I want to make an announcement or two. Because of the inadequate room facilities yesterday, it was almost impossible to get a proper registration of members present. But the registration cards show that there were a total of 156 who registered at yesterday morning's meeting and I am told that there were approximately 75 who were turned away because they could not get into the room. These 156 men represented 22 states, the District of Columbia and Canada. Today we are anxious to get as complete a registration as possible, and I will ask that you please fill out your cards at this time.

There are two matters that the Public Utilities Section is sometimes criticized on. One is the fact that the Gas Companies do not receive sufficient consideration on our programs, as compared with the time devoted to the electric companies; the other is that there is not sufficient time left for the discussion of papers; that our programs are too full, that we attempt to cover too many subjects on one program.

We have attempted this morning to avoid criticism on these two points by limiting the program to two subjects, the first of which is accident prevention in the gas industry; but you will note on the program that the formal discussion has not been assigned to any one person. The discussion is, therefore, an open one, and is turned over to you entirely. I

hope that everyone will feel free to get up and discuss Mr. Van Brunt's paper or to bring up any suggestions or recommendations in connection with accident prevention in the gas industry.

MR. GLIDDEN (Ohio Public Service Company, Mansfield, Ohio): Mr. Van Brunt made the assertion that all of us had heard the paper given in Cleveland regarding the methods of selling the executives on the subject of "Safety First." I would like to remind him that there are some 72 (isn't it, Mr. Chairman?)⁴ new members who probably are present, and I am one of those. I wonder if someone would give me suggestions as to methods of selling the idea to executives?

CHAIRMAN McCULLOCH: There is a good subject that we ought to have plenty of answers on. Who is going to be the first?

MR. VAN BRUNT: I think I have been fairly successful, but if there is any other man in this room who has not tackled that job, and thinks it is easy, I want him to change his mind right now. That is the hardest job. There is no one way that you can sell your executives the thought of the desirability of carrying on intensive safety work in your plants. In talking with your executives there are so many things to be borne in mind.

There are executives who are "Hail fellows well met," and they feel that they are no better than you are; there are others who are so puffed up with the idea of their own importance that you have to take your hat in your hand and ask their private secretary if you may have an appointment with them four weeks hence; there are some who have come up from the bookkeeping and auditing departments, and you must talk dollars to that kind of fellow—that is the only thing he can see. Unless he is an unusually wide-visioned man, if he has come from the financial end of your company to the point where he is an executive, put the almighty dollar in front of his eyes, so that he feels that it is the best way to save money.

There Are Many Types of Executives

Now, if he is the other type—and there are so many types that I can't name all of them—if he is one of the other types, a big, good-hearted fellow, who pats the little kids on the street as he walks along, who does all that he can for the crippled kiddies in the orphan asylums and in the hospitals, who is a member of the various organizations that devote considerable time to the young ones, appeal to his heart, point out to him that when he can go to bed at night—and many of you have done just that thing, I guess most of you have—feeling that he has saved a leg, an arm, a hand, a foot or a life, that is worth all the dollars it cost.

It will be impossible for any fellow who is not connected with that individual company to tell you what to do. I can only tell you what I do, and I did both of those things and then some more. I have had to go to our financial men and show them (and it is a fact) that you can save money, large quantities of it; I had to go to the man with the big heart whose tenderness was devoted toward humanity, and show him that al-

though the dollars were saved, nevertheless, the good that the work did was almost as great, if not greater, than any other work that possibly could be done. Does that answer your question, sir?

MR. GLIDDEN: Yes. Thank you very much.

CHAIRMAN McCULLOCH: Has anyone else anything to add to that? It is not necessary to confine our discussion to the subject of selling executives. The subject is "Accident prevention in the gas industry." It covers inspection, it covers organization, it covers education, any branch of the safety work in connection with the gas industry. I am sure that is a wide enough subject to warrant a 25 or 30 minute discussion.

R. H. KRONE (Union Gas & Electric Company, Cincinnati, Ohio): I suppose there is no company in America that produces gas or manufactures artificial gas that does not have some trouble with carbon monoxide, and Mr. Van Brunt did not tell us anything about that.

Experience With the Inhalator in Electric Cases

I happen to have in my pocket a treatise on the subject of resuscitation, written by three different authorities in one pamphlet, and it is the best thing that I have been able to get through any of the national organizations; and I should like to lay it on the table for anyone else who is interested in it. It pertains not only to the Schaefer Prone Pressure method, which is strongly recommended throughout the country, but deals also with the inhalator and with other mechanical devices. Now, I will let the report speak for itself, but I will say this one thing in connection with it: the pulmotor or the breathing machine, so-called, is a thing of the past. The inhalator—I don't care what make particularly—has been tried by our company and has been found to be very successful.

MR. VAN BRUNT: I would like to ask if there is any member present who has tried any type of inhalator on an electric case, and, if so, what the result has been? We use them only on the gas cases, having been advised that is all that they are fitted for.

C. HOWARD STEWART: (Laclede Gas Light Company, St. Louis, Mo.): We tried the inhalator on a couple of electric cases simply on account of the man being in a weakened condition. We figured that he needed just a little pep to revive him in a quicker manner, and the mask was applied to him just for the purpose of getting a few breaths of the contents, and we think it is a good thing. We had a rather unique experience within the last two weeks. Our crew was called out in the case of the birth of a child, and the child apparently had died while being born; and the physician in the case put in a call for our inhalator; our crew responded and worked on the little baby for about an hour and succeeded in getting a few gasps, but the doctor could not revive the child after we had gotten that far with it, and the child finally was declared dead. That is the first child birth case that our rescue crew has been called out on.

CHAIRMAN McCULLOCH: Before I forget it I would like to ask Mr. Krone if he will just read the title of that paper and who it is published by, for the information of the other members?

MR. KRONE: It is "Resuscitation After Electric Shock," by Wills Mac-

lachlan and others. That is the way it is published in the literature of the National Electric Light Association, at a price of five cents a copy. I am not advertising the National Electric Light Association; I have merely made a study of resuscitation and have found this to be the best treatise on the subject.

In connection with the inhalator for electric shock cases, I have inquired of experts on that subject, and they tell me that it is not necessary for an electric shock case; but in an electric shock case where there is intermittent breathing—that is, where the patient resumes breathing and drops it and we have to start on him again and he drops it again—if you use an inhalator on a case like that, they say it works to great advantage.

MR. VAN BRUNT: The reason for that is that it produces greater inhalation. The person being treated with the inhalator breathes more deeply, takes in more air than you and I do ordinarily, and much more than can be produced even by the Schaefer Prone Pressure method; it does produce much more and in a safer way than either the lungmotor or the pulmotor.

Pulmotors Thrown Out of the Hospital

One of the gentlemen that preceded me told of a particular case. I want to crave your indulgence while I tell something that occurred within two weeks. We make a safety educational motion picture every year. This last year, I put a hospital scene in, using the Cooper Hospital in Camden, New Jersey, because the doctor in charge of that hospital is 100 per cent cooperative. When we went there, we taught 45 of the nurses that were taking the nursing course resuscitation by the Schaefer Prone Pressure method. The good old doctor delivered a little bit of a talk after the motion picture was shown, and the result was that we had a pulmotor, a baby pulmotor, and one other machine thrown out of the hospital. They are now on the junk heap, and any babies that do not breathe immediately will be resuscitated by the Schaefer Prone Pressure method.

CHARLES B. SCOTT (Bureau of Safety, Chicago): Mr. Chairman: I have been wondering whether I ought to say what I am going to, because I feared it might be premature. The subject of resuscitation has been so conspicuously brought to the minds of public utilities, and our efforts on resuscitation problems have been so successful, that executives in the industry are very much interested in it.

About a year ago a group of these men felt that the investigation and study of what really happened to the physical body when electrocuted or asphyxiated, the organic change that took place in the body, had never been thoroughly and scientifically determined. Men that have contributed so much to resuscitation, like doctors Henderson and Drinker and others, have never really made a complete record of effects other than as observed after the victim was shocked or asphyxiated.

Some men who are prominent in the electrical industry have raised a fund and a meeting has been called for the 15th of November to start a real and scientific investigation of the physical change which takes place

in the body in an attempt to find the best remedy to apply in cases of electrocution or asphyxiation. The credit for this new move is due to Mr. John Lieb, of the New York Edison Company, who has made it possible to get the finances to carry on this investigation. Doctor Flexner, of the Rockefeller Institute of Medical Research, is to be chairman of the body which will include a number of scientists.

I am sure you will all be interested in knowing of this new development. I venture to say that when this study and research is completed and when this commission makes its report it will be up to date and that there will be many things brought out which will be not only of great interest to you but of great assistance in this problem. I venture to say we shall all be very much pleased with the results.

That is all I have to say on this subject, Mr. Chairman. You don't know how pleased I am to see the growth of this Section. I have been accustomed to attending meetings of the Public Utilities Section ever since the National Safety Council was organized and my interest has always been in the Public Utilities Section. When I now see this group of men, which is so much larger than the original National Safety Congress, I am proud of the place that the Public Utilities occupy in the safety program of this country. Our industry is to be congratulated on the interest manifested.

Prone Pressure Resuscitation Strongly Urged

WILLS MACLACHLAN (Consulting Engineer, Toronto, Ontario, Canada): I wish to congratulate Mr. Van Brunt on a practical, straightforward paper and to emphasize his point that we must use a number of different methods to prevent accidents.

In Toronto, early in the year, we carried out a series of experiments on laboratory animals to endeavor to learn the effects on animals of the passage of electrical currents. The report will appear shortly in *The Journal of Industrial Hygiene*.

After a thorough examination of the field and with full knowledge of the results of our experiments, one is forced to the following conclusions in regard to resuscitation from electrical shock: that prompt and efficient application of Prone Pressure Resuscitation should be carried out until the patient breathes or the body stiffens; that suitable heart stimulants be administered by attending doctor; and that after resuscitation the patient be very carefully watched and put to bed.

I am fully advised and appreciative of the excellent work carried out by Dr. Yandell Henderson and his associates in developing the method of administering oxygen and five per cent carbon dioxide in gassed cases. Primarily, the object is to free the blood of carbon monoxide and in gassed cases this method is most successful. In electrical shock cases, the carbon monoxide in the blood is not an important factor, even if it be present and the use of the inhalator is not indicated as far as our present knowledge goes. Experimentation to clear up this point is now underway. The use of inhalators on electrical shock cases should be discouraged until the results of this research are available.

Now (leaving resuscitation entirely), I would like to point out possibly one way of getting over an extremely difficult type of accident; call it carelessness if you will,—I don't think it is carelessness. A man is thinking about something else than the work in hand. That may mean the world's series game, which we know caused two fatal accidents in this country, or the good hand he held the night before, or the dance he is going to tomorrow night, or something of that kind. Now, how can you get away from those accidents? The man's mind is some place else.

When you go into your own home and run up the stairs in the dark you won't trip. When you walk into your home in the dark you walk around the furniture, and don't bump into it; you have done it hundreds of times before and habit is carrying you through. Now, why not take that habit and apply it to your industry? I am not saying that we should not educate our men, train our men, but when we are through with the training and the educating and everything else, we are going to have that odd case of accident, the case where the man forgot or was not thinking of what he was doing. Analyze some of those difficult or dangerous jobs; you have got to do it.

Let's take one of them for example: the use of rubber gloves on a pole with 2,200 volts. That is an average case. Every one of us has had the accident of the man going up and working on 2,200 volts live with his rubber gloves on, leaning back on his belt, taking his gloves off and putting his hand into 2,200 volts. You have them; I have had a number. Teach your men to put on rubber gloves, say, at the bottom of the pole, before they go into high tension; teach your men to put on their gloves and take them off only at the place where they put them on. Do that for two or three months and you will never have a man pulling his gloves off when he gets to high tension, and he won't go into it.

Cases of Interference With Prone Pressure Method

MR. RALL (Kansas Power & Light Co.): One point brought out by several speakers that I thought was very good, was the use of the Schaefer Prone Pressure method. I enjoyed the paper that was read this morning very much. The point that we are following in our work is in line with Mr. Van Brunt's paper; and then we are having each one of our men, engineers and all, know the Prone Pressure method of resuscitation; that is, including all the outside forces and every man that works with us or has any contact with us in any way, shape or form.

We are also insisting on their knowing it properly. In our safety meetings we have the company doctor show us the Prone Pressure method, and he times it, not going too fast, giving it a very thorough attention, so that the method is performed in a proper manner. Our idea is for each man to carry it home to his wife and show it to her. I do it with my own son at home (he is only three and one half years old), but it is remarkable how he understands it, and he knows how to be the victim as well as to get on top of his own dad and try it on him. I think we should even train our wives to do this thing. We have found it to be a very good

thing, and it has borne fruit, gentlemen, for it has been a great educational means.

Another point that I want to bring up before this committee is that I have been experiencing a great amount of interference from the city ambulance doctors. They are young and ambitious, so to speak, and they have no use for the old Bible adage which says: "Young men for war and old men for counsel." They seem to know it all. Two weeks ago on the street, while about 2,000 people looked on, I was working on a man and I had to spend about 10 minutes arguing before I could work on this man. The point is this: we must, through some means of our safety council, in our city, have a direct contact with our city council; there must be real cooperation of some kind so that we can practice this method without any argument.

Laying aside resuscitation now, I would like to ask one thing in regard to those electric properties that have underground systems. You have several manholes which must be made watertight. In other words, they are locked in such a way that the water can not get into them, and you must seal them down, watertight. There is, of course, a good chance for gas to accumulate in those things. We do not like to put those in, but we must use them in some places, and I would like to have you tell me how they take care of the proper ventilation of a watertight manhole.

Handling a Difficult Situation in New Jersey

MR. VAN BRUNT: There have been numerous plans discussed for ventilating manholes. Some have gone so far as to say that all manholes should be ventilated, not alone watertight ones, and various plans have been devised; your accident prevention committees have discussed the matter. No definite conclusion has been arrived at, so far as I know, so that we could make a concrete recommendation.

If I may leave that subject just for a minute and speak on one other I would like to say, as I did a minute ago, that the doctor has sometimes been a thorn in our flesh. Those men are not doctors; they have all the conceit but damn little of the knowledge.

I will tell you what we do to them in the state of New Jersey. We have our electric men and our gas men on their toes because we have instructed them this way: "If you are at work on a public service employee, gas or electric, don't let any doctor or policeman stop you."

"Mr. Van Brunt, what will I do?"

"Well, what would you do? Lick them? Sure."

And they do. They sent one young interne back to the hospital and he was on a cot for several days before he recovered, and the man whom they were at work on, and that he tried to stop them from working on, came back to the gang almost 100 per cent.

There is present here this morning our Mr. Robert O. Bentley, Superintendent of Electrical Distribution of Public Service of New Jersey, and he can answer your questions about those manholes better than I can, because he has had more technical terminology.

CHAIRMAN McCULLOCH: I would be very glad to have Mr. Bentley talk at this time.

MR. BENTLEY: I do not know that I can add anything to what was said in reference to ventilating manholes. It is a rather difficult proposition, because if you seal them so that water can not get in, if there is any possibility for the gas to get in it is very apt to stay there. Of course, if they are sealed very tightly, and if there are no gas leaks in the immediate proximity of the manhole, why, you are not so apt to be bothered with gas.

But we have experienced a great deal of trouble on account of gas in manholes, and our men exercise a great deal of care about entering these manholes, and we find that about the safest method to guard against that is to ventilate the manhole, say, before working in it, even by placing a fan in the manhole to blow the gas out, or any foul air that might be in there.

A very simple means that is employed frequently when it is not possible to put an electric fan in there, is to take a blanket—I presume a great many operating men have done the same thing—putting it down in the hole and fanning it back and forth for five or 10 minutes, and it will usually remove any gas that is there. If there is considerable gas in the hole, why, we often keep that process up all the time the men are working in the hole.

Fatalities Following Use of Unprotected Gloves

One thing that many electrical operating men here have been confronted with, and it may be of interest to some of you who have not had this trouble—we have lost three or four linemen recently by electrocution, men working on poles. We found they were shocked through their hands by the current; and in each case the foreman standing on the ground looking at the men thought they had their rubber gloves on. We use a very high grade rubber glove and it is quite fragile. We cover it with a buckskin protector, and in each case where the foreman thought the lineman had his rubber gloves on he found that he had removed the rubber gloves from within the protector and was working on 4,000 volts with buckskin gloves.

So we issued orders and instructions that no employee was to wear unprotected gloves for any purpose. They were all wearing buckskin gloves all the time they were working. We have it arranged so if they want to wear other gloves while doing their work, why, they can't get gloves that look like protector gloves that we use over our rubber gloves. Not very long ago, we lost three or four men from that one cause. They would get up on the pole with their rubber gloves, their protectors and the belt on, remove their rubber gloves and put the protectors on, and then were electrocuted. I thought that might be helpful to some of the men.

C. W. MOAC (Hydro-Electric Power Commission of Ontario): I am connected with the Hydro-Electric Power Commission, and the big end of my business is to teach the employees the Prone Pressure method of resuscitation, which I have been doing for years. We have standardized our system of teaching to the point where I think we could have employees from any part of the province, and they would all carry on exactly the same methods.

Now, I want to stress the point of practice. I will cite you just one instance where failure to practice makes a man fall down. We had one man who had to his credit the resuscitation of three drowned victims two years and a half ago. Just recently I noticed that this employee was not carrying on his regular practice, and I had some new employees in and I thought he would be a real typical man for the purpose of a demonstration. I asked him for the demonstration and he fell down badly. He said, "I don't know what is wrong." I said, "I am going to tell you what is wrong. It is pretty nearly a year and a half since you have had any practice. That is what is wrong, is it not?" He admitted his fault.

Now, we maintain with the Prone Pressure method of resuscitation, that you have got something. We give it to our men. They can carry on without an instrument. They have always got it with them. They don't need to run to get something. I could cite you an instance in the early days of the pulmotor where we lost a man through having a pulmotor. The man got 2,200 volts. There were three employees with him that were trained in the Prone Pressure method, but the Prone Pressure method was not in their minds; the pulmotor was in their minds. They went to get the pulmotor and when they returned it was too late.

I think I can safely say that in 80 per cent of our cases we are successful with the Prone Pressure method without using any other means. We have a man who was burned on the 2nd of November with 44,000 volts. He was so badly burned that he lost his right leg and his left arm. There was only one lineman with him. He lowered the man from the pole and resuscitated him in some 10 minutes. I think that is an example where it will show you that if you know that method you have got the right thing.

Many Men Living Who Were Pronounced Dead

MR. BARADA (Laclede Gas Light Company, St. Louis, Mo.): Mr. Van Brunt made the statement that the M. D. is sometimes a thorn in his flesh. Of course, I suppose none of us will take exception to his statement. We have had quite a few cases of that in St. Louis where one of the men would be working on a man and two other men would be fighting the cops off. However, that is years ago and things have changed since then. But the point I am trying to bring out—in fact, I am looking for information—I am just wondering how many men present know of authentic cases where the patient has been pronounced dead but the operator of the Schaefer Prone Pressure method went ahead and revived the man?

We have one or two cases of that kind in St. Louis. We feel as though there must be more but there seems to be no way that you can find that out, other than by just asking at a gathering like this. We had one case in St. Louis where eight doctors pronounced a certain negro janitor dead. Our man would not take their decision for it, but worked three and one-half hours on him, with the result that the negro is still a janitor in St. Louis today. But what I want to find out is how many men here have had any experience where the patient has been pronounced dead and then later revived?

MR. VANBRUNT: One gas and one drowning case.

CHAIRMAN McCULLOCH: Could we just see the hands, please, of everyone who knows of accident cases like that?

CHAIRMAN McCULLOCH: At least 16. Possibly some of them have knowledge of three or four cases.

MR. BARADA: That answers our question.

MR. STEWART: Mr. Van Brunt talked about the trouble with their men with rubber gloves. We operate an electric company in addition to a gas company at St. Louis, and we try to cover that situation to a large extent in our rubber gloves test. Our gloves are tested every two weeks, and we have several pairs of gloves assigned to each man. Every two weeks when the gloves are tested, the initial test is 10,000 volts and the subsequent tests are 5,000. We have the man receipt for his gloves, and on this little card there is an absolutely definite instruction to him (which he receipts for) that the gloves are to be worn when he is on the pole or handling what we term "Hot stuff."

That might be of some help to some of our men here this morning.

Method of Testing for Gas in Manholes

MR. HARPER (Kansas Gas & Electric Company, Wichita, Kansas): We are getting quite a lot of information now. I would like to ask Mr. Bentley to outline his way of testing for gas in manholes.

MR. BENTLEY: Why, the experienced underground men that we have can usually smell that just as soon as they open up a hole. The gas that we are bothered with most is illuminating gas. It is not very hard to detect it. We do not often have anyone overcome by gas, although we have had cases where they thought there might be a little trace of gas there, and there was more gas than they really figured on; by the time they were down there three or four minutes, they got groggy and came out.

MR. KELTON: We have had considerable trouble this year with gas in the manholes, and when we open the manhole we have a regular miner's lamp, a safety lamp, that we let down in there. In using the miner's lamp, we have to watch the flame, as I understand it, to see if it is working or not; but when you let it down in the hole you can not see it. We let it down in there for five or 10 minutes, and then we go ahead and get down in the manhole. We had several bad flares and the men have been burned. We have had them work in there for a couple of hours and had no explosion. If there is any other method but the lamp, I would like to know it.

MR. DUFFEE (Hammond & Co., New York): I think for the benefit of a number of persons here, I would like to take a moment to outline what I consider the most extensive program that has ever been attempted in a public utility field to my knowledge. The Consolidated Gas Company of New York and the affiliated Electric Companies have recently attempted the problem of training 28,000 employees, 15,000 of whom will be trained three times a year and 10,000 twice a year. We appreciated that standardization in the teaching of the Prone Pressure method was one of the

things to be desired, and to accomplish this we carried on a course of training, having instructions which consist of three lessons of two hours each; and at the termination of the course, in order that an instructor be qualified to receive an instructor's certificate, he had to maintain an average of 75 per cent. He was also instructing the women, the work being done twice a year by a registered trained nurse.

To answer the gentleman's question about detecting gas in a manhole, there is an apparatus made which has been perfected by the Bureau of Mines, and it was used very successfully in Pittsburgh and New York for the detection of sewer gas in manholes. It is called the monoxide detector. I don't recall the author of the paper but it can be found in the Bureau of Mines.

On the question of a man being pronounced dead and being revived, we had a very unusual case in New York in which the employee received a medal. Two doctors had pronounced the man dead. He had been dead without any effort being made to revive him for some minutes. This employee came in, a blanket was thrown on the man and he was laid upon the table. As I say, he had been pronounced dead by the use of the stethoscope by two different doctors. This employee worked for several minutes and the man began to breathe and then stopped again, and he was revived the second time. Before they got him to the hospital, that man had been revived four different times, and six days later he was back on the job.

The Light Down in the Hole is Suicide

MR. MORR (Illinois Bell Telephone Co., Chicago): In connection with underground work and ventilation, up to the present time, I do not believe there has ever been a successful ventilating plan put in. When they first put in the underground in New York City every manhole was sealed with rubber gaskets. They had a blower system in several places. They went so far as to run pipes from the manhole up to the roofs in various places. So I do not think that you can depend upon any system and devise a real test for discovering gas in a manhole outside of the human element.

My friend here mentioned about putting a light down in the hole. I think that is suicide. He mentioned about the man being down there for some time and having an explosion. Now, here is the point you don't want to overlook: you open up a manhole, you ventilate it, get all the gas out, you may put a blower in there and blow it all out, and the men go down there and work; they are down there for two or three hours. Fine, no gas. The wind will change to another direction and blow the gas into that hole. How are you going to overcome that except by the human element discovering it? There have been a number of men killed in the manner I speak of. Absolutely no gas in the hole at all when they started to work; the wind changed and blew it in from another hole.

MR. DILLON (Central Illinois Public Service Company, Springfield, Illinois): Mr. Van Brunt said something about the M. D. being a thorn in the side. The Central Illinois Public Service Company experienced that trouble, as the rest of you folks have, and we started an educational system on the Schaefer Prone Pressure method and cooperated with the

medical association, and we have never been turned down by any one of those associations. Every time we went before them we have had their promise that they would always assist us in this work. In addition to the medical association, we have gone to the fire department and into the police station and have taught this method to those fellows; and in several instances, we have had the pulmotor and the lungmotor thrown out of the fire department and police stations and they have taken up the Schaefer method of resuscitation.

In addition to that, along with the education of employees, we have been teaching our employees this method for a number of years, and we have several crews scattered throughout the territory at the different plants. We have weekly meetings in which this method is practiced at every meeting. All office forces practice it monthly; the others weekly. We not only teach them just how to practice it, but we teach them the method of changing from one operator to the other without any loss of time. I think that is one of the most important parts of artificial respiration, the changing from one operator to another without a loss of breathing.

Prone Pressure Information for the Doctors

CHAIRMAN McCULLOCH: That brings up a question that I believe we could afford to spend just two or three minutes on, and that is what the companies are doing in the way of securing the cooperation of the doctors and getting this information to them in regard to the Prone Pressure method. Some companies have gone into this quite extensively and have developed plans that have proved successful. I believe we could hear just a few brief statements on that subject.

MR. VAN BRUNT: We have visited every medical society in the state of New Jersey and addressed them on the subject. We hired a room in Atlantic City during the state Medical Convention and we got all the doctors we could get in the room.

We had two men in the room who know considerable about this subject. Mr. MacLachlan has done more along this line than any other man present.

CHAIRMAN McCULLOCH: Mr. MacLachlan, have you anything to add?

MR. MACLACHLAN: I do not believe Mr. Van Brunt's statement is quite correct; I have not done more than any other man. In 1924, due to the cooperation of the American Medical Association a Symposium on Resuscitation was arranged and presented at the annual convention. This was taken part in by Dr. Cecil K. Drinker, Dr. Yandell Henderson and myself. The reception that we received was most gratifying. I have also lectured in the Technical Lecture Theatre of the American Medical Association at this and other annual conventions and the reception from the medical profession has been all that one could ask. The medical profession individually in county or national association has been always willing and anxious to cooperate if the matter of resuscitation was presented in a clear way. The professional dignity and ethics of the doctor must be protected and respected. When someone close to you is ill, you

wish to have the utmost confidence in the attending doctors. Do not let us do anything to interfere with the respect for this high calling. It is not necessary to smash a mirror to clear a little fog from the face.

You who have been in this work from the inception 15 years ago, should think back to the cooperation we received then and compare it with what we receive now. I feel that all we need is a little patience and to use all of the diplomacy and tact that we have.

CHAIRMAN McCULLOCH: I am afraid we will have to close the discussion on this subject. We have devoted a little over an hour and a quarter to it. We have another subject which I believe is of equal importance and interest this morning: the subject of "Fire prevention."

Our next speaker will be Mr. P. W. Eberhardt, of Walter Kidde & Company, New York City.

FIGHTING FIRE WITH SNOW; OR FIRE PROTECTION THROUGH THE USE OF CARBON DIOXIDE

**P. W. Eberhardt, Engineer, Walter Kidde & Company, Inc.,
New York City.**

I want first to impress upon you, the safety engineer, the fact that fire protection is one of the major responsibilities that rests upon your shoulders, whether you realize it or not.

Too often this matter is left to an inspector who refers to his rules book and tells you that one approved extinguisher must be supplied for so many square feet of floor space. No consideration is given the possible magnitude of the fire, the conditions under which it must be fought and the hazards to which the operator of the extinguishing apparatus may be subjected.

All of you know what to expect should the extinguishing media be a conductor of electricity; you know the hazards presented by poisonous fumes generated from combustion of oils and insulating materials, as well as poisonous gases generated by the action of heated materials on some of the extinguishing agents employed.

The question may be raised as to the use of gas masks to overcome this latter objectionable feature; but don't overlook the fact that fire in a power plant or sub-station usually occurs like a bolt of lightning out of a clear sky. Your operators, in an endeavor to perform their duty, will think of nothing except putting out that fire, forget all about gas masks, grab an extinguisher and rush to the blaze. I do not mean to infer that gas masks should not be used; they are absolutely essential to safe operation under certain conditions, but are usually not used in the first emergency.

Another point that must not be overlooked is the tripping and falling hazard, always present where excitement reigns, and no matter how well your men are trained, when the emergency arises there is always some confusion.

The matter of fire protection for public utilities involves to a great

extent conservation of life and prevention of accidents, therefore placing the responsibility directly on the safety engineer or those responsible for safety of the workmen.

The extinction of fires through use of carbon dioxide overcomes many objectionable conditions and lends itself very readily to use around electrical equipment because it is a non-conductor of electricity.

In addition, carbon dioxide is non-poisonous, non-corrosive, will not freeze under the most extreme climatic conditions, produces no residue, and does not deteriorate. It can be automatically applied by means of thermostatic or relay control, entirely eliminating the necessity of close proximity to the conflagration on the part of workmen.

In comparing carbon dioxide with other extinguishing media for public utilities use, it may be well to divide the types of protection into three classes, namely:

1. Generator Protection.
2. Oil Switch & Transformer Protection.
3. Telephone Switchboard protection and other similar low potential wire networks.

Generators

In the past, generator fire protection consisted usually of steam or water rings anchored to the inner side of both end-bells, directly opposite the air-gap between the rotor and the stator, the steam or water being injected in time of fire by manually opening two gate valves after the potential was removed from the machine. This operation produced a time lag of from two to five minutes, in which most of the fire damage is caused. After wetting down the generator in this manner, it is necessary to dry out the coils uninjured by the fire after the fire damaged coils are replaced, or reinsulated, before the machine can be put into operation.

In a few cases, carbon tetrachloride has been applied in about the same manner.

With the Lux carbon dioxide system, all manual operations may be eliminated, the trip mechanism of the fire apparatus being tied in with the differential protection of each generator.

On the operation of the differential relays, which in approximately 95 per cent of the cases indicates fire within the generator, the carbon dioxide is automatically released into the ventilating system, extinguishing any flame that may exist in from 10 to 15 seconds. At the same time a delayed release mechanism is set into operation which causes additional cylinders of carbon dioxide to be injected into the machine at intervals throughout the entire deceleration of the rotor, thereby maintaining an inert atmosphere for several hours after the machine comes to rest, preventing any possible rekindling of fire from incandescent carbon that may have been present.

The injection of CO₂ into a generator wherein no fire exists, representing the remaining five per cent of differential operation, can cause no damage to the windings, the only loss being the cost of gas which would be less than one hundred dollars.

Power plant operating engineers are of the opinion that this loss is overshadowed by the value of having an automatic fire extinguishing system.

Several manual remote control stations, as well as a mechanical control at the apparatus, are also provided in case the relays fail to function or the source of electric supply is disconnected, insuring positive operation of the system in case of fire.

In extinguishing generator fires with carbon dioxide, the actual damage is limited to the immediate loss by the fire involved in the rupture, thereby greatly reducing repair expenditures, as well as permitting the generator to be returned to service in a shorter time. This feature is of utmost importance because the average utility is unable to keep pace with power demands and does not have sufficient reserve capacity available for such emergencies. Consequently some of the load is dropped and the consumers suffer.

Oil Switch and Transformer Compartments

Apparently no fixed or standard set up for oil switch and transformer fire protection has been adopted by the utilities at large, although recommendations have been presented by the N. E. L. A. In visiting the properties of the various companies, one finds a conglomeration of types and kinds of extinguishers, although the individual company is striving toward fixing standards.

Originally, fire protection for sub-stations, wherein oil switch and transformer compartments are more common, consisted of stand pipes, sand buckets and soda and acid extinguishers placed here and there upon the walls.

This apparatus was eventually replaced with carbon tetrachloride extinguishers of the one quart size and still later with the one gallon extinguisher under air pressure. (A few one gallon types have direct pump mechanism similar to the one quart).

Foam, in various size portable containers, has also found its way into the properties of the public utilities.

With the use of this type of apparatus, the electrical equipment is usually taken out of service, if not automatically disconnected, and electrical potential removed from adjacent equipment. It also causes the operator to approach through smoke and fumes to a vantage point before being able to apply the extinguisher effectively.

The Lux system of carbon dioxide treats the condition in a different manner. Standard Lux cylinders are manifolded together and connected to a piping system that leads to the various compartments to be protected. In the event of fire, it is only necessary for the operator to open a directional valve in the piping system (directing the gas to the proper compartment) and to operate an electrical control switch, thereby releasing the gas to the compartment in distress, extinguishing the fire, at all points, in about ten seconds.

This operation may be performed without any regard to the presence

of electrical potential. As a matter of fact, tests run in the laboratories of the Brown Boveri Company, at Milan, Italy, on the dielectric quantities of carbon dioxide gas, showed that the flash-over value of an insulator, when subjected to a CO₂ atmosphere, was increased from 158,000 to 185,000 volts, thus proving that no concern need be given to the effect of CO₂ on energized equipment, the insulating values of air being increased by the presence of CO₂.

As in the generator installations, the carbon dioxide is conveyed through pipe, in its liquid state, to the compartment or room to which the directional valve has been opened. Here it expands to a gaseous state, the gas being discharged through monel nozzles located at vantage points around the entire circumference of the room. These nozzles are so designed that freezing at the point of expansion is prevented and are so arranged that the gas is directed over the apparatus to be protected as well as on the floor or platform ledges where burning oil may be collected.

The entire space thus is almost instantly flooded with sufficient gas to reduce the oxygen content in the room below the point where it will support combustion, a sufficient volume of gas being provided to care for openings that may result from windows or doors being either blown open or permitted to remain open.

Tests were recently conducted for a large electric supply company in England where the object was to retain a sufficiently high concentration of CO₂ for a period of one-half hour in a room where in an electric arc was maintained over insulating oil subjected to 365° F. (open flash point): this stipulation being presented by the operating forces so that conditions under which they operate would be duplicated.

The chamber in which the test was conducted enclosed a space of 5340 cubic feet in which was placed a tank containing 287 gallons of switch oil. The oil was ignited by means of gasoline and high tension spark and permitted to burn for five minutes, at which time 320 pounds of carbon dioxide was injected. The fire was almost immediately extinguished and reignition was prevented for a period of 13 minutes.

Three windows, one door and three ceiling ventilators were provided, forming a total area of 87 square feet so that conditions similar to those found in their average stations would be presented.

I should also point out here that due to the extinguishing agent being applied in a gaseous state, all inaccessible ledges and crevices where smouldering may exist are sought out and extinguished immediately.

Telephone Switchboards

Those familiar with telephone switchboard fires know the damaging effect of soda and acid or any other liquid extinguisher and the use of extinguishing agents of this type causes many times more damage than the actual fire.

Carbon dioxide has been used for years by various telephone companies and its value in extinguishing telephone switchboard fires has

been proven. This extinguisher was adopted by the American Telephone & Telegraph Company and is now being supplied to its associated companies.

General Description

In general, the Lux system as designed for central station use, consists chiefly of a battery of standard Lux cylinders to which is fitted a special quick release valve connected to a syphon tube. The valve outlets are manifolded together and are connected to a piping system that leads to the generators or rooms to be protected.

For the purpose of eliminating maintenance the entire cylinder assembly, together with the trip mechanism is mounted on a platform scale to detect accidental discharge or leakage of the gas, each cylinder being charged to 50 pounds of carbon dioxide at a pressure of 850 pounds per square inch at 70° F. To the balance beam of the scale is connected a signal alarm, giving a constant check on the condition of the apparatus.

Equipment supplied for generator protection consists of two batteries of cylinders, one battery being simultaneously discharged immediately on the functioning of the differential relays, the other being discharged, one cylinder at a time, by means of a delayed release mechanism. The time lag for the discharge of each cylinder is predetermined by tests conducted on each generator. The delayed release of CO₂ gas serves to compensate for leakage, thereby maintaining the desired inert atmosphere throughout the entire deceleration period.

Where the system is required to protect more than one generator, electrically operated directional valves are introduced and function on the operation of the system, directing the carbon dioxide into the proper machine. Tests conducted on generators equipped with the Lux system showed that within from 10 to 15 seconds after the operation of the differential protection, a sufficiently high concentration of CO₂ was present to extinguish all flame. About 30 seconds later, sufficient gas was present to permit the dissipation of heat and at the same time compensate for the readmission of air, thereby eliminating the possibility of the fire rekindling.

This concentration was maintained by means of the delayed discharges of gas injected into the ventilating system throughout the deceleration period by means of the delayed release mechanism previously mentioned.

Representative tests for transformer and oil switch compartment protection, where 100 gallons of oil and flowing gasoline were permitted to burn for several minutes in a room having a content of 10,000 cubic feet, showed the fire extinguished in the order of from three to five seconds.

The rapidity in which fires can be extinguished by the Lux carbon dioxide system is based on the principle of carrying the carbon dioxide, in its liquid state, to the point of discharge where it expands to a gaseous

state, at a ratio of about 1 to 450. The rapid discharge is made possible through the use of a special quick opening valve that functions on the propelling of an arm through an arc of about 120°, the arm in turn driving a special circular cutter through a disc, liberating the contents under its own pressure into the piping system. This disc also functions as a safety valve.

Specially designed monel orifices are fitted to the pipe outlets, where expansion takes place, eliminating the possibility of freezing.

With the general trend to increase the capacity of generating equipment as well as transformer and oil circuit breaker equipment, wherein larger quantities of oil are involved, it is logical to believe that fire protection has been proportionately increased. Unfortunately this has not been the case. Fire fighting equipment that may have been adequate 15 years ago when a plant having two or three, 5,000 or 10,000 K. W. turbo generators was considered a fair sized plant, is not capable of meeting conditions of the present day when we speak of 200,000 K. W. generators and of turbo generating stations of 300,000 and 400,000 K. W.

A glance at reports issued by the National Fire Protection Association, as well as reports from insurance companies, shows that fire losses are on the increase. In the United States fire losses for the first six months of this year have increased about 16 per cent over the same period last year, the losses being respectively \$228,785,700 and \$197,547,300.

Fortunately, losses of life from fire causes have slightly decreased. Nevertheless, if injuries involved in fires run true to form, we may consider their increase for the first half of this year to be equal to the increased per cent of fire damage, namely 16 per cent, it being reported that no unusually large individual fires caused this increase.

It is almost impossible to collect data as to the losses experienced by public utilities, but it is reasonable to believe that they have kept pace with the general increase.

A Few Examples of Recent Costly Fires

Here are just a few of the more recent and costly fires.

- (a) Five oil switches fail—fire lasting 1 hr. and 15 min. Loss \$10,000.
- (b) Oil switches and transformers fail—fire lasting 1 hr. Loss \$100,000.
- (c) Switches fail—fire lasting 30 minutes. Loss \$7,500.
- (d) 30,000 K. V. A. turbo generator fails. Loss approximately \$45,000.
- (e) 30,000 K. V. A. turbo generator fails. Loss approximately \$45,000.
- (f) 35,000 K. V. A. frequency changer fails; duration of fire 2½ hours. Loss \$60,000.

In each of these cases, hand apparatus was used (with the exception of the generators where steam was used) without any material effect.

Does this not prove that more consideration must be given to fire protection which is capable of taking care of the severest condition without subjecting your employees to the hazards of fire?

Compensable accidents and fire losses can be materially reduced by employing a fixed system with the use of carbon dioxide as the extinguishing agent, thereby limiting the losses to the actual loss caused by the incipient fire, without subjecting your workmen to unnecessary hazards.

Discussion of Fire Prevention and Fire Fighting

CHAIRMAN McCULLOCH: We still have 20 or 25 minutes in which we can have a discussion on the subject of fire prevention or fire fighting equipment. It will be necessary, then, to leave in order to get over to the Tuller Hotel in time for the luncheon.

MR. HARMER: I would like to have Mr. Eberhardt go into the subject of the maintenance of this class of equipment. We all know that the maintenance of fire equipment is one of the greatest factors in maintaining efficiency. I would like to have Mr. Eberhardt answer how you can inspect this class of equipment thoroughly and how you can maintain it and how you re-fill the containers? Has he any system that he would suggest?

MR. EBERHARDT: Maintenance, I might say, is nil. Carbon dioxide does not deteriorate and is good until used. The only possible chance of it being necessary to recharge the cylinder is where it might leak or might be used on fire, of course. For maintenance purposes, we install the larger assemblies on a platform scale. That scale is connected to an electric contact and will indicate in the operating gallery, or wherever you may want to locate it, where the cylinder may be individually weighed, which one has been tampered with, or is low. The smaller apparatus contains $7\frac{1}{2}$ pounds of CO_2 and is weighed periodically every six months (we recommend), to determine its contents. The CO_2 itself will not freeze under severe climatic conditions and you do not have that condition to worry about.

As to re-charging, any carbon dioxide gas manufacturing company, and there are several hundred in the United States, can recharge your equipment. We have a list of about 100 who are thoroughly familiar with the re-charging and can take care of it, usually locally. Any place where they are making CO_2 for soda water, you can get your cylinders re-charged. The cost varies with the location of the source from which they get the CO_2 , and varies from three to five cents a pound, which is relatively cheap, meaning about 50 cents for a small cylinder.

MR. STEWART: Mr. Eberhardt, I would like to ask as to the reduction of insurance charges. It is of vital importance to the operating company if it knows what the effect is on their fire insurance rates where this equipment is installed.

MR. EBERHARDT: That question is quite frequently put. There is no direct influence on fire insurance rates. We have submitted to the under-

writers certain equipment and we hope in a short while we shall be able to get some discount. In Sweden, a reduction of two-tenths per cent is permitted providing the discount does not exceed the cost of the apparatus; it comes near that for a three year^{ly} term.

In the Marine field, the equipment is recognized and insisted on as an alternative for steam. In plant installation, we have another class of insurance to deal with and it is relatively new. We hope in a short time that some consideration will be given it. I know that the insurance companies with whom we are in contact heartily approve the extinguisher, and have recommended it in quite a few cases. As a matter of fact, that is how most of them get in.

MR. LUECK: Mr. Eberhardt, how close does that extinguisher have to be to your switchboard to make it effective?

MR. EBERHARDT: Your equipment is designed for low tension equipment; and within four feet is close enough for switchboard wiring. The other systems are piped in.

Additional Organization on Fire Protection

MR. HARMER: Due to the close relationship between the fighting of fires and accident prevention, I would like to make a motion for the new administration to consider, and that is that we have a division in our Section—we have one now on electric and gas—I would like to make a motion that we have one on fire protection. We, as accident prevention men, can not lose sight of the fact that we are interested vitally in the protection of our properties from fire. We all know that we have many accidents due to fires in stations and in properties that we very rarely touch on in this Section.

I would like to make a motion like this: that we create another vice-president in our Section in charge of Fire Prevention in Utilities.

CHAIRMAN McCULLOCH: Would you want to include in that, Mr. Harmer, that for this year that vice-chairman be selected by the newly elected executive committee?

MR. HARMER: Yes, that is what I meant.

The motion was seconded.

CHAIRMAN McCULLOCH: You have heard the motion that a new office of "Vice-Chairman in charge of Fire Prevention" for the Public Utilities Section be created. Is there any discussion?

MR. MACLACHLAN: Mr. Chairman, I would like to make an amendment to that motion. If we start creating vice-presidents for every phase of the work that we are vitally interested in, I am afraid we will all be on the executive committees. Wouldn't it be better to create a committee to take this matter in hand under a chairman to look after the situation for this year and leave the matter of the creation of an office until next year? I make the amendment that a committee be appointed under a chairman to go thoroughly into this question and make a report at the next meeting.

MR. HARMER: Mr. MacLachlan's amendment is very satisfactory to me, Mr. Chairman.

CHAIRMAN McCULLOCH: All right, that will be recommended, then, to

the new executive committee, that a committee chairman be appointed by the executive committee, this chairman, of course, to select his committee to consider this subject during the coming year. Is there any discussion now on the motion?

MR. MULLIGAN (Hydro-Electric Power Commission, Ontario, Canada): As both Mr. Harmer and Mr. Eberhardt say, fire protection is closely allied to every safety engineer's work. There was an excellent paper or report of the National Electric Light Association, by Mr. Rutland, who was committee chairman last year. As Mr. Eberhardt mentioned, in electrical fires, our main thing is speed, get the fire out quickly. If we have an oil fire, your station becomes covered with soot; you not only have your interruption due to the fire and destruction of apparatus, but you have got the cleaning up of the station. If you are maintaining service and attempt to clean up a station, all you gentlemen know the hazards that are presented. So speed in putting out a fire is essential. For protection of generators, the carbon dioxide protection, I think, is wonderful for turbine generator sets. On water wheel driven generators I do not know as I have seen any installation where it has been successfully installed as one of your big troubles is ventilation. We went into the matter very thoroughly and found that it was very, very difficult.

Quoting a Paper on Generator Protection

Last May before one of the Sectional meetings of the A. A. I. E., at Niagara Falls, Mr. Johnson, an electrical engineer of the Niagara Falls Power Company, gave a very good paper on generator protection. They used water. Their system is so arranged that if carbon dioxide is further improved, carbon dioxide may be used in place of water. For ourselves, at the present time we have had good success in our new installations by straight relay protection. If your relays operate directly and in a fraction of a second there is very little to burn. Of course, that is coupled with maintenance. It keeps your machines clean and you have good relay protection and you will never be troubled very much with generator fires.

For transformer rooms and all switch compartments, I think that the question of carbon dioxide protection must be taken into consideration when the plant is being designed and the rooms built accordingly. Otherwise, I think it would be an impossibility. For switchboard work, there is a field for an extinguisher such as the type that was demonstrated this morning. We all know the mess that soda acid makes on machines. This machine, I think, will overcome that.

I would like to ask Mr. Eberhardt the length of time of discharge for a cylinder of that nature and the probable area which it would cover? And while I am on my feet, there is one question I would like to raise: the Underwriters insist on sand pails in stations, why do they do so? Our experience has taught us that they are not worth a continental except to throw the sand around the floor to keep the men from slipping, but in putting out a fire in an electrical station we are convinced that they are

absolutely useless, but the Underwriters insist on so many sand pails in so many hundred square feet of area.

MR. EBERHARDT: That depends on the opening of the cylinder, the opening within the cylinder, and the amount of gas; about 40 seconds. On a 50 pound cylinder, we discharge in a shorter length of time by having a larger orifice with the smaller unit, which is fully as adequate; we discharge in the air in about eight seconds, discharging more gas than is in this particular apparatus.

Putting Out Oil Fires in the Tanks

MR. ATWOOD: I wonder if any of you have this type of extinguisher on oil tanks?

MR. EBERHARDT: There has been considerable experience in Marine work on oil tanks. I know of about four cases where CO₂ has been used to put out oil fires in the tanks. In plant experience we have only had one experience, and I have been asked not to mention the particular name of the company using it, but the installation on there is descriptive, where oil kettles are used, boiling kettles. A fire occurred in July of this year. The engineers stated in writing us that the "Fire was more severe than during your test. All that we did was push the button and the fire was out." They immediately went back to work after ventilation. The Marine installations have been quite successful. We have not had any failures as yet. We do not want any.

MR. WILSON: This is a little bit off the line of electrical hazards, but I would like to ask Mr. Eberhardt in estimating that CO₂ for an oil burning kettle, would you pipe that directly to a hooded cabinet?

MR. EBERHARDT: It is possible to apply CO₂ to a hooded kettle by creating a CO₂ blanket over the open spaces. That is accomplished by an arrangement, a nozzle arrangement, whereby the gas will come out in spray form. A certain amount of gas is provided for closing off the opening, and the remaining gas is injected into the space itself. It is preferable, however, in rooms such as shown there, to flood the entire space because of the fact that a flash in one kettle may mean the fire is extinguished from one to the other. They are hooked up to a common ventilating system of some sort that usually causes a fire to continue from one kettle to the other.

MR. RALL: I would like to speak of an instance that came up in the refilling of a carbon tetrachlorid extinguisher. We should use an extreme amount of care to know that that is absolutely carbon tetrachlorid for this reason: there was a mistake involved in one case that I intimately know of in which the carbon tetrachlorid was not put into that extinguisher, due to the fact that they were using the chemical expression and they used one of the most hazardous things that I know of, carbon bisulphide. But they happened to notice it and a catastrophe was avoided. There is only one way to avoid that, and that is to smell of it. Carbon bisulphide smells like rotten eggs. But we have got to watch that carefully.

MR. HARMER: The most simple test for all of us to make, to be sure

that we are using proper carbon tetrachlorid, is to take a box of safety matches, any box of matches, fill it with the liquid that you are going to use, take your match out, and if it lights on the side of the box, it is carbon tetrachlorid. Be sure there is no moisture in the solution that you are using and it is a proper solution. You can make your test in a few seconds. We are instructing our men in testing our extinguishers to make that test every once in a while. I wish we had some carbon tetrachlorid here and I would show you. Tomorrow, I will borrow an extinguisher and show you just exactly how the test is made.

CHAIRMAN McCULLOCH: I am afraid we will have to close the discussion on this subject. We have just 20 minutes to get over to the joint luncheon. I am going to ask that you remain until the final announcements are made in order to avoid confusion.

I feel that I would be remiss in my duties if I did not thank the Detroit Edison Company for providing us with these quarters this morning. I am sure it has been a great help to our meeting, and on behalf of the Public Utilities Section, I want Mr. Opp to convey to the Detroit Edison Company our appreciation.

While on the subject of Mr. Opp, I just want to mention some of the work that he has done for this Section. Four years ago he was chairman of the bulletin committee that provides the posters for this Section. The next year he was elected secretary of this Section. For the past two years he has served as vice-chairman in charge of electrical interests. I am sure we were all pleased to hear this morning of his nomination and election as chairman, and I want to be the first one to congratulate him on this office, and ask him if he wants to say just a word to us.

MR. OPP: There really isn't much, gentlemen, that I can say at this time. You always get the stereotyped appeal from the new, incoming officers, for your help. I am not going to ask for it because I know I am going to get it. I want to measure up to the efficiency demonstrated by the new office boy who came to the boss and said, "Here are my 10 answers to this question." In other words, the same attitude as the school master, possibly, who asked the boy if he were learning anything; and the boy said, "Yes, I am listening to you."

Now, we don't want you to take that attitude with us. Don't expect us to tell you things. We just expect you to help us do things, and I am sure that with the help that has been demonstrated in the past, there isn't any question but that our Section will continue to grow. We have a real responsibility to meet, and we have an increasing membership to serve, and all in all this job spells responsibility. I guess I realize it more than anybody else. If I can, in anyway, have you share that responsibility, I am going to feel free, and I know I will get your cooperation in the solution of the things that need to be done.

I sincerely thank you for my selection to the high office of this particular Section, and you have my promise to do all that I can possibly do.

ADJOURNMENT

THURSDAY MORNING SESSION

October 28, 1926

The meeting convened at 9:50 o'clock, Mr. B. B. McCulloch presiding.

CHAIRMAN McCULLOCH: I want to call your attention to the sectional poster catalogue issued for the Public Utilities Section. This is the first sectional poster catalogue that has been issued by the National Safety Council, and I am sure that it will prove of help in selecting posters to meet your individual needs.

The secretary has gone over the registration cards and finds that there was a total of 163 registered at our meeting yesterday, representing 18 states and Canada. I am sure our attendance is nothing to be ashamed of this year.

It was suggested by one of the members of the Executive Committee this morning that the Public Utilities Section should take into consideration Accident Prevention in water works operation in addition to the electric, gas, telephone and telegraph divisions. I would like to see a show of hands this morning by all those in the room who are interested in water plants. By that I do not mean hydro-electric stations, but water works.

(Six raised their hands.)

CHAIRMAN McCULLOCH: It would be well for the new Executive Committee to take into consideration the rendering of some service to those companies, and that matter will be taken up at their meeting today.

Mr. Opp told us that an unusual accident occurred last night, and I have asked him to take a few minutes before we start our regular program to tell us something about it.

GEORGE OPP (Detroit Edison Company, Detroit, Mich.): This is rather confidential information. Shortly after getting home from the banquet, the lights went down suddenly in my home and finally went out for a period of a minute. Immediately I realized that there was some trouble. The telephone began ringing and I was informed that an operator had been injured and that he was being rushed to the hospital. There were no details available, so we immediately went out to the scene of the accident and found some circumstances that tied in very closely, very vividly, with the remarks that Mr. Dow made yesterday afternoon, and the remarks of Mr. Kettering last night at the banquet.

This young man who was hurt was a modern Romeo. Upon his person we found a book in which he had a directory of the dames within his acquaintance. He had them checked off with various symbols, which perhaps represented the various days of the week.

He had without any instruction made the comment to the operator, "I am going out to look over the plant," and about five minutes later, bang! and the station went flat. He had been asked at 11:00 o'clock, the

time at which he reported for duty, to report in here this morning for an investigation into the accident to which Mr. Dow referred yesterday.

It developed that this same young man was asleep on the job the night this other accident occurred. It is the rule of this company that two men perform any operation. This man who was asleep at that particular time was to be reprimanded this morning. He also had not received recent raises as he expected, so I guess he put two and two together and apparently decided that his jig was up.

On top of that, we found out in making our investigation that he had been asking very peculiar questions of the operators with whom he was associated. In his 14 months with us he had been with quite a few, since the operators, after a brief experience, didn't want him because they said he was no good for the company. They would complain about his going out in front of the sub-station and sleeping in his automobile occasionally while he was on duty. One of the men told us about an instance when he went out to the top of our Navarre station, an outdoor sub-station, to test out the Leopold-Loeb theory of whether a cat lands on all fours when dropped from a great height.

Tragic End of an Erratic Young Man

Incidental to that, he wondered what happened on a rotary converter? He asked another operator if the wrong transformer connection was made, what might happen? He had a very inquisitive mind. He was clever and bright; in fact, although only 29 years of age, he passed the first-class radio operator's license test. Although he was clever and bright, the class of literature we found at the plant indicated the kind of mind that he had.

All this went to show that he had stored in his mind a problem that hadn't been settled, and being on the verge of being fired, he wanted to settle it for himself. We found that he had taken a wire, about a number 12 and had attempted to make contact with the live side of the disconnect switch while standing on a part of the steel structure of the station, and what happened was that the current came down through the wire that was wound around his arm, burning open his arm at the biceps, went down through his middle part and out through two points on either foot. He died three hours later.

There is an example of the kind of mind that Mr. Dow mentioned yesterday in his address at the Public Utilities-Electric Railway Sections Joint Luncheon. The kind of reading that lad was doing was indicated by the book topmost in his drawer, which was one of these lurid-literature magazines. Those books were being read contrary to the company's rules that no literature of this kind be permitted on the premises.

It is the mind that is responsible for a lot of these happenings, and as Mr. Kettering indicated last night, there isn't any question but what that lad was working on impulse rather than on thought.

We stayed up all night; three of us haven't touched the bed yet. In the course of our investigation, we made trips back and forth from the hospital to the scene of the accident in an effort to get the last bit of detail from the man himself, and invariably that same stolid answer came

back, "I don't know! I won't tell you! I don't know," indicating that he was going to hold out until the last.

At the hospital I saw the most pathetic scene I have ever witnessed. His father is a blind osteopath, and his mother is about as small as a bit of humanity can be. She was trying to console this big, blind doctor and he in turn was trying to console her.

CHAIRMAN McCULLOCH: I am sure we all appreciate this frank description of the accident by Mr. Opp. If we were all as frank in describing our own accidents without attempting to cover any details, we would get more benefit from our meetings.

The first paper this morning is to be presented by Mr. E. J. Kallevang, Chief Engineer of the Wisconsin Power and Light Company at Madison, Wisconsin.

GROUNDING PRACTICES

E. J. Kallevang, Wisconsin Power & Light Company, Madison, Wis.

This subject is rather broad and can not be adequately covered in a brief paper.

There are two general divisions under the subject that will be considered: first, the permanent grounding of electrical circuits, and second, the temporary grounding of electrical circuits.

Permanent Grounding

The advantages gained by grounding low voltage lighting and power circuits are now well established and grounding of these circuits is almost a universal rule. However, there remains a great deal to be learned about grounding material and the best method to use for the various soil conditions encountered.

Occasionally one is informed that shocks are received and even deaths caused because the system was grounded. This brings up another matter which I shall not discuss, except to say that the cause of the shock or death was due to faulty construction or improper use of the device or wiring and is not chargeable to the practice of grounding where grounds properly belong.

Most utilities place one or more grounds on each transformer secondary or use a common neutral or grounding wire which is connected to earth at many points. Whether the individual transformer grounding method is used or the common wire, there must be sufficient ground capacity to insure effectiveness of the ground connection under excess current conditions caused by accidental contact or grounding of any ungrounded conductor of the circuit or adjacent circuits including the failure of the insulation in the transformer.

The location of the ground connection must also be such that in case of a break in the conductor between the transformer and any utilization equipment that the source of supply will still remain grounded. This

requires that the ground be at the transformer in the case of a single ground or on adjacent poles in case of two grounds.

There is much to recommend a common or system ground. The cost of such a conductor is not much more, if any, than providing individual grounds for each transformer. Where the water mains are used for grounds, the common grounding conductor will provide economical ground connections for a very large part of the distribution system.

As communities grow, transformer capacities or the number of transformers increase, and additional individual transformer grounds are invariably required, but not always supplied. If the common ground wire is used, the expense of driving pipes or making new connections to water pipes can be avoided.

Types of Grounds

The most common grounding device is a galvanized iron pipe ranging in diameter from one-half inch to two inches and in length from five feet to about twenty feet.

The usual standard is one inch diameter and seven feet long.

There are available a number of patented grounds in the form of cylinders or cones filled with some moisture retaining material and copper covered steel rods. Some of these cones and cylinders are supposed to store water during wet seasons to be given out during dry seasons. There is no doubt that this is their performance, however, the volume of water that these containers can store is very small and is absorbed by the soil in a short time. In spite of this, however, they do have some advantage over driven pipe, in that they furnish a much larger contact surface at the lower end than pipe. The copper covered steel rods have no advantage over galvanized pipe other than increased life and cleaner contact surface. The usual copper covered steel rod is smaller in diameter than the usual galvanized pipe, presumably on account of its cost. This is a disadvantage.

Plates buried in the ground are generally supposed to provide excellent earth connections. Copper plates as large as three-eighths inch by four feet by six feet and in some cases larger, have been used. This type of ground is very expensive on account of the cost of copper plate and because of the large excavation required. I believe in some localities the use of plates has decreased, as in most places the same results can be obtained at considerable less expense by the use of pipes or cylinders.

As to water mains, there is not much to be said except they offer means of obtaining the best earth connection possible, and should be used wherever they exist.

Salt is frequently used to lower the resistance of grounds. While salt does accomplish this at least for a time, the continued use of it will destroy the ground pipe or plate. It is better to spend the extra effort in providing grounds that do not need salting.

To place grounds in service and operate grounded systems without knowing the value of the earth connection in various locations and under

varying conditions, is somewhat like starting the units in a power station and operating them without the aid of any instruments.

If there is a difference, it is because we think we can get by in the first case and in the second we feel that we can not. The many records of accidents due to improper grounds should be convincing statistics that we are not getting by with poor grounds, and we should not continue to fool ourselves, but test and know.

There are many methods available for making tests, none of which are very complicated, nor do they require expensive equipment, the simpler ones being the use of a magneto, single voltmeter, fuse or lamp bank. The magneto and single voltmeter method has very little value, because of the small amount of current used. The fuse and lamp bank is somewhat better, its value depending entirely on the size of fuse or lamp bank used. The voltmeter-ammeter method is to be recommended, of which there are several variations that can be employed.

Again I want to suggest that grounding of secondary lines is essential to safe operation, both along the lines and on the customers' premises.

If there are any states where the Safety Code does not require grounding, the operating utility should include in their construction standards rules and methods for providing adequate grounds. The Company's Service Rules should include rules covering the installation of grounds on the customers' premises when the place is being wired or rewired before service is established. Briefly:

1. Make good connections to earth.
2. Keep a record of all locations and types of ground.
3. Test at regular intervals, the frequency of which will depend on the kind of soil and type of connection.
4. Improve all grounds that are inefficient.
5. Maintain proper mechanical protection over the connections to avoid destroying them and prevent accidental contact by the public and employees.

Temporary Grounding of High Voltage Lines

The grounding of high voltage lines to make them safe to work on is a different problem from permanently grounding low voltage lines.

It would seem some improvements can be made to devices used and their method of application. The devices not in general use are chains, of all descriptions, flexible metal ropes used in the same manner as chains, a combination of conductor clamp and ground clamp connected with flexible metal rope, and permanently installed disconnects other types of switches. Here and there one finds some kind of popular kink used for grounding lines. The use of such kinks should be forbidden and nothing but a business like device considered.

If lines have no permanent overhead ground or static wire and wood supports, temporary ground rods must be used. In the use of the temporary ground pipe lies the first hazards. The placing of a small rod in the ground but two or three feet is not sufficient, except in rare cases.

A good substantial contact with the earth is as essential here as in making a permanent ground for any other purpose. At least the connection must be adequate for the period it is used.

The connection to the pipe ground is usually a chain. Most utilities have at one time or another used arc lamp chains for this purpose and some still consider this a safe practice. An improved chain is made of short twisted iron links heavily copper plated. The short twisted links slide over the conductor more readily, kink less (or perhaps I should say, unkink more easily), and the copper plating increases the conductivity not only along the sides of the links but especially at the joints or contact surfaces between links. These are important features, especially the last.

Connection of the chain to the temporary ground must be well made and should, of course, be made before the chain is pulled up over the conductor.

The length of chain used or available for pulling up over the conductors should be such that the person applying it can not get a hold of the chain. In other words, assuming a 35 foot pole (30 feet above ground) and one 10 foot crossarm, the available chain should be about 45 feet long. In order to avoid carrying chains of varying lengths to meet different heights of poles, a longer chain may be carried and necessary length adjusted at the grounding point.

Two Ropes Should Be Fastened to the Chain

Pulling the chain over the conductors by taking hold of it is a dangerous practice. Two ropes should be fastened to the chain. These should be about $\frac{3}{8}$ -inch treated rope absolutely free from any conducting material. One rope should be fastened to the ungrounded end of the chain with a length such that it will reach over the conductor to the ground. A second rope, to be used in removing the chain, should be attached to it about 15 feet from the other rope. With this arrangement, it is not necessary to come in contact with the chain whether you are pulling it off or on.

Grounding chains have little value as a grounding device unless they are taut. For this reason no one should be in contact with or stand close to a chain when it goes over the line. Should the line be energized and capable of carrying considerable power, the chain would melt or even explode. It is well to have some rule regarding the tension of chains when in service. If the strength of conductors permits, there is no reason why the tension should not be 50 pounds. The minimum should not be less than 25 pounds. Circuits of flat construction carrying three or more conductors should not be grounded close to the arm if chain is merely pulled over the top, as this prevents getting a good contact with the middle wire. The chain should be placed at least 25 feet from any crossarm.

It is the practice of some companies to run the chain around two of the conductors and then back over the third. This arrangement gives very good contact on all three conductors and special provision for shorting two of them.

Let me suggest to those who are especially interested in producing new and useful devices that they direct some of their efforts toward providing

a flexible non-snarling copper cable, whose lasting qualities would be better than that of copper conductor cable for the purpose of replacing the chain now used. A cable of this kind would provide all the carrying capacity necessary and eliminate the hazard of chains exploding.

There also is need for better equipment to be used by field crews in determining whether lines are dead before applying the grounding device. I think in most cases nothing is used to determine this. There are many types of voltage detectors that can be purchased, some of which are light and small in size, hence easy to transport, that can be used by field crews for determining whether a line is charged or not; but practically all of them under some conditions give a false indication, that is, the voltage that causes them to operate may be power or it may be induced from adjacent lines. Some forms of insulator testing sticks can be used in the same manner.

While my experience with devices for this purpose is somewhat limited, yet I believe that several of the present high voltage detectors can be modified to meet this requirement and give positive readings. Some of the insulator testing sticks or instruments now will give a pretty fair indication if comparison in readings is made between a line carrying power and the line that is supposed to be cut out. Testing for voltage on an isolated line—that is one removed from the influence of any other line—is quite simple and generally reliable. The commercial voltage testers are not designed for operation on the higher voltage lines, the limit is somewhere between 15,000-25,000 volts.

There remains, therefore, the insulator testing devices for determining the presence of voltage on the very high voltage lines. Some use the hook stick that is used for applying the grounding clamp to determine if the line is dead, and in stations the disconnecting pole is used. This is better than nothing but not always reliable, especially if no comparison is made with adjacent live lines.

Potential Transformers May Determine Voltage on Line

In stations potential transformers can be used for determining the amount of voltage on a line. This provision should be included in the design if no other means are available.

I think the operators of high voltage lines would welcome a better device for testing out dead lines before applying the ground. Those who have any means for research along this line should do what they can to bring out this very important apparatus.

When lines are constructed using wood poles and no ground wire, there should be included as a part of the standard and cost of construction ground facilities along the line. This can be done by driving pipes near the pole at every half mile. The poles having ground connections should be stenciled "Ground" or other suitable designation. This facility would hasten repair work and avoid some of the accidents we now have, due to improvised earth connections.

Lines having permanently grounded metal supports or ground wire can be grounded quite readily by using a clamp which is first attached to the

tower or ground wire and connected to the conductor clamp by flexible cable; then the conductor clamp is attached to the conductor by the use of an insulated pole or hook stick. The clamps must be so designed that when once attached they will not be loosened by the usual movement of the conductors when worked on. The tower clamps are generally held in place by a set screw and the wire clamps in place by either spring clamps or screw clamps. The latter seems preferable.

Wherever possible permanent grounding devices in the form of single or gang operated disconnects should be provided at stations. While these may not prevent shocks to linemen due to static or induction, they would make the application of local grounds along the line much safer. These switching devices would serve best if so arranged that they would go in place as soon as the line is dead and would be interlocked with the breaker in such a manner that the breakers can not be closed as long as the ground disconnects are closed. These operations can be performed electrically or mechanically. If the electrical supply is not absolutely dependable, then mechanical interlocks and mechanisms are preferable. Reliable equipment for this purpose is a standard product with many manufacturers and has given excellent service.

Voltage Picked Up by a Dead Line May Be Considerable

No definite rule regarding the location of grounds with respect to location of linemen should be made unless local conditions are known. Single circuit lines located a long distance from any other high voltage line will not require grounding as near to linemen as a double circuit line or separate lines along the same right-of-way.

Generally it is sufficient to ground within one mile and on each side of linemen on isolated single circuit lines, and within a half mile and on each side of the workmen on double circuit or its equivalent in single circuit lines along the same right-of-way.

The voltage picked up by a dead line that is close to a live line is considerable and must be guarded against. The amount of induced voltage from adjacent lines will depend on weather conditions, frequency, voltage and load of live line.

The same precautions used in making repairs must be taken when building new lines adjacent to lines in operation. It is also good practice to ground new isolated lines at different points, although either end may not be connected to any station or lines in service. There always is in the air a certain amount of static that if permitted to accumulate on the conductors may cause a shock. Then, of course, there is the hazard from lightning.

I think it very necessary that all ground equipment be only first class, both as to material and workmanship, and further that men operating these devices be fully acquainted with their use and the electrical system on which they are applied.

The man applying a ground expects that all previous operations have been made in regular order, however, he must not assume that the part he is to perform is simple. His is the last operation in killing high volt-

age lines and on him rests the responsibility of making sure that the line will be safe to work on. If through some error over which he may have no control at the time, the line is actually alive, the grounding must be done in such a manner that no accidents to persons will result.

It is very desirable that a "Hold Card" or similar identification be placed on grounding devices if they are not located in the immediate vicinity of the crews who are protected by them. Ground chains that reach the ground should be guarded by one of the crew, if there is the least possibility that they will be tampered with by children or others. I know of one case where a grounding chain, that was in service, was stolen by a farmer living near its location. This was done when the crew was on the opposite side of a hill and about a half mile away.

Statistics Upon Electrical Accidents

In my own state during the year of 1924, electricity caused a total of 87 injuries of which 14 were fatal. During the year 1925, there were a total of 77, of which 22 were fatal. During 1925 there were 10 less accidents, but eight more deaths. Some of the fatal accidents were caused by improper grounds or grounding methods or no grounds at all. For example, one man attempted to place a grounding chain or similar device on a line that he thought was dead. This accident should, of course, have been prevented by having a clear understanding that the line was still alive. However, had the grounding apparatus been applied with the proper precautions, no accident to the man would have occurred.

In another case a lineman was making up the dead ends of a line that was located on the same structure with a high voltage line. His foot slipped, the end of the new wire came in contact with a high voltage line. An effective ground at or near the structure the injured man was working on would have prevented this accident from being fatal, at least.

A grounding chain had been placed over a 33,000 volt line and after the work was completed two men were to remove the chain, and a third was to close the switch after the chain had been removed. The chain was too long for the particular location and as soon as some of the chain had been pulled off the ground one of the men started to coil the chain. The motions of this man's arms were taken by the person who was to close the switch to mean that they were through. The switch was closed while the chain was still on one of the conductors, causing serious injury to the person coiling up the chain.

A lineman attached a ground chain to his belt, then climbed a pole and threw the chain over a high voltage transmission line, apparently thinking that he was on a 2,500 volt line, which had been cleared for him.

A lineman forgot procedure in removing ground chain. He first removed chain from tower and then took hold of conductor to take the chain off. He received serious burns to his feet and hands before another workman grounded the conductor and released him.

A lineman on a steel tower threw a grounding chain over a 100,000 volt circuit which was alive through a misunderstanding. The tower stood on a rocky hill so that the ground current was not sufficient to trip the circuit

breakers, but when the lineman who, of course, was aware that he had grounded a live line, climbed down the tower and placed his feet on the ground, was knocked down and also his helper who went to assist him, and finally a team of horses, tied about 200 feet from the base of the tower, was knocked down, but later got up and ran away.

A brass grounding chain was thrown on a 22 K.V. line entering a substation. The chain was given two turns around the station ground bus. The grounded bus paralleled a 66 K.V. circuit for several miles. After grounding, the workman climbed a ladder to clean some bus supports and with one hand on the conductor happened to touch the steel frame-work with the other. He received a severe shock and was thrown to the floor 18 feet below, the fall being somewhat cushioned by a lightning arrester so that he was not hurt beyond severe bruises. Upon investigation, a small portion of the chain was found to be coated with a film of oil and when shaken there was severe flashing from induced currents coming over the 66 K. V. line. This accident illustrates the importance of keeping ground chain absolutely clean and in putting it on the line to have it pulled reasonably taut in order to get a positive metallic circuit to the ground.

Grounding and Ungrounding Can Be Done Safely

These are records of accidents, each with a different cause. There are many more records which list accidents due to grounding. Again I wish to repeat that if mistakes are made in clearing a line, it must not be during the last operation or in energizing a line, no mistake must be made during the first operation.

Grounding and ungrounding can be done safely. There must be a thorough knowledge of conditions; clear and complete rules are necessary, and these followed; men must be trained to know how; equipment must be designed for the particular work and capable of withstanding the capacity of the line and applied in a manner that insures safety.

There are other important factors, I believe, in providing adequate grounds, grounding methods and the prevention of accidents. Briefly, these are:

Design, management, and foremanship; in other words, the engineer, superintendent and foreman. The design or arrangement must be such that it is entirely adequate to meet all usual requirements and many extraordinary conditions; it must be safe and easy to operate and maintain. The foreman is the right arm of the superintendent; therefore, he should be regarded as the most important member he has. To give a foreman a print or letter and tell him here is the job and then forget it, is not entirely fair to the foreman and the men under him. The foreman's work is not always pleasant nor easy, he needs the superintendent's support, not at the office only, but right on the job. It is the engineer's duty to make the plans, and the superintendent's job to assist the foreman in doing the work called for. The superintendent who places too much confidence in the foreman and leaves too much up to him is putting his right

arm in a sling. Some of the accidents that have been charged to the foreman are largely due to the man above him.

The closest kind of cooperation is essential between these three positions.

The necessity for safety is not accidental. It is scientific and research is essential. In every public utility a safety organization, which includes the entire personnel, is an investment on which the utility and community have a right to capitalize, as it will return tangible dividends and bring to all of us some reward.

CHAIRMAN MCCULLOCH: The subject of grounding is of interest to all men in the electrical industry. It is a subject that has been purposely avoided by the Public Utilities Section for the past few years because of the divergence of opinion among the engineers themselves. It was necessary this year, however, on account of the number of requests, that it be placed on the program, and I am sure we are all glad that it has been done.

About a year ago, the National Electric Light Association, through their General Accident Prevention Committee, assigned this subject to the accident prevention committee of the Great Lakes Division under the chairmanship of Mr. Burton of the Consumers Power Company. Mr. Burton appointed a sub-committee to make a report. Mr. Ivan L. Scott was chairman of the sub-committee, and in the preparation of his report he had the assistance of Mr. Kallevang, who has just presented this paper. The discussion of the paper will be led by Mr. Scott at this time.

DISCUSSION OF MR. KALLEVANG'S PAPER, "GROUNDING PRACTICES"

Ivan L. Scott, Wisconsin Power & Light Company, Madison, Wis.

This subject has been covered so thoroughly and in detail that there is little left upon which to comment. However, there are several things which may be added, and upon which some emphasis may be placed.

Ground connection to electrical equipment is made for several reasons. Among these are safety of equipment, improved operating conditions, discharge of lightning or other abnormal voltages, but one of its most important functions is to prevent accidents by making a path from the equipment to ground so that in case of leakage or breakdown the person who may be called upon to work on or near the equipment will not be exposed to electrical shock.

The importance of grounding lines and equipment can not be overestimated, but it must be recognized that grounding is not a cure for all the ills and evils that beset electrical equipment, and will not make any equipment "accident proof." In fact, there are some cases where it is not advisable, from the standpoint of accident prevention, to ground the case or other equipment.

Grounding secondaries or service transformers and instrument transformers has become a standard practice with most public utility companies. Where this is done, the grounding of instrument cases is not so

necessary. In case the circuit is not grounded, there is considerable hazard connected with the handling of the external parts of any instrument or equipment connected to that circuit, and the safe method is to ground the ordinarily dead parts which it is likely the operator or other person whose work may take him near such instruments or equipment will be apt to touch or closely approach.

It is desirable to ground transformer secondaries first because of the possibility of personal injury or death, and, secondly, because of the fire hazard created when the transformer secondaries are not grounded. If for some reason the primary and secondary coils of a transformer should come in contact with one another the primary voltage would naturally follow the secondary circuit. Any person then touching any part of the secondary circuit would of course ground the primary voltage and the result would be very serious and in all probability fatal.

Insulation Is Very Often Faulty Protection

Most appliances in use on a secondary circuit are ordinarily insulated against secondary voltage. The insulation on many such appliances will not even give protection against voltages as low as 110 volts. It is evident therefore that in such a condition as the one mentioned the insulation of these appliances may break down and cause a fire from the short circuits which would follow.

The proper grounding of transformer secondaries will of course prevent such occurrences as these, and it is here that the securing of proper grounds should be stressed. Testing of grounding connections is important and in no case should this be overlooked if the ground is to serve the purpose for which it is intended. It is not sufficient to make a test of the ground connection at the time of its installation, but these should be tested periodically at regular intervals, to insure that conditions have not arisen that would render the grounds ineffective. It is especially important that the ground connection be tested where the transformer is located a considerable distance from the building served by its secondaries. It sometimes occurs that a secondary ground connection is effective in preventing abnormal voltages on the secondary system only within a relatively limited area. Such conditions as these are due largely to the poor conducting properties of the earth at the point of the ground on the secondary system.

In discussing the grounding of station apparatus and equipment it should be borne in mind that some apparatus is very dangerous even after it is disconnected from the source of energy. Aluminum cell lightning arresters, for example, have a heavy condenser charge for some time after being disconnected, and the cells must be discharged to ground before they can be touched in safety.

Station switches and cables are usually mounted in cells and duct runs so that they are not easily accessible for testing and grounding. The cables are usually heavily insulated and are run in confined spaces so that special methods of testing are necessary for the safety of the men doing the work. Oil switches are usually electrically controlled and there

is always the possibility of a fault in the control wiring that will prevent the opening of the switch or may even cause it to close again after it has been opened.

On account of the enormous amount of power available in a short circuit in stations, the methods of testing must be such as to remove any possibility of a short circuit or ground occurring in case the apparatus tested is found to be energized. It is usually dangerous to place temporary or makeshift grounds on switches or cables, on account of their proximity to other energized equipment. Permanent ground busses with mechanically interlocked grounding devices would seem to be a logical solution of this problem.

The average oil switch carrying distribution primary voltages is something of a hazard if the case and frame are not grounded. Switchboard frames, switch handles, generator and motor frames are all safer to handle if they are solidly grounded. The man handling the equipment is generally forced to stand on a concrete floor. This in itself is a hazard, but the hazard is greater than is usually realized in that the average station floor has reinforcing steel, pipes and conduit imbedded in it so that at many points there will be a thin layer of cement over a grounded metal pipe or rod.

Rubber Mats, Insulated Platforms and Stools

Rubber mats and insulated platforms or stools are used in some places, but the former are apt to be filled with conducting dirt and in some cases painted over, perhaps with paint of a conducting quality, and portable stools and platforms are awkward to move about and their use is often neglected. The grounded switch handle, instrument case or switchboard frame will make the same potential between the equipment and the floor so that should a man come in contact with such equipment his body is shunted by a path of low resistance that makes the flow of current through it practically impossible unless contact is made with an energized ungrounded conductor.

Now, in going from the application of permanent grounds to that of temporary ground connections we are confronted with almost an entirely different problem. It differs in that the methods and devices used are widely varied.

I shall not attempt to discuss the various devices in use for temporary grounding of lines, as this has already been fully covered with a description of such devices and their use. Further, I can only briefly elaborate upon some of the methods which have been considered.

Overhead distribution lines of the usual distribution voltage are seldom grounded and are more often worked hot. There are cases, however, where distribution lines parallel transmission lines for a considerable distance and of course there is some protection in grounding distribution lines in a situation of this kind.

The method of grounding depends largely upon the type of line construction encountered. In working upon steel towers the phases are usually grounded to one of the tower legs. On some pole type construc-

tion the overhead ground furnishes a means of grounding the line. But on other types of pole construction the common method of using ground chains must be resorted to.

Many times safety depends upon the grounds placed on the lines by the operators at the station. In case of parallel transmission lines station grounds do not afford ample protection to men working some distance from the station. In a case of this kind it is possible for the de-energized line to pick up sufficient voltage by induction to cause a very serious accident to the man working on the line, and it is extremely important that additional ground protection be provided near the place where work is being done.

When the common method of grounding by the use of chains is used, every precaution must be taken by the men in applying and removing these chains. These precautions have also been covered before, and I merely wish to emphasize the importance of using the hand lines and rubber gloves in applying and removing ground chains.

Procedure in Using Grounding Chains

Where grounding chains are used much depends upon the proper procedure in clearing the line to be worked upon and the proper application of the grounding chains. Workmen should be very careful not to approach high tension lines or attempt to place the grounds until satisfied that nothing has been overlooked in making arrangements to ground the line at the point in question. The line to be worked upon should first be disconnected from every possible source of energy by opening all oil circuit breakers and disconnecting switches. After this has been done the operator at the substation or power plant should accompany the foreman who is to be in charge of the work and check the actual physical disconnection as well as the grounding connections, and hold cards or tags that have been placed on the opened switches.

As has been said, the chains should not be placed upon the lines until a good ground connection has been established. Again I wish to emphasize the point made in the preceding paper, and that is that it is just as necessary to obtain a good ground in a case of this kind as it is to obtain a good ground when applying permanent grounds. I believe that in many cases linemen feel that the ground chain is used primarily to short circuit the phases of the line rather than to secure an effective ground upon the line. In removing the grounds every precaution must be taken, the same as in applying the grounds.

I have found that some companies require that an identification tag be attached to the ground rod containing information as to who placed the ground, whom it will be removed by, the reason, time, date, etc. This appeals to me as an excellent requirement, because of the fact that the removal of a ground may cause a very serious accident.

I do not believe that I have added anything new to what has already been said upon this subject. In conclusion, however, I wish to state that it is recognized that the proper type and method of applying protective grounds must be governed by the equipment and the operating conditions

of each individual company; and I would like to urge that more consideration be given this subject because of the great hazard involved when improper testing and grounding methods are used.

CHAIRMAN McCULLOCH: Mr. Kallevang's paper was also to have been discussed this morning by Mr. Paul R. Kuhn of the Penn Central Light and Power Company of Altoona, Pennsylvania. I have a telegram from Mr. Kuhn regretting his inability to be present, but his discussion will appear in the records of this session.

I will ask Mr. H. B. Harmer if he will not discuss this subject for a few minutes.

H. B. HARMER (Philadelphia Electric Company, Philadelphia, Pa.): I would like to bring up at this time several phases of grounding practices. We are interested primarily in the prevention of accidents. Our duty, regardless of the apparatus, is the prevention of accidents.

Unpleasant Experiences With Grounding Practice

The grounds that I refer to are those that we have all had unpleasant experiences with, caused by our men coming in contact with foreign wires on our poles. In other words, a grounded circuit of another character or kind, for instance, telegraph, telephone wires, and so forth. We have had very many unpleasant experiences along that line.

There is also another ground that men get in contact with that I will illustrate. A line-gang is installing a service along the back of houses for lighting. One of the men in making the ties on the insulator on the back of the house, leans over the side of the house, laying his neck on a copper rain conductor, and reaches over and tries to tie in a live line. He receives a shock. The shock is of such a severe character that it paralyzes his tongue, and he is choked to death before they can get him away.

That is the grounding question that I think we ought to pay particular attention to. It is not so much the grounding construction, because our engineers are thoroughly conversant with that phase of the situation. It is those grounds due to accidental contact that we have to worry about.

Incidentally, I just want to emphasize a certain kind of accident prevention. Last night I had the pleasure of sitting alongside a man who was connected with the Department of Labor of Pennsylvania. He said to me, "Harmer, we didn't have a fatal accident in our last month's report in Pennsylvania. We had an intensive accident campaign, and we didn't know it."

M. C. ALLEN (Western Union Telegraph Company): Because of the very delicate equipment we have to protect, and because of the operators who come in direct contact with that equipment, we have for a number of years been interested in the handling of grounds. I want to ask if, in the measuring of grounds by the utility companies, they determine the resistance of that ground and if they find certain limits to that resistance which are necessary? The telegraph company and the telephone companies have required that.

I want to give two instances which perhaps show the difference. I was personally involved in the state of Connecticut where we were using submarine cable and exposed it across the Connecticut river. We found after spending a lot of money, that by going 100 feet outside of the river bank and driving the pipe 25 feet that it has entirely cured the trouble.

We had another case where, in a test station the telephone wires were coming in contact with high tension wires that entered the station; and because of the poor ground, jumped to the ground plates and then to the wires leading all over the country, which caused trouble in at least 10 of the stations. We spent all kinds of money driving grounds. We drove the pipe to a distance even of 40 feet without getting a ground that would operate. Finally we drove a pipe for probably half a mile and then we were able to attach it to a water meter which cured that condition.

I am not asking this with the intention of starting an argument, but do you find in your tests that it is necessary to determine the resistance of the ground, and do you find it necessary to check your grounds at least once a year?

Observations on Temporary Working Grounds

MR. BEARDSLEY (Brooklyn Edison Company): We test once a year.

I would like to speak on the subject of the temporary working grounds as applied to our system which is metropolitan and mostly underground. We made quite a number of experiments with various testing devices to find out whether we could get something dependable. We came to the conclusion that almost anything that would give a negative indication to insure safety was not dependable for our use. We therefore set about to make an actual ground test on telephone communications, first having the assurance of the operator that the switches and circuits were open. We started at the generating station on the last piece of apparatus which attaches to the outgoing circuits, a ground test switch. Possibly some of the utility people are familiar with our design down there, because it has been published.

We have a remotely controlled switch, and we call it a grounded test switch. It has a double throw. One throw puts the cable on, with which we can apply test voltages. The other one attaches solidly to the ground which is controlled by a separate operation and is separate from our neutral operation. We can place that ground without any manual application going farther out on the circuits, which are 27,000 volts. This thing can be operated from a point of application without any manual service at all.

In the 150 volt, we are not so well equipped. However, on some of the truck switching operations, which is a 27 volt switch, we also have that equipment. So, we can apply the ground and then close in the switch. We are now engaged in designing apparatus on the 4,150 volt circuit. We have had some accidents, quite serious ones, during the placing of the grounds.

On the cable system in manholes, we have a piece of apparatus con-

trolled remotely by two compressed carbon dioxide gas lamps. We hope before very long to have our system fully equipped with such apparatus that we will have no manual application of grounds.

MR. MACLACHLAN (Toronto, Canada): I would like to raise two points. One is in connection with the ground itself. Is it not general experience that outside of a water pipe ground we are simply kidding ourselves that we have a ground?

A year ago last summer I was called on a case about 40 miles from here. A man was found dead under a shed. On checking that carefully, we found the ground pipe driven 44 inches into wet soil and yet under operating conditions we could get from 295 to 305 volts between the ground pipe. By driving a chisel in the ground about four feet away from the pipe itself, it proved quite conclusively to us that the voltage grading at that point was not steep but very sloppy.

I have another matter in connection with the paper, and that is the use of chains for temporary grounds. I well remember a case in which we had chains solidly on both sides of men working. Unfortunately an outsider threw in a switch in a consumer sub-station which energized this section of the line. The switch was kicked out, I will grant you, but the two men were killed in between the chains. I think the time is coming when the chain ground will be a thing of the past. We will have to go to the use of other types of grounds such as flexible cable with the different types of contacts.

The Chain Is Not Considered an Ideal Ground

C. P. HUMPHARD (Detroit Edison Company): Mr. MacLachlan's last point is somewhat similar to the one I was going to raise. Suppose you have an ideal ground: that is, your copper ground chain, ground plate buried, good connection all the way around, a half mile each side of the line-man. Is that a sure way to have it so that the men will not be killed?

MR. KALLEVANG: I don't believe there is any such thing as certainty in a case of that kind. It is all a matter of what capacity you have got on the line. As I suggested in my paper, there are other things that are far better than a chain. As we know, a chain is limited in carrying capacity. We have got to get something that will carry a great deal more capacity than the present equipment.

It seems to me that as a system grows and gets about so big—and this is what I mean by about so big, we have lots of systems in this country which come into the meaning of being big—there is only one place to ground and that is to ground right at the point where you have the circuit breaker that makes that line hot, so that between the place where these men are working and between these breakers you have considerable line. It is better to do that than to ground right at the point where the fellows are working.

MR. REID (Central and Southwest Utilities Company, Dallas, Texas): In a great many of the towns we have no water system, and the earth in Texas is very, very dry during certain times of the year. We have found it absolutely impossible during the summer to maintain any

kind of a ground. We have experimented with copper plates, used bags of salt, and still there is no luck. That is the reason I was interested in Mr. MacLachlin's question. Our experience in Texas would indicate that we can not depend on any kind of an artificial ground outside of a water pipe.

F. W. BAGNALL (Detroit Edison Company): I would like to know how or what method is used in the grounding of a doubly constructed pole line? You made mention in your paper of the fact of pulling the chain over the line. I was wondering how the grounding of the line is used on a double pole construction?

MR. KALLEVANG: I don't see why you can't with proper rope attach the chains around a single circuit of a double pole line the same as would ground a single pole line. I assumed that the circuits are on separate sides of the pole. If you had two circuits on the same pole and they are both horizontal, it might be difficult to ground the top circuit and leave the top hot. I doubt if that is possible. It is certainly impossible, in my estimation, to ground a single circuit of a double circuit line with each circuit on each side of the pole.

DISCUSSION OF MR. KALLEVANG'S PAPER, "GROUNDING PRACTICES"

Paul R. Kuhn, Penn Central Light & Power Company, Altoona, Pa.

The address of Mr. Kallevang covers the subject of "Grounding Practices" in a comprehensive and able manner. I know we have all secured considerable benefit from his address and that it should be of value to us in our work.

Grounding is daily becoming of extreme importance to all of us engaged in the electric light and power industry. Grounding may be defined as a protective measure applied in the electric industry to insure constant service, afford protection to property, avoid possible fires, and to prevent accidents.

We are primarily interested in grounding from an accident prevention standpoint. This phase of grounding is demanding more and more attention each day. This increase in interest may be attributed to:

1. A wider use of electricity in homes, business places and industrial establishments, with consequent possible augmentation of electrical accidents.
2. A better knowledge of value and relation of grounding in preventing electrical accidents.
3. The interconnection of transmission systems and enlargement of capacity of generating stations and sub-stations, thus intensifying the possible accident effects of any "blow up" in electrical systems or apparatus.

Mr. Kallevang has appropriately divided his address into two divisions: "Permanent Grounding" and "Temporary Grounding."

Permanent grounding, as it relates to homes, business places and industrial establishments, is a tri-party problem for the electric light and power companies, the duly constituted national, state and municipal authorities and the consumers of electric energy. Many electric companies have specific service rules which require electric work to be approved before electric current is cut through. In addition to the company rules, the National Electrical Safety Code has been generally accepted as a basis for state and municipal laws and rulings covering electric installations. The National Electrical Safety Code contains certain specific provisions on grounding for interior wiring and electrical installations. The enforcement of these provisions from an accident prevention viewpoint should concern not only the light and power companies, the duly constituted authorities, but should be welcomed by the consumers of electric energy.

Permanent grounding as applied to electric light and power companies, partakes of several features. Grounding of transmission and distribution lines is being generally followed out today by the companies. The application of permanent grounds in generating stations and substations is also demanding extreme and minute consideration. The attention being given to grounding by the electric light and power industry, in-so-far as it affects generating stations and substations, is best indicated by the exhaustive report issued on the subject this year by the Electrical Apparatus Committee of the National Electric Light Association. The title of the report is "Practices and Methods in A. C. Substation Grounding." This report covers in detail: "Methods of Grounding," "Grounding Systems," "Equipment Grounded for Safety Purposes," "Inspection and Testing of Grounds," and contains six appendices with most valuable and original information on grounding. You will find this report not only interesting but fascinating reading. It will, without doubt, answer many questions which may have been giving you considerable trouble due to the pranks of electricity.

Temporary Safety Grounding

Temporary safety grounding, due to the circumstances surrounding its application, is of vital concern to those persons interested in preventing accidents. As the name indicates, grounding of this nature is temporary, which unfortunately means to some people, that it is not to be taken too seriously. Those of us engaged in accident prevention work know full well the evils wrought by the word "temporary." It has come to mean a synonym for accidents; therefore, temporary safety grounding is of particular interest from a safety angle.

In temporary safety grounding, the human factor forms the most important element. Temporary safety grounds are invariably applied to afford protection to workmen and the success of the protection depends to a great extent upon the intelligence and care manifested by the human element engaged in performing the grounding application.

Theory and practical experience have combined to teach us that merely disconnecting a line from the source of supply is not sufficient protection to the men working on a line. The line must not only be disconnected but grounded and every precaution taken to prevent re-energizing the line until the men are clear of the line. With this idea in view practically all companies have very definite rules and methods governing the grounding operation. The idea of illustrating the grounding procedure in rules and instructions is good, and it is worth while using in the printed rules and instructions if it is at all possible.

Notwithstanding the general acceptance by the light and power companies of the value of printed rules on grounding, some companies still depend upon verbal instructions. Many companies also assume a line-man or workman to be skilled in grounding work without any previous check up. These two things have been contributory causes, if not the exact causes for serious and fatal accidents. My only suggestion to companies still adhering to these two policies is to get busy and change them immediately before some misunderstanding brings on a fatal accident.

I have no time for chains as a grounding device. Their only present day advantage appears to be their ease of transportation. Too many good grounding clamps have been developed by the electric light and power companies and electrical manufacturers to justify the further retention of a chain as medium of grounding. This may sound revolutionary from an operating angle, but from an accident prevention standpoint it is far from being extreme.

The portable grounding clamps in use are all about the same in electrical principle, the only deviation being in mechanical design. Like every piece of protective equipment, the usefulness and value of grounding apparatus depends upon its periodic inspection, good care, and proper maintenance. This program should not be everybody's business in a company (which means nobody's business), but it should be delegated to assigned and responsible employees. Rubber gloves should form a part of the grounding equipment and the men should be informed that they are expected and required to wear them, especially on transmission lines, when applying and removing grounding devices.

Generating Station and Substation Grounding

Rapid advancement has been made during the past few years in protective grounding devices for generating stations and substations. Modern generating stations and substations are of such large capacity that carelessness in proper and effective grounding is apt to destroy property and produce serious accidents.

It is just as essential that proper grounding devices be available and rigid instructions issued in grounding at generating stations and substations as when work is being done on transmission lines. More complications are involved in generating station and substation grounding than in transmission line grounding and the hazard to life is in many

cases as great. The electric light and power industry is well aware of this fact and it is making every effort, as Mr. Kallevang mentions in his address, to arrange its grounding equipment to be fool-proof. In generating station and substation grounding the human element is again a big factor and the importance of printed rules and instructions governing this work is again of extreme importance.

Underground Cable Grounding

The adoption and usage of high voltage underground cable necessitates every bit as much care while work is being done on the cable as employed in overhead transmission lines and generating stations and substations. Grounding of cables and underground feeders is essential for safety to workmen. This problem is engaging the attention of companies operating in the large cities. They are sparing no expense in making equipment safe for their workmen, because they have found from experience that accidents due to absence of grounds or errors in grounding are in most cases serious and expensive ones.

The deduction to be drawn from Mr. Kallevang's address and the discussion thereon, is that proper and effective grounding is most vital in the prevention of accidents. Permanent grounding should engage the attention of the electrical industry at all times. However, its progress is bound to be a little slow, due to the many complications involved in having it rigidly carried out.

The adoption of a temporary safety grounding program is quite different from permanent grounding because its acceptance and use can be very readily effected by the light and power companies. It is chiefly a problem for the companies to solve within their organizations. It can be solved to a great degree through the following suggestions, if put in use by the companies:

1. Every company should have an explicit set of printed rules and instructions (with illustrations if possible) on temporary grounding.
2. Every company should have safe and adequate equipment for temporary grounding and the equipment should be regularly inspected and maintained by assigned and competent employees.
3. Every company should give their employees proper instructions and training in temporary grounding.
4. Every company should have temporary grounding performed under the close supervision of high class workmen.

CHAIRMAN McCULLOCH: So far, in our three meetings, we have devoted little time to the telegraph and telephone companies. We had a description of one of their accidents at the first session which was presented by Mr. Morgan with his interesting model. We now come to a paper which will be of interest to these companies. We regret that Mr. Charles E. Gardner, who is superintendent of the Department of Safety of the Michigan Bell Telephone Company, can not be with us this morning. Mr. E. B. Moore, who is safety engineer of that company, will present Mr. Gardner's paper at this time.

ACCIDENT PREVENTION WORK IN THE MICHIGAN BELL TELEPHONE COMPANY

**Charles E. Gardner, Superintendent, Department of Safety, Michigan
Bell Telephone Co., Detroit, Mich.**

For years before the war, accident prevention was the fundamental consideration of the management of the Michigan Bell Telephone Company through supplying safe tools, materials, and adequate supervision in the performance of work. However, the increase in our personnel made necessary by the demand for increased service in all fields of business, confronted us with the problem of training new employees in safe methods of doing our work. To accomplish this a series of safety meetings were held in which talks were delivered based upon slides showing accidents occurring to employees engaged in similar lines of work. To supplement this, payroll stuffers were used to call attention to various phases of accident prevention.

These things temporarily assisted in maintaining interest, but, as the tide ebbs and flows, so group enthusiasm rises and falls.

If we had a "pepometer" or some mechanical device to register the amount of enthusiasm and interest being expended in preventing accidents, our work as safety men would be easier, but since no such device exists we must continually evolve new methods of securing continued interest. This continued interest is particularly desirable in the telephone business since a large part of our men are working alone upon the highways and at isolated points, making it imperative that each man be largely his own safety adviser and do his own thinking in averting injury. To accomplish this, we considered instruction in first aid as a suitable vehicle to bring home the necessity of accident prevention.

The practice of applying splints to an imaginary injury affords the man an opportunity to visualize his own arm or leg broken, with perhaps the bone protruding, and is a sobering influence which returns when he is tempted to take a chance on some "short cut."

In the spring of 1921 a number of industries cooperated under the sponsorship of the Detroit Safety Council and conducted several schools; among them a school on fire prevention; a school for foremen; a school for chauffeurs; and a school of first aid to the injured. In the latter were placed a number of our men whom we hoped to develop into instructors capable of training the remainder of our employees. The method of instruction was to have lectures by physicians upon various phases of first aid, followed by class practice in various problems. During the period of practice work, the efforts to excel in the execution of bandage and splint work created a friendly rivalry which stimulated interest and helped materially in developing a knowledge of the subject. The general results were very satisfactory. In addition, we profited through the experience gained and found that demonstration work was the feature that appealed to our men.

In the fall we started our first drive to make every plant man in Detroit the holder of a First Aid Certificate, and the instruction of 1,100 men was no small task. The men instructors were drawn from those who had taken the course the previous spring, but to adapt the instruction to our particular needs, it was found desirable to give additional training. To secure a uniformity of instruction, it was decided to drill this group in the execution of specific problems composed of imaginary injuries which might occur in their own class of work.

We were fortunate in having in our organization a man who had been a scoutmaster and had had several years' experience in drilling competitive teams of scouts in first aid work. Placed in the position of chief instructor, with a class of selected men, he communicated his enthusiasm to them and was able to create a sufficient amount of curiosity upon the subject to impel them to seek additional information from the text book.

There is one feature of this work which may be of particular interest, as it illustrates how careful planning of the job assists its execution. Many of our outside men use various knots in their work and a problem which made use of a complicated knot was put first in the initial lesson. This was best accomplished by raising a question about an installer or other employee who, while working alone, might sustain a sprained ankle. What could he do for himself in getting assistance? This was familiar ground. All knew the possibility and the discomfort of a sprained ankle and the exhibition of the ankle bandage, which is merely a complicated knot, awakened interest and a desire to learn its use.

A Clever Plan for Interesting the Man

When each man was invited to try it and failed, his pride in tying knots was challenged. By the time he mastered it his attention had been secured, and a demonstration of the balance of the bandage ties made him eager to master them also. So the general first aid instruction in the Michigan Bell Telephone plant department was begun, and today over 95 per cent of our plant force, some 3,500, are trained first aid men.

These men are scattered over our territory, qualified and ready to render service to the public, not only in telephone work but in saving life and relieving pain. The public has profited in many emergencies by the prompt application of first aid measures.

In one instance in lower Michigan a child had fallen in the river and after considerable time was drawn from the water and lay apparently lifeless on the bank. Attracted by the throng which gathered, one of our repairmen went over to the scene of the accident. By the application of artificial respiration he was at last rewarded by a convulsive gasp and continued to assist until normal respiration had been restored. The gratitude of the parents of this child, which they had thought dead, is beyond the possibilities of word description. The satisfaction to our employee in saving this child's life, and to his company which gave him the knowledge to perform the deed, should be an inspiration to

every man here engaged on accident prevention and first aid work.

Instances of this kind have gradually spread the knowledge of our interest in first aid until the public has come to recognize preparedness of our employees to render this service. An interesting example is seen in the response of an applicant for employment, interviewed by one of our superintendents, who answered the question, "Have you ever had any experience in telephone work" by saying "No; but I have got something which I understand you people demand." And he explained that he had had a course in first aid in the Boy Scouts and later in a naval training school.

In addition to first aid training, another accident prevention feature which assisted us was the decision that responsibility for accident prevention should be delegated to Authority for Production and, to stimulate interest and to disseminate information regarding competitive standing, the "Foremen's Dope Sheet" was evolved. This showed, opposite each foreman's name, the number of months which had passed without an accident to any member of his crew.

Each Division Had an Objective to Strive For

To set up an objective to "shoot at," each division was requested to make an estimate in the nature of a "bogey." This placed responsibility directly up to them and was a reminder of their obligation toward their fellow-employees in averting accidents. The results of this estimate were set up on a chart, and each month the current accidents were posted opposite the "bogey" and enabled all employees to see the results of the contest. Large banners to display on the trucks were also awarded and they proclaimed that this group was a "Banner" or "No Accident Crew."

As a step on the part of the employees in fulfilling their part in the cooperative plan, it was thought that if the accident prevention experiences of all could be collected, this would enable every one to profit; and to obtain material for a proposed safety code, questionnaires were sent out to all plant employees urging them to give descriptions of accidents which had come to their attention and recommendations for avoiding similar ones.

As the questionnaires returned, they were edited by a committee appointed by the Employees' Association and finally evolved into a safety code. It is the result of the efforts of employees working in conjunction with management and is an example of what can be accomplished by everyone working together.

The interest shown by the men interviewed at stockrooms regarding a new type of accident, which resulted in injury to one of our men, prompted the thought that perhaps the periodical posting of a list of significant accidents on the bulletin boards would react favorably in enabling others to profit by them. The summaries are mimeographed on colored paper, a different color being used each time, and a heading is provided which is a terse comment on accident prevention written

as though coming from the boss. This is used to compel attention, while a free use of slang is made in comment on each item to secure a reading by the employees and stimulate discussion. Illustrated bulletins are also used and beneficial results are found to follow the prompt removal of old bulletins so that the boards are vacant part of the time. By this method new material secures notice by its presence.

CHAIRMAN McCULLOCH: I have received a suggestion that a telegram be sent to Mr. Lucas, treasurer of the Philadelphia Electric Company. Mr. Lucas, as you know, was very active in the work of this Section, particularly in the preparation of its programs, and always attended when his health permitted.

CHARLES B. SCOTT (Bureau of Safety, Chicago, Ill.): I move you, Mr. Chairman, that you be directed to send a telegram to Harry Lucas, expressing our deep regret that he is not present and expressing our wishes for his recovery from his illness, and that we miss him very much and remember the meetings in which he has been so helpful to us.

The motion was seconded and carried.

CHAIRMAN McCULLOCH: It has also been suggested that a telegram be sent to Mr. Rutland of the Texas Power and Light Company, who during the past year has been chairman of the Membership Committee (you have all heard of the remarkable work done by his committee) regretting that he was unable to meet with us and expressing to him the appreciation of the Section for the work that he has done this year. I believe it would be well to take some action on that.

MR. STEWART: I make such a motion.

The motion was seconded and carried.

CHAIRMAN McCULLOCH: It has also been suggested that a telegram of appreciation be sent to the Michigan Bell Telephone Company and the Detroit City Gas Company for their courtesy in connection with the inspections and visits to the plants.

The discussion of Mr. Gardner's paper this morning will be led by Mr. B. W. Farris of the Western Union Telegraph Company of Chicago.

DISCUSSION OF MR. GARDNER'S PAPER

B. W. Farris, Construction Supervisor, Western Union Telegraph Company, Chicago, Ill.

The paper presented by Mr. Gardner was indeed interesting and indicates that he has devoted much time and thought to the subject of safety. The information contained in his statements is based on facts, experience and statistics, and should be helpful and educational to anyone who is interested in the Safety First movement. I will endeavor to outline or express a few views for your consideration, which, I think, of major importance or which might, if followed, tend to reduce the number of accidents or personal injuries among the employees or workmen engaged in our line of industry.

The field for safety work in a large plant organization, like the Western Union Telegraph Company, the Telephone Companies and the Electric Light and Power Companies, is of such vast scope and there are so many different views and ideas as to how best results can be accomplished, that I find it difficult to arrive at a decision as to the best methods to pursue to accomplish the desired results.

I have, however, arrived at one definite conclusion, and that is the fact that the heads or supervisory forces of any organization must be interested and sold on the safety idea if the desired result is to be obtained. I mean, the interest and enthusiasm must be generated, conveyed and distributed by the ranking officials or supervisors and carried to the workmen by their immediate supervisors. If the foreman, general foreman or supervisor is not interested in safety and does not talk and indicate this by his actions, it is not reasonable to assume that the workmen will be as careful as they should.

Instruct the New Employee Very Carefully

From experience and inquiry, I am fully convinced that it is of the greatest importance to see that the new man be properly instructed in regard to safety rules and practices at the time he is employed, before he takes up his duties with the company. By this I do not intend to convey the idea that I have in mind the "green man" or inexperienced man only. I am referring to the "new" man, whether he be an inexperienced or experienced man.

My reason is that the "green" or inexperienced man has not been trained in the work he is about to undertake and does not know the hazards or dangers in connection with it. He may be a young fellow from the farm or factory or he may be a clerk or bookkeeper from the office who has arranged for a transfer to the field to learn outside construction or maintenance work; and in any event it matters not what his previous vocation has been, he probably has a very limited knowledge of the safe and unsafe practices to follow in the performance of his new work, and for this reason it is very essential that he be talked to and impressed with the safety idea.

In regard to the experienced man, it is, of course, reasonable to assume that he has more knowledge regarding safety, but it is astonishing and disappointing in many instances to learn that he gives but little thought to safety in performing his work. In such cases, even though the man is experienced, he has not been properly advised or trained on the subject of safety. Therefore, I am a firm believer that all new employees should be properly instructed on the subject of safety; and I will go further and say that the instruction should be by the foreman and not the assistant foreman or anyone else, as the foreman is the man whose advice the gangman will listen to and follow.

When a new man is employed, the foreman, who is the key man and upon whom the responsibility of the gang rests, should discuss the hazards in connection with the work and impress the man with the fact

that the performance of his work in a safe manner is of much importance; not only for his own benefit, but for that of his fellow workmen; and that carelessness will eventually lead to injury, pain and suffering and in many instances will result in him becoming a cripple or being the cause of such misfortune for others. The new men should also be told that the number of deaths as a result of injury due to carelessness has extended into the thousands annually.

To be more specific in regard to instructions to new employees, I would suggest the following:

The foreman should invite the new man to his office or room, have him sit down and make him feel at ease and comfortable, and have a short social conversation with him. He may talk about his present and previous vocations, being careful not to get too inquisitive regarding his personal affairs, but simply talk to him long enough to form some conclusion as to whether or not the man would make a desirable employee and is suited physically for our class of work. If the foreman decides the man is satisfactory, he should then tell him what his salary will be and explain the general nature of the work and what his chances will be for promotion, increase in salary, etc. If this is agreeable and the man accepts the position, the foreman should then tell him that the company has certain safety rules which he would be expected to carry out, and unless he is willing to be guided by same his services would not be desired; and right here the foreman should impress him with the fact that the execution of the rules and safety practices is far more for his own benefit than that of the company.

The Foreman Should Carry a Book of Instructions

The foreman should have in his office a book or folder containing a complete copy of instructions which have been issued by the company from time to time, treating on the subject of safety in connection with the work and he should call to the attention of the man some of the more important or most dangerous practices. He should then tell the man to take the book and look through and read it carefully.

I do not believe it a good practice to endeavor to get a new man to absorb too much at one time, but the most important thing is to get the safety idea instilled in him, and he will absorb more from time to time as he goes along. He should not be told too much at the beginning, for the same reason children are not given too much instruction or heavy tasks when entering kindergarten or primary grades. If they are not overburdened with too many lessons at the start they will master them and be eager for further information; and this is true with men in teaching them safety.

Pole line construction and reconstruction work with the Western Union Telegraph Company is somewhat different from that of other wire using companies, for the reason that a very large percentage of the work is along railroad right of way, whereas the work of most other companies is along streets and public highways; and for this, as well as other reasons, any specific ideas or practices which might be of the utmost

importance in the safe performance of our work on railroads might not apply in connection with the work of other companies. Nevertheless there are a great many things in our work which are the same as other companies and I will name a few of the practices which I consider of much importance and which should be discouraged, and, if possible, not permitted by any company:

1. Do not use defective tools.
2. Do not climb an old pole and untie all wires until convinced it is safe to carry a man's weight. If in doubt, use pike poles or ropes to make the pole safe.
3. Do not drop or throw material or tools from standing poles unless sure there is no one under or near the pole.
4. Do not throw or toss material or tools to man on standing pole. Use hand line and tool bag.
5. Do not stand or work under pole while man is working on pole.
6. Do not stand close to a moving train.
7. Do not get on or off motor car or truck while moving. Wait until it stops.
8. Do not stand up on motor car, trailer or truck while moving.

Safety Meetings a Part of the Regular Procedure

The safety idea with the Western Union Telegraph Company is not entirely new, for printed rules and instructions in regard to unsafe practices in connection with our work were in effect 25 years ago, but I must admit they were not carried out as they are today. The rules were printed on one sheet of paper of letter-head size and captioned "Warning to Employees"; they contained instructions in regard to the hazards in connection with the work, but the trouble was that the instructions, suggestions, good advice or whatever it might be termed, were not followed as of today, and there was not the effort to keep the safety idea constantly before the men.

Safety meetings are now conducted regularly at least once a month and in many instances more frequently, in each of our gangs, and at intervals division meetings are held by calling together a number of foremen with a man from their gang. At the gang meetings various methods are followed in conducting the meetings, but the general practice is for the foremen to preside and a general round table or free for all discussion is held and the men are all encouraged and requested to offer suggestions for improvement in methods to promote safety in the performance of the work, improvement of tools, etc. If the general foreman or supervisor is present when the meeting is held, he naturally joins in the discussion and helps the men along by asking and answering questions. The meetings are held during regular working hours on company time, as it is thought much better results are had, because the men will take more interest than if the meetings were held before or after working hours. As a result of these meetings, many good suggestions and ideas are presented and the men manifest much interest.

During the last year a moving picture film, which was presented at the National Safety Congress at Cleveland last October, has been shown at division safety meetings and to each gang in the United States. The picture, as some of you may recall who saw it at Cleveland, shows a gang engaged in regular work, such as distributing poles from work trains, setting poles, digging holes, attaching and removing crossarms and operating motor cars, etc., illustrating the principal hazards of the job and the wrong and right method of performing the work.

At the meetings where the picture was shown to the gangmen, it was run through at least twice and stopped and discussed by the men, and it is felt a great amount of good was derived, not only for the lessons taught, but it was of value in getting the men to talk and argue. In this connection it might be stated that the beneficial result of this first attempt by our company to use moving pictures in safety meetings was such a success that plans are now under way for filming other pictures to be shown in the near future.

The industrial edition of the Red Cross Manual has been furnished to all of our gangs and we find that it is being read and discussed by the men and they are taking much interest in it. The book is also discussed at the division and separate gang meetings. Demonstrations are given on resuscitation, dressing wounds, etc., and at intervals arrangements are made to have a doctor address the division or larger meetings and advise the men as to good and bad practice in rendering first aid in personal injury cases. As a result the men have learned much and are better prepared to render assistance and first aid at the time of an injury.

The Big Problem is Maintaining Interest

The greatest problem confronting us and any other organization is to arouse and maintain a sincere interest among the workmen and get them to realize the value of their efforts. We feel that we have accomplished much along these lines during the past four years as will be noted from our record since 1923, which is as follows:

1923—	12.46 accidents per 100 employees—	8,257 employees
1924—	10.04 accidents per 100 employees—	8,792 employees
1925—	8.33 accidents per 100 employees—	9,037 employees
*1926—	4.30 accidents per 100 employees—	9,218 employees

*9 months record only.

These figures show a reduction of approximately 53 per cent in our accident frequency rate.

At the beginning of this year we set a definite objective or goal of "20 Per Cent Less Accidents in 1926." For the first nine months we have shown a consistent reduction of about 30 per cent each month. We were convinced we could attain this objective if the idea was properly sold to the men and the results speak for themselves as to the success of our efforts. We are now developing plans for a continuation of this campaign for 1927, which we hope will produce better results, and we feel it can be done.

CHAIRMAN McCULLOCH: We have about one-half hour for discussion. I believe it would be well to divide that time, first, to take up a discussion of this subject of "What the Telephone Companies Are Doing to Prevent Accidents," and at the close of that discussion to devote the rest of our session this morning to an open discussion on any of the papers presented during the last three days.

If anyone has anything to add to Mr. Gardner's or Mr. Farris' discussion in connection with telephone and telegraph accident prevention work, we would like to hear from them at this time.

MR. THOMAS (Chicago, North Shore and Milwaukee Railroad, Milwaukee, Wis.): My name is Thomas and I come from Milwaukee. I guess most everybody knows something about Milwaukee, and nobody knows anything about me.

I have been attending the sessions of the convention from time to time. Of course, after the day sessions were over, I started looking for some kind of entertainment. The other evening I strolled into a show. One of the things that I saw during this show was where a fellow bet \$15,000 that he could tell the truth for one straight business hour. I sat there very interested and expectant and watched the whole thing. By the time the hour was up, he had lost the \$15,000 bet and about wrecked the man's business.

Observations of a "Doubting Thomas" Are Offered

Now, that just got me to thinking. I said to myself, "What kind of a session would we have in the National Safety Council if we all bet \$15,000 that we could tell the truth for one session?"

I don't know just what kind of men I am talking to here. I suppose we have some executives and some branch managers and some safety engineers. Possibly there may be some rank and file employees sitting out here, although I doubt it very much. Before I attended these sessions, I imagined I could come here and hear scientific discussions on accident prevention work and I would be able to carry back a lot of constructive suggestions that I could use on the folks back home. But, you know, I am sorry to say it reminds me a little bit of a convention I attended one time of the Methodist Church. They all got together. They said a whole lot of nice things about the Church, but when the people got back home, and they were asked, "What did you learn at the convention?"

They would reply, "I can't begin to tell you about all the nice people I met over there."

I imagine the same thing is going to happen here. When you get back and they ask what went on up there at the convention, you will say to the boys, "I met a lot of nice fellows, and the ball was a knock out."

I wonder if we are all doing the right thing all the way through? Are we playing square with the fellows back home? Are we telling the truth? I suppose there are a lot of managers sitting here. If I asked you what you were doing along accident prevention lines on your prop-

erty back home, you would probably say to me, "Well, I am making that property safe. I am putting up all kinds of safeguards. I do a lot of protecting. I belong to the National Safety Council. I have a safety organization out there on my property."

Are you really playing square? Are you doing everything you can do on your property to prevent accidents? Here is what a man sometimes does. He gets a safety organization, or he gets a safety director, and they hook him onto the organization somewhere. They would put him on the roof if it were possible, and then forget they had him. If the safety engineer wants something, they keep him waiting a week.

You know, I don't know whether that is true, whether anybody here is guilty of that or not. I think it is high time that we should tell the truth. Some of these safety engineers are good fellows and they mean well. They have an organization and they try every once in a while to get somewhere with it. A great many times they spend a lot of time thinking how alive they are and how dead the employees are, and then they do a lot of complaining. If you were to hear some of them talk, you would think that they had a hard job.

The kind of a man that gets somewhere is the man who gets there in spite of difficulty. Wouldn't it be a good thing if we told the truth, and started a little investigation of ourselves and found out truthfully whether it was the fault of the other fellow or whether there was something wrong with us and the Safety Council?

The Congress a Clearing House for Troubles

You know, I imagined before I came here that this was a clearing house for everybody's troubles. Instead of that, it seems to me it provides the machinery where a lot of people say a lot of nice things about each other, and have a lot of nice balls and dances and luncheons and all that sort of thing. I thought we were going to hear ways and means of meeting the other fellow's problems, but I haven't heard anything like that yet. The chief thing I have heard is the wonderful things that each and every one is doing on his own property.

To hear them, you wouldn't think there were 90,000 people being killed annually in the United States. On the other hand, you would think that this country is a paradise. Certainly we have all reduced our accidents in the last six or seven years. When you look at the newspaper and find that the total is increasing all the time, you don't know whether to believe these eloquent reports or not.

When I get back home, I am going to do just the same as the other fellow; I am going to tell about the fine bunch of fellows I saw in Detroit, and when I say that, I mean you fellows out here.

I hope you won't feel badly about this. I come from Milwaukee, and Milwaukeeans like to knock. We like to knock, because we believe that every knock is a boost, providing it is the right kind. Certainly I don't want to throw the monkey wrench into the machinery here, but I believe it would be a good thing for us all to remember when we com-

plain about the results we are getting, that the best thing to do is to clean our own house first.

CHAIRMAN McCULLOCH: I announced that we had one-half hour for discussion. We now have about three minutes left. If there are any more "doubting Thomas's" in the audience I will be inclined to reduce even that time.

Mr. Thomas said that every knock is a boost. If that is true there is no doubt that he is the best booster in the convention. He also said that he represented an electric railway, and I would like to know why he is not attending the electric railway session this morning at the Tuller.

Before he talked, I was feeling pretty well satisfied with our meeting. He reminded me a good deal of the man that the Toastmaster spoke of last night, that said the only time the employer said, "Well done," was when he ordered a T-bone steak.

I don't know how Mr. Scott feels about it, but if I were President of this Association, I would feel like getting up at this time and offering a little defense on this accusation that we are running an Elks convention here. I am going to call on Mr. Scott and ask if he won't say something.

CHARLES B. SCOTT (Bureau of Safety, Chicago, Illinois): Mr. Chairman, I would like to ask the gentleman a couple of questions before I reply to him.

Mr. Thomas, what position do you occupy with your company?

MR. THOMAS: I don't know that that has anything to do with this question.

Some Leading Questions Are Propounded

MR. SCOTT: Are you the safety man for your company?

MR. THOMAS: I am supposed to be the Service Improvement man.

MR. SCOTT: Have you any particular interest in safety?

MR. THOMAS: Yes.

MR. SCOTT: Have you ever been a car operator?

MR. THOMAS: I was at one time, yes.

MR. SCOTT: A motorman?

MR. THOMAS: Yes.

MR. SCOTT: How long have you been in this new job as Service Improvement man?

MR. THOMAS: Less than a year.

MR. SCOTT: Do you believe in safety work?

MR. THOMAS: Well, I believe in it to a certain extent, but I believe that we could improve on it.

MR. SCOTT: You think we are going at it in the wrong way?

MR. THOMAS: I haven't any very definite conclusion, but I thought I might get some if I raised the question.

MR. SCOTT: Is Mr. Oliver, the safety man for the North Shore road, here?

MR. OLIVER: Yes, here I am.

MR. SCOTT: Do you know Mr. Thomas?

MR. OLIVER: I know a little of him.

MR. SCOTT: Were you connected with the road while he was a motorman?

MR. OLIVER: Yes.

MR. SCOTT: What kind of a motorman was he?

MR. OLIVER: Average.

MR. SCOTT: What was his accident record?

MR. OLIVER: Well, I would say, fair.

MR. SCOTT: What experience did you have with him as a motorman, how long?

MR. OLIVER: Almost four years, and just within the last two or three months he has changed from motorman to Service Improvement man.

MR. SCOTT: For what reason?

MR. OLIVER: He has a good gift of the gab, that is all I know.

MR. SCOTT: When he was a motorman did he take an active interest in the safety work?

MR. OLIVER: Well, not a very active interest.

MR. SCOTT: Did he attend your meetings?

MR. OLIVER: Yes, once in a while.

A Man Not Interested in Safety Meetings

MR. SCOTT: Was he an interested attendant or a disturber?

MR. OLIVER: The only time I can recall his being at a meeting was when he got on his feet to knock some guy.

MR. SCOTT: Mr. Chairman and Gentlemen: I presume the fact that I have been honored with the presidency of this Council, and because of my long active association with its work and the years I have been in intimate touch with it will justify me in making a reply to this gentleman.

There are several thousand people attending this National Congress, many of whom have devoted a large portion of their lives to the cause of safety, and particularly to the prevention of industrial accidents. Because of my active connection with the Council I have the good fortune of a wide acquaintance in this group of men and am familiar with the purposes which prompt them to continue the work. This acquaintance convinces me that most of them are devoting their time and energies to the cause of safety, not through any mercenary motive but because of their desire to help others. As Doctor Jones so forcefully said last night, they are men who have a heart in their work and are thus prompted by the highest of motives and deserve commendation.

The remarks which you have just heard are more significant than you may appreciate, because they reflect an attitude of mind that is not altogether uncommon; a mind which is not in sympathy with such efforts as ours because of lack of faith in our sincerity of purpose; it typifies

a class of people who unfortunately may be found in almost any locality and a class to which we should give our earnest attention.

The gentleman who has just spoken has been very frank in his criticisms and has expressed the idea that the real underlying purpose of our efforts is not so much in the interest of our fellowman as in the interest of economy and the financial welfare of those institutions with which we are connected. He very frankly tells you this and asks that you "speak the truth" so that there may be no disputation about your real purpose.

Every Organization Must Be Based on Sincerity

Such frankness is to be admired, even though the thought of such a challenge may be so unpleasant to us. There are few of those, with thoughts like the speaker, who have the bravery to come before such a body and openly make such a challenge. Every man should be above all things frank and honest with himself; every institution, such as the National Safety Council, must of necessity be frank and honest with regard to its aims and purposes. No institution with the stigma of insincerity upon it can be influential or endure. One of the reasons for the existence of the National Safety Council and for the work you and I have chosen, is that there are so many people like the speaker who are given to loose thinking. If in this country of ours and in our industries we had any considerable majority of people who thus questioned the efforts of industry to do good and looked upon every such activity as ours as being a selfish one, then there would indeed be need for many such organizations as the National Safety Council to cope with such a deplorable situation.

I recall to mind the occasion mentioned by Mr. Oliver when this same man expressed similar opinions in one of the safety meetings of the organization of which he was a part and sowed the seed of discontent and doubt in the minds of his associates. At the particular meeting, a man whom you well know and who is present today (Mr. Gordon) had made a talk at the meeting of employees and had done what he could to present the subject of safety from the more human point of view. It was at this meeting that the gentleman took exceptions to the presentation of safety along the lines of human helpfulness—am I not correct in this statement, Mr. Oliver?

MR. OLIVER: Yes sir.

MR. SCOTT: On this occasion, this gentleman criticized his company for bringing into the meeting a man who had no practical knowledge of car operation, and expressed the idea that the safety department should not send out as an instructor a man like Mr. Gordon, who (as he said) did not know the difference between a trolley and a controller. It is fortunate that the management shortly after this meeting was so wise as to take this man out of the operating department.

It may be true, and doubtless is, that Mr. Gordon does not know how to run an electric car, nor does he pretend to tell trainmen that he has any expert knowledge of actual operation; nor was such information

as details of operation necessary to meet the situation which was presented at that meeting. The technique of car operation was not the needful thing for the group of men who had assembled to hear Mr. Gordon. There may have been, within the group, associates who had been influenced by the previous speaker—who like him may have been thoroughly familiar with car operation; but he and they needed a treatment of the subject entirely different from one of mechanical detail.

Most of you know Mr. Gordon and know that I speak truly when I say that he has made a great contribution to the cause of safety; not due to the fact that he has any trained engineering or operating knowledge, but because he is an outstanding example of those who have heart in the work and are striving to develop requirements more necessary than mechanical knowledge. Mr. Gordon has been very helpful in putting into the organization of the North Shore Road, that spirit of consideration of one man for another, that consideration of helpful service and spirit of loyalty to the company which has made this road prominent as one of the best operated in this country.

These Employees Thoroughly Believe in Safety Effort

Last year this property was awarded the Coffin Medal for its efficiency and advancement in railway operation. The real spirit of safety has permeated this entire organization and brought the men and the company very closely together. The employees very clearly appreciate there is something else in business more important than material and financial success and it is this appreciation that has been largely responsible for the improvement of the property. The gentleman who has just addressed you has a family and they travel on this road. He should certainly be grateful for their safety and for the confidence he has in their being protected by his associates. Most certainly he should have some feeling of gratitude for his connection with his employers and the safety of those of his own household.

Each one of us should profit by the lesson which has been brought out in the presentation this morning. Each one has some such person in the group of men with whom he has to deal in his safety work at home. The reason you have not found this out is probably because similar men in your own organization have been too timid to assert their convictions like this man has. There are many who have the idea that you and the other safety workers are not wholly sincere in your work. They have the idea that you have chosen your particular profession because it presents an easy job, or perhaps believing that you find it profitable. They believe the company has created the safety department and employ you in order that it may make financial gains because of the work you are doing. When you go back to your work you should remember that you will find some such doubters of your sincerity of purpose and those who are looking with doubt on your company's unselfishness in its interest in safety.

Those of you who heard Doctor Jones at the banquet last evening

certainly were given the true spirit of our cause. His talk alone would have compensated any one attending this Congress. It was good treatment for those who may have such "red" views of our work. There is quite a contrast between the estimation of the cause of safety as was portrayed by Doctor Jones and the sordid and contrary view which has just been given to you. It perhaps reflects the two extremes of views on the subject; the one so full of sympathy and the value of human interests—the other so cold and lacking in its appeal; each due to the attitude of mind and the conception or misconception of the better things of life. The one appreciative, unselfish, with a spirit of love. The other resentful, pessimistic and with an atmosphere of selfishness.

It is greatly to be regretted that there are those who have built up within themselves such antagonistic minds to any efforts directed toward the betterment or happiness of people and who are seeking justification of their feelings by looking with suspicion upon all such motives and efforts. There are men in attendance, many of them, who are making financial sacrifices to themselves and their families in following the work they are doing and who are prompted to continue making these sacrifices because of the conviction that they are doing something which is really worthwhile and which counts for more in life than physical comfort or financial ease. I believe this has been evident in all of these meetings where one can not fail to see the hearts of the men who have taken part and can easily determine the purposes which have actuated them in their presentations.

Safety Men Wish to Build a Safer, Happier World

Anyone who goes away from these meetings feeling there has been a lack of sincerity is indeed unfortunate and certainly has not caught the true note. It seems clear to me that nearly all of these men have had faith that their efforts would make this a better world in which to live. These men are factors in this development and are doing their part to contribute to a safer and happier people. These meetings have given us the incentive to renew our interest in our work and our appreciation of responsibilities. We are better and more efficient men for having been here and I am sure all of us are grateful that we are engaged in such a work and are thus permitted to fill a really important place in our industrial and civic life. We should have the satisfaction of knowing that our lives are unselfish ones; that we are doing something for others and we shall probably leave this world a little better than we found it. Such sentiment as this seems to prompt the hearts of the men here and to permeate this entire Congress.

We have no apology to make for the National Safety Council; we have no apology to make for its meetings in this Congress; its needfulness and work are well known; its sincerity of purpose is unquestioned and there are those who know it has served and will continue to serve a good purpose. (*Applause.*)

CHAIRMAN McCULLOCH: Before proceeding with the discussion I would like to make a statement: I hate to burst this bubble, but in de-

fense of Mr. Thomas, I feel that I should explain that this whole matter has been a frame-up. Mr. Chester Thomas was for years the best motor man on the Chicago, North Shore and Milwaukee Railroad, and because of his splendid record in the operation of the trains, including his accident record, he has been promoted to the office he now holds. We asked him to get up this morning to make such remarks as he has in order to break the regular routine of the meeting. I am sure he has carried his part well.

We are now ready for further discussion.

MR. ANDERS: Regardless of the frame-up, I have been lonesome at this Convention this week in comparison to last year. One of the greatest safety men that I have ever known passed away last Tuesday. His name was John J. McCarthy, and he was connected with the Ohio Bell Telephone Company for probably 20 or 30 years. I feel, Mr. Chairman, that the Public Utilities Section of the National Safety Council should express to the officials of the Ohio Bell Telephone Company their sympathy in the loss of such a wonderful safety man.

CHAIRMAN McCULLOCH: That will be done.

The Timid Talker Sometimes Has a Helpful Idea

MR. BEERMAN (Consolidated Gas and Electric Company, Baltimore, Md.): There have been times at these conventions when I have wondered if we have gotten down to a specific problem. We all like to go back with a particular suggestion that we feel we can cash in on and defray or make up for the expenses incurred in attending conventions.

We always receive quite a bit of inspirational remuneration at these meetings. However, I think at our meetings, during the discussion part, we could present a typical problem which will be and should be for our use. I have heard mentioned this morning a question in one of the papers of accidents resulting from alighting from trucks while in motion.

In our Company in 1925 we had a lineman who had been in our employ only 24 hours who was very anxious to get home and tell his wife how he had made out. He jumped off the truck before it stopped and was crushed under the rear wheels. We immediately set about an investigation and called all the truck drivers to our distribution department. A little fellow got up and stumbled and stammered a bit and then said, "I think we can put a bell on with regular rope and have a conductor," and immediately there was a burst of laughter. Well, we let him talk a little longer, and then we got the superintendent of distribution up and he spoke. The result of that meeting was that we now have these bells on. Our trucks are not allowed to make a left-hand turn unless the bell is rung and the man is given full signal to warn traffic behind. We have a conductor back there that stands with one hand on the bell rope. The truck is signalled to stop and nobody is allowed to alight until a complete stop is negotiated. That is just a point that came in our experience.

It may seem a small point, but there is room in these discussions for

these points. We have quite a problem on our hands. Our lines run out of the city of Baltimore about 35 miles to the north and 19 miles to the south. These lines are covered by our gangs in big three and one-half to five ton trucks. They carry from six to nine men and a driver; they carry reels of wire and they carry pike poles and tools of all sorts. Now, these men must stand up on their way to the job. A 20 mile ride in one of these trucks is not so good, especially when a man must shinny up a pole and do work of a tedious nature. I would like to know if anyone here has a blueprint of a truck arrangement whereby the men can sit down on the way going to and from a job involving linemen and the stringing of lines?

C. C. DRUCKER (Glover Gas & Electric Company, Kentucky): If this gentleman will meet me and give me his address after the meeting I will be glad to send him a blueprint of that kind of truck. We have them.

MR. MACKINNON (Nebraska Power Company, Omaha): After what happened to the last man that made some criticism, I am rather dubious about saying anything of a critical nature. However, in Mr. Gardner's paper, there are two main points, it seems to me, discussed. The first was first-aid, and he talked for some considerable time on first-aid. His second point was foremen's responsibility. The criticism I have to make of the paper is that those should have been reversed. Our job is accident prevention, first, last and always. Then teach our men how to resuscitate or patch up a man so they will be prepared for an electric shock or any other type of accident.

The Foremost Duty is to Prevent Accidents

I think that in our electrical industry and in many of the other industries, we are tending a little too much to lay emphasis on first-aid, and if I may say so, on resuscitation. Although I am very strongly convinced that both of these are essential training, we must give to our employees in the electrical industry the thought of safety first. I believe there is a tendency to slop over on that line rather than to hold to your first and foremost duty, which is to prevent the accident.

Another point that I would like to call attention to is the one brought up by Mr. Opp in his account of last night's accident here, and that is the elimination of the careless employee. I think that work can be done through our foremen in instructing their gangs and in teaching their men to think and act safety first. We must add to this the other duty of taking the man whose mind is off his work, who spends his time reading the dime novel, off the job. We have had in our company within the last year two such men, but luckily we got them both before the men actually pulled any bonehead pieces of work that resulted in an accident. They were not quite as bad as the kind Mr. Opp told us about, but they were unsuited to their jobs. They were not bad fellows, but they just simply were a hazard to our electrical system, because their minds were not devoted, not trained for that type of work. Both of them were switchboard operators.

MR. GLIDDEN (Ohio Public Service Company, Mansfield, Ohio): One of the papers brought up the subject of a safety manual. We are endeavoring to make one in our company. May I have your experience as to what is best to put into the safety manual?

CHAIRMAN McCULLOCH: Can anyone give us a little information on that subject? Mr. Glidden sent that question in on one of the cards. We can spend a few minutes on this discussion. The question is, "What should the safety manual contain; in what form should it be published and how often should it be revised?"

MEMBER (Western Union Telegraph Company, New York): The first-aid instruction or manual for employees, depends largely on the type of men you have. Some men prefer a very small pocket edition and some a large book. We have one that is about five by seven and we have used it successfully for about 10 years. I will be glad to send you a copy of it complete, and you can use it if you see fit. If there is any other information you want to know about it, we will be glad to give it to you.

Hazards of Employees Riding on Trucks

You will also find that the Bell System, Associated Telephone Companies have a very nice sized manual.

The subject raised by the man from Baltimore with regard to the hazard of employees being hurt getting on and off trucks interests me. In the Western Union Telegraph Company our employees use a motor railway speeder which a few of the utility companies do not come in contact with. We are compelled to work along the railroads, and many of them are high-speed railroads. Many of you fellows want to get back as quickly as you can, safely, of course. Just remember that somewhere along the line there are groups of 10 or 15 men working, trying to maintain lines of communication, so that should anything happen to you or some other member of your family you might reach them in the quickest manner possible.

These men have got to get to and from their work. Our problem has been to reduce accidents with regard to the operation of motor cars. These motor cars weigh anywhere from 1,200 to 1,800 pounds, and they carry from 10 to 20 men. Our chief problem is to keep the men from getting hurt in getting on and off these cars, and preventing groups from falling off the cars. We have solved the seating arrangement on these cars. I just mention that to bear in mind the class of work we which have to do.

The telegraph company differs in a great many respects from the public utility or the power-using companies or companies that maintain telephone lines. Possibly the seating arrangement which we use on the motor cars may be of some use to you on the automobile trucks. If you will write to some of these motor railway concerns they may be able to help you out. They may have a solution for your problem.

CHAIRMAN McCULLOCH: There were some question cards passed out among you a few minutes ago. Our time is so short that we will not

have time to collect them. If any of you have any questions, will you please submit them personally at this time?

MR. BURTON (Consumers Power Company, Jackson, Mich.): We have found that first-aid work, resuscitation, goes hand in hand with safety work. We put the emphasis, of course, on the accident prevention work. One phase of that situation that has come up several times when we first started to post notices regarding resuscitation was that it got the men thinking and talking about accidents. We have also found that first-aid properly done may prevent another accident. For instance, a man gets slightly injured; if he is not properly taken care of, he is liable to get into another accident, so the two go hand in hand.

We are not over-emphasizing first-aid or safety work, although I agree with Mr. MacKinnon that it sometimes appears that we might be doing that.

I don't know whether it is in order at this time, but we have had an exceptionally fine meeting this year, one of the best in the Public Utilities Section. I think part of this is due to the wonderful accommodations we have. If a motion would be in order to thank the Detroit Edison Company for the courtesy they have extended to us, I would like to make such a motion.

Example of a Very Unusual Accident

CHAIRMAN McCULLOCH: We didn't take official action on that, Mr. Burton, but our appreciation has been conveyed to the proper authorities.

MR. BURTON: I made a note while one of the former speakers was talking regarding unusual accidents. I met a man a week or so ago who is minus an arm. I asked him how he lost it. He is a rather wide-awake fellow and he said, "I was going down the street and a train was going by. I went under the gate and stood there and tried to count the cars as they went by, and the next thing I knew I ended in the hospital."

It appeared that he got dizzy or something, and he seemed to just fall over. That was a very unusual accident to me. You see hundreds of people every day under one of the gates. This was a young, wide-awake fellow, but he lost his arm in that way.

C. HOWARD STEWART: I just want to mention a few things here. There was a matter touched on lightly by Mr. Gardner in his paper. In cities where there is a local Safety Council it is the finest thing in the world for the utility in that city to support the work of the local Safety Council, not only morally but financially. We have a very active Council in St. Louis, that is supported by all of the public utilities operating there, the street car company, the gas and electric and telephone companies.

We have started a number of schools there which have helped greatly with the educational work of the Public Utilities Section. We had a safety school last year conducted by the Bureau of Mines, at which some 200 or 300 men received certificates. The Bureau of Mines is planning on having a similar school this year. We have a Safety Supervisors' course which has been operating now for six or seven years, attended

by 500 or 600 men every year. We have inspirational meetings for the foremen and superintendents which are attended by as high as 1,500 or 1,800 men. These meetings are usually held monthly. We occasionally have a meeting for the executives.

I realize that a good many of the companies represented here today are operating to a large extent in rural districts where this contact with local Safety Council work is not available, but I do want to urge on behalf of the local Councils, the necessity for more of the public utilities getting behind your local Safety Councils and getting your representation on their Executive Committee, if you can, and take an active interest.

We not only have the employee accident to deal with, but we have the public accident to deal with. You will secure a great deal of publicity on accident prevention by concentrating your work and efforts through your local clearing house or local Safety Council. The National organization today, I believe, has 65 local Councils operating with paid staffs. There are a number of volunteer Councils where the work is carried on in a voluntary manner. We have found it profitable in St. Louis. All of the utilities there cooperate to the fullest extent with our local Council. I hope you will give this matter consideration when you get back home. If any of you gentlemen are located in cities where there are local Councils, you ought to consider joining and giving them your heartfelt support.

CHAIRMAN McCULLOCH: We will have to end the discussion. We have one or two announcements, and we must adjourn by 12:45.

I am afraid if we don't watch out, we are going to have another fatal accident in the Detroit Edison Company before we leave. I wish I could borrow a straight jacket to put George Opp in. Since I landed here, he has arranged practically all of the details for the officers' breakfast, the joint luncheon, the plant visits, the room accommodations, and every other detail that you can imagine. He has had no sleep for 36 hours and yet he wants to make some more announcements at this time in order to properly take care of the delegates. I will ask Mr. Opp to make the announcements and then to quit.

ADJOURNMENT

Joint Luncheon Public Utilities and Electric Railway Sections

October 27, 1926

HOMER E. NIESZ, Toastmaster
Manager, Industrial Relations, Commonwealth Edison Company,
Chicago, Ill.

THE Joint Luncheon Session of the Public Utilities and Electric Railway Sections convened in the Ball Room of the Tuller Hotel, Detroit, Michigan, Mr. Homer E. Niesz presiding.

Toastmaster Niesz: Five years ago in this city at the annual Safety Congress, the first joint luncheon of the Electric Railway and Public Utilities Sections was held. Since then we have had these luncheons yearly and they have served to bring together these two closely related Sections of the National Safety Council, and I believe they have in a way helped in building up both Sections.

At the time of this first joint luncheon, the Electric Railway Section was not very active or very large. I believe that the intrusion of the electric power, the gas, and the cooperation of the public utilities have aided that Section in building up its program and its membership until now it goes alone instead of having, as we had for several years, joint sessions with the Public Utilities Section. I believe the bringing together of these Sections makes for unity of purpose and unity of action in the elimination of accidents in the public utilities industry.

Accidents do not happen; they are caused. This is illustrated by a story of a man of a Western state who applied for life insurance. He was asked by the examining physician if he had ever been sick and he replied that he had not.

"Did you ever have an accident?" the physician asked him.

"No, I did not."

"Were you ever laid up for any reason, disabled, not able to work?"

"Yes, I was bit by a rattlesnake once and nearly died. Another time I was kicked by a mule and was in the hospital for four weeks."

"Weren't those accidents?"

"No, they did it on purpose."

So there is a cause behind every accident and it is the elimination of causes that results in the elimination of accidents.

We have for our first speaker today a man who is a recognized leader in the central station industry of the United States; a man who is a power and a leader in his own community; a man who believes and firmly supports safety and other human relations movements in his organization. He always makes it a point to make his points pointed. I have the pleasure of introducing Mr. Alex Dow, president of the Detroit Edison Company.

THE ULTIMATE CAUSE OF ACCIDENTS

Alex Dow, President, Detroit Edison Company, Detroit, Mich.

I will begin by thanking Mr. Niesz for giving me a good start and thereby saving about three minutes of palaver, which I would otherwise have inflicted upon you.

Mr. Niesz says accidents are caused, they don't happen. I have been puzzling my brain at intervals when the brain was not overloaded with other matters, as to the ultimate cause of accidents. I tell you to begin with, that I have not discovered it. I must be getting near to it because I am working backward on its origins. I may of course be working in a circle, but I am going to present to you as the first installment of this talk, a very short installment, some thoughts as to origins and causes of accidents.

All our safety precautions fall into one class or the other, that is, either a mechanical device or a routine (which is the equivalent of a mechanical device), intended to prevent the establishment of conditions causing errors and permitting accidents. The responsibility for the design, maintenance and operation of these safety devices, safety routines, is transferred to a certain extent from the employee, who is up against the actual job, to some employee who by assumption is competent to deal with these cases of routine or of safety appliance. It is a transfer of responsibility.

After a while somebody has to supervise the safety man, and then somebody has to supervise him; and all the time we keep passing the ultimate responsibility backwards to a more select group. Some day in each of our organizations, even possibly in each of our states, we are going to have one ultimate safety man, and he will blow up. If you want such a man you will have to make the specifications for him and arrange to have his grandfather start getting that man in the usual way right now. He will be available 45 years from now. If you try to get him any other way it will happen just exactly as I have said—he will blow up.

Now, is this process of narrowing down going to continue? I am afraid that it must for a while. I look upon it, however, as ameliorative

and not curative. Let me illustrate from a report that was on my desk this morning.

A sub-station operator at such-and-such a station was given an order to phase certain cables and determine the correct rotation of the phases by means of low voltage, using one lamp between the conductors and ground, which is a perfectly orderly and usual routine. The operator picked up the phases correctly on the one cable and proceeded to the other cable of the pair. He went to disconnect the switch of the second cable and he struck his low voltage lamp on the wrong side of the disconnect switch. That is to say, he struck, in this particular case, a matter of 24,000 volts. The phasing equipment was destroyed, but luckily the operator escaped injury. No service was interrupted. From the point of view of the management of the company, of course, that last sentence was most important. The flare-up dissolved some switch gear and did some traveling around as it sometimes does when started.

What happened? A routine absolutely well established and within the competence of one man, which he had carried out correctly five minutes previously was not repeated. Of course the man was thinking about something else. Of course he just wasn't observing the routine. The natural thing to do under those circumstances is to see what is the matter with the routine, tighten it up and ultimately provide another safety device, and then provide a man to watch the safety device.

Another Accident Happened to a Competent Workman

Here is another item out of the same report. A construction man was doing work at a new sub-station. The flame of the oxy-acetylene torch he was using came in contact with, or in the near vicinity of, the live shell of the lightning arrester of the old station. There was a fence between and the man had one foot over the fence. He was considered a competent workman but he didn't realize that the absolute routine that forbade him coming inside that fence line with his equipment was a perfectly good rule. He could have passed an examination on it, no doubt, but he didn't realize that the flame of that torch was an ionizing device and would produce a flare. This is another sample of the sort of thing that happens. Yet the routine, the safety devices are all complete.

Here is another case from recent experience. Cables are sometimes three, five, or ten miles long and it becomes necessary to reroute them at times. They are all tagged, of course, carefully. They are excellently tagged and there is no question about the verification of the marking. There is also a routine that requires an electrostatic test device to be applied before there is an actual cutting in order to see whether the cable is alive or not. The purpose is to eliminate the chance of an assumption that the cable is dead and fit to be worked upon. Very well. A line was diverted quite recently and the section, left in the ducts and

idle for the time being, is to be used at a later date. You understand this is just a reroute.

Now the question comes up immediately, shall there be any change in the tagging or marking of those cables? The answer, carefully thought out, is, no. If you put on a tag that identifies this as a cable out of service, that will be just an invitation to some man a little bit too smart to omit his safety precautions. Consequently the live cable marking is left there, the assumption being that all cables are to be treated as alive.

A perfectly competent and experienced man is sent at a later date to make a necessary cut of the idle cable in a manhole in which the new rearranged cable is also. He has full warning, full instructions, and knows what he is doing. He is equipped to make the proper test. He assumes then he has found the cables properly numbered, knows that the live cable number is left on the old cable, and thinks he has the dead cable. He goes ahead, disregarding the test, and cuts into a live cable.

Two Fatalities Followed This Peculiar Situation

What are you going to do in a case like that? Put an inspector on top of him to say, "Here, maybe you are at the wrong cable—make the test."

Still another case. An excellent rule of good utility practice requires that the sub-station operator shall release apparatus that has to be worked on by a construction crew or a repair crew; that he shall not do anything without instructions from the chief operator and that these shall be checked back, and that the construction foreman shall confirm the check before the chief operator shall say, "Yes, release it."

In this particular case, the sub-station operator reports back everything clear, everything cleared. The foreman knew exactly what that meant, having worked on the same outfit twice before. He confirms that report. The apparatus is released. Then one of the men proceeds to make the final super-precaution of removing the fuse from the circuit, which by some chance might close an open switch and put current on some part of the work. These men say, "We are working behind the relay and the current can't get on," and the necessary precaution known to be required is delayed until after the men get to work.

Just at that time somebody drops a good, heavy load and jars the building. That particular relay is given a sudden jar, hits an instantaneous contact, the switch is closed and two men go to Kingdom Come in very bad shape.

What are you going to do in a case like that? You have all heard such things before. You men who deal with high pressure water, steam, air, you are accustomed to all these things. How far back are you going to carry the responsibility? How many super-checkings are you going to make? I think I hardly need offer the reported illustrations to show you by passing that trouble backwards by check and countercheck doesn't do anything but ameliorate it. It doesn't cure. What is the cure?

Now, I don't know what it is but I am going to give you some thoughts

as to its possibilities. It is not satisfactory of course to say that if this had not been done and that had not been done these things wouldn't have happened. It is not satisfactory to say the men were disobedient. What you want to do is to get at the item of human nature that makes perfectly sound men take chances and makes them go ahead and disregard the things they are supposed to do. What makes them disregard the safety rule, assuming it doesn't apply to them? Let us just step a minute into something else and see what the habit of thought is.

We have in this town an excellent rule providing stop signs on certain streets. That rule means that before coming upon or crossing one of these streets the operator of a vehicle shall bring that vehicle to a standstill, and that is all there is to it. Now, the assumption that a vehicle is not going to shoot out upon them from the side suddenly is taken by drivers as a license to speed on these streets, and they get into the habit of calling them right-of-way streets. There is no such provision. The man on the crossing first has the right of way. If two come together the man on the righthand has the crossing. But two-thirds of all the men who drive on these so-called "stop streets" not only treat them as right-of-way streets but call them right-of-way streets. What are you going to do about that?

The Problem of the Lamp Post and the Automobile

What are you going to do about another matter? You would think that an iron lamppost would be about the last thing that would be run into by an automobile driver. We are not responsible for the lampposts in the city of Detroit. I was responsible some years ago for the design of the present lamppost used in the underground district, and it has served its purpose for 30 years. I have seen that stocky lamppost positively double-up on being hit by a very light vehicle at high speed.

Outside of the city of Detroit my outfit is responsible for most of the lighting in the districts for 40 miles around. We average one lamppost per night that somebody wraps an automobile around and breaks. Any fellow that wants that contract has got to figure on one automobile accident per night. You have an action against the fellow that breaks it, but you might just as well try to collect from a beggar. You sue a beggar, you know, and catch a louse. You repair the lamppost and charge it up to the cost of operation—one a night, 365 a year including Sundays. On Sunday nights it is inclined to run rather high.

Yet, as I say, one lamppost per night is smashed and it shows a tendency to increase. What is the frame of mind that does those things? We are actually dealing with psychological conditions. Now, I am off on another jump for a little and then I will come back to the main track.

In the Century Magazine of October, 1917, the first article in the magazine was headed "Our Moral Anarchy Disclosed Through Grading the Ten Commandments." What the author did was to set up some 500 or 600 people with copies of the Ten Commandments in the King James version and a lead pencil, and say "Grade these Commandments, in-

dicating by number which is the most important; that is to say, Number One being the most important; and grade the relative importance of the Commandments as moral rules."

To the Safety Congress it may be interesting to note that a large plurality number (not a majority), rated as Number One "Thou Shalt Not Kill." The exhibit of the scatteration of ratings which is described as evidence of our moral anarchy is most interesting. You don't find, excepting by implication here and there, any logical rating of the Commandment in answer to the stated problem. In other words, not only those 500 people, or practically all of them, but even the author himself failed to observe that the question of the relative importance of the Commandments as moral rules is the question set up. They have interpreted the question to be as to the relative sinfulness of the breaches of the rules; that is to say, they consider that murder is the greatest sin. Therefore the Commandment against killing must be the most important Commandment.

Observations Upon the Ten Commandments

There is an utter failure to realize what the question is, and even the author comes under the implication of not being quite sure what the meaning of his question is. To show you what I mean: if you rate these as moral rules you must rate them with respect to collective morality and not as aids to the saving of the soul of the individual. They are group rules for the people at large, and a very slight analysis indicates that the Commandment against killing is by no means the most important. You must go further back and eliminate the inclination to kill. You must realize that one doesn't kill for the fun of killing. There is no pleasure in killing. Killing is an expression of a mental condition which has its roots in matters that don't contemplate any killing.

If you study these Commandments as moral rules you will arrive at a first conclusion such as, that society can not exist unless there is a reasonable amount of truthfulness. Therefore the Commandment, "Thou Shalt Not Bear False Witness" as a moral rule is most important. Second, you will place the Commandment against covetousness, because that establishes the right to personal property. Third, you will take the Commandment, "Honor Thy Father and Thy Mother," because that provides for the existence of the family. You will notice by observing these three Commandments you will have obtained, first, a society which can continue to exist because there is habitual truthfulness among its members. By observing the next you will have implied respect for the property, for the ownership, and ambitions, for the hopes and desires of other people because you will not covet. Then the family, which is, after all, the basis of our civilization, is provided for, and with these three you can have society, and without these you can not have society, and as moral rules these three are the most important.

Here are a representative group of educated people whose evident fail-

ure is to appreciate the force of the question and to see what is put up to them. What is wrong with them all?

Now I am going to jump off again in another direction. People say I am a pretty well educated man. I have good sense, I have studied and I have read. I began to scratch for my own living when I was entirely too young, but I was under the necessity of scratching. I now have to keep on as a matter of habit, and consequently my education is seriously incomplete from the point of view of the system of scholastic education. Nevertheless, my education has been a liberal education. Looking back upon my own experience I am again going back toward the root of things. I remember as a child of seven I was drilled in the habit of exactitude of expression. The question was "Do you mean that, or do you mean this," and then a correction. When 10 years of age I was drilled in parsing. I will venture that a good two-thirds of the people in this room don't know what the darn thing is, do not know the analysis of grammatical construction so that the expression of the idea shall be grammatically correct. They have accepted the way the crowd talks, or may have suffered from the latest vagary of education, which is self-expression, and they have continually a haziness that puts them in the same class as Don Marquis' Hermione, who used to say, "If you get what I mean."

Children Are Not Being Educated to Accuracy

Take a look at the people you are dealing with. Up to a certain point the more educated they are the worse they are. Now, let us take a look at the present system of education. It calls itself opening windows on to the universe for these young minds. What these young minds need is ability to understand the spoken and written language and to express themselves with precision in this language. What they need is a quick acquaintance with the simpler arithmetic. What they need is a chance to write with a hand that is legible so they will not find it necessary to pack a typewriter with them. These are the things they need. Given these, they have the elements of an education. They have the means to educate themselves. They have the possibility of doing what many of us have done, of developing a liberal education because precision of thought has been inculcated, precision of speech has been taught, precision of understanding, and the analytical mind,—“Does this mean what it says?”—have been drilled into them from the very beginning.

The drilling that I remember as having been of most use to me in this connection was what you would call “trick questions.” Such things have been recently rediscovered and applied in the army test, out of which we have been informed that the average American has the mentality of a 14-year-old minor.

I think that in this matter, in the scatteration, the dispersion, the triflingness of our education of today lies one of the roots, possibly the most important root, of our chapter of accidents. The feeling that an order

doesn't mean what it says, the feeling that there is something implied or permitted, is the feeling that causes us absolutely to overstate all our laws. We mean that people shall travel 25 or 30 miles an hour on a road and we write into the law 20 miles and a penalty above that. We mean that various courtesies and considerations shall exist, and we write something that becomes an exasperating mandatory law. We mean that people shall be truthful and yet we plaster up all our legal procedure with affidavit after affidavit. In the state of New York I discovered in the preparation of some official statements of financial affairs, to be filed for record, that one had to be identified and re-identified and that the notary public had to be identified and then somebody had to go and identify the identifier. The assumption is in point of fact running through all our practice that precision of expression will be non-existent. Accuracy in the nature of truthfulness can only be secured by imposing the penalty of perjury upon inaccuracy, and having imposed the penalty we never enforce it.

A system that catches our children and runs them through half-hour periods of this, that or the other thing; this, that or the other method of expression; this, that or the other interesting development, gives them just these dabs and dashes, and at no time undertakes to make them read precisely, think precisely back of the reading and speaking—that system of education is wrong, and it is out of this that comes disregard for the obvious, evident intent of safety instructions and safety routines.

An Absolute, Inefficient Method of Education

I commend that thought to you, that the most important root of our trouble is in our present inefficient method of education. A man has to get into the post-graduate classes in one of our universities before he discovers how much time has been wasted. Most people, however, have to begin to scratch for themselves at a reasonably early age; and it would seem to me that if one would take a much reduced curriculum, with precision and exactness of thought and speech in every branch, the curriculum would help wonderfully toward the bringing down of industrial accidents and would help wonderfully toward the efficiency of Americanization.

Now I will go to another part of my talk which is entirely unrelated. We are all working more or less to the glory of God and to the good of mankind. We may not express it just that way, but we at least like to feel that is about what it means. Therefore let us not talk altruistic motives. We don't say in these Safety Congresses and elsewhere, "I am my brother's keeper." Any motive that is altruistic is not to be considered, but is to be assumed.

What have been the driving motives of progress? Why is society better today than it was years ago? Why is business more orderly and industry more careful of our people? Is it absolutely the extension of what you might call the higher morality among us, or is it because an

enlightened selfishness teaches us that it doesn't do to impose upon our neighbors?

In other words, the motive of profit, the motive of saving (if you will call it so), the motive of personal interest—is that not, after all, one of the largest driving motives? It is there and there is no use denying it. We can do a few things for the good of our fellow mortals or for the peace of our own souls if we think we have souls, but all the same we must realize that most of the improvement in business methods, most of the betterment of business, is had through enlightened self-interest.

In safety you are a little inclined to get away from the motive of self-interest in its simplest form. I don't mean to say that you don't point out that accidents cost money; of course they do. Let me call your attention to something and let me give you a little suggestion on it.

The Cost of Accident Has Been Imposed Upon Industry

I am going to offer you a proposition that I think is heretical. What is the object of insurance? To distribute the burden of accidents. Does it always work as it should? Does the person who is insured always look upon his duty to the insurance company as a duty to his neighbor? A student of business ethics, and I have been such a one for a great many years, rather questions that. He recognizes the forcefulness of group ethics but he doesn't find in group ethics the regard for what may be called the common stock of resources that develops in the individual with regard to his own stock of resources.

Now in propounding this theory, I would say that one of the best results of the Workmen's Compensation Law was the improvement in general safety because the cost of the accident was absolutely imposed upon the industry, which is as it should be. I have observed, however, in many cases there is still this little inclination to say, "Why should we worry about it? Insurance covers it."

I wonder if we could bring into effect again the motive of personal profit by some such legislation as this: No factory employer shall be allowed insurance for more than two-thirds of the loss. The other one-third shall forthwith be a lien against his business and property, assigned automatically to the state. The state will make good to the employee and that lien will be equivalent to a tax lien.

That will mean that the man who makes more accidents than his share will actually suffer to a limited extent. It will mean that the cost of the accident will come right back to him. He will be obliged to figure in a different way from the way he does now on the cost of the necessary provision to reduce the probability of accidents.

Please think of it. I am asking you to consider whether it would not be worth while in all these schemes of ours—not by any means avoiding the condition that makes the state after all responsible for the payment of compensation—but seeing to it that directly out of each accident there shall fall upon the employer a direct and immediate part of the burden

attributed to that accident. The suggestion, as I have already given it to you, is that insurance shall be limited to two-thirds compensation, that the one-third shall forthwith and automatically be a lien, automatically assigned to the state and collectible by the state and against the employer and the employer's business.

Please think of it. I think it will help.

TOASTMASTER NEISZ: Gentlemen, again we are indebted to the great Detroit Edison Company for a most excellent presentation by Mr. Dow.

We have one more speaker whom I shall call upon now, who will give us a very brief account of the safety work in one of the great lamp factories of the General Electric Company. Last week we celebrated the forty-seventh anniversary of the birth of the incandescent lamp, an event which has done so much to advance the comfort and convenience of the people in the country and all over the world. I take pleasure in calling upon Mr. Harry C. White, supervisor of industrial relations, Edison Lamp Works of the General Electric Company, Harrison, New Jersey.

THE SAFETY THOUGHT

Harry C. White, Supervisor of Industrial Relations, Edison Lamp Works,
General Electric Co., Harrison, N. J.

I am not going to speak about the great plants of the General Electric Company. Mr. Neisz made a mistake when he said that. I am going to talk about America first—and this part of my talk did not come by accident—about the wonderful man whose birthday we have celebrated. This did not come by accident, nor did the day that we celebrated, the birthday of one of the greatest safety men that I know, come by accident. I know of no man who has contributed more to the safety of the people and the building of the great mightiness of America than he.

I am willing to wager as I visited Cambridge not so very long ago, that that particular day did not come by accident, but was perfectly planned by a Power greater than you or I, a higher Power above. I honestly do believe that the act that prompted the Pilgrims to visit this colony, and then the power that awaited their coming, was no real accident, because they absolutely had planned and were determined to hold back the mighty forces on the opposite side and send them back where they belonged, so that there might be a flag such as I stand in front of at this moment.

I am willing to wager, too, that the North and South misunderstanding was planned to unite and make possible a greater understanding of the people of America so that they might carry on the purposes and bring to fruition the great ideas which we so happily enjoy at this moment. We are not living in the days of ox-carts, but we are living in the days of airplanes and we are speaking through the elements to the farthest parts of the world. These things, my friends, were positively not accidents.

So I do honestly think that every safety man is here in Detroit because

of a program definitely planned away back in the early days. Maybe it is because time has not permitted the building up of a mighty Utopia that you men are meeting together to awaken in the minds of those whom you serve the pressing need for greater action now.

Might I suggest that you become better salesmen for the job which is yours? I can't think of a safety man as anything else but a salesman selling something that is vitally important to the great mass in and about America. I can classify your job as fully as important as that of any clergyman, priest, or rabbi in its privilege of making life easy and safe for those who toil for the corporations which you represent.

We are not living, gentlemen, in the days when they used a queer little lamp, like an open saucer. I want to build or profit by the progress made since then. That old lamp was used 600 years before Christ. But there are some people today who quite forget that we are not living back 600 years before Christ and that we are living in 1926.

Progress From the Ancient Days of Darkness

In those days they went out at night in darkness and light was little known; they brought back the body of their enemy and cut him up and put him in a bowl like this and burned it to keep the evil spirits away. My God, what a way to live! We are not living that way today—in darkness. It is a great job to help and to serve and to guide others out of darkness into safety.

I have here a little decorated pottery lamp. Gentlemen, I listened to those statements of Mr. Dow's, the wonderful laws of God. They are the only laws that are of real service in preserving the safety of man and country. But in the day of the pottery lamp man was not very much nor was he worth much to himself or others. Soon, however, he began to awaken to the fact that the earth held not only clay but it also held iron, which my forefathers were able to find and use both in lamps and in many other wonderful ways.

This lamp looks like a soup ladle. Well, I suppose it was used for that. They had a hook attached to it. They were satisfied with it because, as I have told you, there was little to live for, no place like we have today where they could go; rough roads; plenty of time, no use to hurry. In fact, I hardly believe they needed men with brains back in those days. They had no places to work, just a life like the Indian.

I want to pass through a great many changes. There was given to us in America a new birth and a new start. Take for instance the little whale oil lamp. It is a wonderful lamp. There was some danger, though. The people used to go out every night and kill a couple of whales so they could have light. Can you picture your wife saying to you, gentlemen, "I am glad you came home, dear, because there is no light. So, like a good boy, will you go down and get a couple of whales?" I want to tell you that we haven't any whales today, we don't need them. Now you can stay home and enjoy your nights. Safety—now we get the change.

Here is where our job began to come into being. They began to get away from the little community. They began to get out in the great metropolis and they got away from the center point of activities. Give us the days of yesterday when we used as a guide, comfort and inspiration the camphine lamp.

Some of us still stop for a moment to wonder if we have passed out of the ox-cart stage. If you would go to Mount Vernon, and George Washington could step out of that grave, he would say, "John, old boy, when is the next stage coach for Washington?" And you would say, "Why, George, you have been dead for 100 years. We are not riding in stage coaches. We are riding in high powered automobiles and we are talking through the air today. We have the radio and we are broadcasting to all four parts of the world."

Safety is a Thing Cautiously Planned

What you men need is the safety thought. Let us develop to the mightiness of it and let me stop just a moment to say that 600 years before Christ safety was not thought about; but in 1926 we are dealing with the masterpieces of science. We men have lived behind closed doors to make possible this change with the harnessing up of 30,000 watts, 125,000 candlepower. We are putting together enough heat and enough force in a small lamp that if I should drop it it would blow this banquet hall and the windows apart. That is then the point where safety starts with electricity. You say to me, "What is safety?" Well, it means the little things. You can now compare the two. Here I offer you the smallest lamp in the world. Now it is your job, but it isn't a big job.

However, it isn't a thing that is done in the twinkling of an eye. Safety is a thing which is cautiously planned. It is something that has a vision and a future ahead of it. It is something we must seal by that thing Mr. Dow spoke about, "Education and Power." You can't give the people a book and have them read it and understand it, but you have got to offer to them the little points in life. Safety is what I will illustrate now. I want to give to you the meaning of safety. I want to hold in my hand modern science. Safety is to be cautious in what we do. I frankly and honestly believe that if your corporations would be responsible for a certain territory around your factory and in the schools, not once a year, on "Safety Week," but every week, every month, awaken in the little children's minds what safety means, the safety idea, like the little light, would grow to mightiness.

A little baby creeping across the floor knows nothing about safety or cautiousness, and she will pick up a tack from the floor and place it in her mouth. Nobody is there to tell her it is dangerous. Even if her mother were near perhaps the baby wouldn't have understood. Well, we have machines, we have rails and signs about us, but somehow or other a baby will pick up a tack and do the very thing we hoped that it wouldn't. However, science has kept pace with you, and the pulmotor will bring life back again.

I stood by Dr. Coolidge the other night and asked him, "What does it mean when that little ray of light which is nearly a foot and a half from the point of that tube begins to blaze?" When I saw that blaze I closed my eyes and immediately I said, "My God, man, I hope it isn't the thing they are speaking about over in Europe that will be able to destroy life. Is it for the destruction of man or will it be your contribution for the construction of man?"

He replied, "I hope it will never go more than two feet from the tube."

I could see the building of tissue, the building of power, for in that ray of light we have radium, and it is so cheap that the poorest man in the world can use it. Lincoln said, "God must have loved the poor people because he made so many of them."

It isn't the big things that count, but the little things of safety we teach; and in conclusion I want to bring to you the man who largely contributed to your job. It will take me six minutes and then I will stop.

I'd like to talk to you about this particular fellow, Mr. Steinmetz. He was a small man and a cripple. If he were here he would not stand as tall as I do. But every stack that smokes, every mill that turns, every light that blazes, every generator that functions, does so because of Steinmetz. I want you to see him when he leans over his chair and watch him with his long stogey in his mouth speaking to you this wonderful afternoon.

Memories of a Meeting With Steinmetz

I was able to meet Steinmetz under very peculiar circumstances. I was walking down the corridor of the General Electric Company plant and Steinmetz was directly in front of me. As I passed to the side of this genius I watched him and I removed my hat. I want to tell you, gentlemen, he has contributed mightily to that progress in which we need safety men. He looked at me a moment and he said, "Who are you?"

I said, "My name is Harry C. White."

"Where do you come from?"

"Harrison, New Jersey."

"Why are you here, Mr. White?"

"I am here to speak to the students at Union College this afternoon at four o'clock."

Looking at his old dollar watch, he said, "It is now half past two, very near to this hour."

We entered that room in which those things were made that helped you to climb and he said, "Take a seat," and I was able to sit down. We talked a little bit about Edison and his life.

"Doctor," I said, "we have talked of Edison so many times and his mother. I never heard much about yours," and that brought from him this:

"Oh, Mr. White, I have never known much of my mother! She passed away shortly after I was born."

Gentlemen, that sacred night that Steinmetz entered the world there

passed through the eye of a needle this child, with a back so out of place, a body so tired.

"Doctor, your father?"

"He was a companion to me. More than once my father would sit around the table figuring the money that he earned, and with what was left, Mr. White, after my tuition was paid, we could eat, and sometimes we did not eat."

"Why did you leave Germany?"

"Mr. White, I was a damn fool; I talked too much. I was not a radical, I was not a socialist. I was constructively thinking of building up men, but they misunderstood me. My whole life was misunderstood. I did not leave Germany, I ran away. That night that I said goodby to my people, that night that I shook my father's hand, I left for some place, but I do not know where. I did, however, go to Switzerland."

"You came to America, doctor. Why?"

That brought from him the statement that he never knew a moment in his life without that pain in his back. He was leaning over the table, around the chair, and he stopped a moment and said, "God, please a moment, my back! Oh! That is better now." And he smiled a great smile with pain again defeated. It was Steinmetz, who contributed largely to the safety of millions, taking the drudgery out of life, awakening in men the power of God, locking up the electricity and making it a slave where yesterday men slaved!

"Now, lastly, doctor, you said you would never take any money from the people of America. What really prompted you to say that?"

"Oh, Mr. White! there are some people who can not be real honest. There are some people who can not be reasonable and decent. I was thinking, as I stood on the gangplank, that soon I would be in America. There was a man standing there who said I did not belong near the gangplank. I did not understand your ways and your language."

"That man pointed to me and told me to get out of the way, and then he ran up the gangplank and he threw me down and he laughed and said, 'You dirty cripple, in another year you will be a public charge.'"

"I asked somebody what he had said, and when I understood and when I was standing on the shores of America I raised my hand to the Heavens and said, 'As long as I may live I will never take a penny from the people of America except only that which will keep life within this body.'"

Steinmetz's salary was \$150,000 to \$200,000 a year and he never accepted one cent except that which would keep him alive, and the rest he would give to others.

Through kindness, willingness to help, and honesty, I believe when the safety men of America become salesmen and they form a partnership with those who are interested, the best part of accidents will be blotted away, for they will be thinking of others, not of themselves. Do unto others as you would have others do unto you, is my standard of a safety man's religion to humanity.

ADJOURNMENT

Quarry Section

New Officers of the Section

CHAIRMAN: L. R. CARTWRIGHT

Mid-West Crushed Stone Co., Indianapolis, Ind.

VICE-CHAIRMAN and NEWS LETTER EDITOR: D. C. SOUDER

The France Stone Co., Toledo, Ohio.

SECRETARY: A. C. HEWITT

EXECUTIVE COMMITTEE: (The Officers and)

EDWARD E. EVANS

The Whitehouse Stone Co., Toledo, Ohio.

October 28, 1926

E. E. EVANS, Chairman

President, The Whitehouse Stone Company, Toledo, Ohio.

THE Quarry Section of the National Safety Council convened at 9:45 in Parlor B, Fourth Floor of the Book-Cadillac Hotel, Detroit, Mr. E. E. Evans, chairman of the Section, presiding.

CHAIRMAN EVANS: I see the faces of many of you who attended the joint session yesterday morning. To those of the cement industry who are present, I want to extend a cordial welcome. The meeting was a very successful one, because of the fact that we had so many interested cement men in attendance at that meeting. We want you to be equally interested in this, our Quarry Section.

Many of our problems are of the same nature. If we men of the Quarry Section can contribute anything that will be of benefit to you, we shall feel that we have accomplished results.

ADDRESS BY E. E. EVANS

As your chairman, I presume it proper that I should give you a brief resume of the activities of the Section since our last annual meeting. You will remember this Section was organized in August, 1924, in the city of Toledo, where a few Quarry operators met upon call of Jay Thompson, then secretary, now manager of the Toledo Safety Council.

Prior to that date, there was no concerted action on the part of the stone producers in the safety movement.

Since our last meeting in Cleveland there has been a meeting, or annual session, of the National Crushed Stone Association, which was held in Montreal last January. At that time the question of safety was brought to the attention of the members of the Crushed Stone Association, with the result that a resolution was unanimously adopted. That resolution I will read for your benefit:

"WHEREAS for humanitarian and economic reasons, safety is a consideration of primary importance to quarry operators, and

"WHEREAS the National Safety Council by organizing a Quarry Section, and the United States Bureau of Mines, by providing a separate statistical service for the quarrying industry in a National Safety Competition, have already demonstrated their desire and ability to assist producers of crushed stone in promoting safety.

"THEREFORE BE IT RESOLVED: That the National Crushed Stone Association in Convention assembled heartily endorses the activities of the Quarry Section of the National Safety Council and the National Safety Competition conducted under the auspices of the United States Bureau of Mines, and

"BE IT FURTHER RESOLVED: That the National Crushed Stone Association recommends to all of its members that they participate in these two worthy movements."

That action was taken by the National Crushed Stone Association. By the way, if there are any quarry operators here who are not members of the National Crushed Stone Association, I believe it highly important that you become affiliated with that organization.

During the past year there has been an 80 per cent increase in membership, which would indicate that the quarry operators are giving serious thought to properly safeguarding the employee against accidents. At least four meetings of Ohio operators have been held the past year, the last one at Columbus upon call of Mr. Kearns, Superintendent of the Division of Safety and Hygiene of the Industrial Commission. The stone producers are to cooperate with this Commission in preparing a code of safety rules to govern its operations in the state.

We find, in the application of safety rules and proper education of the employee in safety measures, that efficiency has been on the increase,

greater care is being exercised and more consideration extended to one another by fellow workmen.

Equipment maintenance cost has shown a decrease where safety is practiced, which is of economic value to the employer aside from the humanitarian element, which is a factor to be considered.

Some stone operators are not sold on safety and apparently give the safeguarding of the employee but scant consideration, which is unfair to those operators who are spending time and money in the interest of accident prevention. In fact, the laxity on the part of many of the operators, principally the smaller ones, who do not practice safety in their operation, means penalizing the operator who does.

When we employ an individual, a contract is made, the workman agrees to sell his labor which we agree to purchase. The workman expects and is entitled to safe employment. If hazards which can be eliminated exist, we, and not the employee, should be held liable.

A very good plan which I believe can be put into effective operation, is for the stone producers in each state or community to have representatives from individual plants form a safety group, and visit the plants in that state or community and check up hazards and apply corrective remedies. Doing this would very soon standardize Safety and make accident prevention a thing worth while.

With those brief remarks I am going to confine myself strictly to the program.

If there is any one duty I am going to perform this morning, it will be that of introducing to you the speaker who has been assigned the opening subject. To many of you crushed stone producers this gentleman needs no introduction.

He was formerly identified with the United States Bureau of Roads in the capacity of chief engineer, in charge of tests. Because of his fairness while conducting that department, the National Crushed Stone Association, desiring to acquire the services of a capable engineer to direct their business, were able to procure the services of Mr. A. T. Goldbeck, who now occupies the position of manager of the engineering department of the National Crushed Stone Association. It gives me pleasure to call upon Mr. Goldbeck and present him to you.

FINANCIAL ASPECTS OF THE SAFETY MOVEMENT IN THE CRUSHED STONE INDUSTRY

**A. T. Goldbeck, Director, Bureau of Engineering, The National Crushed
Stone Association**

Merely to consider the financial aspects of the safety movement, to the exclusion of the more vital phases of safety, seems almost inhuman. The complete subject of safety, however, looms up as a tremendous one when all of its ramifications are joined together. Each phase merits detailed study, the inhuman as well as the human, for their individual development can not but advance the entire safety movement.

If one is to consider fully the financial aspects of safety in the quarry

industry it is quite necessary that an analysis be made of a great many factors entering into the problem. It will be apparent that although many of the effects of a safety program are definite in character and may be accurately evaluated, there are a number of other effects which, although resulting in financial return, are difficult to evaluate.

As one crushed stone producer very aptly puts the matter, "Any campaign for betterment of conditions in which you are able to enlist the interests of all your men stimulates their minds; makes them favorable to the problem in hand and develops the team spirit and the desire to win, and we find that safety campaigns are no exception." He points out that through their safety campaign they are inducing a team spirit in their men with a resulting double benefit, less accidents and more and better protection. The installation of safety devices assists directly and indirectly in the betterment of operation. Such devices protect against machinery and they establish more confidence in the minds of the men. The men thus become assured that the company is trying to protect them from injury and such protective devices are also a stimulant to cleanliness; and cleanliness stimulates better workmanship and pride in the men, to the end that much better operation results.

Included in the Economic Cost of Accidents

When severe accidents occur, invariably the morale of the workmen is much lowered and production suffers for an indefinite period thereafter, even though the men do not actually quit work for the remainder of the day, as so frequently happens. These are intangible things in that they can not be evaluated but there can be no doubt of their financial bearing. As has recently been pointed out* the total or complete economic cost of human accidents must include:

- a—Premiums for compensation insurance to cover compensation paid for lost time and cost of hospital and medical attendance.
- b—The portion of the lost time wage suffered by the workman for which he is not compensated.
- c—The lost time and delayed production caused by the numerous occurrences of the production accident, represented by the human accident.
- d—The lost time and the temporary decreased production resulting from the breaking down of the morale, etc. (especially large if the accident results in a fatality).
- e—The lost time and delayed production resulting from the breaking in of a new employee.
- f—The increased liability of human and production accidents happening to or caused by the new employee.
- g—The economic loss through the killing of a workman who has no dependents. Few state laws require any compensation except burial expenses to be paid for fatalities to persons having no dependents.

*"Measurement of Accident Prevention by Compensation Insurance Rates," by Bryon O. Pickard, (Pit and Quarry, March 14, 1926, p. 61.)

h.—Incomplete compensation for fatalities. It is estimated by the U. S. Bureau of Labor Statistics that the economic loss through a fatality is 6,000 shifts. If each fatality was compensated for this amount of time at one-half time wages, using an average wage of \$5 per shift, the compensation for fatality based on the economic loss would be \$15,000, but the average actual compensation paid for each fatality is about \$3,000.

He further estimates that if the above items are considered in the cost, that the loss due to human accidents in industry is as great as, if not greater than, five times the amount paid out in compensation for lost time wages.

It is quite evident, therefore, that the losses sustained by the employer extend far beyond the mere payment of insurance premiums, although even this item is a very considerable one whose reduction would be well worth the effort. Such premiums are of necessity based on accident experience records and this is fundamentally so whether the insurance is carried with an insurance company or whether the producer is carrying self-insurance.

Experience records must serve as the basis for the control of yearly insurance premiums and if the accident experience record is a bad one in any industry the premium rate must be correspondingly high to permit the insuring company to finance the accident cases and continue to do business. Obviously if a group of producers is to enjoy a low insurance rate, that group must demonstrate that such a rate will properly care for the accidents which past records indicate are likely to ensue. A low accident experience is therefore necessary to bring about a reduction in premiums and this can result only through the development of safety measures and the carrying on of safety campaigns in ways such as are being discussed at this conference.

The Financial Benefits From Safety Measures

It might be interesting to cite the experiences of others to show the financial benefits accruing from the adoption of safety measures. In a certain mining district, safety work was started in July, 1924. During the year 1924, the district produced 1,044,554 tons of concentrates and during the year 1925, 1,507,450 tons of concentrates, an increase of 44 per cent. During these same periods the accidents increased only 28 per cent and, furthermore, the "Lost Time Accidents," that is, accidents in which the miner lost more than the day on which the accident occurred, were decreased from 59.2 per cent in 1924, to 38.9 per cent in 1925.

Comparing similar statistics it has been found that whereas during the last six months in 1925, 28 mines produced an average of 1,733 tons per accident, during the first six months in 1926 these same mines produced 2,051 tons per accident. Furthermore, the percentage of "Lost Time Accidents" was decreased from 42.8 per cent for the last six months in 1925 to 37.2 per cent for the first six months in 1926. In addition to this, a study of the costs of insurance showed that whereas during 1923 nine of the cooperating companies were paying \$5.04 to \$8.47 for compensation

insurance, on a \$4.06 base rate per \$100 of payroll, in 1926 these same companies were only paying from \$4.18 to \$6.52 per \$100 of payroll on a \$6.25 base rate.

In other words, had the experience rating of these companies remained the same for 1926 (on a base rate of \$4.06 per \$100 of payroll), their insurance would have cost them from \$7.75 to \$11.04 instead of the present cost of \$4.18 to \$6.52 per \$100 of payroll.

It is stated in connection with a particular mine and smelting company that the question of safety has been given very careful consideration during the past two years and the results of their efforts have been very gratifying. During the year 1925 the actual cost of carrying insurance on their property was \$2.20 per \$100 of payroll, including the cost of adjusting and medical, and figuring their insurance on a basis stipulated by the rating bureau for their classification, they have made a saving of 51 per cent. For the first eight months of 1926 their actual cost per \$100 of payroll has been \$2.10. Including cost of medical, adjusting and miscellaneous their saving below the classification rating will be approximately 60 per cent.

Figures on the Money Cost of Accidents

The financial savings to this company on account of various safety measures and the whole-hearted cooperation they have been able to obtain from their department heads and their foremen in making all working places safer, has been entirely satisfactory and more than was anticipated.

During the first six months in 1924 the lost time on account of injury was 1,678 days. The income of the employees losing this time would have been \$5,104.72. The total compensation benefit they received was \$2,688.64, leaving a net loss to their employees of \$2,416.08, or over \$400 per month.

During the first six months in 1926, or after the various safety measures had been enforced for one year or longer, the total lost days on account of injury were 1,073. The income of the employees losing this time would have been \$3,245.33. The compensation payments on account of lost time were \$2,095.04, leaving a net loss to the employees of only \$1,150.29, less than \$200 per month, or just one-half of the monthly loss two years before when safety measures were not so thoroughly undertaken.

It is said that accidents in the construction industry cost that industry \$120,000,000 annually. Judge Gary of the U. S. Steel Corporation says that "Accident prevention is not only good morals and good ethics, but also good business."

J. W. Robinson, secretary, Construction Section, National Safety Council, cites a number of cases in which financial savings have resulted from the adoption of safety measures. Thus, as a result of "Accident Prevention" efforts James Stewart & Company, Inc., has secured a credit of 64 per cent on its insurance rate, or a saving of \$2,800 on each \$100,000 of payroll. Fred T. Lew & Company, Inc., has reduced its accident rate 76 per cent.

In ten years the U. S. Steel Corporation expended over \$9,000,000 for accident prevention which netted them a return of over \$14,000,000. The Bell Telephone Company of Pennsylvania and associated companies in ten years increased the average number of employees from 3,703 to 7,796, while the days lost due to accidents decreased from 6,883 to 1,396. The American Car and Foundry Company expended in 14 years approximately \$1,000,000 for accident prevention work. After auditing their books they show a saving of \$2,700,000 represented by reductions in liability and compensation payments. These are very definite cases where considerable financial savings have been effected through the adoption of definite safety measures and by the carrying on of well regulated safety campaigns.

One crushed stone producer in the middle west gives his experiences as follows:

One-Half of the Serious Accidents Eliminated

"At the beginning of the 1926 operating season we undertook to work along the lines suggested by the National Safety Council, using their posters and bulletins at the plants and having foremen caution workmen with reference to their own safety and installing additional safety devices wherever possible. The direct result of this effort is shown in the following figures taken from our last year's report up to October 1st, 1925. Accidents from which employees lost one or more days work, 27. Accidents reported for which no time was lost excepting for first aid, 14. Our 1926 records taken up to date show only 14 accidents from which employees were compelled to stop work for one or more days and 12 accidents from which employees lost only time necessary for first aid.

"These figures seem to indicate that our safety program has had practically no result as far as minor scratches and bruises are concerned, but that practically one-half the serious accidents have been eliminated. We are so well satisfied with this program that we are planning to inaugurate organizations among the employees themselves for the promotion of safety at the beginning of next year's operation.

"Aside from the humanitarian viewpoint this reduction of serious accidents will reflect itself in reduced compensation premiums and in more efficient and unbroken operation. Whenever a serious accident occurs the workmen are not fit for duty the rest of the day. Things are wholly disorganized and production greatly reduced for the time being. We are thoroughly convinced that we can afford to spend a considerable amount of time and money to promote safety from both humanitarian and financial viewpoints."

H. G. Jacobsen of the Portland Cement Association has stated that the cement industry has saved several hundred thousand dollars over a period of the last five years due in part to many of the member companies carrying their own insurance and also to obtaining a complete revision in basic rates. In one case a particular company had just completed a new plant about two years ago in a state where there was no other cement

plant and the rating bureau in that particular state applied a most excessive basic rate to this plant. This matter was taken up on the basis of experience records with the result that a reduction in the insurance rate of more than 40 per cent, with a corresponding saving to the member company of more than \$4,000 per year, was brought about.

Is more evidence needed to demonstrate the fact that safety does pay big financial returns? If such huge industries as represented by the United States Steel Corporation have found savings of millions of dollars over a comparatively short term of years, does it seem unlikely that another huge industry, the crushed stone industry, will not have a corresponding experience if a thorough safety campaign is undertaken?

Discussion Following Mr. Goldbeck's Paper

CHAIRMAN EVANS: I am sure we are very greatly indebted to Mr. Goldbeck for coming from Washington, not only to present this paper but to meet with us in session today. His paper would indicate that he is thorough in everything that he undertakes.

I think I made mention in my opening remarks that the Quarry Section had its inception in Toledo. We could not have gone very far in our activities, particularly in the state of Ohio, if it had not been for the hearty cooperation which we have received from the Department of Safety and Hygiene of the Industrial Commission. I want to take the opportunity to introduce to you the superintendent of the Division of Safety and Hygiene of the Industrial Commission of Ohio.

I want to say to you men that notwithstanding the fact that Pennsylvania has been the pioneer state in adopting and carrying out a quarry code, it will not be long before Ohio will have adopted a code and we will not be compelled to pattern in its entirety the code of Pennsylvania. I want to introduce to you Mr. Kearns of Ohio.

THOMAS P. KEARNS: Mr. Chairman and Gentlemen: I don't believe that I ought to take up very much of the time of this Section this morning, because I doubt if there is anything I could say to you now that would be particularly interesting or helpful. I am certainly glad to be with you this morning and to see this large gathering here. It seems to me it is rather an encouraging sign of the times to see so many men getting together to discuss this very serious and important problem of accident prevention in quarries.

As the chairman has intimated to you, we have recently started a drive, as it were, in Ohio against quarry accidents. Just a short time ago we held a safety conference of quarry operators of the state. Through the assistance, support, and cooperation of the operators, particularly your chairman and vice chairman, who have been very active in the Quarry Section, the meeting was a decided success. We discussed all phases and all angles of quarry accidents at that time and also discussed ways and means of preventing these accidents. It also developed at that meeting that the quarrymen of our state were very anxious to have a quarry code, and we expect in the very near future to begin the work of

compiling a complete set of safety regulations covering quarry operations. It might be interesting to you to know about how those quarry codes are handled in our state.

They will be handled through a general advisory committee which will be composed of an equal representation of operators and workers. They will in turn appoint sub-committees who will also be comprised of an equal representation of employers and workers. This plan has been adopted, because we felt it insured a practical code when it was completed.

While I think a code will be decidedly helpful and useful in the matter of preventing accidents, the code itself or the enforcement of code regulations alone will not eliminate quarry accidents. Along with the enforcement or administration of this code, it is going to be necessary for the operators to do educational safety work in their plants. Unless the employer himself is sold on the safety problem, unless he is doing educational safety work, unless he makes a real, whole-hearted effort to reduce the accidents in his quarry, the codes themselves or state laws are not going to prevent accidents. There is a lot of educational work necessary amongst the men themselves. We realize that.

Thorough Survey of the Operations to Be Made

Our department has been organized for the purpose of assisting the quarries of the state in this educational work among the workmen in the different industries and operations. We are going to attempt this amongst the quarries of our state in the very near future, by making thorough surveys of the plants or operations, by arranging if possible for meetings of the workmen and delivering safety talks to men, attempting to point out the hazards of the operation in so far as it is possible for us to do it and to encourage the workmen themselves in following worthwhile practice, in observing the safety rules of the organization, and in other words, to work and think safety at all times.

But, of course, the operators must set the example. It seems to me that the very best way to start that would be to comply with all of the state regulations or all of the requirements of this code, or whatever code or regulations you may have in the different states. It seems to me that that in itself is the best way for the employer to demonstrate to the workers that he himself is interested in their welfare, that he is doing what he can to protect them from accidents and injury. If he will do that, I am sure that he can get the cooperation of the men in his safety work.

CHAIRMAN EVANS: I am going to further digress from the form of the program. Mr. Kearns's brief talk, mentioning as he did something with reference to safety education, has convinced me that it would be proper at this time to have that subject up for consideration. I believe we are convinced in our own minds that we need the education, that our employees need it, and anything that we may acquire that will be along educational lines it is our duty to carry back to the employee, so that

he may receive some benefits in an educational way. Without any further introduction, I am going to call upon Mr. W. F. Smith, of the Safety Department of the Ford Motor Company, located in Detroit, Michigan.

SAFETY EDUCATION

W. F. Smith, Safety Department, Ford Motor Company, Detroit, Mich.

There are two reasons why I am interested in your industry. The first is because it is one of the oldest—no matter how far back we turn the pages of history, even into the most primeval days, we read about men engaged in quarry operations. The second reason is because it is one of the most dangerous. I am convinced that the average man does not even realize what tremendous risks are connected with your work, and he therefore does not appreciate what a wonderful safety record you have established. I therefore feel very happy indeed in being able to discuss with you the subject of Safety Education.

The subject of my address has been divided into three headings, as follows:

- (1) General, as it affects the whole industry.
- (2) The new employee.
- (3) The trained or experienced employee.

A leading professor has stated that education is simply the appreciation of what we study and read in books and gain in experience. For example, we can give a man a complete set of rules on the safe operation of his job. He may be able to repeat every rule word for word, but unless he can fully appreciate the reason and value of each rule, then the education has been a failure.

It has been truthfully said that safety work is 75 per cent education and 25 per cent mechanical. Therefore, our efforts must be concentrated on the training and instruction of the employee. A leading safety engineer was once asked if he would prefer a plant with no guards on the machines and men who had education in safety, or a plant with guards on every available place and men untrained in safe operation. He at once favored the plant where safety education was established.

No matter how much we protect an industry with mechanical devices, they are of very little avail unless the operator is trained, and our training must be thorough.

The question of thoroughness reminds me of the story connected with an old crossing watchman. One dark night when a fast passenger train was rushing along the tracks, an automobile passed the crossing watchman and was hit by the train. Damages were claimed by the relatives of the injured and in the court old John was put on the witness stand and subjected to a cross examination something like this:

"Did you swing a lantern over your head as a warning on the night of the accident?"

"How long before the train arrived at the crossing did you do this?"

"Do you declare on oath that you stood at the crossing with the lantern?"

To all of which John replied in very emphatic terms, "Yes, sir!"

The railroad company won the case, and outside the court the president extended to John his congratulations on the loyal spirit he had shown in standing his ground in the face of a most penetrating examination. John replied, "Yes, sir, but it's a good job the judge didn't ask if I had a light in the lantern."

So, gentlemen, we must be thorough in our safety system and always have the lantern lit.

The new employee is our greatest responsibility. I do not believe we realize just what it means to enroll a new man and put him to work. There are so many handicaps and small details that contribute to his danger:

- (1) The newness of his surroundings.
- (2) The anxiety of making a success of his new job resulting in an over-enthusiasm to rush in with no thought of danger.
- (3) The suspicion that he will be despised if he shows signs of nervousness.
- (4) He may have been out of employment for a considerable time and carry a lot of worry regarding his home and family.

Educational Activities Begin Upon Employment.

To overcome these handicaps the first step is to instruct the man immediately he reaches the employment office, thereby giving him confidence that his new field of activity is going to be among men who believe and practice safety.

Safety bulletins on the wall and a card of welcome containing safety rules are practical samples of making the new surroundings appear welcome.

Next, the employee should be examined as to his fitness to do the work for which he is making application. This test, of course, should be physical as well as from the point of view of experience. There is no question of the hazard of putting a man on a job for which he is mentally and physically unfit.

Providing he meets all the requirements of experience and has received the preliminary instructions in safety, his road is more or less easy and supervision in safety work should do the rest.

The following are a few sample of educational activities which will help in training the new employee:

- (1) Bulletins in employment office.
- (2) Safety cards outlining general safety rules.
- (3) Instructions by foreman.
- (4) Set of safety rules governing his job.
- (5) Safety moving pictures.
- (6) Safety Committee man in his department.
- (7) Personal talk by safety engineer.

Practical demonstration of safety equipment and application of rules are among the most effective methods of convincing the new man. There is no use lecturing and wandering into paths of theory and rhetoric unless we get down to earth and show the man by demonstration that our ideas and equipment will protect him.

In a certain foundry the men left leggings and shoes off, and considerable trouble was experienced in making them wear this particular equipment, because they falsely thought molten metal would simply go through just as if it were tissue paper. The men were collected and two or three pairs of leggings spread on the floor. Molten metal was poured on them and it rolled off into the foundry sand. This experiment proved so successful that no future trouble was experienced. Therefore, we must be leaders and let the man see the safe road. Then there is no question but that, in the majority of cases at least, he will follow the trained or experienced employee.

Some Bad Violators of Safety Rules Are Old Employees

Last is the trained or experienced employee. It is a peculiar and also regrettable fact that some of the worst violators of safety rules are the experienced men. It very often happens that men of 10 years' service are among the offenders. This is probably due to familiarity with their job on the one hand and a false impression of their skill on the other.

Education by discipline is probably the best remedy.

The question of discipline immediately creates a long, drawn-out argument, but there is very little question but that the enforcement of safety standards is essential to accident prevention. Of course, we must be leaders before we are dictators and very often men will admit that they are violators.

One system which has proved most successful is the method of having men who violate safety rules come to the office and study safety posters in their own time. And a very high compliment is paid to the National Safety Council poster service when I say many men after they are told to go home request to look over the remainder. Care is always taken to avoid humiliating the man when he comes to the office. Taken all together, this system has proved fair, popular, and has brought results.

Another incentive in training the experienced man is to promote men who have a good safety record. This encourages the others to realize that a man must be first-class in safety as well as in his particular line of work.

Education is the beacon light on the sea of safety. The more luminous we make that light, the more readily will the dangers be observed.

There is something sacred about safety work when we realize that our efforts are crowned by something other than the cold metallic ring of cash.

To get the true perspective of safety, there is no question that the empty chair carries the real significance. The safety engineer's training should include the operating room and compensation office.

CHAIRMAN EVANS: Mr. Smith, on behalf of the members assembled, I want to thank you for the splendid talk that you have given us this morning.

There is one thing that I had forgotten, and that is the appointment of a Nominating Committee. I think my reasons in hesitating are because of the fact that I had some reluctance in severing my connection with the Quarry Section as its chairman. The compensation received, not in a financial way, has more than reimbursed me for any feeble efforts I may have made, and I want you gentlemen to take this as my swan song, because whomever this Nominating Committee may select, it is my wish and desire that I be not considered as a prospective candidate for chairman of this Section. I think that the honor should pass on to hands more capable than are mine to conduct its activities.

I should like to ask Mr. Jay Thompson to sit in with this committee, because of his familiarity with the duties of the official family of the National Safety Council. Mr. J. R. Davis, I know, will consent to act as chairman of that committee. Assisting him will be Mr. Martin Gross, safety engineer of the Holstein Quarry Company of Strawberry Plains, Tenn, and Mr. Charles A. Briggs, connected with the Woodville Lime Products Company's main office in Toledo. This committee is appointed and will take time and use great care in the selection of the officials for this Section. I think that we can very well excuse them at this time.

C. FRED WOLF (Travelers Insurance Co., Hartford, Conn.): I find objection to wearing leggings and goggles in many foundries. I hear the worn-out excuse that the metal will get in on top of the legging. Personally, I know that isn't so if the legging is a properly fitted one. However, has any trouble arisen from this source?

The Problem of Goggles in the Foundry

I want to ask another question as to the wearing of goggles by the men in pouring. Many foundries will tell you that they consider it more hazardous for the men to wear goggles than not, because the fumes from the metal seem to fog the goggles, and they can't see where they are walking. I don't think that is a good excuse, because I know there are some foundries where they do wear them, and if some of the metal should splash and fall into the man's eyes, he probably would be blind for life. I wonder if you have had any such experience?

MR. SMITH: I certainly appreciate your remark and the two questions you ask me. We have had very decided trouble with the same thing—not only in the foundry, but in the wearing of the safety equipment and other phases of operation.

We have found the question of the goggles becoming befogged with perspiration, to our mind and our experience, is purely a mental attitude. As to whether they are more dangerous than if he didn't have them on, I only wish you gentlemen could come to the Highland plant, to the safety office, to see a large bulletin which has at the top, "1925 goggle record," and then subdivided we have goggles pinned to it showing how

they saved men's eyes. Under the classification "foundry" we have a very, very large number showing the beneficial results of a man wearing goggles.

Many men in the past thought, "Anybody can make that up and stick on a pair of goggles." They considered it artificial. Now we put on the goggle and the man's badge number. We organized the cribmen to bring the goggles which saved an eye into our office, and we treasure them as living examples of observing safety rules and symbols of the effect of wearing them. To offset that mental attitude, we bring the men there and let them see this board and point out the goggles to them and convince them by this method as to their efficacy.

Another method we adopt when a man gets a metal splash and his eyes are saved by goggles: we take a full photograph of the man with the goggles on, and place a little piece of bandage on his face. We put that in the department and let the men see a real safety man who has benefited by wearing goggles. That more or less offsets that biased idea that goggles are uncomfortable and dangerous.

Leggings and Proper Shoes Prevent Accidents

Regarding the leggings: I don't see where they are a hazard. We never yet have had a man injured who wore foundry shoes and foundry leggings. As I tried to bring out in my address, a practical demonstration of pouring molten metal will convince him of the efficiency and practicality of the method. If he is taken before the bulletin board and shown the photograph of a man whom he knows, together with the accident report, his badge number, and every piece of evidence in the world that the human brain needs to make it believe, we find he becomes convinced. But it is a big battle, and that practical demonstration in educating these men, more particularly the foundry workers, will help a great deal in putting the idea across.

H. W. MUNDAY (Editor, Pit and Quarry, Chicago): I should like to ask Mr. Smith to answer a question for me that comes up as the result of two illustrations he used. The first one had to do with the man who wouldn't wear the goggles and used the case of no lens. I imagine there are varying degrees of intelligence in your shop, but the thought that occurred to me was: is there any bad effect from that method? It occurred to me that it could be properly classified as subterfuge and would be humiliating. The question has come up in dealing with safety whether it is practical to humiliate the employee. I thought possibly Mr. Smith had considered this and thought of the matter in connection with the workman and come to some conclusion.

The second point has to do with holding the workmen after working hours on their own time for infraction of the rules. The reaction I got was that the workman was treated like a school boy. I want to know from Mr. Smith whether they have had any bad reaction from that method?

MR. SMITH: That also is a thing we have had a very personal experience with. Gentlemen, you have to be very careful in dealing with the

question of violations and you must use the most complete tact in handling the situation.

The most important thing is to inform the general foreman of the detail surrounding the violation so that he will be willing to cooperate with you regarding bringing the man to the office. Then when the man comes up there we take off the acid taste of humiliation by telling him that it is rather a ludicrous thing for an intelligent man to be brought up and made to look at a poster on the wall. We impress upon him the fact that when he leaves the office he will have learned something worth while.

As a direct contradiction of the idea that he feels humiliated, in 70 per cent of the cases when we turn to the man and say, "We think you have had enough time to study here," the man turns around and says, "I have got about 15 more and I should like to continue until the end, if you don't mind," and he continues to look at them. That certainly pays a very high compliment to the posters of the National Safety Council.

Regarding the case of the goggles, there is no question but that you must meet conditions with similar arguments. It does no good to repair a watch with a sledge hammer or use a rubber dissector on the operating table. When a man adopts the arrogant attitude that the goggles are no good and gets away with it, there is no question but that at lunch hour he will tell the rest of his friends around him, "Just give them a good line and you will get off with it." Then you will have a bad apple in a large barrel of apples which if allowed to continue would be a very, very bad offset to safety.

When the "Safety Business" Is Genuine Stuff

The particular case mentioned resulted in the men around that particular territory remarking among themselves, "Well, this safety business is genuine stuff and you can't kid them." We have had excellent results since.

I think Mr. Munday meant to convey the idea that there is a legal aspect connected with this. We agreed there was. There is also a legal aspect to a man coming to look at the safety pictures after they have completed their eight hours' work. But when we appeal to them—and this is education, too—along the lines of illustrating to them what is done to make them safe in the plant, then they respond in every case.

Here is an example of what we say: "Do you realize that when you state that you are not going to that auditorium to look at the safety moving picture that you are giving a very poor reward for all that is being done for you? Do you realize that you have clean conditions under which to work? There is not a part of the plant that is not swept from hour to hour. Do you realize that the brains of the engineering world have been concentrated on making the machinery safe to operate? Take the lunch you buy at the lunch wagon; we analyze the food, determine the number of calories, and make sure it comes up to health requirements. We analyze the water you drink from the fountain. We had a

man leave who was sorry for it afterwards because he missed the drinking water.

"Do you realize that we have first-class compensation, medical transfer development, where you can go to be transferred to a job more suitable to your condition, first-aid stations dotted throughout the plant, first-aid medical equipment to take care of you, a suction system to take away dust from the air, and a full time safety department struggling day after day with the problem of accident prevention, working out schemes, drawing up blue prints, making up sets of rules, holding meetings for your benefit? We expend thousands of dollars for you. And the very head of the organization has said that production without safety is inefficient. Yet in spite of all we have done for you, you refuse to spend 50 minutes out of 365 days in a year as your small contribution to making this factory safe."

That never once has failed to bring results.

Goggles in Cutting and Welding Operations

MR. HAWK: I should like to ask Mr. Smith a question. We have different types of trouble with different employees. I should say that probably the greatest difficulty is with the eye. Have you any set rule as to what glasses to use for cutting and welding? We don't seem to be able to satisfy our employees with the different colored glasses used in cutting and welding. Is there any way we can overcome that? I know that is the greatest problem with all the quarries I have talked to. Some say the glasses are too dark, and others say they are too light. That is a matter I would like to have discussed.

MR. SMITH: The first attempt to solve that problem was to investigate thoroughly the most efficient type of goggle for the operation that the man is going to work on. We need only to take a walk around the wonderful exhibit of the National Safety Council to see the articles that science has developed to bring into reality the type of goggles most suitable to that job.

After a thorough investigation, and after taking the opinion of all kinds of men—more particularly the man who wears the goggle—we finally adopted certain standards for chipping goggles, for welding goggles, for the lens that would be used in the foundry, and for the lens that would be used in all the other operations. We made a standard box with a lock on it, and that box is locked. No one is allowed to go in there except certain people who have the authority. As goggles come into the plant they are examined to see that they are perfect. We have a level gauge on the lens to make sure there are no waves in the lens, no sand pits. If you don't inspect the goggles thoroughly, the men will be wearing lenses that are just a mass of specks from the grinding wheel and will be using inefficient lenses. Adopt a standard box and make sure by inspection that every goggle is up to specifications.

We have had very little trouble except in contending with the idea that they are uncomfortable to wear when they wear the standard lenses.

If you would care to come to our plant, we will willingly show you this box of standard goggles, used throughout the whole organization. They have proved very efficient, indeed. So that I would think the answer to your question would be to adopt as standard the best quality that is in the market today—and that is the best you can get—and apply it on the job. Then by education you can eliminate many of the misunderstandings that are created among the men.

MR. LABAR (Star Accident Insurance Co.): How do you provide for wearing goggles with regular lens?

MR. SMITH: Last week I had a man who came to the safety department, and said the safety inspector had found him wearing his own glasses on a production line where we nail up the parts of the automobile for shipment. We have the thick lens for that job, plus all the specifications that go with it. He said the safety man told him to report to the safety department because it is unsafe. It undisputably is, because it is more dangerous to have a man wearing his own glasses on nailing and spiking than if he didn't wear them. If the glass would become shattered and enter the cornea, it would produce a complicated case for the medical department.

An Illustration of the Value of Goggles

We illustrated that by a sample test for the goggle lens. We took a 22-inch tube with a five-eighth steel ball and put it on the lens and dropped the steel ball down. It hit the lens and is supposed to remain intact, that is, the cracks are not supposed to splinter. If it breaks at all, it is merely supposed to crack it. That shows the practical necessity of having protection of glasses from the impact of the nail. Then we told him if he dropped his own glasses and broke them, he would have to get a new pair. If the man is unfit to wear these glasses on that job, we consider that there lies a hazard; and we transfer him from the nailing job to a job where he can work free, without any glasses at all.

It is just the same idea, gentlemen, of the greatest hazard from an eye point of view: a man with one eye operating on a job where there is a danger is a very great hazard, because then you have the hazard of complete blindness, which is ranked by the Bureau of Statistics as a fatality, a total disability. We don't subject a man with one eye to any eye hazard.

The answer to your question would be if he is incapable of wearing safety goggles, then he needs to be transferred to a job where the hazard does not exist.

C. S. HURTER (E. I. du Pont, de Nemours & Co., Wilmington, Del.): I understand the goggle people put the man's original lenses back. Do you use such a feature?

MR. SMITH: Yes, there is a type of goggle that some of the manufacturers make by which the safety goggle slips on to the rim of the man's own glasses. Sometimes that has resulted in the excess weight breaking the nose piece of the man's own glasses. Sometimes the bow is snapped

because of the excess weight, and some men consider it very comfortable to use it. I would say that where it is practical, the men may do it. A lot of men find they can't, so that it is a matter of classifying them again. The man who can wear those safety goggles over his own finds them comfortable and he can work with safety.

MR. HUETER: I just wanted to say that I am under the impression that we have an arrangement with a goggle company whereby you can send the prescription for the men's glasses to them and they will make up special goggles that will fit the eyes.

MR. SMITH: That is getting safety down to the finest point. There is no question about it, if that system could be made practical we would have a 100 per cent safety protection for eyes. But, gentlemen, circumstances alter cases. In the case of a small shop, where you know every man as Jack, Bill, and Jim, it is very easy to apply that method. If you take 70,000 in one plant, 40,000 in another, and so on, it would be a tremendous problem to take every man and examine him as to the fine points of his vision and then adjust the goggles through an optician to fit him. It is far more practical to transfer a man from a job and replace him by a man who can wear the standard equipment.

Difficult to Prevent Steaming of the Goggle

MR. UMBRETT (Standard Accident Insurance Co.): Will Mr. Smith kindly go into the detail of the construction of the goggles worn in foundries in the case of men pouring metal? Can he tell us what is done to prevent their steaming?

MR. SMITH: I could do this more easily if I had our standard specifications with me. We have a standard box of goggles. We have a blue print, if you will, of the specifications, which must be met in regard to the foundry and chipping goggle and welding goggle. We have an amber lens of a certain thickness and color which we use in the foundry.

I do not know of anything that we have adopted to prevent steam or perspiration coming over the lens, except to have a man take off his goggles occasionally and wipe them, plus the fact that we increase the ventilation as much as possible on a leather piece that comes from the eye to the bow, and we get the maximum ventilation to go through. Then we have the man adjust the goggles by making sure that the bridge doesn't come close to the eyebrows and thereby press against the face too much and permit a sealed joint between the space and the goggle. You have to be very careful in adopting that method because we used to have some men who bent the bow and bent the front, so that there was enough slack so they could have the goggles down until an inspector came along. Then they would stick up on their foreheads, and when the inspector came, down came the goggles. When he would ask, "Are you wearing your goggles?" they would reply, "Yes, sir." So when you come to adjust that goggle, be very careful you don't get them up on their head so they can slip them down.

We have men who had to go into the boiler flues, who crawled through

a little manhole inside the job and poked around the flues. The heat was intense. Because of the necessity of turning these engines in the round house, one man adopted a sort of solution which he found to give results. He smeared a solution over the goggle and thereby prevented the perspiration from getting on the glass. I think there is some kind of a substance you rub on windshields that serves the same purpose. It may be that by the application of something like that you could meet the difficulty. So the answer to that question is the possible application of some kind of solution to prevent the steaming of the lens and the adjusting of the goggle by keeping it away from his forehead and making a sealed joint and the increased ventilation of the leather sides.

MR. HAWK: Do you permit using a plain goggle with a cutting torch?

MR. SMITH: We certainly do not, the reason being that any man who is using a cutting torch is having his eyes subjected to something they never were meant to. The human eye was never meant to stand the high illumination which results from the glare of an open furnace door. You will get an extreme case of high flashpoint and high illumination that will cause serious injury to the eyes.

Training the Employee in First Aid

There is one practical angle to that; and that is that many men on the bonding jobs, just as they begin heating up the metal, before they cut keep up until they get a line on the job, then drop, and go right along. From a practical angle, we more or less consider that all right, because there are many times when it is difficult to see a line with the dark lens, and hence the man may not cut the job. But the answer there is that we do not permit or recommend a clear lens for bonding. From a practical point of view, we sometimes let him go ahead until he gets the line of pouring and the torch heated up, and then he puts the goggle on.

F. S. SPEHAR (First aid instructor, Western Electric, Chicago): Through Major Shields we have taken up first aid work through the American Telephone and Telegraph organization.

A short while ago a gentleman asked a question of Mr. Smith about the 50-minute period taken. In this district alone I have trained something like 300 men, and not one of those men took time except after supper. In other words, he took his own time to obtain the Red Cross 15-hour instruction course. All these men we instructed for 15 hours of their own time, which was once a week for a two-hour period. All obtained certificates. Out of something like 300 men we instructed almost 90 per cent. There were a few who objected to not getting paid for that instruction period, but the majority of them were so enthusiastic that they are trying to get instructor's cards.

In most instances I found they were perfectly willing to allow that time for their self-education. I think that the gentleman can get records from our department installation branch and also get records from the Michigan Bell Telephone Company, which is at the present time running classes of 60 men at a time, with one instructor for every 10 men. They don't seem to have any difficulty with the men objecting to the amount

of time they spend. That has been our experience with the first aid work.

MR. SMITH: There is a distinct difference between dealing with 300 men and dealing with 70,000. That system is a very commendable one, and we adopt it from year to year. Through the Detroit Safety Council we have sent men to specify courses in safety, to attend after supper on their own time and ultimately get a certificate from the Council certifying they had attended a safety course, and then have had men volunteer after supper to come down and use the auditorium of the plant for a full-fledged safety meeting with their families. We take advantage of the opportunity to have expert people get on the platform and give them instructions in safety. That is a form of school which is excellent, in which the man has his wife and children beside him. We run moving pictures and comedies and get them there.

But when it comes to getting every man to attend—and that is the object—there is no question that if you touch only certain men by the volunteer method, you are only going to touch the men who have the safety spirit, and the man who needs to attend the meeting isn't there. The man who needs to attend the safety meeting and look at a safety moving picture is the man who can't understand English and who can't read English but who can see safety on a film. That is the only method left to instruct him. So I would say in the application of the method of education, where it is practical to adopt an after-supper arrangement, do so.

A Course of Instruction Through the Winter

Where you have a large body of men, then it is necessary to adopt the other method, because we start our meetings in the auditorium about October and run every night in the week except Saturday and the night previous to a holiday. It takes us until the middle of May to have every man go through that course of instruction. We also go to great pains to relieve a man from attending who has home troubles and who has complicated matters to attend to outside. Then we wait a month, two months, or three months, until such time as he can attend. We keep a tag on him until we finally get him to the meeting.

MR. SPENAR: I think most of the men understand the size of the A. T. & T. In our part of the Western Electric Manufacturing plant at Chicago we train something over half the men in the Hawthorne plant. That doesn't take effect only in the small groups of men. On installations alone there are something like 20,000 men in the United States. We have a doctor in some town where we congregate to take over the work to give first-aid instruction, so that these men can obtain an instructor's certificate. Then these instructors from the laymen are transferred into the various towns to do the work. While they are on this job, doing the work, they make up the first-aid classes.

JAY THOMPSON (Toledo Safety Council): In the Ohio Bell Telephone system they do this first aid work on the time of the company. I should like to present this thought: It doesn't make any material difference

which way you go at it. It is a sales proposition. If you want to get together on your own time, do it. If you want to do it the other way, do it. It is really a question of getting the job done in the most practical way for your set-up. Particularly in quarries with a small organization, it is easy to find out which is going to be the most acceptable way to put it over. You will compensate them in some way for taking their own time. It adds to the wealth of the organization, makes higher wages possible if they do it on their own time. The other way around it is just as effective. The only idea is to have these meetings and get the job over.

MR. SMITH: In this system you speak of, how many men can be concentrated at one point?

MR. SPEHAR: We have in Michigan at the present time close to 500 men. They are scattered throughout the areas.

MR. SMITH: You see, gentlemen, it comes back to the question of numbers. If you have 500 men split up or 200 men in one locality, it is simple to adopt one method. If you have about 40,000, 50,000, 60,000, or 70,000 men in one spot, then it seems the other method must be adopted. As Mr. Thompson has illustrated, whatever method you use will balance itself.

CHAIRMAN EVANS: There is one individual here whom I am going to call on next, who has had much to do with safety as applied to quarry operation. He is connected with a stone industry that has approximately 17 plants, and is in charge of the explosives exclusively in the operation of these many plants. During the 10 or 12 years that he has been connected with this institution, I have yet to learn of any fatality in connection with their blasting operations. I am going to call on Mr. McLaughlin, explosives engineer, France Stone Company, Toledo, Ohio.

HANDLING EXPLOSIVES

F. F. McLaughlin, France Stone Company, Toledo, Ohio

No smooth, level, even-working commercial industry of today found its way to such a state by "happen-so" methods or simply of its own accord, without direction. Ever since commercial and humanitarian statistics have proven the value of human safety in industrial programs, we find that by leaps and bounds safety measures have entered among the major policies of industrial management throughout the business world.

Faith in the rightness of a thing has often been the only foundation on which great results were finally built. Many of our great industrial organizations had for their beginnings only men with faith in an idea. The growth and success of such enterprises have rested upon the perseverance, patience and toil required to justify that original faith. Human mental attitudes can build nations or tear them down.

"Safety First" was just such a faith-provoking idea in its beginning. It has not reached its present status in the world of industry by any haphazard course best designated by the words, "chance" and "luck." We

here today, meeting as a part of the Fifteenth Annual Congress of the allied safety interests of our country, are but beneficiaries of all the faith, patience, perseverance, and toil it has taken to make such an expression of the spirit of "Safety First" possible.

Faith, after all is said and done, may be simply described as an attitude of certainty regarding a cherished object. In this sense, industrial safety must, first of all, become a personal attitude with us on our jobs before the practical operation of its meaning and value can follow.

In many industries safety can be provided for workmen by mechanical means, but not so in this work of handling and using explosives. This is one of the many occasions in which the attitude of safety must first predominate before safety can become a fact.

It is possible that some of you are under the impression that to actually associate the idea of safety in connection with the handling of explosives is sufficient cause for a gentle snicker of derision. Perhaps you do not quite realize that today explosives are as indispensable as capital and labor in the development of the original sources of all our industrial processes. Quite a number of the pages of this paper could be devoted to statistics showing you the diversified use, every year, of many million pounds of this concentrated energy, and those statistics would also show a surprisingly small toll of human wreckage compared to the supposed and real hazard its use creates.

The Psychology in the Thought of Explosives

It is not so much the total number of accidents, however, that makes us think of explosives as one of the necessary "bad actors" in the industrial world, as it is the totality of devastation and horror created when its power is unsafely loosed.

The ordinary commercial explosive such as we buy and use today, will do no more of its own accord than will a pile of sand. It doesn't go into unexplainable tantrums and produce an effect without a controllable cause. It can be generally said that all results, both good and bad, from the use of explosives are directly due either to human direction or misdirection of its true function. Knowing the terrific power explosives develop, yet the logical conclusion is this: a careful, informed man is far safer while using explosives than he is crossing a street heavy with traffic in one of our large cities; but an uninformed, careless man might just as well be playing on a railroad track ahead of a fast train, as with a case of dynamite, so far as his personal safety is concerned.

It is not chemical explosive deficiency, but a human mental deficiency that is almost totally responsible for blasting accidents. True it is that an uncontrollable caprice of the elements will at times enter and destroy our well laid plans for safety in the use of explosives but even such things as stray ground currents, storms, hot sparks and lightning can be anticipated by the foresighted blaster, and guarded against.

The greatest cause of blasting accidents is composed of careless, ignorant men—ignorant, I mean, about the proper and safe use of explosives. This seems as simple as saying twice two is four; but if saying it t.n

thousand times, right here and now, would help to seat this fact firmer in your minds and by its guidance give you future relief from blasting accidents, it would be worth our time and interest to repeat it that many times together.

In handling and using explosives the sensible way is the right way and the right way is the safe way. To be free from blasting accidents requires no miracle. It is only necessary to be sensible—and being sensible with explosives is simply knowing what to do and doing it.

Truths are facts and facts are details, not generalities. Safety with explosives is a matter of knowing the actual details of its nature. The first step in learning how to prevent blasting accidents is to learn how they occur—and this step must deal with the explosive itself as well as the human factor involved in its use.

Details in the Manufacture of Explosives

Nitrated chemicals form the explosive base of most of the explosives in use today. Ordinary starch, ammonia and glycerine are treated with acids in such a manner that the resulting chemical will produce a large volume of gas in an infinitesimal space of time when given an initial detonating impulse. It is by confining for a short time the rapidly expanding gas from a detonated explosive that we make it do its intended work of fracturing or rupturing some material in which we have located it. These acid-treated chemicals are mixed with and are carried in a non-explosive base material to make them much safer to handle and use. Combustion, explosion, or detonation of an explosive can only occur from certain specific causes and under specific conditions.

High explosives will detonate of their own accord when heated to 200 degrees centigrade. They will begin decomposition at a temperature as low as 60 degrees centigrade. For this reason they should not be stored in a place excessively warm nor located for blasting purposes in a hot bore hole. Neither should they be stored or used in a place excessively cold, unless made specifically low-freezing, because some explosives become rigid, congealed, or "frozen" under such conditions and are much more susceptible to explosion by friction when in such condition. As a rule, when a paper cartridge wrapper shows a brown, oily, stain, or when the cartridge is hard and rigid, or when it is wet and soggy, do not use it. Call in the manufacturer's representative and let him advise you.

Most explosives start burning easily and burn rapidly, partly due to the paraffined paper wrapper in which it is packed, and partly to the inflammable nature of the chemical itself. A small spark will set it afire, and if the gases of such combustion can not readily diffuse with free air the increased temperature will lead to its explosion. Avoid sparks or any kind of fire from all sources during any part of your blasting operations. The steam shovel, locomotive, crane, hot carbon of gas engine exhaust pipes, matches from the men's pockets and dottle from their smokes, metal, or imbedded rock on the tamping pole can all produce a fire hazard to the explosive. Take steps to prevent these from occurring.

High explosive, under some conditions, will explode or detonate from

the friction of rough handling in or out of the box or bore hole. Mark this word "rough." High explosive will stand a lot of abuse when it is in a normal condition, but this fact offers no excuse for forming habits in using it that become potential accident makers when the condition of the explosive is not normal.

Lightning will detonate explosives or any of the commercial detonators for explosives. If you have located explosives on a shot, in or out of the bore holes, and lightning approaches, avoid possible trouble by removing all your men to a good safe distance until the disturbance is well gone. Do not poke, or jar, or hammer an explosive roughly or heavily with any kind of a tool, wooden or otherwise, and do not tamp the explosive if you wish to be thoroughly safe. Tamp the stemming above the explosive if you will, but keep the tamping rod well away from the detonator or its connections. The detonator caps are even far more "sensitive" than the explosive, and their nature must be respected and treated in this light.

Avoid the Hazard When Many Men Are Exposed

Avoid having any more men working on or about a shot than is absolutely necessary. The safety of all can be endangered by one man; the more men the greater the chances for trouble and the more affected when trouble does hit. A foresighted manager can usually keep his blasting operations sufficiently ahead to make rush jobs unnecessary.

I wish to repeat to you a suggestion made in our meeting in the convention of last year, that you give earnest consideration to the quite reasonable amount of safety provided in blasting operations by the use of a wooden peg and rope with which to lower explosive cartridges in bore holes. Four things this practice assures—it prevents "hung" or lodged cartridges in the bore hole, and the subsequent possibility of trouble involved in dislodging them; it prevents rough treatment of the detonator and its connections; it prevents excessive friction on the explosive; it gives the blaster exact information regarding the location of every cartridge in the bore hole.

This practice may seem to involve a considerable amount of extra work; but we have developed, with the cooperation of the explosive makers, the use of 25 pound cartridges of five-inch diameter, in both the pulp type and gelatin. Either of these will handle easily on a peg, and when you can thus load a case of explosives in two movements the labor argument against "pegging" is largely dissolved.

Several explosive makers have indicated their willingness to cease packing explosives so snugly in the box as to make it necessary to knock off the lid, turn the case upside down, and dump the entire contents in order to loosen the explosive from the case. It is a better way to have the explosive case of sufficiently greater length than the enclosed cartridges to make it easy for the men to open the lid and lift the cartridges from the case, leaving the packing and the box to be removed entirely from the shot. Loose paper and sawdust are not good companions for the explosive around the bore hole.

The task of connecting the detonators or "hooking up" a shot requires.

quite specific knowledge and should be committed to a very few good men who know what they are doing and how to do it, and for their ability to think before they act. This part of your blasting is more safely accomplished after all other workmen have left the shot. Electricity, invisible, and therefore dangerous to human life, when used with electric blasting caps to detonate explosives, should be used with the exercise of every available precaution to prevent a premature blast.

Power lines adjacent to a blast should be well insulated and located off the ground. Power lines with frayed insulation resting on wet ground can cause stray currents to enter detonator wires with the comparatively small amount of current it takes to fire one. Be sure that your mechanical methods of connecting current to the blast are in such a location, of such a type, and are used in such a manner that a premature blast is impossible; that the shot firer can not be reached by flying fragments from the blast, or that anyone can open or close the switch save one to whom is delegated that responsibility. Any of you men who have had to pay compensation costs because this was *not* done know wherein the sense of it lies.

Making Use of the Blasting Machine or Battery

A blasting machine or "battery" often spends much of its time exposed to elements injurious to its health. Knowing this, many older blasters, preparatory to its use in firing a shot, will push the rack bar down three or four times to "pep" up the magneto in the generator. It is totally unnecessary to connect the leading wires from the shot to the blasting machine until the moment before firing the blast. Observe this precaution and avoid premature blasts that may occur if the blaster unconsciously "peps" the blasting machine with the lead wire tied to it. Misfired or unfired explosive charges in the midst of the mass of a made shot form one of the extremely hazardous results that can occur. After it is done there is no safe cure for it.

Prevention is the sensible course. Misfires are ordinarily caused by detonator failure or improper connections or improper use of current. The two last causes you can control. As for the first cause, I regret to say that there has not yet been made and sold a continuously 100 per cent efficient detonator. So long as this is a fact we can not have perfect freedom from misfired holes. There still remains this mark of attainment for detonator manufacturers to strive for. So long as there is an unfired cap located in an explosive charge, with the chance of anything hard striking the cap with force, there is a chance for a serious accident to occur. Explosives will sometimes detonate when loose in blasted material and struck with a shovel dipper. They will almost always detonate if an imbedded cap is discharged. Even explosives that have lain unexploded in a shot for some years do not always have their power dissipated to a point of safety.

When cordeau is used as detonator, misfired charges can be caused by broken lines, wet or poorly made connections, the cordeau curved in too

short an arc, and by ignoring the proper detonating sequence of rows in connecting multiple row shots. In laying out the ground or connecting line of cordeau distance should be so considered that multiple row shots will fire from the face back. Countered cordeau only should be used in the holes because of its greater strain strength and resistance to the friction of loading explosives and stemming in the bore hole. Cordeau only should be used on top to connect the cordeau in the holes. It is a safer, simpler manner of detonating the holes than the practice of detonating the cordeau in each hole with a cap. It is unwise to depend on one cap to a hole. If the single cap happens to be faulty, a misfired hole will be the usual result. Do not bend a short right angle in that short part of the cordeau that arises above the hole. Let it stand straight up and at right angles with the connecting line. Protect all cordeau connections from possible dampness.

Where electric blasting caps are used, misfired charges can be caused by the detonator wires having been broken or bared and shorted, due either to the method of loading the explosives or tamping the hole. By testing each electric cap with a galvanometer before using it, and rejecting those that indicate an exceptionally high resistance, you can control a part of the trouble caused by faulty caps. There is, however, no way for you to determine the condition of the detonating chemicals inside the cap. Use at least two No. 8 electric blasting caps in each separate explosive charge in a bore hole.

A Blasting Machine Gives Variable Results

Be sure that a sufficient amperage and voltage is available to care for an electric blast. Most of the explosive makers have prepared, and will send you for the asking, a table for figuring current needs for different conditions. I personally think it is wise to use not only the same make caps in all the holes of a shot, but also to use the same length exploder wires on all the caps in a shot, equalizing, as nearly as possible, the action of the electric current on all the caps. Avoid multiple connections as much as possible, especially when using alternating current, for this is a prolific source of misfires. It is better to arrange your transformer to have sufficient current to be safely able to connect every cap direct to the lead line on the shot.

A blasting machine will give variable results. Do away with its use if possible, but if you must use one don't forget that with a two post machine all the caps must be connected in one series or circuit. In general, when using electric blasting caps do not abuse the insulation on the wires; make all splices or connections good and tight, and keep all bare wires off the ground. Scrape to brightness all wires to be spliced. When you encounter trouble in the electric blasting process don't go on and trust to luck. Get some one on your job to find and tell you what is wrong.

Fuse and ordinary blasting caps, used mainly for block-hole work in secondary blasting, can cause an extraordinary amount of trouble if not stored and handled properly. An immense amount of energy is stored in the business end of a blasting cap and can cause some costly damage if

it lets go at the wrong time and in the wrong place. They are very sensitive to sharp blows and should not be mashed in the blacksmith shop between the anvil and a hammer. It may seem just a little foolish for me to use your time telling you that a pants or shirt pocket, or an open box, is not a fit place to carry or store blasting caps, and that they ought never be stored or carried adjacent to explosives. In an Ohio State Safety meeting last month we were advised from a creditable source that last year over 900 accidents were caused by the improper use of blasting caps.

It pays to buy and use well made 40-second fuse—but don't kink it or unroll it when it is cold and brittle, and don't expect it to function when allowed to draw dampness. A good "pop-shooter" is a valuable man. He gets the big pieces down to small ones for you, and he doesn't leave any unexploded charges in the rock to go through the dipper into the cars, and down to the crusher to finally let go with a shower of hard rock in your crusher-feeder's anatomy. But don't skimp his good work with poor, cheap fuse; and don't growl about the extra six inches he cuts on the length to make himself and the rest of the boys 20 seconds safer.

Be Positive Everything is Ready for the Blast

Is it necessary to say that when making any kind of a blast the responsibility rests with us to be positive that everything is ready for the blast before we fire it? Highways should be guarded by men with red flags, respect should be given to possible approaching electric or steam trains, your men should be all well in the clear. Insist on the elimination of the chance takers. We may as well get into the habit now of being responsible for human safety adjacent to a blast, because it won't be long until we will have to consider even the traveler in the air. Place a good sensible man, who has the time to actually be on the blast himself, in charge of your blasting, and you will have gone a long way toward the prevention of accidents due to the use of explosives.

Let me say in conclusion that the writer of this paper realizes its incompleteness—that it is not possible, in the time given for this purpose, to deal in sufficient detail to satisfactorily answer your individual needs—but you can, by your participation in the following discussion, bring to bear upon the subject your own individual experiences and questions. Because of all the knowledge about explosives and blasting represented in this meeting it will be absurd for us to leave the subject without each of us having gained a new hold on our determination to conduct our blasting sanely and safely.

CHAIRMAN EVANS: Mr. McLaughlin, your excellent paper has been graciously received by the men who are here.

MR. HURTER: As I represent one of the explosives companies, I can probably give you one or two highlights. One feature that has come under my personal observation in a number of cases of accidents has been where the fuse started to burn, the coils were around, and the man pointed them around, and the charge spit and nearly caught the man. Fortunately, he wasn't killed.

In regard to the use of alternating current in firing spots, our recommendation is that the 25-cycle current be not used in the series connection. The closest measurements we can make show that the electric blasing cap explodes in the minimum time of .014 of a second after application of current. With the alternating current, you must be absolutely sure the crest of your alternating current will pass through the bridge wire of the cap. The half cycle of the 25-cycle current is .02, which is longer than .014. There is the chance that you may catch that on the cycle so that between the two crests some of your holes are likely to miss and that is more likely to occur with the fuel hole than the large hole.

In regard to straight currents, there is one very good precaution that has been developed in the last speaker's paper. That is to keep your lead wires short circuited at the point near where you connect. Keep those short circuited up to the time when you are ready to connect the blast. Then after the current leaks on the point of circuit, instead of having only a pair through the explosives, you have a short circuit of least resistance, a current going out and possibly causing an accident.

MR. SHAY (Atlas Portland Cement Co.): In speaking of explosives, we look at the extreme cases and try to safeguard them. I remember that when we were children we used to run across a carpet, turn out the gas jet and hold our fingers up to it and light it with the tips of our fingers. Could we on a cold, clear day in any way get a static charge in our body so that we could touch lead wires to the exploder and explode it?

Making Speed in Loading the Holes

MR. HURTER: I doubt whether that could ever happen. The amount of electricity necessary to heat the bridge wire to redness is about half an ampere at half a volt. While the voltage for the static electricity is high, I doubt if you would get the amperage necessary to heat the bridge to redness.

MORTON GROSS (Holston Quarry Co., Strawberry Plains, Tenn.): I should like to ask about loading holes down the line. What speed do you make in a case like that, going over 35 or 40 holes with 12,000 or 15,000 pounds of power?

MR. McLAUGHLIN: That is a good question! The method I have advocated and used and will continue to use is one I have made use of during the handling of several million pounds of explosives. With my own two hands I know I have put at least five million pounds of explosives in bore holes. I do it quickly, because I have an enormous amount of that stuff to control. I do it with the use of a peg.

Lately we have had an advantage I have mentioned in the book. I don't want to indicate anything that is going to carry your men to any erroneous conclusion, but my personal conviction is that without any undue haste the sooner you get the blasting operation accomplished, the less will be your hazard. To do it rightly and do it speedily with safety is a creditable accomplishment.

When I first started to work with explosives, the large stick we had was of five-inch diameter, and a 12-inch length. In the gelatine form it came four to a box, and each stick weighed 12½ pounds. To peg that size stick takes an enormous amount of labor. I have loaded many a ton of it, and it is a back-breaking job. We then rose to the status of a 5 by 16-inch stick, weighing 16 2-3 pounds. For the last three years in the gelatine type we have been using the 5 by 24-inch stick, which is 25 pounds to the cartridge, two cartridges to the case. You can see how that increase of length enables you rapidly to put an enormous amount of explosives in a bore hole.

I did not tackle the N. G. pulp powder or ammonium pulp powder, because I am a little more cautious with those two types of powder because of their increased sensitivity and consequent hazard over the gelatine type. Yet, as far as blasing is concerned, it is not possible to use any one type of explosive under all the conditions we encounter in our blasting efficiently. For that reason we have had to develop the efficient and safe use of the type of explosives indicated for the work.

Splitting the Wrapper Not Necessary for Efficiency

We recently have received and used a few tons of our first attempt to introduce the 5 by 32-inch long N. G. pulp carton. I want to tell you it works the prettiest of anything I have ever used. I am just a little bit enthusiastic about the details of my job. I like to shoot stone. I have some banks in which it is necessary to load and shoot as high as 10 tons in eight hours. We prepare ourselves to make that blast. We make sure our holes are clean, measure out the powder, lay it out, and then one-two-three, things click. But we take our time. We find it easier to do that within the reasonable time limit set for making a blast by the use of the larger sticks.

MR. ROBERTSON: Is it ever necessary to split the wrapper of one of these cartridges?

MR. McLAUGHLIN: Your own blaster will tell you, "Yes." If your own blaster has been giving you good results, I have no desire to get you into an argument by telling you something different. I will make this reservation. It is not necessary from a standpoint of efficiency. When you have your drilling and blasting properly correlated and the proper explosive, it is not ever necessary to split the cartridges.

MR. ROBERTSON: I suppose it wouldn't do for me to ask what sort of knife you use. We are trying to get something suitable.

MR. HURTER: We use a clasp knife, a straight knife like a paring knife, made of steel.

MR. ROBERTSON: We have been trying to fix up a copper knife but have not been successful.

MR. McLAUGHLIN: I don't believe there is any use in quibbling over the type of metal you use. If you are going to use metal, you are using metal. Explosives in the normal condition will stand exactly the thing you are talking about with comparative safety, but again I repeat that

you must not by that process form a habit that might lead you into trouble when the explosives are not in the right condition.

MR. ROBERTSON: The reason I asked that question was because we are trying to get our men out of that habit.

MR. McLAUGHLIN: You are dealing with the problem of the efficient use of explosives when you say it is not necessary for a man to split the cartridge and drop it in the bore hole and fill it full of explosives. That is a practical matter and not one within the province of this Section to determine.

A. C. HEWITT (Engineer, American Lime & Stone Co., Bellefonte, Pa.): My question may sound like a very stupid one to those of you who have more experience in the quarry than I. My experience has been mostly with crushing and some in the cement plant. You made a statement about dropping the cartridge into the hole. I should like to know some of the details of how that is handled, how you attach it to the stick, and how the stick is removed?

Details on Dropping the Cartridge Into the Hole

MR. McLAUGHLIN: We have done it in our Bluffton, Indiana, plant. We just used it Monday. It is nothing more nor less than an ordinary hickory stick. Usually I go to the stockroom and get a good-sized hammer handle and take the draw knife in the shop and draw it down to a point on one end and tap it. I use that hickory because the sharpened end usually stands up better than any other wood. Then I bore a hole near the end, run a loop through of a size not too large and yet not too small. It should not be too large, because part of the value of the peg and rope is helping him in determining just where that cartridge is located in the hole, especially when the walls of the hole are rough and have different angles. If the rope is too heavy, it isn't sensitive enough to give him the information he wants. It is likely to cramp his fingers if it is too small, on the other hand.

After all is said and done, the operation is taking the dynamite cartridge and lifting up the flap of the end if the point won't penetrate, pushing it down in the cartridge and then lifting it down. The wooden peg is short. Then the rope is lifted to see if it is pushed sufficiently far to get the friction, and then it is lowered down.

You can see that when you have that cartridge tied on to the end of that rope it can not get away from you. It is not anything like an approach to the condition that occurs when you stand at the top of the bore hole and look over and drop a cartridge down there. Then what are you going to do? It has got to be larger. There is no telling how many feet there are between where the cartridge lodged and the top of the charge you previously made. You have got to get it down and go after it with a pole, most of the time a wooden pole. But a wooden pole is no protection if you hammer away at it sometimes. You get explosive mixed up with the cuttings that have occurred from the drilling still sticking on the sides of the wall. If you get that mixed up with the end of the pole and start a grinding motion, you might get friction or

even a spark under such a condition which will ignite the cartridge. There isn't any need for that.

NATHAN C. ROCKWOOD (Rock Products, Chicago): Don't the cartridges ever jump off? What is your factor of safety in the hold of your peg on the cartridge?

MR. HURTER: Don't you find it necessary to put in a few notches? A great many do that.

MR. McLAUGHLIN: I will say this, speaking from my experience with dynamite, you have got to give the explosives manufacturer credit for putting out a better packed product than ever before, and you can depend on that to some extent.

MR. GROSS: You say that you lay down the dynamite ready to shoot before you start loading?

MR. McLAUGHLIN: No. I didn't. It brings out a point in detail that you may want to know. Some of you quarrymen whose books are always in red may be so financially involved as to find it a heart-breaking proposition to put an extra man out; but to all of you who are outside, it is just as easy to station a man adjacent to the loading of a hole, whose duty it is to open the boxes and lay the cartridges as used by the hole, and then remove the boxes. It is just as easy and takes no more labor, with no more dynamite exposed out of the case than reasonable usage at a time.

CHAIRMAN EVANS: Gentlemen, I want to say to you that we will be here but a very short time longer, and during the few minutes that remain we are going to have a demonstration, if I might term it such, that will put into practice everything you have heard in the last two or three hours. Mr. Thompson will make a practical demonstration of first-aid. I am sure that it will be of material benefit to you, because it can be adopted and practiced at home as well as in the quarry.

By way of introduction I might say to you that this gentleman is largely responsible for the formation of a Quarry Section in the National Safety Council, and he is not connected with the crushed stone industry.

Mr. Jay Thompson, the man who will next talk to you, is manager and secretary, and several other titles, of the Toledo Safety Council. He is big enough and broad enough—at least, tall enough—not to confine himself to the safety movement in the city of Toledo, but he is big enough to embrace all lines of endeavor.

FIRST AID AT QUARRIES

Jay Thompson, Manager, Toledo Safety Council, Toledo, O.

On this question of taking care of minor injuries, there is one point which I would like to have you consider, and that is, as we are scratched and barked from injuries in industry, we develop an anti-toxin, which protects us from blood poisoning as long as we have that particular set of germs around us. We are absolutely immune, apparently, to blood poison. We go along and bark our fingers day after day and nothing hap-

pens. But I want you to bear in mind that as in smallpox vaccination, you can scratch and scratch on a man and not have it take, and all of a sudden, for no apparent reason, it does take. He passes out of that period of being immune and becomes subject to the disease.

President Coolidge's son died from that little scratch on the heel. A great many farmer boys might have had a similar accident day after day and had nothing develop from it. The fact that you can scratch your hand and not get blood poisoning proves little. You have got to consider that at that particular time you may have run out of anti-toxin for the germs which that particular cut has picked up.

On the way here I had to use a little first aid on myself, and I will show you just what it was. I got a cinder in my eye. I looked at my eye like this (pulling the lid of the eye out with my finger) and saw it in the mirror. I might have put my finger in my eye and pulled the cinder out, but I did not. I used a little stunt which should be used only in emergency. It is, as a rule, only told to railroad men, because they are the only ones supposed to be far enough from a doctor to make it safe to tell them. Take two matches, light them, blow them out and then sharpen one with the other down to a little needle point. Then you have an antiseptic needle that is free from slivers, and with reasonable care you can remove an ordinary particle with safety.

Infection the Big Danger in Eye Accidents

In addition to that I went into a drug store and bought some boracic acid and a little eye cup and washed the eye out.

Don't forget that your big cause of danger in eye accidents is infection. You can cut an eye quite seriously and the doctor can repair it as long as infection is kept out. In fact, the eye is one of the most quickly healing parts of the body.

This is all I will say concerning minor injuries. They are largely in your plant a matter of discipline as to whether you have your rules followed out or not.

Now I am going to get into pure safety work, which is selling the safety idea. In that you will use visualization, sales letters, campaigns, contests, and with every sales proposition you will find some failures. It does not follow that the contest has been a failure if there are some accidents. You have got to keep the subject alive. Try a half a dozen different things.

In an individual case in a plant up at Elyria, a safety man had had a hard time to get a workman to clean up with his crane before going home at night; he tried all kinds of schemes, all kinds of appeals. One day he went to him finally and said, "Jack, I want you to tell me something. There are three or four ties down here along the side of the track. I have talked to you about cleaning up and you have not done it except while I was talking to you. Now, if a railroad man fell over one of those ties tonight and lost his leg, or lost his life, left a family, would that be absolutely his fault? Or would there be some part of the accident that would be your fault?"

The workman admitted he had never looked at it in that way. And this safety man, after about eight months, told me that never again had he found anything left in the way of a railroad trainman who would have to work in that plant after dark. There are millions of ways to teach safety, if you will get the right psychology for putting over your sales proposition.

Take a certain case in California, where the manager called in every man. I did not look at this as a case where the men were bawled out for getting into trouble. I considered it a case where the sales manager had found a customer who was not buying goods, and called him over and talked the matter over with him, man to man. That kind of psychology, calling a spade a spade, and the manager of the plant himself getting in on the matter, is the all important element in putting over safety. If the managers will go that far, they will get results.

Bleeding to Death is a Very Rapid Process

To demonstrate safety, I have a sort of a ritual for first aid. It takes only from three to seven minutes for a person to bleed to death. You have two hours to take care of most infections, but you can bleed to death very quickly from a serious cut. To emphasize the value of safety work and to emphasize the value of medical attention, I want to go through this little ritual, which you must pass on to other people if it is going to amount to anything. You have to be in this safety game just like these little danglers along the railroad where there is a bridge. Each of you must be a rope that is going to knock somebody on the head. I do not mean knock them down, but tickle them up and tell them something is going to happen.

For a cut in the palm of the hand, fold the meaty portion of the hand down, close the fist, squeeze it tightly, and walk to the doctor. Have the injured person hold it higher than his heart. He won't bleed to death.

For a cut in the wrist, which might happen anywhere—and don't forget you have got to put this over in the home; you have got to have it with you all the time—for a cut in the wrist place one finger above the cut and one below. A steady pressure—you have got it. He won't bleed to death. You don't have to get a rope and a crowbar and put a tourniquet on. Your patient won't bleed to death with this grip.

For a cut in the forearm, just imagine this upper arm of mine is a broomstick, with a rubber hose running under it through which a valuable liquid is flowing. Imagine a cut in that rubber hose, and now press your fingers up here on the upper arm as if it were a broomstick. You don't have to take his coat off. You rest the arm up over a chair and the hand goes to sleep because you have stopped the pulse. Just a little pressure with your fingers does the trick.

Take this wrist shut-off and apply it to the throat, one thumb above and the other below the cut. With this grip you can walk your patient to the hospital. I know a doctor who walked a man to the hospital with two of those big veins cut, two blocks, and didn't get the patient's collar bloody.

Here is another shut-off, a little V is here in the shoulder blade. Put your finger down in this V and press good and hard. By this you have shut the blood all off, just like turning a tap.

A little girl on the Boston L had her arm cut off near the shoulder. In three minutes she was dead because no one knew enough to put his finger in that little V and press down there good and hard.

You have the same shut-off in the leg. It is half way down in the groin. Use the heel of your hand. Shove it in good and hard, because that part has some meat around it on most people and requires more pressure than the shoulder.

Another way to perform this shut-off is to use something similar to a bath towel or a jumper; tie a knot in it, put the knot in the groin, one end through the belt, tie it in back with a square knot, and then give it a little twist with your hand. It will produce the pressure on this groin shut-off and the person's life is saved.

If a foot is cut off, if you should shoot it off while out hunting, the shut-off is made with the fingers here in the hollow of the knee with the thumbs on top. You can use something the size of a billiard ball in the hollow of the knee and tie the leg back to add to the pressure. In cases where you use a tourniquet, you have got to loosen it up every ten minutes to keep the blood from coagulating where the pressure comes. If it does, your victim is just about as good as dead. When you have a blood clot form in a large vessel, it is quite apt to float back to the heart. You must let it wash itself out.

Using the Tourniquet to Stop Bleeding

If you were out motoring and a man had a cut in his forearm, a bad one, and you wanted to drive your car and get him to a doctor, you couldn't hold him and drive the car. You should take your tie, pass it around the upper arm, get a little piece of wood, tighten it up and fasten it, so that it wouldn't unwind, then drive for ten minutes—stop—open the tourniquet up, let a little blood out to wash itself and then fasten it up again. Drive another ten minutes. Repeat.

When you have once put a tourniquet on a man, it is your obligation to him to see that it is taken off. In other words, stay with him. There have been cases where a tourniquet has been on under the coat of a patient and it was not removed in time.

When you are putting a tourniquet on, use a broad strap like a belt or a tie. Never use a piece of wire or a small piece of rope, because these may injure the blood vessels permanently and the doctor may not realize it. If he does, he can go in and cut them open and patch them together again and take care of the distorted nerves and so forth. But that is an awful chance to take. Use a wide tourniquet.

For puncture wounds, you have your ten fingers. In gun shot wounds, falling screw drivers, or any kind of a puncture wound, put a finger in the opening. It is better to take a chance on blood poisoning than it is to wait that three or four minutes and be as fussy about it as you might; you may not get anything that is cleaner than your finger when you do.

For simple cuts (say a man had a cut across the top of the forehead), put one finger on one side and the other finger on the other side, and close the opening. Don't apply a big wet rag and expect the cold water to make the blood coagulate. It won't. Water will keep the cut open. Close the opening, and in 40 seconds it will start to coagulate. Then if you have any first aid material, put a little strip of adhesive across the center of the cut and take the patient to a doctor.

If you have multiple cuts on the scalp caused, perhaps, by being thrown through a windshield or hurt in a quarry, just shut all those blood valves off with a little pressure applied by means of a belt or tie passed around the head at the forehead. There will be no loss of blood with this shut-off, absolutely none.

In cases of broken bones, a leg broken in a quarry, perhaps, take any cloth, make a pad, shove it between the knees and then tie the legs together. Put your first tie just above the break and tie four places in all; one above and one below the knee, one at thigh and one at the ankles. And one other thing, remember to fasten the toes together, so that the leg won't wobble. Your main idea is to relieve the patient from shock and pain and keep him from getting in any worse condition than he is when you find him.

A Compound Fracture May Result from Carelessness

Arms are taken care of by just fastening them to the torso. For a broken shoulder, fasten the arm to the torso. A doctor told me of a case in Pittsburgh where a man had both legs broken. They just bundled him into a taxicab, and they had two compound fractures when they got to the hospital; the bones had punctured through. It took the doctor four months to keep that man from losing both legs, whereas if they had fastened the two legs together, with a piece of board down the middle of their pad, they would not have had such a serious case.

All this information is, we believe, so elementary that we are teaching it in the elementary schools in Toledo. We taught it to children last summer on the playgrounds and they learned it. They had to be members of the playground safety club. You fellows ought to get it in one demonstration and you ought to pass it on to others.

After you have stopped the flow of blood and looked for broken bones, your next move is to return your patient to consciousness. If one of you men had fainted while I was talking about puncture wounds, and occasionally that does happen, I would have walked over to where you sat. I would have put your head down between your knees and held it there for a minute, you would have come up by yourself with a nice red face. When you faint the blood goes down to your stomach and the face gets white. If a man falls down in a faint, pick up his heels and push his knees in on his chest.

A sunstroke is just the opposite. Your face is red from blood rushing to the head; also with a fractured skull your face is red and your breath is short and sharp. Your remedy is to elevate the head. The blood is

up there; you want to get it out of the head. Lift the head and put your cold compresses on the back of the head. Then you have done all a layman can possibly do to bring that fellow through.

Treat a sunstroke and fractured skull just the same. When the face is white, lift the heels, and when the face is red, lift the head, just like you would a bottle if you wanted its contents to go one way or the other.

For drowning or electric shock you have to apply what is popularly known as the Schaefer method of resuscitation. We will call it artificial breathing. Any one of you can squeeze the breath out of any girl you ever had. That is resuscitation. That is elementary resuscitation. If you do that at the intervals at which you breath, you will bring her back to life.

If they are out from electric shock or any other form of suffocation, it is not the best way to do, but it fills the bill.

I have here a little bottle that will show you the operation of your lungs. The sides of the bottle are the walls of the chest. The little balloons inside the bottle are the lungs. A rubber at the bottom represents your diaphragm. It is what you exercise when you laugh.

Press on the diaphragm and the balloons collapse. Remove this pressure and the atmospheric pressure rushes air in and fills the lungs again. In the case of this bottle they collapse completely, but in the case of the human being, they do not collapse completely. There is 25 to 40 per cent residual air left in your lungs in order to keep the walls separated from each other.

The Danger in Some Pump Breathing Machines

The danger of some pump breathing machines, which are still used in a number of places, although they have been abandoned in large industry, is the collapsing of the lungs. The mask which is put over the face, particularly after it is a little old, loses a little of the air which the pump pushes in; then when the pull of the pump draws the air out of the lungs, more comes out than goes in. Eventually you have pulled that 25 per cent out and the lungs collapse. If you do not know what has happened, (and the chances are you won't know) your victim is soon beyond any help that can be given him.

In electric shock you have got to remember that the cause of suffocation is the paralyzing of the nerves that are right around the mouths of the little balloons in your lungs. They are paralyzed. They are contracted. And a countershock tends to make them vibrate and open up so that you can get air in and out. You can countershock in several different ways. One is to just slap the victim on the cheek. The old way of applying resuscitation was to pick up the victim's heels while he was lying on his back and let them drop to give him a countershock on the heels. But that has been passed up for the slap on the cheek. That does the work just as well. After starting resuscitation in electric shock, get someone with a stick to give your victim a "hot-foot" about every five minutes as a counter shock.

Your patient's position is flat on his stomach with one arm out in front

of his head, for the purpose of keeping the tongue from going back into the roof of the mouth. The cheek is laid on the other hand in order to keep the mouth up out of the sand or dirt and to make sure that you have a free inlet and outlet for air.

In getting a man in this position, you do not do it all at one time, but you keep giving him a bump on his breathing apparatus. You want to get that circulation of air. In fact, as you carry him in out of the water, or pull him out of a room that is filled with gas, or from some other awkward place where you can not work on him, try and give him a few squeezes in some way. The linemen in Cleveland, as they come down the pole with a man who has been electrocuted, have one arm around him, and they keep giving him a jolt, trying to get the air circulating through him. The quicker you get it going, the more confident you may be of results. If your victim has gone so far that he is completely out, you do not need to worry about hurting him. Do one thing at a time, and between times give him a little circulation of air.

Practical Instruction in Prone Pressure Method

Now, to get the position of your hands, you kneel astride of one knee of your patient, put both palms on his back and pull them back sharply till they come to a natural resting place, at the hollow of the back. Turn them to an angle of 45 degrees and you are on the floating ribs. Keep hand away from the spine, with about the width of your hand between the heels of your two hands. Keep your fingers parallel with each other and do the work entirely with your back. You can not help but make air circulate in that position.

Now, if you want to change operators, if you have knelt over one knee, then another man can kneel over the other knee, and as you are applying pressure he can give you an elbow, throw you away entirely, and then drop into place with his hands.

The ritual for this is, "Out goes the water, in comes the air"; and that will time you fairly well. "Out goes the water, in comes the air." When you say "Out goes the water," you are pressing down; "In comes the air," you are sitting back on your heels getting a breath of air yourself. If you hear any noise which might indicate an obstruction in the air passages, it is probably something lodged in the patient's throat; maybe a cud of tobacco or his false teeth. Set yourself back a little, give him a little harder thrust and remove pressure slowly, and you will find whatever is in his mouth is right where you can get hold of it with your fingers and remove it.

One life saver told me of an amusing case where he brought a man back from drowning and the man got mad because they had lost his false teeth in the shuffle. That really happened out east of Cleveland.

Occasionally you will hear of infants choking to death from croup. I know of a case where the fire department of Shaker Heights was called out and when it got there the woman met them on the porch and said, "My baby is suffocating with croup." Those firemen walked in and revived that child, a two year old boy, by the Schaefer method of resusci-

tation. She happened to use the word "suffocation." The child had suffocated from croup. They knew what to do for suffocation and they went ahead and did it, and they got a big return.

In case a child should get an apple core or something of that kind in his throat, slapping him on the back may help, as it knocks some of the wind out. If it don't, place your hand right over the floating rib, grip his heels with your knees, then give him a thrust and come back slowly, so the gust of wind coming in does not pick up the object and force it back.

You can all use this first aid. You don't know how soon you may need it. I hope not soon, but all ought to know how to save life by these methods.

I hope you will go out and begin selling this idea of first aid. It will pay you in your plant to know how to use these finger shut-offs. You are going to use them every once in a while.

A man bled to death from a little cut in the cheek, where a man held it open and poured water in it. If he had worked the other way and held the cut shut the man would not have lost any blood at all.

CHAIRMAN EVANS: Jay, I want to thank you in behalf of the members here and also the victim for the practical demonstration. If you will be patient for a minute, we will listen to the report of the Nominating Committee. Unfortunately, the Chairman was compelled to leave on the one-thirty train. Therefore, the duty of advising us as to who your officers will be has been delegated to Mr. Thompson.

MR. THOMPSON: The recommendations are as follows:

Chairman: L. R. Cartwright, Mid-West Crushed Stone Co., Indianapolis.

Vice Chairman: D. C. Souder, France Stone Co., Toledo, Ohio.

Secretary: A. C. Hewitt, American Lime & Stone Co., Bellefonte, Pa.

CHAIRMAN EVANS: If there is no objection on the part of the members here, the report of the Nominating Committee will be accepted as final and considered an election of the officers that have been designated. I want to thank the Nominating Committee and also congratulate you members on having secured the services of men who will be competent to carry on the work of the Quarry Section of the National Safety Council.

ADJOURNMENT

Rubber Section

New Officers of the Section

CHAIRMAN: W. L. SCHNEIDER
The B. F. Goodrich Rubber Co., Akron, Ohio.
VICE-CHAIRMAN: M. A. QUIRK
United States Rubber Company, Detroit, Mich.
SECRETARY: R. C. SALISBURY
Fisk Rubber Company, Federal Division, Cudahy, Wis.

Committees

POSTER: C. L. HUNGERFORD, Chairman
The Firestone Tire & Rubber Co., Akron, Ohio.
PROGRAM: E. R. LAWLER, Chairman
Hartford Rubber Works Company, Hartford, Conn.
STATISTICAL: S. MANSFIELD, Chairman
The Goodyear Tire & Rubber Co., Akron, Ohio.
SAFE PRACTICES: HOWARD W. LOW, Chairman
The Miller Rubber Co., Akron, Ohio.
HEALTH HAZARDS: DR. J. NEWTON SHIRLEY, Chairman
Hood Rubber Co., Watertown, Mass.
MEMBERSHIP: R. H. COCHRAN, Chairman
Kelly-Springfield Tire Co., Cumberland, Md.
ENGINEERING: J. E. CONGDON, Chairman
United States Rubber Co., New Haven, Conn.
ADVISORY COMMITTEE: H. H. GRAEF
The Goodyear Tire & Rubber Co., Akron, Ohio.
E. W. BECK
United States Rubber Co., New York City
E. A. HOENER
The Firestone Tire & Rubber Co., Akron, Ohio.
A. L. VILES
The Rubber Association of America, Inc., New York City.

October 26, 1926

H. H. GRAEF, Chairman
Manager, Employees' Service Division, The Goodyear Tire & Rubber Co.,
Akron, Ohio.

THE Rubber Section of the National Safety Council, convened at the Hotel Statler, Detroit, Michigan, at 10:00 o'clock, Mr. H. H. Graef, chairman, presiding.

CHAIRMAN GRAEF: The first thing on the program is the reports of the various committees. I will call on Mr. Salisbury, vice-chairman, to make his report covering his activities for the past year.

R. C. SALISBURY (Manager, Health and Safety Department, The Fisk Rubber Company, Cudahy, Wis.): The activities of the vice-chairman were confined somewhat to just the getting out of a monthly news letter. Some of the outstanding features of the work were getting the smaller companies to assist us or to participate in the news letter itself.

We heard from Van Cleef Brothers in Chicago. They had submitted an idea to prevent rolls of stock standing on end from falling over. R. B. Harkness of the Cupples Company of St. Louis volunteered some information concerning fires from sulphur.

Altogether, we produced during the year but seven news letters. If I made a report without stating that the editor of the news letter should have more active cooperation, I would be failing to say something very necessary, because as most of you know the news letters can not originate from one man, nor be kept up by one man; and I would like to solicit your cooperation, your much better cooperation, for him than was given during the past year.

CHAIRMAN GRAEF: I might say that our original plan was to get out one news letter each month for the Rubber Section, and we did not necessarily intend to confine that news letter to the rubber companies that are members of the National Safety Council; in fact, we felt that it might be a medium for having companies which had previously shown very little interest in our work become actively associated with us.

Our chief idea was to have this news letter not only serve as a medium for the exchange of our ideas and experiences, but also to have it serve as a medium for making inquiries and getting replies from various companies, using that as a channel.

We hope that in the year to come, now that we have got it started and the rubber companies know what we are trying to do, they will cooperate a little more closely and give us enough material to get out the letters according to schedule.

Next I will call upon Mr. Schneider, the secretary, to give us his report.

REPORT OF W. L. SCHNEIDER, SECRETARY, RUBBER SECTION, NATIONAL SAFETY COUNCIL

Your secretary has attended the meetings of the Rubber Section Executive Committee, which were held on November 20, 1925, at Akron; March 5, 1926, at New York, and June 16, 1926, at Chicago.

He has furnished the members of the Rubber Section with the minutes of these meetings, following up the detailed correspondence in connection with the same, and carrying on the routine correspondence.

In addition he has assisted the various committee chairmen in every way possible in connection with their activities.

He has also corresponded with the Rubber Section members in regard to criticisms and hearing of the proposed Mill and Calender Safety Code of which the Rubber Section and the International Association of Industrial Accident Boards and Commissions are joint sponsors.

The chairmen of the various committees will render separate reports.

CHAIRMAN GRAEF: Mr. Schneider has certainly fulfilled his obligations to the Rubber Section in a very conscientious way during the past year. There has been an unusually large amount of correspondence due to the fact that the question of the Code for Rubber Machinery has been, I might say, paramount in our activities, and Mr. Schneider had all of the inter-committee correspondence on that subject.

The next report I would like to have is from the chairman of our Membership Committee, Mr. Lawler.

REPORT OF EDWARD R. LAWLER, CHAIRMAN, MEMBERSHIP COMMITTEE

Number of members in Rubber Section September 25, 1925.....	43
New memberships during the year.....	4
Memberships cancelled during the year.....	4
Total number of members in the Rubber Section to date.....	43

During May, 1926, with the assistance of W. L. Wheeler, Service Extension Department, National Safety Council, we sent out over 100 letters to rubber concerns. These names were secured through the kindness of the Rubber Association of America who are members of the Rubber Section. Evidently our sales letter didn't get across, as I believe only about two of these new members are due to our letter. Very few even acknowledged our letter and total replies were only about 15.

In addition, we wrote several other concerns who made inquiries and supplied them with detailed information plus bulletins, copy of the *National Safety News*, etc. Some of the replies read like this: 'We are members of a local safety council, making available to us a vast amount of literature, posters, etc., and we feel we are engaged in this work to a sufficient degree.'

"We feel that our safety program is sufficiently well organized and posted to serve our purpose."

"Our insurance company handles our safety work in a satisfactory manner."

In the replies of several, reading between the lines, it seems to be a question of finance for not becoming members. Although interested, it was impossible to overcome this condition in spite of our stressing a greater saving in an earnest effort to firmly establish safety in their plant.

Personal contact is the principal factor in selling our membership and possibly the new chairman will be in a locality where there are opportunities for visiting prospects, as letters in many instances receive scant attention.

Present members are the greatest assets we have to assist in this work and we trust during the year to come they have the time to assist us in increasing our membership.

EDW. R. LAWLER: Just one other thing more. It was impossible for me to go and visit rubber companies located outside of my state and for that reason we had to depend upon correspondence. Mr. Schneider, the secretary, did a lot of personal work there. He wrote to friends that formerly worked with him, and also gave me one or two other leads, and while we were not successful, in time we may be able to grab them off.

Our membership remains the same, but I think if any of the members know of concerns that are not members at the present time and have any one there they can get in touch with, in that way we can gain members. I think we can do far more that way than we can by writing just to strangers, you might say. So if during the year any of the members will assist the new membership chairman by submitting names and assisting in that way, it will help considerably.

The Small Manufacturers Need the Council

E. W. BECK (Supervisor of Safety, United States Rubber Company, New York City): Adding a few words to Mr. Lawler's report, some of you might be interested in knowing that the National Safety Council has taken this question of the small factory into serious consideration, trying to see what they can do to get the small manufacturers into the National Safety Council. It has been quite a difficult task. They have hired a field secretary, a field man to go out and make personal contacts with these smaller concerns.

They have run up against the same thing that Mr. Lawler reports, that is, they feel that they are getting all they can from the insurance company, and that their work or their experience does not justify any expense. Now I think the problem is to sell them safety rather than to sell them a membership. The problem is to sell them safety because if they are sold on safety I think they naturally will join the National Safety Council.

It is a personal job, you can not do it very well by correspondence. It is a case of all of us pitching in and doing what we can with the industries in our territory that we can get to join.

CHAIRMAN GRAEF: I intended mentioning the experience the national organization has had with these small factories, which included any plant where there were from 200 to 300 employees. They had a man out who made on an average four calls a day for over a month. I know in our Section we have always felt that personal solicitation is the best method, and I think there is no question that it is far easier to explain what you are trying to do in a few minutes in personal conversation than it is to try to do the same thing by correspondence. Our committee has always been handicapped in this respect due to the fact that the man who was in charge of our membership work was

located in a certain city and had his regular job to do for his company. He had no way of getting traveling expenses or the time to make a trip around the country interviewing people in these smaller plants that were not members. For that reason we had to confine ourselves almost entirely to correspondence, except where we could call on some member of the executive committee who was not necessarily on the membership end but was located near a plant that we wanted to get in contact with, and ask him to go out and make the contact for us.

I think that is what you are going to have to continue to do.

What the Rubber Section is really fundamentally interested in is having the various rubber companies know what activities we are engaged in and what benefit that work would be to them if they actively participated in it. I feel sure if we get a point of contact with some of these companies who are not now associated with us, and can get them to see just what we are doing, they will come in with us; not just because they are going to join the National Safety Council, but because they realize that the work we are trying to do is valuable and beneficial work and they can derive equal benefit in participating in it.

Now next I would like to call on Mr. Quirck, chairman of our Poster Committee.

REPORT OF M. A. QUIRCK, CHAIRMAN, POSTER COMMITTEE

Last year when I took over the chairmanship of the Poster Committee, it was a pleasure to find that Mr. Sanders, my predecessor, had very capably and successfully carried on his work. He turned over to me or the council sufficient posters to carry us through at least the first three or four months of the period I served. Naturally that gave me some good ground to work with. In April, when our posters got to the point where we needed more, I sent out an appeal to all members of the Section. I was rather discouraged in the results from this first batch, because we received only three replies. Fortunately in the replies we did get, we got 33 cartoons and photographs. I think it is only fair to mention those people, the Fisk Rubber Company, the Hartford Rubber Company, and Mr. Sanders, of the Kelly Springfield Company.

Realizing that we had to get some material for the future if I was to leave the Poster Committee in the same condition as I found it when I took over the chairmanship, I immediately started to send out individual appeals to people whom I knew and who would come through; and I must thank three members again, Mr. Lawler, Mr. Partridge and Mr. Sanders, and myself,—I think I owe myself thanks too.

It was my thought when the new chairman took over the work he really would have some material to work with, and in the communication that I just received from Mr. Keefer—and Mr. Gardiner, they inform me that the Council is well prepared right now to go into next year and carry us over nicely through the Congress.

I think we take the wrong attitude. I don't think we cooperate enough. At one time every poster I saw was a Goodyear Tire and Rubber Company poster. I do not think it is fair to let one firm or one man do it all. I think if we would all resolve right now to go out and make just one poster next year, just imagine what we would accumulate! I think if the next chairman would assign to each member some particular hazard he wanted to work up into a good poster, have us work it up and send it in, we would accomplish something, rather than go away from this meeting and have the chairman start in anew when he does not have anything to work with. If the new chairman does that and if we all resolve to leave the meeting with that one thought, that each one come through with one poster next year, we would have enough to go through two years. I would like to make that as a suggestion and put it up to the new chairman.

The condition of the Poster Committee now is pretty well taken care of, and I think when I turn over the material I have to the new chairman he will be pretty well fixed for the new year.

CHAIRMAN GRAEF: I think Mr. Quirck is right, along with the other gentlemen that he mentioned. He really has a great deal of credit coming to him personally. He has done a lot of work and he has done it all practically single-handed.

I am going to omit the report of the Special Reports Committee this morning, and I would like to appoint next the Nominating Committee, and ask them to be prepared to make their report at our meeting tomorrow morning.

The Nominating Committee is Mr. Hoener, of the Firestone Co., chairman; Mr. Lawler, of the U. S. Rubber Co.; and Mr. Mansfield, of the Goodyear Tire and Rubber Co.

I feel personally that we have been very fortunate in having Mr. Weston, the president of the Ajax Rubber Company, come here and talk to us this morning, and I know he is going to have something very interesting and instructive for us.

ADDRESS

J. C. Weston, President, Ajax Rubber Company, Trenton, N. J.

I am quite certain you will agree with me that anyone should experience a feeling of gratification for an opportunity to say a few words to a group of men who are taking such a necessary and constructive part in present day spiritual, educational and industrial progress; and I have already begun to feel a degree of inspiration in the realization that I am participating, in a slight degree at least, in a meeting of men whose statements and a report of whose activities are awaited by the whole industrial world with a considerable degree of eagerness.

Also, I am experiencing a certain measure of fear or awe at standing in your presence and realizing that I am not as familiar with the detail of your work as I should be; and perhaps in my official capacity as head

of a manufacturing company I have not devoted sufficient time to the development of safety measures; so here I am in a decidedly mixed frame of mind, gratified on the one hand and a little frightened on the other, and, believe me, it is rather a paradoxical thing to sit in a National Safety Congress and be afraid.

I doubt if the average business man fully appreciates the constructive effort that is constantly being made by the men who constitute this great national organization. Perhaps one of the reasons for this lack of appreciation is the commonly accepted belief that safety work is absolutely necessary—it must go on because of the constant daily need—therefore it is easy to assume that it is being carried on. Also, we read in trade papers, the daily press, and magazines, articles written for the purpose of indicating the great advance that has been made respecting safety devices and the adoption of methods that direct and coordinate movements of men and women in their daily tasks.

Statistics Say We Are Getting Better

Statistics are turned out by the ton which prove that we are getting better "every day in every way." However, it would seem that a greater measure of appreciation respecting this important phase of our daily lives might be developed if we were to engage in a little deeper thought regarding the meaning of safety work, and apply for the time being a different yardstick to measure its purpose and progress.

First, it would seem essential to consider safety in the broadest manner possible. In other words, eliminate from our thoughts with respect to safety that it means only prevention of accidents in factories, on railways and on our highways. At least we might set aside these common, every day, safety difficulties which most often come into our thinking whenever the word "safety" is heard and turn back the book of time to the early association of men in an endeavor to accomplish all the tasks of life.

We should not think of safety as something new, something that has been discovered by the great industrial minds of recent years, something that is dependent wholly on "good business," but rather we are concerned with the progress of one of the oldest phases of our lives and that is the protection of the body and mind against all of the elements of destruction.

Let us take the development of our own country. In the beginning, it is quite natural to assume that men worked at the tasks of that day, clearing land, planting, harvesting and other similar activities in small groups, undoubtedly in a cooperative way in order that the small communities might exist; and because of the stress of primitive conditions we surely would have found efforts being made to provide safety. In other words, spiritual safety, moral safety, safety with respect to such hardships as hunger, disease, and many other things. In fact, the acceptance and application of the Golden Rule which is nothing more or less than the practice of safety.

Undoubtedly the United States of America enjoys a unique reputation

throughout the world for the development of machinery for use in the production of nearly every article necessary to human existence and comfort. It can not be said in truth that our machinery supplants or replaces hand labor but rather it is a cooperative element in aid of such labor; which, considered in a broad sense, improves the quality and usefulness of all articles produced and, of course, permits of production in such great quantities that costs are lessened to a marked degree. Hence as a commercial nation we are able to hold our place among the nations of the world even though labor and living costs are lower in most other countries.

It seems fair to assume that the development of machinery in our country proceeded more rapidly than our understanding of its operation by groups of men; or, to express the thought in another way, the development of machinery quickly brought about the building of large factories and the consequent grouping together of large numbers of men and women and, in this rapid development, perhaps little thought was given to the confusion and the lack of coordination between the human being and the machine. Hence a long period of time may have elapsed before there came the realization that educational and supervisory organizations must be built to prevent the machine working even a slight degree of injury on the mind or body of the workers, and undoubtedly with this recognition of the needed readjustment with respect to man and machine we gave birth to the present day safety idea.

Safety Work is Not Inspired by Fear of Laws

Too many people think of safety organizations in factories, or safety work with respect to railways and highways, as something which is inspired by fear of regulatory laws or that it has been organized and is conducted by industry because "it pays" in dividends or in reduced compensational losses or lessening of legal battles with respect to responsibility for accidents; whereas if one will give the matter a sufficient degree of thought, it should not be difficult to see the true meaning of safety work—that it is a very important part of the progress of civilization. In fact it stands out as a symbol of the development of our national life in the same degree as the work of leaders in medicine, law, engineering and other major agencies for progress.

As industry is organized at the present time, we are trying in every way to produce more and better goods with machinery, to work shorter hours in an effort to increase our earning capacity at the same time, in order that we may live more complete lives and participate in all of the known and accepted comforts and pleasures of life.

Undoubtedly our eagerness to participate in all these things, produce all these things, makes for a degree of carelessness which requires that we shall be watched over more than ever. Therefore, the future for safety work undoubtedly holds greater opportunities than have ever been presented. This situation is rather paradoxical as one would naturally conclude that a greater development and refinement of the "human critter" would make each individual think for himself. However, that does not

seem to be true and here we find ourselves working in the mass, so to speak. Mass production of manufactured goods, mass enjoyment of sports, mass living in cities and community efforts taking the place of individual social activities—hence the greater need for organized safety; and inasmuch as the rubber manufacturing industry is the specific concern you gentlemen are interested in, I might say that what applies to all industry and all civilization is equally true of the rubber industry—in fact, a little more so, as it is one of the outstanding industries rendering service to mankind in every phase of life.

I am satisfied that we are going to make greater progress in this industry with respect to the establishment of safety organizations, in appreciation of what it means, and that we will all “put our shoulder to the wheel” to help in this great work, not because it means minimizing the losses of respective companies with respect to accidents in the factory, not because we fear municipal, state or federal legislation governing the use of machinery, not because we fear the antagonism of our workers, but because of the big, broad conception I have tried to convey to you as to what safety means in the whole progress of civilization.

We must teach safety by individual example, promote its practice and try to realize each day that organized protective effort, as represented by the National Safety Council, is one of the great world movements built up on the foundation of the good old Golden Rule—“Do Unto Others as You Would Have Them Do Unto You.”

Cooperation With the Rubber Association Expected

CHAIRMAN GRAEF: Mr. Weston has hit the nail right on the head when he says our chief activity and our chief source of trouble is failing to have the workman educated up to the point so that he takes care of himself, in spite of what we may or may not do in making the machinery at which he has to work as fool proof as possible.

As to Mr. Weston's suggestion with regard to the rubber association and the help which he feels they can give us, I feel safe in saying that he will undoubtedly hear officially from us. We will be very glad to accept his suggestion and we hope that it will turn out as favorably as he thinks it will. That is one of the things that the executive committee has hoped for and wanted for a number of years, but we never have quite reached the point of doing what Mr. Weston suggests this morning.

I appreciate, and I am sure we all do, Mr. Weston making this trip here to give us this talk, and I personally got a lot of good out of it. I want to thank him in behalf of the Section.

MR. WESTON: It is a great pleasure, indeed, gentlemen, for me to be here.

MR. BECK: It has been a great pleasure to us. I want to assure Mr. Weston that those present this morning represent a very large majority of those employed in the rubber industry. No doubt you realized that.

When I analyzed the statistics which you mentioned, I went right

to my own figures of the United States Rubber Company, with its 23 factories, and I found, just as you anticipated, that those companies that are organized in safety do not have the high rates that are mentioned in that report of the Labor Department, and there is no question but what the smaller rubber industries have had a great deal to do with running up that rate. Those are the fellows that we can help and we can help them best through the rubber association. In other words, the rubber association can help us and we can help them. I feel that we should have their close cooperation.

MR. LAWLER: Talking for Mr. Weston's information and your information I know we took up with the rubber association the question of getting a list of names. I think there are approximately 175 members of the Rubber Association of America. We only have 43, and so you see there is a great deal of difference; there are 125 to work on. I second the motion on that being a wonderful suggestion.

CHAIRMAN GRAEF: In connection with the next item on our program, the idea we had in mind was that in spite of the fact that one of our plants may make boots and shoes, another tires and another hose, (and there are a thousand and one things that are made in our different plants), still there are many conditions in all those factories that are similar where the same hazards exist and we all have the same fundamental problems.

Perhaps in one plant you have attacked this problem in one manner and in another plant you have tried to solve the same question in another way.

Not getting together any more frequently than we do, not having any way of visiting back and forth and seeing at first hand the things which we are doing in our factories, we thought perhaps we could get together a group of pictures showing these hazards and how they have been protected and taken care of in different factories. If we saw three or four ways or a half a dozen ways of taking care of the same thing, and had a little explanation from the man who had furnished us with this information, we thought it might help us to improve conditions materially in our plants.

Planning the Presentation of Safety Kinks

With that idea in mind we asked Mr. Sanders, of the Kelly-Springfield Company, to get this material together for us and have it put in the form of lantern slides so we could project them on the screen this morning and get a little explanation of just what the hazard was and what had been done to eliminate it.

Mr. Sanders recently left the Kelly Springfield Company, and took a position entirely outside of the rubber industry, and Mr. R. H. Cochran, who is now connected with the Kelly Springfield Company, very kindly consented to complete this part of the program for us. He had no conception that the job was going to be shoved on him until the last

minute, and I want to assure him personally that I appreciate very much his undertaking to handle it.

I think perhaps the way for us to get the most good out of these pictures is to ask the man who has furnished us with this material to give a brief explanation of just what the picture covers, and in that way we will get the information correctly and first hand. Every one may feel perfectly free to ask any questions.

SAFETY KINKS

R. H. COCHRAN, Kelly-Springfield Tire Company, Cumberland, Md.

(Slide.) MR. COCHRAN: That is a bead flipping machine. We had several accidents with the rolls. You can see them there just under the guard. We put that guard on. Since that time, about eight months ago, we have not had an accident. I would like to ask of any firms that use that kind of flipping machine, if you have got a better guard, any better type of guard? That is one of the first types they made; the "Utility."

(Slide.) MR. COCHRAN: That was a shower we placed close to our dipping tanks. In case the workman should catch on fire, all he has to do is to step under the shower and pull the lever out.

R. B. HARKNESS (Cupples Co., St. Louis, Mo.): Mr. Chairman, doesn't water have a bad effect on certain burns?

MR. BECK: I know of one plant in particular where they have an oil bath, a large boiler with linseed oil in it. In case a man catches his hand on fire, he can dip his hands right into that oil bath, which serves the purpose very well. I do feel, however, in the case of clothing being on fire, that this is much better than dipping in oil.

MR. COCHRAN: Some of the workmen are in the habit of wearing overalls so long that they become full of cement, gasoline and benzole and readily catch fire.

W. L. SCHNEIDER: I might mention in that connection—Mr. Cochran mentioned overalls getting full of cement and I suppose he means solvent—we have a quick removable apron, which the workman can take off at the slightest pull. The material is made of treated fabric to repel the cement solvent. The material itself is made by the Cleveland Liner and Manufacturing Company in Cleveland, Ohio. It is a very easy matter to make the aprons out of it, just the application of a strap and clips.

(Slide.) MR. COCHRAN: This picture shows a Cameron bias cutter. Once or twice we had that cable break, and when it does it flies around and might hit the operator. So we put those guards on, to guard the entire cable both below and around the wheel.

(Slide.) A. M. PARTRIDGE (Fisk Rubber Company): The guard is at the lower end of the knife carriage. The carriage comes down through the

slide there. That is exposed and we put on a metal guard. One fellow caught his finger in there as he was adjusting the knife and somebody started the machine. We put that guard on to keep them out.

(Slide.) This little box on the upper section is used to put broken blades in. They had a habit of throwing them around the floor or laying them on the edge of the machine. In one instance, somebody cut his finger. So we put all the broken blades in that box, and that box is going to last a long time.

(Slide.) That is the top of the knife sharpener which we developed in Fisk. The fellows use a large knife in the compound room and cut their hands quite often sharpening knives on an ordinary stone, so we put on that metal shield near the handle of the knife, which prevents the knife from cutting the hand. It works out very successfully.

M. A. QUIRK: In that connection we have made a rubber handle guard, so we can take off the guard and put it on a new knife. We found that it saves us considerable. It is just an ordinary rubber handle that we put right over the knife. We are using it in all departments now and it is working very effectively.

Another Guard for a Small Knife

MR. BECK: Speaking of a guard for a small knife, I came across a good scheme to keep the hand from sliding over on to the blade and cutting. Right where the index finger comes there was a small piece of metal with a slight curve to it which would keep the hand from sliding off on to the blade. It is a piece of metal only about five-eighths wide, the width of the stock of the handle, about two inches long. There was just enough curve there so it would serve to give a better grip, and it had the same contour as the index finger.

(Slide.) MR. PARTRIDGE: Here is a type of wheel that is used on friction. We had a lot of trouble when they turned those wheels by hand; the fingers of the operator would strike on the metal guard and abrade the skin. Of course, it was not a serious accident, but there is always the danger of infection. The man on the machine suggested that the spokes be built in a bowed position, so that the rim of the wheel should extend out quite a distance from the guard itself. Since the wheels have been made that way, we don't have any trouble at all.

(Slide.) MR. PARTRIDGE: This is a type of tube heater. In one instance, we had the head of one of those heaters shift a bit, and they have devised two safety pins, one on either side, that fit into a hole that is drilled right into the metal. Those pins are hung by chains so they will always be in position.

MR. BECK: May I ask if you depend upon the human factor, upon the man to put that pin in there?

MR. PARTRIDGE: Yes, we have to, of course; they won't go in themselves.

MR. BECK: We had a problem where we had a head blow off and kill

a fellow. We have designed, although we have not put it into practice yet, a device whereby automatically we lock that head. So long as there is any pressure within the press, there is an internal pin that keeps the head locked, so you can not turn it. I think that is the only safe way. While there is considerable expense in working up a device to lock automatically, it may be well worth while.

MR. SCHNEIDER: I would like to ask Mr. Beck how he controls the minimum pressure on that? Your gauge won't measure less than a pound per square inch. We have had several instances where a door has blown open with as much as that pressure on.

MR. BECK: If I remember correctly, there is a diaphragm arrangement back on the line that is very sensitive. A half pound will readily keep that pin in place.

Problem of the Pipe Wearing Through

MR. PARTRIDGE: I wonder if any of the boys ever had any trouble with this pipe wearing through? It wears a hole through there and the steam comes out. We almost burned a fellow's leg there, so now they have put metal boxes over all those locations so in case the pipe does break or the steam blows out, it won't go out sufficiently to burn anybody. There will be enough warning there to prevent them from getting hurt.

MR. SCHNEIDER: Is that an extra heavy fitting, Mr. Partridge?

MR. PARTRIDGE: Yes, it is.

E. A. HOENER: The cause of that fitting eating out is due to the fact it is on the drain end and the water, if analyzed, will have a certain sulphur content which eats out the iron. We found it economical on our tube heaters to get a drawn iron fitting on that particular place. By doing that we have eliminated all our trouble. We have found it is corrosion that causes that fitting to weaken, rather than any pressure or action of the steam.

As to the matter of the pins, we have tried out two similar devices as mentioned by Mr. Beck. Our trouble has been corrosion. We have developed a pin, an interlock, which would act upon one pound pressure. Our trouble has been that after a period of time this device became inoperative, due to corrosion. I feel there is some excellent work that can be done on this particular phase of safety work. We do not use a safety pin, but we do use a system of painting with a special heat resisting paint, so that when the door is not properly closed on the tube heaters, it leaves a gap in a circle. That has been our most successful method of determining that, because the inspector at a glance can see that possibly they have not got the door completely closed. But up to the present time I do not know of any absolutely fool proof device that has been either put on the market or developed by any one along those lines. That is a very great hazard in the rubber industry. I think a lot of work should be done on it.

(Slide.) MR. PARTRIDGE: Here is a type of guard to go in between

the rolls on the calender. That is one that was developed after a lot of study. You notice there are three or four slots at the upper edge; it has a large strip of metal going across there. Those slots were cut so that the operator on one side of the calender could look through and see the fellow on the other side.

MR. QUACK: The minute I received that picture, Mr. Partridge, I noticed that particular guard. We had the same experience. One night two new operators were on a calender and they took off the guard and one of them went in and lost his hand. So I appreciated very much the photograph. I have almost the same kind of guard you have. It shows how helpful it is if you only all shoot the stuff over.

MR. BECK: Did you ever notice, even in lower rolls on calenders, where they are spread, that quite often they could be spread more than they are? If they are spread more, if a fellow gets caught they may prevent him from receiving a serious injury. I know we had a fellow get caught where the rolls were only about three quarters of an inch apart; if they had dropped them further, say an inch and a half or two inches apart, the injury would not have been anywhere near as serious. My point is, when they spread the rolls it does not make any difference how far they spread.

A Guard for a Tube Skiver

(Slide.) MR. COCHRAN: This is a guard for a tube skiver, simply a gate which protects the cutting knife, going down on two guides. That raises and lowers as you shove the tube forward or backward. It runs down covering the sharp knife which does the skiving at the time the tube is inserted, keeping the knife fully covered except when the tube is in position to be skived. It does not slow up the operation at all.

(Slide.) This other picture shows a cement churn or mixer, simply showing the application of a fan and exhaust. It is a known fact that fumes are dense and naturally go down nearer the floor level. We have found it clears the atmosphere very readily. That is a slotted opening in the front which takes the air in and the fumes in and out through the exhaust.

(Slide.) MR. COCHRAN: This is simply the application of guard features, some of which you can not read because of the size. It simply features guarding the calender as completely as possible, the overhead chain with wind-up, and all the worm gears are fully enclosed, the pulley gear is fully guarded, the mesh wire and steel band over the face, and the pipe roll around the feed, the toe guard at the base.

MR. HOENER: One question: we seem to have more or less difficulty on the matter of safety rope or cable and a bell rope for signalling the calender. We have tried out in a number of cases an electric bell, that is, by using a push button, but due to the vibration of the machine and so forth, we have not been very successful and they had a good deal of maintenance. We finally got some cable and started a red sash cord for the safety rope and then an ordinary sash cord for the bell rope;

they use an ordinary car bell for signaling purposes. I wonder if anybody has a suggestion that might overcome the possibility of the man grabbing hold of the wrong rope when he wanted the safety rope.

Mr. COCHRAN: I think your location would have a great deal to do with that. For instance, if you simply had an ordinary trip bell with a rope on it, you could make it a short rope with a knot on the end and mount it in such a position that there would not be any question about it. The bell is visible at least on one side. If you want to go further than that, you could have a bell on each side of the calender. The rope leads to the bell. There is no question about getting the right rope.

Mr. BECK: There should be only one rope and that the emergency rope, because any man when he is caught is not sane, he is going to grab, he is liable to do all kinds of things. I feel we ought to be very careful and not have more than one rope and that rope should be hanging so if he strikes it it does not go away from him. I think it should be either a permanent bar or a cable that is fastened at both ends; but by no means have two ropes, one a bell rope and the other a safety.

Mr. HOENER: Regardless of Mr. Beck's statement that those cables are desirable and very easy to put on, at the time that first photograph was issued by the U. S. Rubber Company a number of years ago, showing that cable and bar and also bars between the rolls, I immediately equipped a calender with that particular device. Due to our operations and arrangement of the calender and auxiliary operations, it was absolutely impossible for us to keep the cable on the inside of the housing; nor did we have any success with fastening a steel cable at the bottom of the housing or putting a bar across the front. That is on account of certain other operations in the way of preheater pipes and things of that sort that interfered with that installation.

The Operator Wants the Bell Rope Handy

There is a possibility of locating those ropes in such a manner that we can do that, but it has been more or less difficult because as the man gets the stuff started, he wants to have the bell rope handy, so that he can give the signal to proceed at fast speed, instead of possibly having to walk around the side of the calender some place to get at it. There is quite a problem there. What I am primarily interested in, is to work out some system whereby we can have the two near each other, at the same time fixing them in such a manner that there won't be any question about which is which. As far as the man himself tripping the safety device, we have yet to have our first accident either in the mill or calender room. A great many of these safety devices are very good from a purely mechanical safety set-up, but we must not lose sight of the fact that in order to sell safety to the management and also to the operating department and get their cooperation, we must try to have safety devices so they will not interfere with operating methods and also either cut down speed or increase labor costs in handling equipment.

MR. LAWLER: We tried out bells and we found that they were not very satisfactory; in fact, the head calender man had to do a lot of running around. So we substituted a traffic cop's whistle, signals of one, two, three. They have worked out very satisfactorily. He has the whistle around his neck, and it is always available.

MR. QUIRCK: I was rather surprised at Mr. Hoener's remark when he said that in his case he never found where a man caught in the bite tripped the mill or calender. We just finished a survey covering about three years, and we found that in 50 per cent of the cases in our plant, the men tripped it themselves. Some three or four years ago Mr. Beck instituted a special form. The minute a man is caught in a calender we make out that special form, which tells the distance from the floor to the roll, and so forth, and the kind of trip that we have, whether the man tripped the bar himself, or whether it was some other man. We found that to be of much value in our work afterwards.

MR. BECK: In our 23 factories we had about that same proportion.

A Circular Cutting Knife Guard

(Slide.) MR. COCHRAN: Here is a circular cutting knife guard. I am not sure whether very many factories use that or not, but this is a guard device for protecting the knife. It is the only way we knew of because that knife is adjustable to cut gaskets. It simply consists of a sheet steel band around the face of the chuck. It is simply to keep them away from the knife. The rotating arm raises and lowers as the stock is put underneath on the table.

(Slide.) That is a section of a mill with guard features shown in a diagram. Cradle switch and conduit mounted on each individual mill in connection with the trip bars.

(Slide.) We clean molds that way. It consists of an exhaust system, in which the mold is put into a chamber and cleaned through an aperture. In some instances, soapstone is used; in other instances very fine sand. Of course, the exhaust is strong enough so that it does not get into the room. The workman does not have to breathe in the fine dust.

(Slide.) That is the same as the other mill shown in the previous picture with the exception that these are all hood mills; the exhaust is over the top.

MR. BECK: Have you any baffle plates in there?

MR. COCHRAN: No baffle plates whatever. There is an air washer, the suction just being strong enough to retain the compounds inside and not take them out to the atmosphere.

MR. BECK: Speaking of an air washer, in one of our locations we have quite a serious problem regarding the exhaust from one of our operations; in fact, we have exhausted every means of taking care of the fumes, even tried to wash the fumes. We are stumped practically on the problem of getting the odor out of the factory. Does anybody know how to get rid of the odor?

MR. COCHRAN: You might put in water.

MR. BECK: We did that. We put in a very expensive system.

MR. COCHRAN: I do not mean a spray. I mean a direct bath.

MR. BECK: That is what we are doing.

MR. SCHNEIDER: The Philadelphia Rubber Company has the same problem, and they have been unable to solve it. You might write Mr. Day, chief engineer of the Philadelphia Rubber Company. Probably they have got something up by now.

(Slide.) MR. BECK: When we were asked to send suggestions down to the chairman of the committee, I thought right away that one of the best safety things that we had accomplished was to establish a little competition among the factories along the lines that Mr. Weston spoke of this morning. I think our big job from now on is not so much mechanical, although we must never lose sight of that, but it is educational. I am doing a little thinking now about carrying our educational work even further than the factory itself. In some of our locations where we have one or two factories, and where we are practically the only industry in town, we are thinking of negotiating with a local moving picture house and putting on some safety educational films, not only for our employees but for the members of our employees' families.

I will say that this contest, which we have been running for several years, has assisted us materially in reducing not only our loss of life and limb but also our costs, and we have a very complete system of measuring costs, which I think is very necessary, because there are people that you can not put some things over on, unless you talk dollars and cents. I feel that the safety man should always be fortified with some cost figures. Our contest has brought about that very thing.

Guards to Protect the Bite of the Rolls

(Slide.) Here is a collection of guards we have been using to protect the bite of the rolls. There are just three rows of the calender shown, three not being necessary in this case.

We have come to the conclusion that one particular type of safety guard will not always do, especially on a calender.

We are doing now what I think Mr. Hoener is doing, putting the calenders in series, and there you have quite a different problem.

(Slide.) Some of our suggestions came from our neighbors across the border, from Canada, others from the states. The one which we are using more than any other is a stationary guard, and is made of two bars going across the bite of the roll. When we first put them on, they were stationary, and we thought it was to our advantage to fasten them to a plate on each side of the housing and allow a little play, so that if a fellow should get caught he would have time enough to pull his hand out due to the play in the rod. If the rods give a little you could tie them in the middle but we have not found that necessary. We have a standard blue print showing the spacings of these distances in accordance with the diameter of the calender roll. There you see the man's hand, it will allow him to put his fingers through to fit the fabric, yet he can not reach the bite of the roll. We have found that particular guard on our calenders most successful for general purposes.

(*Slide.*) This guard here is probably one of the first that we used in our tire factories. It is a G. & J. at Indianapolis. About seven years ago we had no guards on our calenders and one of our fellows got his fingers caught. The factory manager said that they were going to devise a guard, and they put a guard on there, but the men took it off; they said it was in the way. But the factory manager was just a big enough man to say the guard was going to stay there, whether the men did or not. That was seven years ago; the guards have been there for seven years and the men stayed, and we have not had any fingers caught in a calender where they had this device, which is composed of four bars stationary right in front of the rolls.

(*Slide.*) Take this device here, just one bar; here in Detroit we have a wooden bar going all the way across that, with a collar on the end, allows it to revolve on the roll, the collar giving it clearance. That has been recently put in.

The Roll on a Pivot Releases a Man's Hand

MR. QUIROK: That is very successful and also a little slot on the end of the collar so that can rise.

MR. BECK: In case the fellow does get caught in there, that roll is on a pivot so that it just lifts say three-quarters of an inch or a half, enough so that a fellow can pull his hand out.

This upper right-hand roller is similar to the one I just mentioned. You see there the roller is traveling on the lower roll. You can see the slot so if a fellow gets caught in there it raises up. This is wood, which makes it light, the timber is of pretty good size, large proportion; you see its ratio to the roll itself.

MR. SCHNEIDER: I would like to ask Mr. Beck if there is not a tendency, if stock is coming from a higher level, to draw that up, pull that guard up; consequently that would leave you a pretty good sized opening there between the bottom roll and your guard.

MR. BECK: That is true. If it can be changed to be fed from a low level it should be done, but there again you have a condition which you can not change. In that event you have to design a different guard.

In every case we recommend as standard practice a rod or bar going full length of the roll, which may be tripped or moved in either direction. At one stroke it will automatically stop the rolls. In some cases we have cables coming down on the side of the frame fastened to the floor, so that a man can swing either way and grab that cable. In other words, you see how our experience is differentiated from, say, Mr. Hoener. He said he has not had a case where the man has tripped the rod himself. We made a very complete survey, we have accurate records, and in 50 per cent of our cases our men have tripped the rolls themselves. In other words, we have given him that opportunity. He may be alone. Wherever you have the man tripping the roll himself, you usually have a less serious accident, because you have that time factor.

R. C. SALISBURY: How many accidents did you have, Mr. Beck, to investigate with reference to the men pulling the rods themselves?

MR. BECK: We probably average eight or 10 a year. Now remember that is where a man has got caught in the bite of the roll.

MR. HOENER: What is the percentage of those on calenders as compared to mills?

MR. BECK: I would say there were a few more on the calender, where people have been feeding them in. For that reason we have gone to this extreme, we have guarded everything. I think Mr. Hoener's experience is that his men are probably not as near the bite of the roll as our men.

Another thing, Mr. Hoener is probably not operating small factories that are 40 or 60 years old, where you have inadequate equipment and make products that he does not make, like in our footwear division.

MR. SALISBURY: Did your survey include the severity rate on those accidents?

MR. BECK: Yes, although I do not recall the figure exactly. We use the scale of lost time in accordance with the standard method of, say, 300 days per finger, or whatever it might be. It would not show the actual days lost, but it would show the severity of the accident, regardless of the permanent disability.

MR. SALISBURY: I think that would be very interesting information, before we decide to put guards on rolls similar to these you have. In other words, I should consider the separated roll more dangerous than rolls that come together.

The Mental Caliber of the Operator a Factor

MR. BECK: Well, as a matter of severity, that is correct; that is, the degree of separation often determines the amount of feed that a man is giving in there, but all our rolls are separated to some extent, and the mental caliber of the operators of the calenders, I think, does not bring about any quick, alert action. They are not of that type. Now, you take the piece workers on tires, you know the type of man there, he is a speed artist, but we do not get that particular mental capacity on our mills and calenders. You are liable to have colored fellows, and they do not react always as quickly as some other folks do. But we are sold on the proposition of guarding the bite of the calender.

E. A. OSWALD (General Industries, Elyria, Ohio): I would like to ask you, Mr. Beck, about guarding rolls in the manufacture of shellac composition. Have you had any experience in that?

MR. BECK: I am sorry I can not answer that. What is the operation?

MR. OSWALD: It mixes the shellac composition for shellacing molded parts and solid parts. We have some rolls where we mix this shellac and since I have been looking this over I don't believe they are guarded. Of course, it is different, it is more like dough.

MR. BECK: Does it go into the hopper on rolls or horizontal?

MR. OSWALD: It is thrown in by the operator, and he works it in there and rolls it out there; they keep doing that until it is thoroughly mixed up.

MR. BECK: It is overhead, vertical?

MR. OSWALD: No, horizontal.

MR. BECK: It is a mixing mill?

MR. OSWALD: Yes.

MR. BECK: And you throw it into a hopper?

MR. OSWALD: No, he has to force it in there.

MR. BECK: We have in one location a hydraulic plunger that forces stock between rolls.

MR. HOENER: My suggestion on similar operations is to use a small Banbury mixer, and then put it on a sheeting mill. That would eliminate one accident hazard.

(Slide.) CHAIRMAN GRAEF: I guess that one looks like one of my pictures. It shows a pneumatic truck tire building machine. We had some difficulty with our operators on large size tires, because, being on a piece work basis, they didn't want to take the time to walk around the machine from one side to the other to throw the power on and off.

They wanted to reach over the machine to operate the control and when the machine started up, many of them were injured. So we put an auxiliary control on, just a hand wheel, with a long arm, so that the man could operate the machine from either side, without having to reach over the tire.

MR. QUIRCK: Are your switches in that case operated by power or hand?

CHAIRMAN GRAEF: Mechanically by power. You probably all have in your curing rooms or other departments on the first floor of your building, manhole covers leading down into the basement, where you have piping and all that sort of thing; it has been our experience that when mechanics go down there to do work, they quite frequently leave the manhole cover off, which entails quite a hazard.

A Frame for Protecting the Manhole

(Slide.) This other picture is simply a frame made out of pipe, it is in collapsible form, and fits inside the manhole opening, so when men go down to work, they can leave the cover off and get some light and ventilation and at the same time protect the opening. When they are not using the guard, it folds up and occupies very little space.

(Slide.) I had this picture made because there has been a lot of comment and talk in different meetings about the safety pop-off valve on the lid of heaters. That valve right on top of our bead heaters is for releasing the pressure. That valve has to be opened and the steam allowed to blow out until nothing more comes, before they are permitted to unlock the heater.

MR. QUIRCK: It is not interlocked mechanically?

CHAIRMAN GRAEF: No, it is operated by hand.

(Slide.) This picture does not show very clearly what I wanted illustrated. You probably have all had ply pickers on bias cutters when they are reaching up here and get their fingers caught. So we had a sheet metal guard made that runs right underneath there, that is firm enough for the fabric to run through but not enough roof for

the fingers to get in. That runs the entire length of the machine. Since we had that we have not had any of the ply pickers get their hands pinched in the clamping bars.

(Slide.) CHAIRMAN GRAEF: This shows an ordinary grinding wheel. We all know we have a lot of trouble in our plants in buffing, in polishing, or holding tires in different positions. This shows the protection on the shaft and over the buffing wheels where we had to leave them exposed due to buffing different parts of the tire. We can not just leave a little space open in the front, we had to leave quite a bit, and I just took a picture of the guard over the end of the shaft and the buffer.

(Slide.) This is a picture of a carton labelling machine that girls operate, and shows the guards that were put on to keep the girls from getting their clothes caught in the mechanism of the machine.

Guards for the Cement Mixer in Each Department

(Slide.) That is a rotary cement mixer. We used to handle all our cement in a central cement house; but we found in distributing it out to the departments they were not in just exactly the proper condition, so they put these cement mixers out in the department, and they keep them constantly in motion to keep the cement agitated and in proper shape. We put these guards over the cement mixer while they are in the departments, so the men won't walk into them.

MR. BECK: Are they taken out every night?

CHAIRMAN GRAEF: They are all taken over to the cement house at night and brought back in the morning.

MR. PARTRIDGE: Does that increase your fire insurance rates any?

CHAIRMAN GRAEF: No.

MR. SCHNEIDER: What type of plugs do you use there?

CHAIRMAN GRAEF: I don't know the make of it. It is just one of those big rubber plugs. There is no spark in the type of motor used there. I believe they call them squirrel cage motors. That is gear driven.

(Slide.) This is a grinding wheel. You will notice the guard is in the up-position. We found with a number of our big grinding wheels, they were quite carefully balanced, and when the man was through using them and shut the power off, the wheels sometimes would coast as long as 20 minutes at a high rate of speed. It was practically silent and by just giving it a casual glance you could not even tell whether it was running. We had a lot of men bump into it, so we made this guard. When the wheel is in use that guard is up. When the man is finished with it and wants to throw the switch off, he pushes that guard out and it falls down and covers the entire wheel. So when your wheel is not actually in operation it is completely enclosed.

MR. QUIRK: Does anybody here use the Perks washer?

CHAIRMAN GRAEF: Yes, we are using it. We have 145 all equipped with a Perks washer. That is a vulcanized rubber washer on a steel base made by a patented process by the B. F. Goodrich Company, sold through a safety equipment concern here in Chicago. It holds the parts

of the grinding wheel together due to the suction created between the rubber disc and the grinding wheel.

(Slide.) We had a great many men caught in our debearing machine with the loss sometimes of a few fingers or a hand. We were at a loss to know what to do about it. So they finally changed the machine. This machine is in operation now but it is in very crude form and they are all being rebuilt. In order to operate the machine the man places his tire up here and it is carried; there is an automatic feed on the other side that rotates it and keeps it in position. Then he has to come over here and put one foot on this pedal and the other hand on this switch over here, so that he can not get up where the knife is while he is actually cutting the bead off the tire. The point is that the man can not get where the knife is when he is running the machine. He has to be over here with one foot on the pedal and the other on the switch.

MR. HOENER: The secret of that is to get a proper guiding device. That safety feature on the machine is due to the odd shape of the guard.

MR. QUIRK: Is that a commercial machine or did you make it up yourselves?

CHAIRMAN GRAEF: It is one we made ourselves. That is another picture of the truck tire building machine. It shows the hand wheel control that extends through to both sides of the machine.

MR. QUIRK: In connection with that, may I ask you what kind of stitch your people use?

CHAIRMAN GRAEF: We use a ball bearing steel disc. We do not have any fiber or wood.

The Location of a Bad Accident

(Slide.) This picture I took to show you where we had a bad accident. These two rolls are connected on an air hoist on the chain calendars and they regulate the tension in the fabric before it goes into the main calendar rolls and at the same time serve as an ironing device and take out the wrinkles in the fabric.

When the machine is started the fabric has to be threaded through these rolls. The fabric has to come down over this roller and between these two rolls and then over to the calendar. We had a man get his hand in between these two rolls which operate under hydraulic pressure, and it ground his hand off.

(Slide.) This thing here is a piece of sheet metal shaped like a trough. It comes down and fits right into the bite of the rolls, so that all a man has to do now is just drop the end of the fabric into the top of that little chute and it goes through itself. He does not have to reach in there with his hand at all.

MR. COCHRAN: Are those rolls rubber covered?

CHAIRMAN GRAEF: Yes. That is the installation on the tread cutter. All it was taken for is to simply show the method of guarding up there where the stock comes through.

MR. HOENER: The tread cutter?

CHAIRMAN GRAEF: Yes. We just put guards across where the knife is. You see them over the wheels on the other side.

(Slide.) We use quite a lot of oxy-acetylene in the plant for cleaning the molds. Mr. Schneider showed you a picture of cleaning molds by sand blasting. We also use the method of burning them out. They use a large number of these cylinders of gas and they were continually standing them on end. Every once in a while somebody would run a truck into them and it meant they would upset. They were rather heavy and we did have some accidents. Now wherever we use them, we have an I-beam that runs along between building columns or a building wall and column with a chain. The chain goes around each bottle and then fastens to a place in the beam and it keeps the bottles from upsetting.

CHAIRMAN GRAEF: That concludes today's program. This last item we have had is something entirely new, and I would be very glad if you gentlemen at some time would express your opinion as to whether or not this sort of thing is constructive and worth while. When we try something new we like to know whether or not we are getting something that is worth your time to look at, and we would appreciate your opinion on it.

MR. BECK: I make a motion that we have the same thing next year.

MR. QUIRCK: I second that motion.

CHAIRMAN GRAEF: I am glad to know you liked it. I know there has been quite a little work put in on it by the various members of the Section. I feel sure that now we have had a sample of what we want to do next year, knowing what you have in mind, you men will be able to give us more pictures and better illustrations of conditions in your plants.

P. W. DEMPSEY (Westinghouse Air Brake Company, Wilmerding, Pa.): The last picture you showed there about your tanks, we handle that in an entirely different manner. We have two-wheel trucks, and we fasten our tanks on there; we have our hose and everything connected to the tank, and we push them right to the benches and burn out the molds. Do you take your molds to a separate room to do that?

CHAIRMAN GRAEF: We have separate rooms. We use those two-wheel trucks with two tanks on a truck for the ordinary welding and burning such as the mechanics do around the plant on repair work; but in this burning operation we have anywhere from 150 to 200 bottles in a room at a time, so we can not use trucks.

ADJOURNMENT

WEDNESDAY MORNING SESSION

October 27, 1926

The Section convened at 10:00 o'clock, Mr. H. H. Graef, chairman, presiding.

CHAIRMAN GRAEF: I am going to have to make one or two apologies. The chairman of our Statistics Committee sent in a telegram stating he would be unable to get here, as did also the chairman of the Health Hazards Committee, Mr. Horan. There will be no reports naturally since the men are not here, but I know they have their material all ready and the reports were ready to present. I will have these reports mimeographed and see that each man that registers here this morning gets a copy.

Now one other committee report that we have this morning is the report from the chairman of our Engineering Committee, Mr. Hoener of the Firestone. I think our Engineering Committee has probably done more work in the past year than any other committee in this Section. I will allow Mr. Hoener to present his report and he will undoubtedly give you a more complete description of their activities.

REPORT OF E. H. HOENER, CHAIRMAN OF THE ENGINEERING COMMITTEE

It is very difficult to put down in writing the exact work which has been done by the Engineering Committee and the various checks and things that have been developed due to these tests.

Personally, I feel that I have been amply repaid for any work I have done on the Engineering Committee, because I have learned things in making these tests on our own equipment in Akron which were certainly an awakening to myself and also to the company.

We have been able to develop, in cooperation with the manufacturers of electrical equipment, for instance, on calendars, stops which we had never even dreamt of on such equipment and with a minimum cost. For example, by installing a certain contactor on a D.C. control board at an expense of about \$45, I think we improved our stops on calendars between 30 and 40 per cent.

That never would have come to pass if we had not taken the time and effort to check into it in detail just what could be done under various conditions of loading and various speeds of the equipment.

On mills and calendars, mills, wash lines and items of that kind, by proper alignment and watching the alignment of your clutches and your brakes—it is surprising what can be obtained without going to the great expense of new equipment. It is an easy thing to say, "Well, I

can not stop this old equipment. I've got to have new equipment; "but I often feel from our own experience that we do not go into it deep enough to find what could be done with existing equipment, which is really the thing that the management is interested in. If you go to the management and tell them you have to have \$4,000 for new clutch installation or new motor installation, your chances of getting it are fairly slim, whereas if you go to them and say for \$150 or \$200, by making certain small changes, I can improve the stops a certain percentage, why, you will most likely get it.

Now that is the field that the Engineering Committee has been trying to work on. My only regret is that it is a little difficult to bring all those points out in detail, because conditions vary so much. But the Engineering Committee of the Rubber Section is willing to go into specific cases of any company where we can be of benefit, and tell you how to improve your stopping distances, without going to a great deal of expense. We can not say that we have got a cure-all or anything of that sort, but we do feel from our own tests and experiments that we can be helpful in showing you what to look for. There are a lot of kinks to it that the ordinary master mechanic in a rubber mill will overlook.

Attacking the Problem From an Economic Standpoint

We have also had made up a testing device which really grew out of the outfit which was originally made by the Cutler-Hammer Company. We put a coil in there so that the same testing outfit can be used for both clutch circuits and D.C. circuits. In other words, we put a coil in there with a tumbler switch, so that you can stop your calendar, your stopping distance on your calendar or mill stop with the same device, without going to a great deal of added expense and combinations of equipment.

We found that by having the tests made it has put the mechanical division of the various factories where these tests have been conducted, much more up on their toes, knowing that if a line showed up bad on stopping distances that they would be criticised for it. The result is there has been a great deal more pains taken in the proper alignment of clutches and the proper tension on brake bands and things of that sort.

We have tried to attack the problem from an economic standpoint, knowing that it is necessary to do this work at a minimum expense, and that is the thing that really sells itself to the management side.

Now, with the permission of the chairman, I will deviate from the strict report and cite just a few concrete instances of accident hazards which I have personally become familiar with during the past year, due to the fact that we have had a number of unusual accidents, the circumstances surrounding which were rather peculiar.

It seems that it is not the every day, common, visible accident hazard which gets you into most of your serious trouble. We find from experience that it is usually a group of unusual circumstances. We may have had each one of those operations performed just like it was performed

at the time of the accident, but never were they all grouped together at the same moment.

I will cite as a concrete case the matter of curing tires in a heater without having the heater full of tires, in other words, what we call a split heat; for instance, having four or five molds in a heater when they rammed up into the vulcanizer. That has reference to the hydraulic vertical curing press. We had done that a great many times before and never had any particular trouble, but it so happened that the man in cooling those heats would use extra precautions. Well, this particular time the molds were cured the same way, and the man on the heater tender did not take the extra precaution in cooling the heat. The result was there was a lot of boiling water and so forth on the inside of the ram, which, when the heater was opened and the last mold taken up, boiled suddenly over the top of the heater and caused quite a serious accident in our plant.

A Combination of Circumstances Caused the Accident

We had a check-up and found we had cured thousands and thousands of tires that same way, but that thing had never happened. Why? Because there were certain other circumstances which had not been present.

We put safety equipment on our mills. We can put safety equipment on our calendars, stops, and have the delicate mechanism. At the best, as far as we can develop a safety device on a mill line or calendar, it usually only succeeds in cutting down the severity of the accident; it does not prevent the accident usually. There are some cases possibly where it does, but you will find in the majority of cases safety equipment on mill or calendar tends to reduce the severity of accident rather than prevent the accident.

We look into why these accidents happen. It is not the normal operation of the man when he gets hurt. It is straightening out a wrinkle, trying to pick a thread off the calendar, the fabric, or reach into the mill after a knife, or his glove gets caught in the rolls or he cuts up too far on the roll.

Now the ideal thing, of course, is to keep a man away from the hazard and not try to stop the machine after the man is caught. I think the biggest step which has been taken toward safety on mills is the raising of the mill height. We have a program in our factory whereby we can raise our mills with a minimum expense. What we have done is to develop a new set of gears, and in every case where we had a gear to replace we replaced both the gear and the pinion and put some filler blocks under the mill; the result is that we got all our mills eventually raised up to the new height with practically no cost whatsoever outside of the filler blocks, because your gears have to be renewed anyhow and the slight additional cost of the gear you will never mind. That has helped a whole lot, and we find that the men are happier working

lower down on the mill than they would be if they were leaning right over the top of it.

Another thing we did recently was to put a bar across the front of the mill slightly above a man's knee. We tried it first on one mill and tried some experiments with it, and the man after it had been on there for a while refused to work on the mill if that bar was taken off. Now the whole object of that bar is to give a man a brace so that in case he ever gets snagged in the rubber, he has a chance to brace himself and pull himself loose. From our past experience that has been very desirable.

We also have developed a great deal of work on some of our other equipment such as calendars, in the way of keeping the man away from the hazards and trying to educate the workman. The thing which the safety inspector or foreman should do, and which a great many of them do not, is to place himself in the workman's position and study the job from the possible hazards. It is not always the in-running roll alone that causes the accident hazard. We had a case not so long ago where a man was caught in the wind-up. Usually a wind-up accident results in a broken arm, sometimes a compound fracture necessitating the amputation of the arm. In this particular case it swung the man around in such a way that his head struck an iron beam, and the result was a fatal accident. Those are some of the things that will happen. This man had been on that job for six years, had been doing that job day in and day out, and he had certain instructions on where he should work, and he took a chance with fatal results. He reached in after straightening out a wrinkle with the calendar running at high speed.

Proper Lay-out of Equipment is Important

Now the matter of the engineering department providing safeguards, that is a good thought, but I do feel that the engineering department can do an awful lot towards having the accident hazards removed when the machine is originally designed, when the processes are figured out. I happen to have charge of the engineering department, the lay-out division, and so forth. It makes a lot of difference how you lay out equipment in a shop as to whether it has got a great accident hazard or a small one. How close do you make the man work to an in-running roll? Keep him away from it, then you won't have to have such delicate stopping equipment as is necessary after the man is caught, because our experience has been that a safety device on a mill and calendar, as mentioned before, does not prevent the accident, it usually reduces the severity of the accident only.

We have had a number of cases in our organization where if proper thought had been given by the foreman or supervisor of the department in looking ahead for these accident hazards, we would have prevented some of them. But the safety inspector at best can not possibly cover each and every individual case and can not put brains into a workman who is persistently careless. We have had a great many experiences

where the result has been more or less disastrous; but if we can keep the workmen away from it, that is the thing we have got to do.

Take, for instance, a tire building machine. A tire building machine looks like a minimum hazard. We had a case not long ago where a workman in putting a core on the tire building machine did not properly fasten it, did not see to it that the chuck was properly fastened. The result was that the core, chuck and all came off the machine while it was revolving. Fortunately nobody was seriously hurt, but it might have been quite a serious accident.

So I feel there is in every machine a potential accident hazard, and it is up to the engineering department, safety inspectors and the operating department to observe those particular machines from that view point; it is easy enough to lock the barn door after the horse is stolen, after a specific accident happens. It is not very often that the unusual accident will occur twice, because usually after an accident happens you take the necessary precautionary steps to prevent repetition. It is too bad that in many cases it is necessary for a man to sacrifice a hand or an arm before proper safeguards can be provided or necessary arrangements can be made; but often the safeguard is not provided until after the accident has happened.

Everybody knows if you have in-running gears you are supposed to guard them. State compensation departments and safety inspectors will all be looking out for those particular types of hazards, everybody pays attention to those; but the thing that the safety man has got to do and the engineering department is to look for unusual conditions or circumstances which never occurred before. There are a lot of them at the best. No matter how careful you are, you won't get them all. But that is the point I want to make; you have simply got to watch for those particular items in the engineering department.

Use of the Engineering Committee is Urged

I do feel that the members of the Rubber Section have not availed themselves of the facilities at hand. The experiments that have been conducted by the engineering department are available; but, as I say, it is very difficult for us to put them down in writing, as there would be a lot of sketches, drawings and photographs necessary, and the conditions in the various factories vary. So I want every one to keep in touch with the Engineering Committee of the Rubber Section and avail themselves of the opportunity for bettering their equipment and cutting down accidents from that viewpoint.

CHAIRMAN GRAEF: I knew that we would all enjoy Mr. Hoener's report.

There was one point I noticed in his talk that will be of particular interest to the production department rather than the engineering, although both are interested in it. This bar that he spoke of that the Firestone Company placed across the front of the mill between the housings in front of the front roll and slightly above the knees of the

workman, in addition to helping the workman by giving him a brace in case he gets caught in the rubber, is also of material value on mills where rubber is being broken down, crude rubber. As you know, that very often breaks loose from the mill roll and flies up with considerable force. Occasionally it hits the workman but a great many times where we have a safety located as they usually are, it stops the mill and the mill line. This bar greatly reduces the number of times that the mill line will be stopped, because the rubber will hit the bar first.

That concludes the reports of our committee chairmen. I am going to go from there down to our program. Mr. C. F. Horan was to have given us a talk this morning, but I received a telegram from him yesterday stating that he would be unable to come here.

The other speaker that we have on the program this morning is going to give us a talk on occupational diseases in the rubber industry. As you know, a great many of the states have passed amendments to their workmen's compensation laws including occupational diseases as an industrial hazard for which compensation must be paid.

Dr. Millard, who is the head physician of our plant hospital, and who has had a great deal of experience with these various occupational diseases and is held in very high regard by the Industrial Commission of Ohio on this particular point, is going to give us a talk on that subject.

OCCUPATIONAL AFFECTIONS OF THE SKIN IN THE RUBBER INDUSTRY

Dr. J. S. Millard, The Goodyear Tire & Rubber Company, Akron, O.

In the rubber industry the vast majority of our occupational disease claims are brought about by one of the various skin eruptions caused by ingredients in rubber compounds.

Therefore, I will confine my paper to the discussion of occupational dermatitis in the rubber industry. To cover all occupational diseases in the Rubber Industry would be exhausting to my audience as well as to the essayist.

According to Pusey, the health of the skin may be affected by:

A—Causes which act directly upon the cells of the skin.

B—Causes which affect the supply or composition of the blood and lymph.

C—Causes which influence the cutaneous nerve elements.

In the majority of instances it is impossible to draw a sharp line of demarcation between the symptomatic disorders of the skin, conditions in which the cutaneous lesions are but secondary manifestations of some derangement of the internal economy, and the idiopathic dermatoses, diseases which originate in the skin itself and confine their action to this organ alone.

The factors which lower the resistance of the skin or increase its susceptibility to attack are: age, sex, race, nationality, seasons, occupation, general health, habits and environment. Organic and constitutional

disease may coexist with or be a forerunner of a cutaneous disorder, such as acute and chronic nephritis, rheumatism, gout and tuberculosis.

Diabetes mellitus is often associated with certain types of eczema, pruritis, furunculosis and carbunculosis. Focal infections may cause various cutaneous maladies.

The exciting causes in diseases of the skin may be internal (constitutional) external (local) or both.

The internal causes may be toxic or nervous. Unfortunately in many instances it is difficult or impossible to define accurately or locate the exact causative factor.

The causes of skin affections are numerous and varied. The skin is exposed to an endless variety of irritants and harmful agents, acting on it from without, and to numerous influences acting on it from within.

Each irritant sets up a type of reaction which manifests itself in some form of clinical lesion or eruption.

A large number of local irritants of animal, vegetable or mineral origin are capable of causing a dermatitis. Some produce an inflammation on any skin, others only do so if the individual has an idiosyncrasy towards them. This susceptibility may be a natural peculiarity, or it may be an acquired condition owing to a diminished resistance of the skin from ill health, or from some pre-existing skin affection.

When a dermatitis has been produced by the action of some local irritant, the individual affected becomes extraordinarily sensitive to that irritant, and likely to suffer from dermatitis from a far slighter exposure to it than was necessary to produce the original attack.

This hypersensitiveness, or anaphylaxis, is supposed to be due to the action of protective substances called forth in the blood, when the first attack took place.

An important group of occupational diseases are caused by the action of local irritants, such as: itch from handling flour and sugar, and so-called "rubber poisoning" from handling hexamethylenetetramine by rubber workers.

Immunity and Anaphylaxis

Natural or acquired immunity in relation to diseases of the skin has recently attracted much attention—closely connected with it is the condition known as "Anaphylaxis." A state of hypersensitiveness which occurs when the organism has reacted to some toxin or irritant, and then reacts more intensely to a second dose of the same toxin.

Natural immunity is frequently met with in connection with skin diseases; certain individuals are naturally less susceptible to some skin affections than others. In local infections this may be due to differences in the texture of the skin, greater protective capacity, or absence of greasiness which might form a suitable soil for the growth of micro-organisms, while if the infection is a general one, it may be the result of the presence of certain anti-bodies or protective substances in the blood itself.

Acquired immunity is the result of the production of protective bodies in the blood, which are called forth by some local or general infection, and which render the individual for a longer or shorter time, proof against a further attack.

Inflammations of the skin produced by external contact with irritating agencies, whether solid, liquid or gaseous, are classed under the term "dermatitis venenata."

Occupational affections of the skin are in the above class. As there are no positively distinguishing symptoms or appearances associated with this class of inflammations, diseases and affections of the skin seen in the industries give no little concern to physicians handling industrial cases, as well as to compensation boards of state industrial commissions.

Workmen who lose time from their work on account of skin pathology due to the nature of their work, may receive compensation for lost time; but as it is often impossible to determine positively whether or not the skin lesion in question is occupational, several factors should be brought to bear on each case before making a decision, as follows:

Pertinent Questions on the Problem.

Are the substances used or handled by the workman capable, in the concentration and manner used, to produce the lesions in question?

Has the workman had a similar skin affection not traceable to occupation?

Are his fellow workmen affected in the same manner?

The rapidity of onset and decline;

The characteristics of the primary lesions—their situation, color, changes, etc.;

Does the skin condition improve when not exposed to the suspected irritant?

Is the skin pathology general or confined to the parts exposed?

Difficult as a true diagnosis may be in some cases, the situation must be met, and a just decision made, based on all the factors at hand.

Not only must the physician, the employer, and the compensation board be satisfied with the diagnosis, but the patient as well; for if the skin lesions of an employee are not occupational, he must be convinced of it, otherwise you have a dissatisfied, suspicious and therefore uncontrollable patient to deal with.

This is most easily accomplished by showing the patient a picture of his skin disease and letting him read the description of it in some book on dermatology.

In the rubber industry the parts of the body usually affected by occupational dermatitis are the face, neck, shoulders, forearms and hands.

The causative factors may be classed under two headings—mechanical and chemical—as follows:

1. Mechanical irritants are inert substances such as soapstone and zinc oxide, which in the dry state in which they are used have a drying effect upon the natural moisture of the skin, and cause the skin to

become dry and thickened, attended often by intense itching. Because of the itching the patient scratches his skin and the areas excoriated from scratching become infected. Because of the infection the glands become enlarged and painful, and the workman is obliged to quit work.

All this may be prevented in most individuals by protecting the skin in the early stages with a soothing protective ointment, applied just before going to work each day, and again at night for a period of two weeks or until his skin gradually adjusts itself to his occupation, after which the ointment is seldom needed.

2. The second class of irritants are chemical in the nature of their action. Examples of these are sulphur chloride and hexamethylen tetramine. The action of sulphur chloride is similar to that of an acid irritation; inflammation and destruction of tissue.

The skin first shows signs of acute inflammation and later thickening and scaling of the skin of parts affected (the arms and hands) and fissures appear around the finger nails which are very painful.

As in the previous class of irritants, the treatment is protection and to avoid contact with the irritant so far as possible.

The arms may be protected with a protecting ointment, and the ends of the fingers dipped in a solution of celluloid dissolved in amyl acetate which protects the fingers and prevents cracking of the skin.

Hexamethylen tetramine is fast being eliminated as an accelerator in the rubber industry, because of its irritant properties to workmen, and will soon cease being a factor in that industry.

A Protecting Ointment is Available

For those factories still using hexamethylen tetramine, a protecting ointment containing an alkali has been found very helpful in preventing dermatitis, due to the fact that the skin irritation is caused by the liberation of formaldehyde, as a result of the reaction of acid sweat on the accelerator. Keep the skin alkaline and your trouble is eliminated.

For occupations which cause skin irritation, dark, oily skinned individuals with black hair and eyes, are preferable, as they are more resistant to skin irritation than blonds; negroes are nearly immune.

Sensitiveness of the skin to irritants varies with the individual, therefore by eliminating from any particular job those whose skins react unfavorably to the work an immune crew can usually be obtained.

The accompanying prescriptions for lotion and ointment are useful in occupational dermatoses.

Considering the fact that processes of manufacturing are constantly changing, where one may be having occupational dermatitis today it is somewhere else or gone tomorrow. Therefore there is no value in naming the processes where dermatitis is found today.

In summing up I have the following rules to give:

1. Study a new process well before starting manufacturing by it, that the workmen may be safeguarded against poisoning or injury.
2. Workmen engaged in hazardous occupations should be frequently

examined to safeguard their health. The nature and extent of the examination to depend on the nature of the work.

3. By a process of selection, weed out the highly susceptible workers.

4. In occupations where dermatitis is prevalent, protecting rather than medicated ointments should be available to the workers in their workrooms, where they may use them freely while at work. Medicated ointments to be prescribed by a physician to suit the individual case.

5. Where occupational dermatitis exists, eliminate as soon as possible the exciting cause, by a change in the process of manufacture, or changing the offending chemicals or substances used.

In closing let me sound a warning note regarding anti-oxidants which are being put into rubber to prevent aging.

Those which are best known on the market now seem to be harmless, but the chemists tell me that as new ones are developed, they should be carefully tried out before putting them into mass production, as they are likely to produce a dermatitis similar to that experienced by photographers, and caused by similar chemicals.

Skin Lotion

R

Acidi carbolic	3ss
Zinci Oxidi	3ss
Glycerini	3ss
Liq. Calcis Q s Ad	3viii

Sig—Sop on skin freely for itching.

Note—If skin is too dry leave out the zinc oxide.

A Soothing and Protecting Ointment

R

Para wax	6 lbs.
White wax	10 lbs.
Cotton Seed Oil	16 lbs.
Sodium Borate	6 oz.
Distilled water	7 lbs. 10 oz.

Sig—Apply freely to parts affected three times a day or oftener as required for skin irritation.

CHAIRMAN GRAEF: The only other item on our program this morning is the report from the chairman of our Nominating Committee, Mr. Hoener.

E. H. HOENER: (Chairman, Nominating Committee): We have drawn up a proposed list of officers for the ensuing year to place before the committee or the group here today. These are suggestions based upon the best judgment of all concerned. We would like to bring up for your consideration for the ensuing year the names of Mr. Walter Schneider, of the Goodrich Company, as chairman; Mr. M. A. Quirck, of Morgan and Wright, as vice-chairman; and Mr. R. C. Salisbury, of the Federal Division, Fisk Rubber Company, as secretary.

CHAIRMAN GRAEF: Gentlemen, you have heard the report of the nominating committee. As Mr. Hoener says, I know that that report was given careful consideration and the men mentioned are men who have been associated with this Section for some time and who have all given us valuable and conscientious service. I would be glad to entertain a mo-

tion that the report of the Nominating Committee be accepted and approved.

MR. BECK: I move it be accepted as read.

(The motion was supported. There being no further discussion, the motion was put to a vote and prevailed.)

CHAIRMAN GRAEF: On concluding the meeting I would like to say that there has been considerable work done by the Rubber Section in the past year. For that I claim no personal merit at all. The work was done almost entirely by the various committees, and I want to take occasion to thank the chairman of those committees and the men who so kindly worked with them.

I would now like to turn the meeting over to the new chairman, Mr. Schneider of the Goodrich Company.

CHAIRMAN SCHNEIDER: It gives me great pleasure to serve you in this capacity. About all I can say is if I can serve half as well as Mr. Graef, I believe I will feel as though I had done something worth while. I know that he has worked hard personally, and despite the fact that the committee has also worked well, I believe he has done a great deal to elevate the Rubber Section to the place it occupies today.

We have a little time left, and it might be well to turn the meeting into a general discussion and perhaps someone has some particular subject which they would like to enter into a discussion on. I would like to suggest that some particular subject be brought up for discussion for the short time which we have up until the close of the meeting.

Age of the Worker Influences Skin Affections

R. B. HARKNESS (Cupples Co., St. Louis, Mo.): Two years ago in Louisville a gentleman from the Eastman Kodak Company remarked that they had discovered that men over 40 years of age working in their chemicals were less susceptible to skin infections than younger men. I believe the gentleman from Morgan and Wright, if I remember correctly, corroborated this statement. So I went back and in the last two years we have tried hiring men over 35 years anyway for the compound and mill rooms. It seems as though these men are less subject to eruptions and the effect of the compound and also more steady than men under 35. I was wondering if anyone else had the same experience, or whether our doctor friend could tell us whether there was really anything authentic about men being so susceptible to this eruption.

CHAIRMAN SCHNEIDER: If I get your question correctly, your point is whether there is a median there, either over or under 40 years, where the susceptibility is greatest?

MR. HARKNESS: It is awfully hard to keep men in the compound room. They generally quit more than in the tire room or inner tube department. We have found they will stay better if they are over 40, but it may only be a chance.

DR. J. S. MILLARD: Well, I think it has a good deal of truth in it. You take young fellows with delicate, tender skin; they can not stand the irritating substances half as well as a man of mature age, 35 or 40.

something like that; but then you go a little bit further, about 60, and then they do not stand certain irritants at all. As we get older, our skin gets drier and drier. You put an old man into a compound room where he handles a lot of zinc compound, and he just dries up. They have a terrible time. But I think your point is well taken. Women do not stand it well on account of that tender skin. You take men from Norway and Sweden, light hair and blue eyes, thin skin, they do not stand irritants at all. The darker the skin the better—like negroes, they can stand anything.

MR. HARKNESS: You say negroes will stand it?

DR. MILLARD: Oh, yes, a negro will stand a tremendous amount of skin punishment.

MR. HARKNESS: May I ask one more question? The gentleman over here said that he put a bar in front of a mill for the man to put his knees against. It seems to me, if I recall correctly, you put the rubber into the top at the bite of the rolls; in breaking it down it goes down through and you reach down underneath and get it and pull it out.

MR. HOENER: Yes.

Further Discussion About the Mill Bar

MR. HARKNESS: If you pull that between the bar, you are going to have the man break his arm. I think that would be a worse accident hazard. In fact, we had a bar in front of the mill and a man broke his arm.

MR. HOENER: There is a possibility, if you get your bar in between the two housings too close, that will happen; but you should put that bar all the way out by the adjusting screws, not up near the rolls. You have to have ample space for the man to get in there. If you get that bar too close, it is a failure. It must be out to the front of the housing in order to be at all effective. It is absolutely no interference with cutting, because we tried them on all mills, on all processes; we have the warming up, cutting off rubber, mixing. Certain mills we have do not have aprons. Where we have aprons, the apron itself when it is down acts more or less as a knee brace on our mills. On mills where we do not have aprons, we have tried it on both mixing and batching off, warming up. We have had absolutely no trouble with it. But be sure and have it out far enough, because I agree with you it is a great accident hazard if you put it too close.

MR. HARKNESS: If you get it out too far, you can not reach the mill.

MR. HOENER: Oh, yes, you can, unless you have an unusual mill. If you send us a sketch or cross section of your mill, I will be glad to sketch on there how it should be put on.

CHAIRMAN SCHNEIDER: I would like to reiterate what Mr. Hoener has said about the members availing themselves of the opportunity of getting information through the Rubber Section. It is your Section. That is what our job is, to give you the benefit of our experience, and work out your problems for you. We are waiting to help you and we want your suggestions. We are very glad to give you anything we can in

the way of guidance, and we solicit your suggestions in any way, so that we can work them out for you. Do not hesitate to write in to the secretary or any of the members and we will endeavor to work out your problems for you, if you can give us the information.

P. B. MARTIN (Industrial Commission of Ohio): Referring back to Mr. Hoener's remark on split cures, I think Mr. Hoener omitted an important part there with reference to the elimination of that hazard with reference to the center plate.

MR. HOENER: There is one point I did not bring out because I felt it might be an isolated instance. I am not familiar with how many other people in the industry are using what they call either the Dill or Schrader internal tree, on cord tires.

Originally the vulcanizer was equipped with a top platen, as we call it, on top of the ram, and that platen has an opening about 10 inches in diameter, and the process requires a base to support the tree, and the base is set on top of this platen and the tree is built up on the inside of the molds.

An Outside Tree Where the Hazard Does Not Exist

Now in most of our plants we are using an outside tree where that hazard does not exist, but by covering up this internal hole with this plate, there is an accident hazard available, and we have found out from actual checking and experiment that at least 32 square inches of area are essential in the ram opening to prevent pressure being built up during a cure on the matter of a split heat. That is just another case where we had cured thousands and thousands of tires by that particular method, but we had never had the group of circumstances, as mentioned before, of two or three things coming at the same time.

We had done considerable work on a similar item of equipment on the matter of having a ram valve stick. I don't know whether anybody has had any experience with that or not, but we do once in a while find that a ram will go up with a heat of molds; that is, when you raise the ram to hook your lid on, the ram will keep on going with a stack of molds on top. We have worked out a safety device whereby the minute that goes up it automatically opens a valve on your hydraulic and prevents it from going up. We have had a stack of molds go up and tip over. Nobody was particularly hurt because everybody ran, but it certainly disorganizes your whole outfit and does a lot of damage.

CHAIRMAN SCHNEIDER: Does any one here use the the Dill connection?

G. E. RUEFNER (Ajax Rubber Company, Racine, Wis.): We use the Dill connection. We have not experienced any trouble yet. Of course, we have not had them very long. We are just going into it. I am glad to know these points, however.

CHAIRMAN SCHNEIDER: Is there any one else that has anything on that subject? Have you, Mr. Beck?

MR. BECK: Not on that subject, but I was interested in knowing the present status of the pressed steel metal book. Has any one had the

opportunity to try that out? At the last meeting of the executive committee we had a sample of it.

MR. PARTRIDGE: We had a little experience with the metal book. I think we had 12 of them put into service and they lasted us about three weeks, bent all out of shape, the edges got rough and torn, and they were not a success. The manufacturer has taken them back and he is trying to develop a new type.

MR. BACK: That is the one that was shown at Chicago?

MR. PARTRIDGE: Yes.

MR. QUIRCK: We had the same experience. We had 15 of these steel books and they did not last at all. They warped, the edges got ragged, and we took them out of service and sent them back.

CHAIRMAN SCHNEIDER: For the benefit of those not familiar with that subject, this matter was brought up at the Chicago meeting of the executive committee of the Rubber Section. A salesman of a certain concern brought in a steel tread book which was to supplant the wooden type which was used heretofore in various plants, which according to claims caused a great many small injuries. He furnished each member with information and blue prints, and we were to carry back the message to our own plants, but it seems it did not act favorably. Has anybody else had any experience with the new books? Have you, Mr. Graef?

The Metal Book Has Not Been Developed Satisfactorily

MR. GRAEF: We had a dozen of the books in the plant and had the same experience that these other men did. They are not satisfactory in their present form.

MR. QUIRCK: I would like to ask some one who is curing tires on water bags, whether he has a system of inspection. We had a great deal of trouble in our plant with bags bursting just prior to the time they come out of the molds, as lamp black (or whatever it is) accumulates around the valve stem and it builds up an internal pressure in the bag and it explodes. We had some very serious burns. I was wondering if anybody had any special system of inspection of their bags, or what they are doing to prevent those bags from bursting?

CHAIRMAN SCHNEIDER: I assume you mean, Mr. Quirck, the scrapings and corrosion that takes place inside of the bag. We had some trouble some years ago, and we worked out a specially constructed valve for that purpose. It is not 100 per cent fool proof but it does eliminate a large portion of the trouble which we had before, in allowing a free passage of water that it does not plug.

MR. QUIRCK: Is it a larger hole?

CHAIRMAN SCHNEIDER: We have a series of holes and its position to the valve with relation to the inside is that it extends down through, not flush, with the upper section.

MR. QUIRCK: We tried the same thing and it was a failure with us.

CHAIRMAN SCHNEIDER: The first valve we made had a series of holes bored at various angles but it did not work out as well as the one

we are using now. I would be very glad to see if I can get you the information.

MR. QUIRK: We have made some stems with larger holes. We feel we are going to contrive to cut it down a little bit.

CHAIRMAN SCHNEIDER: Of course, there are some conditions that arise there, such as a weakness in the bag itself; some of the conditions are internal, for which no visual inspection can be made. The best plan is to figure out what you consider the life of your bag is, and when you get to that point throw it away. Keep track of the number of heats it is used on and throw it away. We find it is cheaper in the long run to do that.

E. A. OSWALD (General Industries, Elyria, O.): I would like to ask the doctor the proper way to dress a small burn on the arm caused by steam?

Dressing a Small Burn on the Arm

DR. MILLARD: I do not know as one way is much better than any other. We are rather partial to boric acid for burn dressings; picric acid ointment and anesthizing them, which is supposed to relieve the pain somewhat. We have not tried it out long enough to come to a conclusion that it justifies the increased cost over boric acid. If the burn is extensive you have got to give the patient morphine. Anything you put on the outside is not going to be sufficient to relieve the pain. There is an extensive absorption and picric acid is somewhat poisonous. Of course, the small burn would not require morphine. The smaller steam burn is not so painful that it is unbearable. If you put on boric acid, cover it up, and the pain does not last long.

MR. OSWALD: We have generally bandaged new burns in our first aid room, and lots of times that causes infections. We have even heard fellows say, my burn will heal up quicker if I leave the rag off, but the first aid room requires them to keep the rag on.

DR. MILLARD: Anybody who has burned himself knows how painful it is to leave the burn open and exposed to the air. The minute you cover it up with ointment it is soothed and the pain is much diminished. See that the skin is clean around the burn and then put boric acid on, which, of course, is only slightly antiseptic, still it is sufficient to protect the small burn. Most deep burns become infected anyway, because there is so much necrosis of the tissue caused by the burn that it is impossible to prevent it.

MR. HARKNESS: Doctor, do you think it is just to refuse to take on a man when he is found to have a hernia when he is examined?

DR. MILLARD: No; personally I think that a man who has a small hernia which may be held up by a truss should be given employment but the Goodyear Tire and Rubber Company, I presume because the labor market is plentiful enough so that they do not have to take men with hernia, have recently made a rule that no man shall be accepted for employment who has a hernia and wears a truss; but any man who before this rule went into effect was in the employ of the Goodyear

and who had a hernia, is not turned out. We keep all those that we have but we do not take on any new men who have hernia, even though they have a small hernia with a properly fitting truss. I do not think it is right myself, but they had some trouble.

I suppose what brought it up was two or three men came in with a hernia and finally came around and said their hernia had enlarged and had increased their disability. Under the law of Ohio if you have a pre-existing disability and you are accepted for employment by any plant, the plant that accepts you last for employment assumes the responsibility. So if he can prove his hernia has become larger, or he can not wear a truss and has to have an operation, then they are stuck for the operation.

MR. BECK: I am quite pleased that this question of hernia has come up, because it has cost our company enormous sums of money. I am also pleased that there is a state representative here to hear what we have to say. In certain states, I know in Ohio and I know it is so in Connecticut: in one small factory we had as many as 17 hernias in one year. These men come to us and we employ them and we are responsible for the aggravation of any pre-existing condition and the men go before the commissioner, and there is no question but what we are stuck.

The Problem of the Man With a Hernia

Now it is working a hardship on labor. There is no doubt about it. Suppose we had a hernia and we were going around to these different factories looking for a job and they turned us down. We ought to go right to the commissioner, that is where we should be sent. I believe it would be good policy for all of us in the industry to tell our labor department to send the men down to the commission to find a job for the fellow with a hernia, and let them see what we are up against. We do not like to turn those fellows down. They should have some labor, but if we are going to have to pay bills for their condition, which may be a disease, not an industrial injury, I feel we are justified in trying to do something.

I believe if we can get together and bring about a better understanding so that we are not going to turn these people down but we are going to give them a square show, that we have accomplished something that is really constructive.

I know in certain states the tendency is to tighten up rather than to be a little more liberal. After once these laws are on the books it is almost impossible to have them changed. If New York, Connecticut and Ohio say industry is responsible for all hernia cases, the first thing you know Vermont, New Hampshire and Maine will adopt the same attitude. I feel that this is a very important subject, and I would like to hear from the state representative.

MR. MARTIN: Mr. Beck, I am sorry to advise you that I am not with the division of claims. I am with the division of safety and hygiene. Therefore, I am not able to answer that.

MR. BECK: You must have an opinion.

MR. MARTIN: I do happen to know of one case that happened in one of our Ohio cities not long ago where a man went to work who claimed a hernia and his doctor friend decided it was an emergency case and rushed out to operate on him immediately, and then the industrial commission refused to pay the bill, because he had not consulted them previous to the operation; and I know that both the doctor and the hospital were stuck for their bills and did not get their pay.

I am not trying to make any excuses for the laws that have been passed in the state of Ohio; but as to the question of the law on hernias, I can not answer you.

CHAIRMAN SCHNEIDER: I doubt if anybody can settle that controversy. I know in Ohio it is one of the things we have to contend with and always will, I presume; but I think your suggestion is meritorious and perhaps the spreading of that word around would do some good.

Development of the Hernia Rulings in Wisconsin

MR. MARTIN: I might say that there is a law existing now, or rather a ruling of the industrial commission of Ohio, that no hernia can be operated on, except it be an emergency, unless they have permission from the industrial commission to do so.

DR. A. C. SEIDLER (Fisk Rubber Co., Cudahy, Wis.): In Wisconsin they adopted the industrial commission in 1913, and from the time of its adoption until three years ago we did not recognize occupational hernia. During those 10 or 12 years we recognized only hernias caused by an immediate accident. Surgeons of Milwaukee contended that all men had a congenital hernia. During this period Wisconsin had a rule that if a man contended he had acquired a hernia in industry he had to specify how and when he acquired it.

The leading case that was the rule in Wisconsin for some years was this: a man was loading a truck with barrels, 20 barrels, and while loading the barrels he felt a pain in his groin. He discontinued work and filed claim for the hernia. The industrial commission ruled against him because he did not specify what barrel caused the hernia. This ruling was sustained by the Wayne County Circuit Court and later by the Supreme Court of the state.

During the past three or four years, however, we have necessarily recognized the industrial hernia. We watch those. When we see a man with a potential hernia we keep our eyes on him, and if it develops at all we might advise a truss without admitting liability and continue to watch the development. In these inguinal hernia cases, if there is no acute enlarging of the ring and acute tenderness there, we do not recognize it as a liability case.

DR. MILLARD: Personally I am very sure that the size of the rings has little or nothing to do with the development of a hernia. We find just as many men with hernia, or beginning hernia, who have small rings as those who have large rings. We examined men two or three years ago where we could put two or three fingers up in the ring, where

they did not develop hernia; other men where you could not get the small finger through developed a hernia. I do not think it is the size of the ring but length of the mesentery which has the potentiality to cause a hernia.

CHAIRMAN SCHNEIDER: That is very interesting to know, from my limited knowledge of that subject. I was always under the impression that enlarged rings were most dangerous and that small rings were more or less minor.

MR. QUIBCK: I would like to ask Dr. Millard if he thinks it advisable to examine men working in the compound department?

DR. MILLARD: We go through the department about once a month, looking, of course, for lead poisoning more than anything else, but we pick up other things as well. All the men are examined more carefully every two months, but once a month we try to send a doctor through, and they talk to each man just a word or two. If there are any suspicious signs we examine the man, then next month we look him over more carefully. Of course, that does not mean to strip them off, but to ask them some questions: Have you any abdominal pains? Indigestion? Look at the gums. Then if the doctor finds anything in going through the plant, he sends the man up to the hospital for a more careful examination.

CHAIRMAN SCHNEIDER: I would like to hear from Dr. Seidler on that.

DR. SEIDLER: We do not make it a fixed rule to examine the men. Due to some labor conditions in our town we do not like to get down into the mill room to excite them. However, we meet up with them without any fixed time, and if we see any indication of lowered vitality or lessened resistance in an individual, we like to take him out of any department where he would be susceptible to the absorption of any poisons.

MR. HARKNESS: Would it be in order to make a suggestion that might be of interest to the members on general safety, not specifically in the rubber industry?

CHAIRMAN SCHNEIDER: I think there are a number of us that are interested in general safety.

The Careful Children's Club in St. Louis

MR. HARKNESS: There is a movement started in St. Louis which appeals to me very greatly, and I think it is one of the best educational plans that has been devised for quite a while. Mr. Girard C. Varnum, manager of the St. Louis Safety Council, I believe is the originator of this idea. It is called the Careful Children's Club, and they broadcast on KMOX every night except Thursday. He has a great many catchy songs. Then the children will send in their names to this St. Louis Safety Council asking to be members of the Careful Children's Club, and then he sends them a big list of all these songs and they sing them at home and they broadcast them.

Now at Cupples we cooperated with Mr. Varneman on this and

organized the Cupples Division of the Careful Children's Club. We put this in the plant magazine, and on the first returns out of a possible 600 we got about 400 answers from children who wanted to join the Careful Children's Club who wrote in saying their father worked at the Cupples Company, and they wanted this information. We got these children all together and got their pictures taken and will run it in the plant magazine and also in the *St. Louis Globe Democrat*.

My idea is that we talk about the education of the employees aside from mechanical safety guards. All our fundamental reactions I believe are the results of our original innovations and concepts taught to us in school. We still believe in Santa Claus with a big beard and several other fictions we had that we got in Sunday School and other places.

It might be of interest to the members here to organize similar clubs. The mothers brought their youngsters down and we got a chance to talk to the mothers. The fellows that were on the night shifts brought their youngsters down to have this picture taken, and we got a chance to talk to them. The youngsters were interested in it, and you are getting it into the home and incidentally into the children and it will last.

CHAIRMAN SCHNEIDER: I think you have touched upon a very interesting phase of accident prevention there—education. That point was brought up at one of the other meetings, just how far the various plants ought to go in trying to educate the children, the workers' children. I think a good many plants today have community houses and various other features to carry on work of that sort. I think it is largely a matter of the policy of the various plants, how they handle that.

ADJOURNMENT

Steam Railroad Section

New Officers of the Section

CHAIRMAN: J. D. WHITE
Illinois Central System, Chicago, Ill.
VICE-CHAIRMAN: E. R. COTT
The Hocking Valley Railway Company, Columbus, Ohio.
SECRETARY: J. E. LONG
The Delaware & Hudson Company, Albany, N. Y.

Committees

PROGRAM: C. F. LARSON, Chairman
Missouri Pacific Railroad Co., St. Louis, Mo.
MEMBERSHIP: FRED W. MITCHELL, Chairman
New York, New Haven & Hartford Railroad, New Haven, Conn.
POSTER: HARRY GUILBERT, Chairman
The Pullman Company, Pullman, Chicago, Ill.
ACCIDENT CAUSES AND REMEDIES: THOMAS H. CARROW, Chairman
The Pennsylvania Railroad Co., Philadelphia, Pa.
PUBLICITY: D. G. PHILLIPS, Chairman
Wabash Railway Co., St. Louis, Mo.
PREVENTION OF HIGHWAY CROSSING ACCIDENTS: C. E. HILL,
Chairman
New York Central Lines, New York City.
PUBLIC RELATIONS (U. S.): E. R. SCOVILLE, Chairman
The Baltimore & Ohio Railroad Co., Baltimore, Md.
PUBLIC RELATIONS (CANADA): W. A. BOOTH, Chairman
Canadian National Railways, Montreal, P. Q., Canada.
TRAIN SERVICE ACCIDENT: C. T. BAILEY, Chairman
Oregon Short Line Railroad Co., Salt Lake City, Utah.
ENGINEERING REPRESENTATIVE: F. HARTENSTEIN
Lehigh Valley Railroad Co., Bethlehem, Pa.
EXECUTIVE COMMITTEE (The Officers and)
L. G. BENTLEY
Chesapeake & Ohio Railroad Co., Richmond, Va.
ISAIAH HALE
The Atchison, Topeka & Santa Fe Railway System, Topeka, Kan.
H. A. ROWE
The Delaware, Lackawanna & Western R. R. Co., New York City.

A. V. ROHWEDER

Duluth, Missabe & Northern R. R. Co., Duluth, Minn.

ROBERT SCOTT

Atlantic Coast Line R. R., Wilmington, N. C.

October 26, 1926

A. V. ROHWEDER, Chairman

Superintendent of Safety, Duluth & Iron Range Railroad, and Duluth, Missabe & Northern Railway Co., Duluth, Minn.

THE opening session of the Steam Railroad Section of the National Safety Council, held in the Ball Room of the Statler Hotel, Detroit, Michigan, convened at 2:15 o'clock, Mr. A. V. Rohweder, of the Duluth & Iron Range Railroad and Duluth, Missabe & Northern Railway Company, of Duluth, Minn., presiding.

CHAIRMAN ROHWEDER: Gentlemen, the Steam Railroad Section of the National Safety Council will come to order.

Mr. L. F. Shedd will give the invocation.

L. F. SHEDD (Rock Island Lines, Chicago): Almighty and everliving God, God of mighty love, we are not unmindful that we are again privileged to gather here in convocation to discuss the ways and means that will redound with credit to Thy creatures, and we pray that all we do, every word that is uttered and every action likewise, may be acceptable to Thee. May we be guided in our deliberations by the thought of Thy Son, Jesus' advice when He said that He came to earth that men might have light and have it abundantly. Be with us; we ask it for the sake of Thy Son, Jesus, our Lord.

(The members joined in singing "America.")

OPENING ADDRESS OF CHAIRMAN A. V. ROHWEDER

For some reason or other I never got into the habit of making an address; but I have a few ideas and a few things that I want to comment on in opening this session of the Steam Railroad Section of the National Safety Council.

Your chairman has performed the regular duties as chairman of your Section in as capable a manner as he knew how. Working with a committee such as I have had during the past year, with a secretary like Cott, and a chairman of the Program Committee like Shedd, and a chairman of the Membership Committee like Long, and the rest of the fellows on the committees, it was a comparatively easy job to act as chairman of your Section. The results of the activities during the past year, of course, speak for themselves.

I want to mention two or three things with which probably some of you are not familiar. One was recognition by the Steam Railroad Section, and, in fact, the National Safety Council, as a whole, of one of

our past chairmen who died a little over a year ago, and whose memory and life's work we honored at the Northwestern Passenger Terminal in Chicago on April 5, 1926. We have here today the wax replica of the tablet, made of bronze, that is placed on one of the pillars in the Northwestern Passenger Terminal of Chicago as an everlasting memory to the origin of the safety work on American railroads. The presentation of that plaque was made by Mr. Robert W. Campbell, who was one of the first presidents of the National Safety Council, a life long friend of Mr. Richards; and it was accepted on behalf of the Northwestern Railroad by Mr. Fred W. Sargent, president of that railroad.

In outlining a program for this congress, we had in mind two or three things. In the first place, it has always been my idea that we have started more or less from the wrong end of the line in our National Safety Council Congresses—bearing in mind, of course, that we have an employee problem and that we must interest the employee and the organization that represents the employees and so forth. But I have also felt there is a decided need that something be done by the Steam Railroad Section of the National Safety Council, and by any other agency devoting its time to spreading the gospel of safety, toward bringing the executives, supervisors, and other officers of American railroads to the point where they will realize their personal responsibility and where they will actually get in and work and put over a definite safety program, just the same as they are putting over a definite operating, maintenance or mechanical program in their respective departments.

Program Planned Along New Lines

A lot of people will say, "My president, or my general manager, or my medical department is just as much interested in safety as those on the other railroads." But in looking around, I have often wondered how much real constructive safety work those men are actually doing? In order to get the idea of educating our officers, we decided in making this program, to ask representatives from departments and organizations relating to the Steam Railroads to come in here at what we termed "Executives' day," which will be tomorrow, October 27, and tell us just what is wrong with the safety departments on the American railroads and what their respective organizations would like to see done to bring about a reduction in accidents in their respective lines of work.

We may not get this year, at least not at this congress, the results that we expect. We may not get the ideas advanced from those particular groups that we hope to get, but we are at least recognizing that an association, for example, like the American Railway Engineering Association, has it absolutely in its own hands to either bring about an increase or a decrease in the number of accidents in the maintenance of way department on our railroads.

We are getting a start and with that start, imbedding the idea in the organizations that they will be represented in this convention from year to year, they will in turn devote a part of the time of their annual congresses to the discussion of safety, so that their delegates may come

here with a very definite message to each and every one as to just what they can do to assist us.

We also have changed the usual manner of handling our program. About a year ago we tried out in St. Paul at a regional meeting the proposition of assigning a man to handle specific subjects for one hour each during the day, so that this man might inject into the meeting some new ideas that probably would not have been thought of by a single chairman. So we have designated five men to act as chairmen of the various sessions of this congress. They are men who have been going to these conventions for many years and have very definite ideas of what should be done in handling a meeting, and we are going to give them a chance to show what they can do.

Close Contact with Safety Organizations Valuable

There is a rather peculiar situation which has developed in the minds of some of the railroad people of this country in connection with the relationship of the American railroads to the National Safety Council. I am not going to say a great deal about it, but I simply want you to carry back one thought to the management of your property, and that is, that the contact you are having here this year with the safety officers from the iron and steel business, from the Paper and Pulp Section and all the various other sections, some 20 or more in number, certainly is well worth any outlay of money that your company may have put forth. There is also the public relations touch that you get through a membership in the National Safety Council, and I want to suggest to you that if you have never been in the offices of the National Council in Chicago, you make it your business to go through that institution the next time you are in Chicago, and find out what they have and begin to use some of the service that they have available. There is no organization in the United States that has as much real, live, up-to-date service as the National Safety Council on the subject of safety; nor is there any organization that can give you any better engineering or mechanical advice in connection with the subject of safety than through the Engineering Section and through the staff officers of the National Safety Council.

In conclusion, I want to express my appreciation for the privilege of having served during the past year and up until the time of this congress as your chairman. I have enjoyed the many contacts I have had with each and every one of you gentlemen, and I hope that through the years to come I can continue to be of service to you in any way you may see fit.

We have a few changes in our program that we want to make. The first is to change the order of the reports from committees and call on Mr. C. W. Frey, Superintendent of Car Shops, Michigan Central Railway, West Detroit, Michigan. That change is made so as to give Mr. Hill, General Safety Agent of the New York Central Railroad, an opportunity of hearing Mr. Frey, and Mr. Hill's absence later on is due to the fact that he is to speak before another meeting in a few minutes.

HOW SAFETY CAN SUCCESSFULLY BE HANDLED IN A RAILROAD SHOP

**C. W. Frey, Superintendent, Car Shops, Michigan Central Railway,
West Detroit, Mich.**

Teamwork

In order to promote safety in any railroad organization and make a continued success, it is first necessary to be a firm believer in all of the principles, and then embody these principles in the minds of everyone under your jurisdiction.

Teamwork is an essential factor if you ever expect to obtain results, and unless you receive the cooperation of every individual under your management, you will never accomplish your purpose.

In the first place, a supervisor must be a salesman of the highest degree and sell his ideas on safety to each and every employee under him; to do this he must have plenty of patience, the same as a school teacher has with children, for you know that to become a successful salesman, patience is the essential factor.

To build up a successful safety organization requires plenty of time, but each step that you take should lessen your future burdens; although safety demands constant attention at all times and you should never expect it to take care of itself.

Teamwork must not only be confined to your own supervisors and the workmen under their guidance, but must also extend to your safety agents, claim department officials as well as every higher supervisor above your own position.

The shop managers and their foremen must work at all times and give the safety agent their best cooperation, for without this teamwork the safety agent will have a difficult time in getting the best results.

The safety agent must be a diplomat and know how to approach each and every type of person, as there are no two individuals with the same personality; the safety agent, in my mind, is the person responsible for a successful safety organization and his position must be recognized by those under his guidance.

Factors Necessary in Building Up a Safety Organization

The first requirement is to study your accidents in a railroad shop and devise schemes to eliminate chances of re-occurrence in the future; the head of every department should be furnished with a copy of every accident report, along with a bulletin explaining causes of accidents.

Watch each individual injury and if the injured party loses any time, be sure that you trace his movements; for I have had numerous cases where men could have returned to work at their regular duties, but we were charged with a lost time accident through the fact that the foreman did not follow up the man.

Don't overlook the fact that your employees may be carrying accident

insurance in one or more companies and that their revenues from this source may exceed their regular wages during the interval of time that they claimed to be injured.

Often we have had cases where an employee reported to his foreman that he had been injured while on duty, after failing to report for work, and upon investigation, it developed that the injury occurred away from duty. These cases must bear careful watching, or else your company is going to be charged with an injury, with possible payment of compensation, depending on extent of time lost.

During the first three months of the year 1924, we had 24 lost time accidents of more than three days at our West Detroit Car Shops on the Michigan Central, and being in charge of this place, I came to the conclusion that something must be done. A special meeting was called among all the supervisors and every form of suggestion was made by them. At this meeting we developed the idea of following up each injury by sending foremen to the homes of our employees with a possible view of getting them back to work at their regular duties before the three day limit had expired, to avoid being charged with a lost time injury.

This practice proved successful as we only had nine lost time injuries for the second quarter of 1924; and by continuing this idea, along with many other schemes, we only had 11 lost time injuries for the last six months of 1924. This was further reduced to six for the first six months of 1925 and for the last six months of 1925 we only had one injury of more than three days lost time in the entire shop, comprising 720 men.

Safety slogans are valuable and the continued use of bulletin boards proves beneficial; but don't forget that the best advertising feature for safety in any organization is the workmen themselves. When you can get these men to sell safety ideas among themselves, you have accomplished an aim which is greater than any other form of advertising.

Any person that will watch another work in an unsafe manner, is not a fit employee to have in the service, and with careful training you can get employees to warn one another on unsafe practices.

If you saw children playing on the street, the first thing you would do, in case you noticed an approaching automobile, would be to warn them of their danger; and in all probability if any of these children were your own, you would scold them for their carelessness. Is there any reason why workmen in a railroad shop can not adopt this same method and warn others of their failure to work with safety? In connection with this feature if you are responsible for a body of workmen, don't forget to practice what you preach, as the worst handicap to safety is to have a supervisor violate safety rules in the eyes of his own employees.

It is only natural for employees to get careless if the supervisor fails to comply with safety rules.

Inspection of Facilities, Tools and Machinery

This is one of the most important features of safety work in a railroad shop and this inspection should never be made by a foreman or

supervisor, for the reason that too many other responsibilities are placed on these men and the best results are never accomplished.

Appoint some first class mechanic who is a safety convert to handle this inspection and give him full authority to condemn tools which are unsafe to work with; also see that such tools are taken away from the workmen and not returned until proper repairs are made or new tools furnished.

Give your men to understand that the party making this inspection has full power and see that a report of his inspection is made to the highest authority in charge of the shop; also do not let any discussion arise between the foreman and this man over this inspection. The supervisor should be notified that results obtained are for the benefit of all concerned.

If you will study your accidents monthly, you will find that quite a few of them can be attributed to the use of defective tools or machines improperly guarded; if the departments are large enough, one man from each shop should be assigned for this inspection.

Tool room attendants should have a certain time whereby all tools furnished workmen should be recalled to tool room and given a thorough inspection periodically, and these attendants should also be invested with full power to condemn tools that are not safe for the workmen.

These safety inspectors, whom you appoint, should also report all unsafe conditions which they find existing in buildings or appliances in or around same.

Applying Discipline to Unsafe Workmen

None of us in a supervisory capacity likes to apply discipline to a workman who persists in performing operations contrary to safety rules; but I am sorry to say that often this is the best policy and gives best results.

After you have spent all of your available time in teaching safety to a workman and he fails to follow out your instructions, the only feasible plan is to apply discipline of some sort to this man. It is for his own good that such action has to be taken; also, it has a moral effect on the rest of the employees in that department and conveys to them that the supervisor intends to have a safe organization, even if necessary to employ new men to get the desired results.

From my experiences, I can readily see that the safety movement has been to the advantage of the workmen, as they derive all of the benefit when supervisors are continually guarding their interests; and for this reason they should cooperate at all times with their foremen and not oppose any method which the latter may adopt, when applying discipline.

The worst trouble we had in this respect was with employees failing to wear goggles. Continually warning the men did not produce any effect. Conditions became so bad and we had so many eye injuries that a set of rules had to be adopted. After several employees were disciplined and one or two men discharged from the service, the men saw that rules were for their own good, with the result that very little trouble

is now experienced, although this is a matter which has to be watched daily.

Applying discipline to employees in a railroad shop is no different from methods employed by judges in courts, and while no one may have been hurt, it is always for somebody's good that fines or punishments are imposed.

Laws are made to be observed, and with safety organizations punishment in certain cases is the only remedy for correction.

CHAIRMAN ROHWEDER: I will ask Mr. Guilbert of the Pullman Company to discuss Mr. Frey's paper.

HARRY GUILBERT (Pullman Company, Chicago): Mr. Chairman, Ladies and Gentlemen: I read this paper twice four weeks ago. It appealed to me as a very intelligent paper, and proved conclusively in my mind that the speaker had studied his subject very carefully. I feel that when the car shop got Mr. Frey, the safety department lost a good representative.

CHAIRMAN ROHWEDER: We will now go back to the first part of our program. I will ask Mr. Cott, our able secretary for the last four years, to make his usual annual report.

REPORT OF E. R. COTT, SECRETARY OF THE SECTION

The report of the secretary must of necessity be brief. First, because there is little to report. Your secretary is busy more or less, depending upon his inclinations to work throughout the year, and his work, as the work of your chairman, speaks for itself. If you like the job, you don't need necessarily say anything about it. If you don't like it, you will have an opportunity sooner or later to get a new secretary.

I have enjoyed the association of four years as secretary with such gentlemen as Mr. Rohweder, Mr. Hill, Mr. Bentley and others with whom I have been privileged to work. It has been pleasant, and in some measure I shall hate to give up, but we can't be selfish.

I want to read a telegram from our good friend, W. S. Wollner:

"Regret inability to be present at Steam Railroad Section meeting. Am sure it will be a great success and much will be accomplished. Northwestern Pacific making remarkable safety record. Thirty-seven months without employee fatality; injuries reduced 30 per cent."

Here is a telegram from a good old friend, Mr. John T. Broderick, whose road is ably represented here today. It is addressed to Mr. Rohweder:

"Cordial greetings and best wishes to you and other members of the Steam Railroad Section. Congratulate you on your good work as chairman."

Mr. Carrow's former right hand, Mr. Chapin, sends regards to all the boys. I know it comes from his heart, because he always liked to be with us.

I have here a group of letters from the different presidents of the railroads which some time later, if we have an opportunity, we will read to you, because you will enjoy some of the good things that have been said about us and about you and about your good work.

I want to make a suggestion. I have been secretary of this Section for four years and as I tell you, I am resigning that office at the adjournment of the session today, and now I can speak my piece.

The duties of a secretary are somewhat difficult, provided he does his job right, something I have never taken credit for doing. The news letter ought to go out monthly to the membership and I can't claim any such record. It is not a very difficult thing for you to write a news letter yourself, but it is quite a difficult job to put out a monthly letter and turn your office upside down in turning out a stencil of five, six, or maybe 10 or 12 pages.

I don't know who will be secretary this year, but I hope he will do a better job than I have done. It may be out of order, I haven't consulted with anyone about it, but it seems to me that we ought to pass the hat around for the secretary and not let him have a penny of it. Let him put on a clerk, make it worth somebody's while to get out these news letters regularly to the membership. That doesn't go in your dues.

I have a boy in this audience who has done a good deal of work. We aren't going to pass the hat for him at all. It seems to me you put a burden on the secretary and those who help him in his office. It is not just. I am ready to kick in for the incoming secretary. You can talk about that on Thursday, but I wanted to get it off my chest. I told you last year the only substitute for complaint was silence.

CHAIRMAN ROHWEDER: The life of any organization very largely depends on the kind of Membership Committee you have. We were fortunate this year in having Mr. J. E. Long, of the Delaware & Hudson, as chairman of that committee. Mr. Long did a remarkable piece of work, as you will observe from his report.

REPORT OF J. E. LONG, CHAIRMAN OF THE COMMITTEE ON MEMBERSHIP

We started the fiscal year in September, 1925, with 95 members of the Steam Railroad Section. During the year we lost four of our members, two of them by cancellation and two of the smaller lines by consolidation with larger companies. The Yazoo & Mississippi Valley Railroad consolidated with the Illinois Central and the Ann Arbor with the Wabash, so I don't think we need to worry especially about the safety activities on those particular properties.

The new members during the year were Mr. E. J. Goodsell, of the American Railway Express Company, the Buffalo, Rochester & Pittsburgh Railroad Company, the East Erie Commercial Railway, the Nevada Northern Railway Company, the Oklahoma Union Railway Company, the Brotherhood of Locomotive Firemen & Enginemen's Magazine, the

Pittsburgh, Shawmut & Northern Railroad Company, the Cumberland & Pennsylvania Railroad Company, and the Mississippi Central Railroad Company, a total of nine.

To summarize, we started with 95, we lost four, added nine, and we have closed the year with an even hundred.

CHAIRMAN ROHWEDER: Mr. LaFountaine had charge of the bulletins. You see them displayed on the rack today.

Due to a new scheme that they are trying out on the Great Northern Railroad, combining the safety work with some sort of an operating examination, Mr. LaFountaine was unable to come down to attend our congress at Detroit. However, he has sent in a written report and we will ask Mr. Cott to read it at this time.

REPORT OF C. L. LaFOUNTAIN, CHAIRMAN OF THE COMMITTEE ON POSTERS

As chairman of your poster committee during the past year, I beg leave to report that during my term of office we prepared the material and published:

5 posters 17x23 inches.

34 posters 9x12 inches.

1 large public poster.

On Sept. 23 and 24, Messrs. Galaty, Metcalfe, Gardiner and myself met in Chicago and were able to secure material suitable for posters sufficient to care for the next three months' supply.

While I wish to acknowledge with gratitude the assistance given me in preparing posters by different members, especially Messrs. Rohweder, Metcalfe, Johnson, and Bailey, I too feel that I should call to the attention of the entire membership the need of greater cooperation on their part in assisting the Poster Committee.

It is a much more difficult problem to handle efficiently than one would ordinarily think, and if they are to get out posters desired by the membership, they must at least have suggestions from the members from time to time, indicating the kind of posters desired, subjects they wish covered, etc.

This is not said in a spirit of criticism, but with the hope that the entire membership will more fully appreciate the needs of the Poster Committee and give them 100 per cent cooperation.

CHAIRMAN ROHWEDER: I will ask Mr. Galaty to present his report in connection with the Publicity Committee.

S. M. GALATY (C. & N. W. Ry., Chicago, Ill.):

There isn't a great deal to report. Your committee cooperated with the National Safety Council in publicity. We handled the publicity for the Richards' Memorial.

I do want to say just one word. Each one of you members can help your Publicity Committee by sending the committee your magazine and also sending them some information of what is doing on your road, so that they will have some material to work with. I sincerely trust that

the members will bear that in mind and help the chairman of the incoming committee so he can do a better job than I did in publicity.

CHAIRMAN ROHWEDER: We have a committee in the Steam Railroad Section entitled "Prevention of Highway Accidents." That committee is dovetailed with the committee of the American Railway Association.

The chairman of that committee is D. G. Phillips, of the Wabash Railway, who is not only chairman of the Steam Railroad Section committee but is a member of the American Railway Association committee as well. I will ask Mr. Phillips to give us his report at this time.

REPORT OF D. G. PHILLIPS, CHAIRMAN, COMMITTEE ON PREVENTION OF HIGHWAY ACCIDENTS

If there is anything that tends to take the joy out of the first meeting, it is the reports of these committees, and there is a disposition to avoid first meetings on that account.

As your chairman stated, the highway crossing question is very close to every railroad, very close to every railroad man and is being handled by a committee in the A. R. A. Section proper, and for that reason our work is so interwoven it is hard to tell what we as individuals do, whether we are doing it as members of this Section or the other section, and for that reason I am not going to refer to what we are doing, but rather just a word as to what the National Safety Council itself has done during the last year to help us in this great and as yet unsolved problem.

The National Safety Council distributed for us 100,000 of our "Careful Crossing" bulletin. They ran a great many articles in the NATIONAL SAFETY NEWS, supporting the movement to the very best of their ability, and as you know, all over the country they have organized local councils. These local councils have a regular course of instruction and all of them that I have heard of yet have a general plan of meetings, sometimes once a week, sometimes every two weeks and sometimes once a month. At least once each year one of those lessons of their careful drivers' club is on the matter of highway crossings. They take up the time of one whole meeting discussing highway crossing accidents.

In the city of St. Louis they have two safe drivers' clubs. The ladies have one, and I had the pleasure, the honor of talking to that convention of 300 women. I also went before the safe drivers' club, as they call it, some 3,000 or 4,000 members, and talked to them about the problem we have; and we have had wonderful cooperation all over this country from the National Safety Council and their lesser organizations. I want to say that in the city of St. Louis the assistance the Wabash Railway alone has received in this careful crossing campaign has been of more monetary value to the Wabash than every cent that all the railroads in the United States have contributed to the National Safety Council.

I am a crank on this crossing situation, because, listening to the kindly advice of Mr. Walsh of the M. K. & T., I became convinced that the railroads were not doing what they could themselves to prevent crossing

accidents, that we had things we could do. For instance, the one idea that seemed to possess a good many of us was that this matter of whistling needed attention. Our engines were whistling back at the whistling post where nobody could hear it; that was not a good idea. Then the old crossing rule, two long and two short blasts of a whistle, was not a proper whistle.

As most of you know, the engineers at Montreal made a recommendation that the whistling rule be changed from two long and two short blasts of the whistle to two long, a short and a long blast of the whistle. All of you know this, but I want to recount this anyway. That rule was submitted to the General American Railway Association Rules Committee, and Mr. Carrow, Mr. Rowe and I had the honor of appearing before that committee in support of that rule. I don't know just what we are going to get, but I am going to tell you that is the best whistling rule. I happened to see the address of the superintendent who is going to speak here tomorrow and he says the same thing.

Accidents Fewer Under New Whistle Regulation

Here is the solution of the matter. We have found the whistling proposition can best be handled to reduce automobile accidents at railroad crossings by two long, a short and a long blast of the whistle. The idea of the last blast of the whistle being long is so that the whistle can be held until the crossing is reached, that is, at a place where the driver of the automobile can hear that whistle.

A number of railroads, without waiting for the action of the A. R. A. committee, have changed that rule already and here is what it has done on the Wabash Railroad. I am just going to refer to the last two months. In September and October of last year, under the old rule which we enforced, like all other railroads, we had about 60 crossing accidents, and we killed 18 people in 14 different accidents. In the month of September and first 23 days of October, the same period as last year, we had 20 crossing accidents in which we killed three people, and it is the opinion of every operating official on the Wabash Railroad, many of whom were bitterly opposed to that rule until it was put into effect, that almost the sole cause of that reduction is whistling at a place where the whistle can be heard.

FRED HARTENSTIEN (Lehigh Valley Railroad, Bethlehem, Pa.): I want to tell you about another railroad. Shortly after I received a letter from Mr. Carrow, the Lehigh Valley Railroad adopted the same method of sounding the whistle as described by Mr. Phillips. We laid aside the old rule calling for two long and two short blasts of the whistle at railroad crossings, and verbally we have instructed our engineers on the railroad to sound the whistle two long, one short and one long, and carry the sound of the last whistle to the crossing and over it, if they consider necessary, leaving it entirely to the judgment of the engineer.

CHAIRMAN ROHWEDER: We have a gentleman from Canada with us who has been a member of our Executive Committee, W. A. Booth, of

the Canadian National Lines, and he is chairman of the Committee on Public Relations. Mr. Booth, may we hear from you at this time?

REPORT OF W. A. BOOTH, CHAIRMAN, COMMITTEE ON PUBLIC RELATIONS

When our chairman asked me to say a few words about the Public Relations Committee, I must confess that I nearly had a heart attack, for the reason that public relations are so hard to define.

There is a story of a Scotchman going from Glasgow to Edinburgh, a place I visited last year. The trip takes about 45 minutes. They have local trains taking a somewhat greater length of time. This Scotchman took the local train and at each station he got off, went into the station and bought a ticket to the next station, and so on.

After doing this half a dozen times, his friend said, "What in the world is the matter with you? You have me all unnerved jumping in and out."

He said, "I will tell you why I have been doing that. I was to see a doctor the other day and he told me that I had heart disease and that I might die very suddenly so you don't think for one moment I was going to buy a through ticket, do you?"

There is not much to say in connection with the Public Relations Committee except that I have had the cooperation of our friend, Harry Guilbert, and our work has been a sort of assisting provincial safety leagues. Our country is divided in provinces, as no doubt most of you know. There are 10 or 12 provinces and each one is fitted with the proverbial safety leagues. We assist them all we can in their safety parades and similar things. We have also assisted some of the cities of the United States along that line. For instance, we had one in Battle Creek.

I hardly like to make mention of this, but some time ago there was bulletins and posters distributed to the various members. May I say, I was requested to get out either the November or December? I have been led to believe by the chairman of that committee that perhaps there are more of those being ordered than any other, which news I was very glad to receive.

The last time I was on the floor, I believe in St. Louis, I made mention of the fact that we had prepared a book of safety rules and instructions and at that time I promised to send every representative a copy. You will find these on your return home.

I have emphasized the fact that our railroad, perhaps the only railroad on the continent, has a series of radio stations. We have 10 radio stations in all and we make use of those by broadcasting safety news, which I also think may come under the head of public relations.

You all give your best, I am sure; to the different school commissioners' work, speaking before children, all that sort of thing, and in that case we not only try to give the word of safety there to the children, the

teacher, or head master, but we also deliver a little of the literature that is received from the National Safety Council.

CHAIRMAN ROHWEDER: We now come to the fifth item of our program and that is the report of the Nominating Committee. Mr. Bentley of the Chesapeake & Ohio is chairman of that committee. We will ask for his report.

REPORT OF THE NOMINATING COMMITTEE

Your Nominating Committee regarded this assignment this year as one of very serious import. For that reason we met in New York City on September 25 for the purpose of naming the nominees for the Steam Railroad Section for the coming year; and from among the wealth of material at hand we named for each office two candidates, and as I read the names of those candidates, you will recognize that you have the choice of selecting for each position one of two good men.

For chairman we nominated Mr. J. D. White and Mr. W. S. Wollner; for vice-chairman, Mr. E. R. Cott and Mr. W. A. Booth; for secretary Mr. J. E. Long and Mr. C. L. LaFontaine

CHAIRMAN ROHWEDER: We will appoint as tellers Mr. D. G. Phillips, of the Wabash, Mr. Galaty, of the Northwestern, and Mr. Satterfield, of the C. & O. We will declare a recess and have the ballots passed around. These envelopes may have the name of the company, the name of the safety officers and in the left hand corner the number of votes that railroad is entitled to. Only the gentlemen who receive one of these envelopes with the name of his company can vote. Every member of the Steam Railroad Section is represented in that package of envelopes.

While we are waiting for the votes to be counted, we will proceed with the program. The next speaker is W. H. Jones, Assistant Director of Safety and First Aid, Canadian National Railways, Montreal, Canada.

My first experience with Jones was when we sneaked out of one of the sessions at the convention in St. Louis and went to see St. Louis and Cleveland play a game of ball. I think the score was 11 to 2 and he came to the conclusion he would rather see a game of English cricket. As a result of some of the discussion we had at the ball game, we decided Jones would be a good man to talk on welfare as applied to safety. Canadian railroads are particularly prominent in this work and have worked out a particular program of welfare among their employees.

WELFARE AS APPLIED TO SAFETY

W. H. Jones, M. A., Assistant Director, Safety and First Aid, Canadian National Railways, Montreal

The terms "Welfare and Safety" are sometimes used synonymously and are often regarded as being joined together in the formation of a worthy human destiny. But technically speaking "Welfare" is simply a condition, whilst "Safety First" is action. "Safety in Action" is one of the flowing rivers that enter the vast ocean of human welfare.

This quest for betterment is one of the earliest cries heard in our development and long before the scientist formed his theory of the "survival of the fittest" the human race marched onward along the lines of the "survival of the best." The milestones of its evolution were those periods when society respected and responded to this universal yearning of mankind for the "best that is yet to be."

It is obvious that within our social unity lies our individual protection against the intruding forces of destruction, and that within society are to be erected those floodgates, that can stop the onrushing currents of dangerous influence. Primitive society was effectively taught to feel affection for its individual members as well as to realize the possible danger of offending its associates. Naturally enough, this approved policy was safeguarded by the adoption of two dominating practices that were then in vogue; that the man who caused destruction to a fellow member of his group could expect the wrath of his associates; and that the man who was injured by a stranger could count on the aid of all his own associates in pursuing and avenging. It is not for me to decide whether our modern social groups have advanced beyond even these crude stages of protection but suffice to say that these were the principles upon which all social units were organized.

Three Important Truths About Welfare

But I am tempted to say that modern industry in its approval of even these rudimentary principles must, in order to prove its value, regard them simply as seed for a larger and better accomplishment: larger to the extent of knowing no limitations of kin or race and better to the degree of eliminating vengeance and wrath. The industrial welfare must welcome a policy that is larger than the safety merely of its own group. It must expand its inheritance to include all mankind and exclude none. So that all uplifting and noble achievements can be practised irrespective of color or clan. Accident prevention is an agent of universal welfare and must not be confined, cribbed or cabined by sects or groups. It is a policy larger than all railways and bigger than all corporations. It is as large as the world and as big as humanity.

Giddings, in that attractive textbook known as "Elements of Sociology," gives a thought which I shall paraphrase to read:—

"A society is a number of safety individuals who know and enjoy their safety and are, therefore, able to work together for common ends."

We have, then, three important truths which are worthy of our further attention:—

1. That welfare is based upon the safety of the individual—"a number of safety individuals."
2. That welfare in its nature is social consciousness—"who know and enjoy their safety."
3. That welfare in its scope is cooperation of all concerned—"working together for common ends."

"Individuality is everywhere to be guarded and honored as the root of all good."—Titan.

It is absurd to expect to build an industrial state of safety or welfare in its entirety apart from specialization on the value of the individual who constitutes that aggregate. The larger the group of employees the harder it is to recognize the value of the individual. In a world with its supply of man service larger than its industrial demand it is an easy matter to lose our admiration for the single life.

It was in this respect that Tennyson even lost his affection for nature, for he said of her: "So careful of the type she seems; so reckless of the single life." And undoubtedly his conception coincides with his statement of nature's brutality as being "red in tooth and claw."

Welfare Built on Value of the Individual

During the late war men were grouped into regiments, battalions and brigades and these were known by numbers. It was never expected that any military general could recognize the individual soldier of these vast units. John or William was lost in the vastness of the groups. Individual identity became a non-entity. Perhaps this explains the old saying that—"War is a biological necessity."

But what is true in times of emergency can not be true during our industrial tranquility. A successful welfare must be built upon the value which is attached to the individual. I do not mean that the foreman should know only the members in his gang but that even the general superintendent may inherit a goodly portion of this gift of personal acquaintanceship with those who form the working unit of all departmental groups.

In my first experience in a railroad career, I had the privilege of reporting to a vice-president and general manager who, in my estimation, was a genius in this art of knowing personally his individual employees. I often witnessed his arrival at different terminals and invariably I would see him go up to the engineer and say "Good work Jim;" or after a noon hour address at the shops he would descend from the platform and mingle with the men, addressing them by their own names, with such an effect that one could see them swelling with personal pride. And I do not hesitate in saying that the secret of that vice-president's railroad career is not so much detailed railroad knowledge as his particular gift of being a student of human nature.

When you touch men as individuals and not as mechanical units you have produced mutual relationships, and these are the basic principles in any industrial safety or welfare. When industry has lost that qualification it has suffered an irreparable loss of its soul.

In 1922 Babson's report contained this statement: "Relation between employer and employee is fundamentally a business relation and anything which injects into this relationship a flavor of charity is misplaced." Mr. Babson is speaking about welfare in industry. I heartily agree with him that "business" is the fundamental policy in industry but would also

suggest that this business, in its relationship to man, must be maintained by dynamic influences and not left entirely to mechanical processes.

Before you get the best out of man's strength you must enter his heart and soul. This is not charity but conformity to human justice. To say that a business concern has no sentiment is more of a callous "foolosophy" than a practical "philosophy." I think there is more concerned than mere dollars and cents in the matter of industrial accident prevention.

At any rate an approach to our employees must be along humanitarian principles. For one of the deep seated instincts that sways normal men is not so much loss in material production as a repulsion from personal pain and suffering. This is the key that opens the door to the heart and head, sentiment and consciousness of our employees. And when you have successfully entered a man's heart you will soon be able to govern his conduct. Welfare deals with human values and saves them from being subordinated or foolishly slaughtered. The greatest capital entrusted to industry is its man-power and everything must be measured by a standard of human values. The message of welfare applied to safety is, therefore, "That not one of these should perish."

Welfare in Its Nature Is Social Consciousness

"A sound mind in a sound body is a short but full description of a happy state in this world."—Locke.

Two important words in the definition submitted are "knowledge and happiness" or "consciousness and emotion." While the basic principle in welfare is individualistic, the nature of it is entirely social. The individual now removes the shackles of self-aggrandisement and launches out to aspire for the welfare of the whole group.

In other words he now begins to live for others. He "loses himself," so has to find himself in others. The self-conscious attitude is replaced by a social consciousness. The fault finding tendency of his past selfish and small world has now been replaced by happiness and contentment of his larger world and sphere.

The bane of human life today, you say, is discontent and I agree with you. But 99 per cent of that discontent in society, whether industrial or national, has been due to some individual culprit who has tried to squeeze the interests of the whole group into his own selfish desires and thereby the vision of true welfare has been lost by the glare of limited safety. For, after all, safety is but a physical protection while welfare assumes a psychic adjustment. It is generally conceded that a large majority of our accidents today can be traced to these psychic causes.

Recently while investigating a number of accidents which occurred in one of our shops, I was amazed to find that certain conditions not in the shops but in the home were the real causes of these accidents. The men never should have been admitted to work, if their state of mind and personal attitude could have been previously detected.

Our railroads today have made rapid advancement in the erection of proper guards and the installation of safe working conditions, but all those modern devices are inadequate without a further advancement in caring for the mental and the emotional forces which are uppermost in the human construction of man. You may say that industry has no business to interfere in such psychical realms; true, but when such factors do influence the physical, then I say it is to the advantage of the employer to assist in making the employee realize the importance of a clean mind and contented heart.—“A conscience void of offense.”

Let me illustrate. In the training of the medical man today he is compelled to study many sciences which (speaking from my own experience) he may justly have complained during his student days were unnecessary to produce a real doctor. For his conception of a doctor's vocation then was simply to give away pills indiscriminately, to use the knife freely and to charge exorbitantly. But medicine has been relieved of the tortures of such embryonic quacks and it is now acknowledged to be one of our most important sciences, with the result that the successful physician can make use of all those bothersome sciences of his collegiate days to assist him in his work. The quack treats symptoms but the scientist goes after the causes.

Safety is also a science. It must be approached as such and especially by those engaged in its application. You can not prove its truth by reading arguments or concocting committee reports. For it is not a matter of truth and falsehood only; it is a matter of life and death. Hence we must acquaint ourselves with causes and not mere effects only in applied safety. Its mission is to construct a bridge from the past, with its cripples and sightless, to the future, with its perfect men, strong of body and resourceful in mind.

Welfare Demands Trained Effort—Organized Knowledge

To do this is a gigantic task which will tax the very best of human knowledge. The subject of the care and protection of men in all its varied forms of welfare and safety is gradually restored from illiterate hands and placed in charge of intelligent and competent leaders. I am not speaking disparagingly of the progress made by energetic workers of the past. For they have done well and contributed splendidly to the achievements of the present. But on the other hand I do fearlessly insist that the future must depend upon more than energy alone. It must have trained efforts—organized knowledge. The day is past when any company will entrust the care of this important work to certain members of their personnel because they have nothing else to offer them.

This branch of a railway enterprise, I say, is too important to be managed by those who are inadequately trained. Perhaps the tendency of our various railways in the past has been to look rather suspiciously upon the college trained man and become rather prejudiced against education. But the railroads of tomorrow, as far as this subject is concerned, must demand the best that training and education can supply.

Prophecy is no argument. But I can see the day coming when the mat-

ter of human welfare as applied in industry will be given as much prominence in the college curriculum as that of engineering or agriculture. For the man in charge of industrial welfare must be thoroughly qualified. He is called upon not only to inspect and install guards against the visible dangers of machinery but also to erect barriers against invisible and destructive influences that attack both heart and mind. So that if welfare and safety are to attain their true objective, then, the man in charge must be a psychologist as well as an engineer.

It is a gigantic task and we have done well with the physical phase of it, but I am not sure whether as yet we have launched intelligently into the psychical aspect of it. But to abandon the stage at this time of our splendid progress is to retreat all along the line. I admit that there are limitations to our success in this respect, especially in formulating adequate solutions to our psychic problems, but to leave the battle because of past failures is a confession of ineptitude. The struggle of the future will be centralized upon this problem of safeguarding successfully the minds and hearts of our employees. For these, after all, are the causal factors in destructive accidents.

The Safety Platform Is an Important Ally

Therefore, our safety platform is an important ally of welfare to bring about not only safe conditions during working hours in the shops but also contentment and happiness that can reach even to the home and community. There is nothing so satisfying as the production of a happy workman: a man whose countenance gleams with the joy of contentment. It matters not how greasy his overalls or oily his hands, there is beneath all a pulsating heart for service and a mind cleansed from all evil intentions. Such is the man who best serves his employer, for he knows that his employer respects his best. Such a man has no sympathy for restlessness that breeds contempt and dissatisfaction.

Welfare and safety, both hand in hand, can change not only the environment of man but help even to change the man himself. So that the hope of the world for better men today depends very largely upon organized industry or, may I say, upon that industrial welfare which can be humanitarian enough to benefit the working man at his place of work as well as at his home.

And I know of nothing more beneficial to the business relationship between employers and employees than this state of contentment or happiness in the workman himself. Welfare and safety help to eliminate the social restlessness so characteristic of our age. Fault finding which breeds antagonistic relationship between employers and employees has not even a dog's chance. Of course there will always remain with us a few individual fault finders—they are like some religious enthusiasts that think they are bigger saints because they call Satan a Devil, or some enthused officials who think they are bigger railroaders because they make fun of other railroads. These culprits are like the poor; they will always remain with us.

But the need of the hour is for an enlarged vision. A vision of safety that can foster not only accident prevention of human bodies but also accident prevention of human minds. The task is big but not too big to be accomplished.

Welfare in Its Scope Is Cooperation of All Concerned

"Whatever may be the issue we shall share our common danger, one safety."—Virgil.

I trust that you have noticed the threefold angles of these scattering thoughts; as outlined by the definition, they are:—

1. TO BE. 2. TO KNOW. 3. TO DO.

So the very essence of welfare as applied to safety is action—"To Do" Cooperation of all the various agencies for one common end of welfare. There are many branches now growing on this handsome tree of welfare. Some of them are indeed bearing luscious fruit. I shall enumerate only a few.

1. *First Aid.* This is one of the most important corner stones in the architecture of welfare. In the railroad company to which I have the honor to belong the safety department is inseparably attached to our first aid. They both work together, as they should, and to my mind it is impossible to perpetuate a 100 per cent safety policy if it is separated from this ally.

2. *Dental Clinic.* If it is true—according to the contention of medical science—that most ills and diseases originate in the teeth, then the establishment of such a clinic would prove beneficial to any industrial concern. How elaborate should be the scale on which we shall adopt this is not for me to say. It is simply mentioned as one of those social agencies that formulate a real welfare in industry.

3. *The Visiting Nurse.* Such an appointment can be very beneficial one to any company. A nurse who knows when and how to enter the homes of our employees could be productive of much good and bring about a great deal of comfort and assistance to many a sorrowful and helpless home. But such a nurse must be tactful. For a flippant visiting nurse can do much harm.

4. *Athletic and Social Activities.* These are worthy activities when operated efficiently, for they help to promote an "esprit de corps" amongst employees. Physical training builds health and strength while social events produce good fellowship. And both these factors are of inestimable value to any industrial company. I know of nothing so valuable in building up the morale of men as social or "get together" meetings. And I know of nothing so productive of increased business to a railroad company as a properly conducted "get together" meeting. After years of experience in charge of such activities I could enumerate many instances, especially in competitive towns and cities, where the company increased 100 per cent its former patronage and business.

But these various agencies, after all, must depend upon the cooperation of all concerned. It is absurd to expect the company to shoulder all the

responsibility. There must be a realization that each employee is a spoke in the wheel of the successful company. The one-man-safety and the single-life-welfare ideas carry but little weight. But each railroad with its safety unit must realize that it is a unit in the whole fabric of universal welfare. Just as the individual man is helpless apart from the cooperation of his fellow beings so is a railroad in this respect. It matters not how keen the competition may be in business activities; in safety and welfare there must exist all possible cooperation. The railways of today are now linked together in the expansion of this work of protection and care of mankind.

Professor Guyot, of Princeton, says that progress in the world is like the development of plant life. It has three periods of growth. The first is that in the soil—growth by the root. The second is more accelerated—growth by the stem. The third is the most rapid of all—growth by the blossom and fruit.

The welfare of humanity has been growing by the root—obscurely, lingeringly and slowly. It is now, after ages of acquired root, growing by the stem; I believe it is now ready to break into blossom and its fruit bearing will be surprisingly rich and wholesome.

Welfare properly applied to safety, therefore, is not only humane and social but it also increases dividends on capital invested. Show me two railroads both giving transportation service of equal efficiency, and I will tell you that the public, every time, will support the one which maintains the highest order of organized protection and care of its patrons. So the "value of man" makes our work a sacred trust and the prosperity of our company makes it a valuable asset. Safety work is our contribution to bring about the realization of that human destiny—Welfare. May the day hasten when all shall cooperate to the fullest in making man as he should be—Happy and Safe; Happy in his heart and Safe in his Home, to his Employer and to his Community.

CHAIRMAN ROHWEDER: We have assigned to the discussion of Mr. Jones' wonderful paper the chairman of the Safety Section of the American Railway Association from the Sesquicentennial town of Philadelphia, Mr. Thomas H. Carrow.

DISCUSSION OF MR. W. H. JONES' PAPER

T. H. Carrow, Pennsylvania Railroad System, Philadelphia, Pa.

I have listened with much pleasure to the illuminating address just presented by our good friend Jones. He has evidently been studying histology, biology, and all the other "ologies" in the dictionaries for a suggestion for a study on the ills peculiar to mankind.

I thought the address related to first aid and then I happened to look at the program and it said "welfare." Then I woke up to the very important reference that he made, something that I think we will all be able to ponder over with much benefit after we have gone home.

I am going to refer to certain aspects of his paper a little later on, but in order to avoid being too conspicuous, I have asked the chairman if he wouldn't let me combine my report as the chairman of the Committee on Statistics with my response to this address, so I shall give you very briefly the result of the accident situation in the United States in the first six months of this year, then I will return to Mr. Jones' paper.

There were 3,145 people killed on American railroads in the first six months, which represents an increase of two, a very unsatisfactory showing from the standpoint of fatal injuries. There were 62,484 injured, representing a decrease of 3,090, a net reduction of five per cent, which lends my good friend Bentley, who is so energetic in putting out his monthly bulletins, reason to hope that with the enormous progress that our railroads have made, particularly in the last six months, we will be able to get by the remainder of the year with a little better than five per cent.

I have listened to a great many papers in my life and the paper of my good friend Frey is really the finest thing I have ever heard. If we can get a few people on the railroad to see that people are laying down on the job and calling them accidents, we will make a very good improvement in our railroads. I saw that because we show a reduction of only five per cent in all accidents; but 15 per cent in non-train accidents, and nearly all of that was made up in the shops and the Pennsylvania Railroad contributed about half of it. That was because we hadn't awakened previously.

Getting the Injured Employee Back to Work

One of the important things is getting injured employees back to work. I recommend to you people that you pay a little more attention to that as you go along. It is a most discouraging thing to read the record and find that train accidents increased nine per cent. I had hoped that the time had arrived when we could look forward every six months of every year to a decrease in accidents, but the subject that is confronting the A. R. A. more than any other is the reduction in train accidents. As my friend Scott pointed out, a few mashed toes, a few lacerated fingers and maybe a mutilated hand is infinitesimal compared with a tragedy such as we have had time and again during this present year.

Crossing casualties have shown a very marked increase in number, perhaps not on a ratio basis, but 16 per cent in the total number of casualties. I shall not make any comment on that because I presume that will be covered under another head. I do wish to recommend for your consideration, however, an effort that is being made by the New Haven Railroad, which I discovered in Boston last week. They have in their principal station, which I understand is the biggest passenger station in the world, a reproduction of the crossing flashlight. It is my purpose to present that to our Executive Committees in the different regions of the Pennsylvania Railroad at the very earliest opportunity. I can think of no better way of advertising care at crossings than this

flashlight that Fred Mitchell has stuck in the middle of the train floor at Boston.

By the way, we have in Philadelphia a sample of a little electric train showing this flashlight, and you would be astonished to know, as my inspectors have discovered, the utter ignorance of a vast majority of the people as to what these flashing lights mean. All of us ought to start a campaign to educate the public to know what that light means. We can not overlook the fact, friends, that people do not cross railroad tracks in front of trains carelessly and negligently when we see men who are just as competent as we are doing it. We have to take into consideration that it is our job to apprise them of the approach to the crossing.

Now I am going to return to Mr. Jones. The prevention of accidents may be divided under two heads, and first is the proper construction, education, organization and persuasion. On our railroads, on all of the railroads, we have made wonderful success in that direction. I don't think it is necessary for me to dwell upon that. That is not the purpose of my discussing his paper. The second item is first aid, medical attention and supervision to get the men back on the job. That is what I thought I was to discuss, the first aid proposition and all of its implications.

Thousands of Days of Disability Lost

I don't want to disillusion anybody, but I am of the opinion that many of the accident records made on the railroads of the United States (and from the bottom of my heart I give every man credit for every single part of improvement he has made), the vast majority of these records, in my judgment, have been largely made up not by preventing the accidents, but by getting the men back on the job. I suggest that you consider that very carefully, and if you do that and if you are situated as we are on the Pennsylvania, you will find a very large field for improvement. Thousands of days of disability have been lost by the mere fact that the doctor would say, "Stay off a week," or "Stay off three days," instead of saying, "Go back to work and let your superintendent find you something that you can do that won't imperil your health."

I want to illustrate that. Would it be conceivable that the railroads in the state of Missouri would have an accident rate of, let us say, 250 per thousand, and the railroads in the state of Oklahoma have a rate of four per thousand? Is it conceivable that a plant with 600 colored laborers with feet as big as an acre of ground, handling ties and rails and all the other paraphernalia that go into a steel mill, would go 30 days without an injury?

We determined to cut injuries down and we got these fellows together and put them on their pride; we organized them into safety committees, and, now, almost over night, from a regular slaughter house, we eliminated all of these accidents and we have the perfect record. Just think of the lack of frankness of any representative, of any reputable business in America, putting a thing over like that as accident prevention without

giving us the benefit of their experience; but more particularly think of the stupidity of such people as the present speaker, and some other gentlemen who are listening to me, in not having the intelligence to detect it before the year of our Lord 1926.

I addressed a body of surgeons on Saturday morning. I did it with a certain amount of fear and trepidation. There is one thing that I rather pride myself on and that is I believe I know my own work, but I am thoroughly conscious of what I don't know. I never pretended to know anything about medicine, although I passed through a medical school. I don't pretend to know much about psychology, although I have read a little about it. I leave it to the technical men to know their subjects; but it requires no acumen, no enormous intelligence to recognize the fact that 50 per cent of the doctors do just what your mother and my mother did when we were children. Anybody who can't treat the lacerated finger and some of the simple things we are confronted with in the shop is lacking in ordinary human intelligence. The doctors have formed a clique and they have gone to the legislature and they have passed laws that a first aid man and a nurse can only do so many things; and what is the consequence? We have to employ highly trained medical men to do the things that a man without an education can do if he is properly trained in first aid, and, that, gentlemen, is a mighty important thing in the accident record of the railroads of the United States.

Maimed Men Should Have Best Scientific Care

Talking about serious consequences following first aid attention, putting men back on the job when the first aid attendant has given a man a little Brown's mixture for a cold or a little paregoric for cramps—there isn't anything in it. I told those physicians so.

There is nobody that is more sympathetic than I am. I would contribute a nickel any time to a blind man. I say that men who get their legs broken, men who have their vision impaired, men who are crippled and maimed ought to have the very best scientific care that can be accorded; but don't let us dignify these little scratches and bruises as major injuries and have to drag men away and keep them off the job week after week.

After I finished my talk the other day, one of our company physicians came to me and said, "Carrow, I have been listening to you and when I go back home I am going to experiment. I am going to send the men back when there is a chance for them to work and when there is no chance of injury."

Another fine doctor (you could tell he is intelligent) said to me, "We have cut that out in the American Steel Company. Not long ago an Italian injured his back. He came to me and said he wanted to get off. I told him he didn't need to get off. He did a certain sort of inspection work. I told him I would put him in a chair and let him sit there and do the inspecting, and his wound would heal and he would convalesce just as quickly as he would if he were to sit at home and worry about his trouble. The Italian came in the next day and I put him on the job

in the chair, and before noon he was around just as lively as he had been the previous day.

I want to suggest to you fellows that when you have anything to take up with your executives, cut out the generalities and get right down to brass tacks and give them some information that they can work on. I want to tell you that the amputations on the railroads amount to one per cent, but the sprains and strains, that indefinite thing that is descriptive of something for the most part that never occurs, is 19 per cent. If any individual in the railroad circles or industrial life will develop some means to determine what a sprain and strain is, his name will have a place alongside that of Mr. Richards, the father of the safety movement.

Bruises are 40 per cent of all the injuries, and what is a bruise? Nineteen per cent are lacerations, some of them no more than a scratch. And fractures, the most important of all, are only six per cent. Fractures and amputations, the most serious of them all, make up a measly seven per cent.

Twenty-Six Per Cent of Accidents Cost Three Days

I will tell you something that is even more convincing, and it will show you how our good friends, the Union Pacific and all these fellows who have led us, have awakened to it long before we did. What percentage of the accidents on a big road would you think cost three days? Twenty-six per cent, a little better than one quarter. The injuries from four to 10 days, 45 per cent; and the injuries from four to 16 days, 46 per cent; or in the first two weeks of disability, 72 per cent. Think of it, friends, what a remarkable field you have for getting men back on the job and not impairing their health. Seventy-two per cent of all the injuries on all the railroads of the United States only result in two weeks' disability, and half the time if you had master mechanics with the acumen of this gentleman who spoke here first this afternoon, half of that 72 per cent would be right back on the job where they belong, and even if it costs a little to put them back on the job, it has a wonderful effect on the morale that Jones mentioned. It makes the men feel they will not break their safety record and it keeps everybody liking to have a good record.

This "keep off the grass" attitude of the supervisory forces is another thing to which we can attribute a very large percentage of our accidents. The laborer is injured and the gang foreman says, "Mr. Relief Doctor, I turn this man over to you forever and a day," and he can stay there until hell freezes over and the supervisor doesn't pay any attention to getting him back. That combined with the kindly attitude of the doctor, places the man in the same category as that described by John Fitzhugh this morning. He told me about a friend of mine who had goat fever. He separated that man from the sheep and goats and this fellow was put in the hands of the doctor. The foreman had washed his hands of it, the general manager, the president, and everybody else in the railroad

had done the same thing, and this fellow was more or less of a derelict until a doctor by his kindly offices put him back on the job.

Now I want to tell you something. You know I am great for confessions. You remember in the prayer books, "Oh, Lord, our Heavenly Father, we have done those things which we ought not to have done and left undone those things we ought to have done." If somebody had come with the same enthusiasm that I have today and told me five years ago all about these details that I am telling you, our record would have been 25 or 30 per cent better. I am anxious not only to improve the record of the Pennsylvania Railroad but the record of all American railroads, and whatever I have you can have, and whatever everyone of you have, you ought to give to me.

One of our shops issued a notice like this, "Any employee who loses time hereafter on account of an accident will be called on at his home by a company physician and a representative of this shop within three days after accident occurs." From May 6 to October 31 the foreman or one of his assistants accompanied by a company physician, when necessary, called at the homes of 62 employees who had received minor injuries and failed to report on the following day of duty or who failed to report the accident at the time it occurred and reported off duty by telephone or through employee. Upon investigation it developed that the injuries of four of these employees were of such a nature that it was necessary for them to remain off duty one or more days. In several cases where sprains were reported, the diagnosis of the company physician proved them to be lumbago. In other instances it was learned they were off duty on account of the illness of one of their family. Where employees had remained from duty unnecessarily on account of a slight injury, they were induced to return to the shop and resume duty at their regular occupation.

While this method is still in force, it is seldom necessary to resort to it. A very important factor in obtaining these results was the hearty cooperation of Dr. J. B. Hillman, Chief Medical Examiner, and his entire staff.

Friends, I want every railroad to get the advantage of what we do on our railroad and I think everyone of us ought to come right across to each other and give the advantage of the other's experience. That will dignify the railroad business and in the end we will all be better off.

Partial Report of the Resolutions Committee

CHAIRMAN ROHWEDER: Tom Carrow never fails to put over a talk that has original ideas but he puts it over in such a way that it seems to leave an everlasting impression.

We have a Resolutions Committee for this Section. Mr. J. E. Long of the Delaware & Hudson is chairman. I will ask for his report at this time.

J. E. LONG (Delaware & Hudson Railroad, Albany, N. Y.): The Resolutions Committee wishes to offer the following for your consideration:

"Whereas, There is no uniformity in the manner in which financial

assistance is rendered to local safety councils by steam railroads; therefore be it

"RESOLVED, That the chairman of the Steam Railroad Section, National Safety Council, be directed to appoint a committee of three to confer with the officers of the National Safety Council with a view to arranging a meeting with the committee of local safety council managers to determine a policy in this respect."

(The resolution was regularly adopted.)

CHAIRMAN ROHWEDER: We will now have the report of the tellers on the election.

Announcement of Election of Section Officers

MR. PHILLIPS: Before this election, your chairman stated that six of the best men in the Steam Railroad Section of the National Safety Council had been nominated for these offices, and I want to assure you the result of that ballot verified that statement. There wasn't a single "has been" and also there isn't a single "also ran" in that bunch of six. They all ran good races.

We found, as a result of your ballot, for chairman for the coming year you chose Mr. White; for vice-chairman, Mr. Cott; and for secretary, Mr. Long. (*Applause.*)

CHAIRMAN ROHWEDER: I am going to have Mr. Cott make announcements in connection with the meetings tomorrow and other matters he has here.

SECRETARY COTT: I have been looking over our membership list and I want to tell you something about which perhaps you are not aware. There are seven roads not represented here today. That is not unreasonable; it is not really reasonable to expect them to be represented here. I wonder if the members know that we have one member in South America, one in the Hawaiian Islands, three in Canada and two in Australia that have been members of the Section for a number of years, pay their dues regularly without complaint; and I have had the pleasure a few times since I have been secretary of having a letter from several of the overseas members. It certainly should be a point in favor of them when that far away they continue to belong.

I want to call to your attention that you will have on tomorrow's program the representatives of various associations who will come here to present the views of their association to us. There may be some time for general discussion tomorrow, but out of courtesy to these representatives, there is to be no discussion of the papers presented tomorrow. There is time left in Thursday morning's program to discuss such subjects among ourselves as may be brought up in the papers presented by the gentlemen I refer to in tomorrow's program.

CHAIRMAN ROHWEDER: We have completed our afternoon's program. We are going to take one or two minutes to ask the incoming chairman to say a word to you, and then the meeting will stand adjourned.

CHAIRMAN-ELECT WHITE: Gentlemen, I appreciate very much the honor that has been conferred upon me today, not only upon myself but upon the railroad that I represent.

I am going to put forward my best efforts to make this Section a grand success the coming year, and I ask the cooperation of all of you to help me make it the best year we have ever had.

ADJOURNMENT

WEDNESDAY MORNING SESSION

October 27

J. D. WHITE, Chairman

Superintendent of Safety, Illinois Central Railroad Co., Chicago, Ill.

The second session of the Steam Railroad Section was called to order at 9:45 o'clock by Mr. A. V. Rohweder, chairman.

CHAIRMAN ROHWEDER: As you have observed by the program, we have quite a bit ahead of us and we are going to get right down to the set program.

Mr. Carrow, of the Pennsylvania Railroad, would like about one minute in which to present a resolution.

MR. CARROW: Mr. Chairman and Friends: It has been my observation of these meetings that some of the best thoughts frequently die after we leave, and in order that we may accomplish something of a definite nature on a subject that is bothering us more than any other, I would like to suggest that a committee of three persons be appointed to consider immediately a set of propositions for the prevention of train service accidents, and I would like to suggest that the chairman appoint Mr. C. T. Bailey, of the Oregon Short Line, Mr. McCampbell, of the New York Central, and one of our men, Mr. Mikusinski, who has made some very definite studies along that line, with a view of bringing back to this meeting, not later than tomorrow morning, a set of propositions which will assume the nature of a recommendation for action with respect to the prevention of train service accidents.

I want to report that during the first six months of this year there were 339 train and enginemen killed and 14,841 injured, representing a decrease of eight killed and an increase of 1,185 injured.

I have information that leads me to believe that some of the railroads, particularly in certain yards, have made excellent progress in the prevention of train service accidents whereas some of our other yards and some of our other divisions (I am speaking of the railroads as a whole) I have a lamentable record in this direction; and for that reason, Mr. Chairman, I would like to suggest that these gentlemen be appointed.

CHAIRMAN ROHWEDER: Gentlemen, as you have observed on the program, we have asked Mr. J. D. White, of the Illinois Central Railroad Company, to act as chairman of this meeting this morning. He is not only acting chairman but chairman in reality. We will now ask you, Mr. White, to take charge of the meeting.

(Mr. White took the chair.)

CHAIRMAN WHITE: I first wish to express my thanks to our dis-

tinguished chairman for his courtesy in designating me to preside at this morning's session. I am going to have the pleasure of introducing a program that is, I know, both interesting and important, and we are all going to enjoy it because our Program Committee has selected some eminent representatives of railroads to be here.

I have the honor to introduce to you this morning a speaker who has achieved distinction in railroad circles and I know that you are all very anxious to hear him; without any further remarks, I present to you, Colonel J. T. Loree, Vice-President of the Delaware & Hudson Railway, Albany, New York.

ADDRESS

J. T. Loree, Vice-President, Delaware & Hudson Railway, Albany, N. Y.

It is not so difficult a matter to address a gathering whose ideas of value and necessity as to your subject are so similar. Not for one moment can the slightest difference of opinion exist between us as to the vital need of an active and unceasing elimination of hazards in employment.

Nor is it much more difficult to state the reasons for this agreement: Self-protection—Increased efficiency—Financial need—Love of our fellow men—reasons good and sufficient, to each of us undeniably insistent, easy of comprehension.

When the subject was suggested it seemed to me that the reasons were so clear and self-expressive that I could only re-echo your thoughts, but as I reviewed the matter it occurred to me that the so-called "Safety First" activities and results might find different values to the occupants of different positions in our profession.

That this not only might be so, but of necessity must be so, became more and more apparent, the reasons being the difference in the point of view, perhaps best illustrated, if you will call to mind a series of photographs of a city. First, you have separate pictures of each house from each of its faces; then perhaps you have groups of houses, fronts and backs in blocks. Then whole streets of houses, and finally those bird's-eye views taken from an aeroplane hundreds of feet above the city, showing not only the city proper but its environs.

In the first picture, we plainly see the most minute detail of each separate building but not its relationship to anything else, and as our pictures take in more ground so the details vanish and the relationship becomes more apparent.

This picture series illustrates the changing points of view of the different grades in our business structure and as the responsible area of control of an employee increases, the detail becomes merged and the relationship becomes accentuated.

The vice-president, charged with operations, may be said to view safety first with the railroad displayed in an aero-photograph, having in the past examined the other pictures.

The history of a profession sometimes sheds great light upon its problems and their solution and it is particularly true of ours in a time when, through indefinite language and the efforts of many, the true reasons for a composition of rail transportation systems are befogged.

From the earliest historic time, the necessity has existed of bringing the thing produced to the point of consumption, and almost exclusively it was this transportation which gave value to the commodity. As the needs of the people grew through education and their gregarious instincts the sources of supply became more distant and ever the need of quicker and cheaper transportation increased. This need prompted the efforts of Stephenson, Bevin, Watt, Jarvis and Horatio Allen. How pressing the need is most aptly illustrated when the whole progress of steam rail transportation is comprehended within the single life of at least one employee upon our own line.

But this great transportation machine, produced to satisfy this need, is a most complex thing dividing into three distinct components: capital, management, and labor.

The first may be described as the portion of earnings one man saves and invests, and which some other man may spend.

Management is the co-ordinating and directing force producing the product by the employment of capital and labor. Labor may be defined as those who work under direct or indirect supervision of management.

The combination is a system organized for gain, to be had by the transportation of persons and property.

Losses to Capital, Management and Labor

Now, in this system lies a certain risk to each component. To capital it is loss through mismanagement, changed condition or desire, competition, hampering or confiscatory action of public regulation.

To management, it is risk of lack of capital or labor, and unknown conditions arising from the same causes as constitute the risks to capital.

To labor, it is those risks capital and management run in a lessened degree and, added thereto, the risk of bodily harm.

Our profession is a hazardous one as all occupations must be those which have to do with movement. This we call the inherent risk. There are two other risks, those arising from conditions and those from practices.

You may recall that upon September 15, 1830, the opening day of the Manchester and Liverpool line, there occurred the first railroad fatality—Mr. Huskisson, a passenger, being fatally injured, crushed from the thigh down by the "Rocket."

Lamentable as this accident was, when you read the words of the *Edinburgh Review* that "it was wholly attributable to his own carelessness," you are much more depressed by the fact that it began the long list of dead and incapacitated which has resulted of the same cause.

From that first day the work began of guarding against accidents

arising from this new danger, for the general movement for safety is as old as the human race.

Do we not state, "Self-preservation is the first law of nature"?

Every cave occupied in the early days and every fortification in the trenches of the late war, were safety first constructions.

Every weapon of either offense or defense, from the pointed stick which served as a spear to the latest gas bomb, constituted efforts at safety first.

Every vine and log bridge of the aborigines to the great Tunnels under lakes and rivers are but illustrations of man's unceasing efforts at safety first.

The movement is not new. It is very, very old; sometimes more active than at others, sometimes quite obscure in its direction, sometimes even defeating its own purpose, it has, however, ever been progressing; and this brings us down to a most modern time and to a modern problem in the present state of the movement and the topic which I have been asked to discuss—"Safety From a Vice-President's Point of View."

Loyalty and Discipline May Offset the Risks

As he views the property under his direction, as in an aeroplane photograph, he sees the components of the system—capital and labor—each in its relationship to the other. He sees in the suburbs, as it were, the history surrounding the development of rail transportation. He sees the risks run by capital, labor and management, with the failures of the past and the efforts to offset a repetition.

His is the responsibility and to him has been given the necessary authority.

To offset the risks he has two weapons—loyalty and discipline.

Against the risks to capital he must interpose the knowledge of the profession possessed by himself and every other employee, an alertness, a willingness for personal sacrifice, an untiring devotion, and cooperation. He must, with the aid of all, anticipate changing conditions and precede them, not meet them. He must insist that the service be so good that successful competition is impossible. He must, by public education, prevent adverse and destructive legislative action. This is safety first to capital, from his point of view.

For management, he must so conduct the business that investment therein will be attractive and safe and that conditions of wages and working conditions will attract the best elements of labor.

He must by study, observation and research, reduce unforeseen emergencies to a minimum. This is safety first for management.

For labor, he must by care and skill produce capital and earnings to enable them to be employed, and he must minimize their bodily risk; it is this last effort that too often we regard as the one and only "Safety First" movement.

To a vice-president, the safety first movement is one of good business, not maudlin sentiment.

Railway workers, to produce results, must be able-bodied and efficient,

and to maintain and produce either, the safest possible conditions and practice must be established and maintained.

A timid man is most apt either to get hurt, hurt others or, in his terror, do poor work. Therefore, for efficiency, men must know that the conditions are as safe as possible; that unsafe practices are stopped and that their fellow workers are likewise careful.

In every employee, from the engineer to the youngest laborer, the company has an investment varying from some \$5,000 down. This investment must not unnecessarily be rendered useless or less efficient by death or disability.

Each man has a place in the organization, and if you introduce a substitute the whole team slows up and you lose part of your momentum.

Railroads are great tax payers and every family made destitute by the loss of the earner's ability, in whole or in part, is supported partly through these taxes.

This may sound cold-blooded and material—is it not—simply sane? No one can see a fellow human being injured without a surge of pity, but if this is all you feel the condition or practice will remain to trap the next one. Be as sympathetic for the individual as you can. That is natural; but only by viewing safety first for all the components of the system as but a part of one's personal duties will best results and those of a really lasting quality be obtained.

Mr. Guilbert Responds to Colonel Loree's Address

CHAIRMAN WHITE: Brother Loree has favored us with an exceedingly fine address. I am going to call on Mr. Guilbert to tell him how much we enjoyed his address.

HARRY GUILBERT (Pullman Company, Chicago): There is one thing that Brother Loree neglected to mention in giving credit to the safety department for the record of the Delaware & Hudson, that is the fact that he set the example, because without that, the safety department, could not assist in making a record.

Colonel Loree has been trying to hide his light beneath the bushes, but I don't intend to permit him to do that. I have made exhaustive inquiries about this gentleman and the road which he represents, and boiled down here it is:

Colonel Loree is strictly a business proposition and a fine gentleman. His undivided attention is given to the task before him, and he is familiar with and keeps in touch with every branch of the Delaware & Hudson system.

He is deeply interested in the welfare of his men. He is a leader in all railroad activities, including safety, athletics, etc., and incidentally he has a war record, having served with General O'Brien overseas.

In a few words Colonel Loree is the illustrious son of an illustrious father, judged on all the information I have received from authentic sources, and I want to congratulate Colonel Loree and the Delaware & Hudson system for having an executive of that type.

There is another thing I want to mention. This is my fifteenth convention and I have been a safety man for 21 years, and I don't know of many railroad executives that have appeared at those 15 conventions. That is why I feel very strongly about it and we should be deeply thankful to this gentleman for appearing here today.

I have also noticed at this convention Mr. W. A. McGonagle, President of the Duluth, Missabe & Northern Railway. I do believe, boys, that our work will be made much easier and we will have a better record if we can get executives of this type at these conventions.

CHAIRMAN WHITE: Mr. Carrow made a motion here this morning which you all heard. May I hear a second to that motion?

(The motion was seconded and carried.)

MR. CARROW: Did that include the appointment of Messrs. Bailey, McCampbell and Mikusinski?

CHAIRMAN WHITE: Yes.

I want to announce that the committee named in Mr. Carrow's resolution will get together and arrange to carry out that resolution and report at tomorrow's meeting.

Our next speaker is a veteran of the transportation department, having come up through the ranks as operator, agent, dispatcher, chief dispatcher, train master and superintendent, and he holds one of the key positions of safety work. I now take pleasure in introducing Mr. Victor Parvin, superintendent, the Ann Arbor Railway and also representing the American Association of Railway Superintendents.

WHAT THE SUPERINTENDENT CAN DO TO PROMOTE SAFETY WORK

**Victor Parvin, Superintendent Ann Arbor Railroad, Owosso, Michigan,
Representing the American Association of Railroad Superintendents**

In the first place I wish to extend to you greetings from the American Association of Railroad Superintendents, which organization I have the honor of representing.

Our association is composed principally of chief dispatchers, train-masters, superintendents and general superintendents, but we have numbered among our membership, vice-presidents, general managers and others, and I am proud to say that the gentleman who preceded me on the program is a member of our association.

The members of our association, in line with the duties of the superintendent, deal with all phases of operation. The superintendent is one man who can not specialize.

While for several years our association in convention has dealt with the grade crossing problem, this year in convention was the first time that it has devoted any time to strictly safety first matters. Some of you are aware that we had with us at Montreal, in June, Mr. Carrow, who put across his message in his usual able manner, and I can assure you that his presence was greatly appreciated. I believe that it is going to do

a great deal of good to have members of one association appear before other associations and present their individual problems. And right here I might state that it was greatly due to Mr. Carrow's presence and influence that the superintendents' association in convention unanimously approved the two long, one short and one long as a standard highway crossing whistle, to be adopted by all railroads in the country, provided the suggestion may meet with the approval of the American Railroad Association.

The duties of a superintendent of the present are entirely different from what they were 20 or 25 years ago. At that time, as I recall it, the principal function of the superintendent was to see that his passenger trains ran as nearly on time as possible, or at least that today's train arrived before midnight tomorrow; and that when an engine left the yard, it carried as many cars as there was room between the locomotive and caboose; which method of handling tonnage kept the superintendent pretty well occupied.

Procedure of a General Staff Meeting

A superintendent's duties of today are entirely changed. This can probably be best illustrated by giving you an insight into a general staff meeting, which might be held on any railroad, and no doubt many of you superintendents of safety and safety agents have attended such a staff meeting. I believe the procedure is about as follows:

The freight traffic manager has entered a complaint on account of symbol or time freight trains running late; next comes the passenger traffic manager with his story about certain important passenger trains not making the time; the general superintendent has considerable to say regarding the matter of transportation ratio and failure to handle as much tonnage per train as he thinks should be handled; we next have the superintendent of freight claim prevention telling about the great amount of damage due to rough handling; the chief special agent speaks of superintendents being rather lenient at times when men get caught with their fingers too far into the door of a box car; the chief engineer informs the superintendents that they have not been watching their maintenance expense as closely as they should; and then the superintendent of safety proceeds to tell the superintendents that their divisions should be more safely operated.

You might suppose that after spending a day at such a meeting the superintendent would be about ready to throw up his hands and say, "What's the use," but if he is a man of this caliber he would not last long as a superintendent. The average superintendent can leave such a meeting, go out and get as many laughs out of a show as anyone else, or play as good a game of poker, but when the superintendent returns home he begins to feel around and find out where the rain drops are coming through, or in other words, he begins looking for the leaks. He takes up each matter in the order of its importance and endeavors to bring about a correction or improvement in each, including his safety first

record, and that is what we are going to deal with in the balance of my talk.

I have heard the statement made that a division is only as safe as the superintendent wants it to be. I believe this statement should be changed and we should now say, that a division is only as safe as the superintendent of safety helps the division superintendent to make it. It is the superintendent of safety and the safety agent who have made the division superintendents safety men, although there may have been many cases where it was necessary for this to be accomplished through the general manager; but regardless of methods, the average division superintendent of today is a *safety man*.

The superintendent of safety is the man that should sell the idea to the rank and file and lay down the foundation for safety work on all operating divisions. And after listening for six years to such capable speakers as Mr. Carrow, Mr. Hale, Mr. Bently, the late Mr. Harry Adams, our own Duff Phillips and numerous others, I am satisfied that you can not only sell safety to the men down the line but you can do it far better than any superintendent, because it takes a certain amount of oratory to do the job and this is one thing that you fellows have that the superintendent has not.

Responsibility Rests in Hands of Division Superintendent

After the superintendent of safety, or safety agent, has laid the foundation, then the responsibility for safe operation of a division rests absolutely in the hands of the division superintendent, and from then on he should not offer any alibis for failure to have his division as safe as any other division on his railroad. Whether or not a superintendent has a safe division, in my humble opinion, is wholly dependent upon discipline properly administered; in fact, I feel that the entire railroad structure, as far as it has to do with operation, is thus dependent and there is no exception with relation to safety.

When I speak of discipline properly administered I have in mind fair but positive discipline, and superintendents should require the same compliance with rules or special instructions which deal with matters of safety, as they would any other rule in the Book of Rules. You can rest assured that when the superintendent "winks" at the violation of any rule or regulation, whether a safety rule or any other important rule, that particular rule is going to be habitually violated, not only by one individual but in time by all of the men on the division. On the other hand, if the superintendent can instill into the minds of his men that observance of rules and regulations means safe operation, and anyone failing to observe such rules and regulations will be promptly disciplined, it will go farther toward making the division safe than any other one thing that he can do. And this is his responsibility and no one's else.

You have often heard the saying, "You can not teach an old dog new tricks." There are many employees on the railroads who have been there for years and they have formed certain habits in doing their work that we all admit are hard to change. In the case of the older men, it is going

to require a great amount of educational work and considerable patience, but the educational feature can best be taken care of through the medium of the safety first committees. I believe that one of the most certain methods of lining up an old employee in the interest of safety is to make him an active member of the safety committee. With the younger element the problem should be a much simpler one.

It has always been my habit in employing men to explain to them that the forming of habits is a simple matter, that it always seems to be easier to form bad habits than good, but they should bear in mind that it is much harder to break themselves of a habit than it is to form one and for that reason they should start into the game of railroading with the resolve that they would form, as far as possible, only good habits. With this same motive in mind I believe I have a positive recommendation to offer that will in years to come simplify the safety work on the part of division superintendents.

We all understand that brakemen, switchmen and firemen are employed principally by trainmasters and road foremen of engines, and I realized one day that new brakemen, switchmen and firemen would be on the railroad several weeks, possibly months, before I would even become well enough acquainted with them to know them when we would meet on the street. So I put into effect the plan of having each new man come to the office for a personal interview after he had been in the service a few weeks; and I always close this interview with a lecture on the hazards of the work and the importance of practicing safety and of forming safe habits. I am satisfied that this scheme is going to have a great effect, not only on the mental attitude of the new man toward the company as a whole, but particularly his view-point on the matter of safety, and it is safety that is mostly stressed and the last thing mentioned in my talk with these men.

Problem of Boulevard Stop at Railroad Crossings

In one other important matter I believe the superintendent can do as much, or more, than anyone else, and this is in connection with establishing the boulevard stop at railroad crossings in cities where the city itself establishes the boulevard stop for its through or important streets. Railroads have gone a considerable length in protecting the public at the various highways, both inside and outside of city limits; in fact, they have gone farther to protect the public than the public has ever gone to protect itself; and if city officials see fit to establish boulevard stops within their corporate limits at street crossings, it is certainly only reasonable that they should do so at railroad crossings not otherwise protected.

The argument that I have been using with city officials is that they see fit to cause automobiles to stop at numerous street crossings to avoid possible collision with a body of about equal weight, where fatalities seldom result; but they will permit, as far as they are concerned, an automobile to drive without hesitation on a railroad crossing in front

of a locomotive which may weigh half a million pounds. This attitude on the part of city officials is certainly not consistent, and while some superintendents have already succeeded in getting for their railroads boulevard stops at railroad crossings, I do not believe that the surface has been scratched and there is yet a great deal of good work to be done by the superintendent.

In conclusion, and on behalf of President Harmon and the American Association of Railroad Superintendents, I want to thank you sincerely for extending an invitation to have present at your convention a representative of our association. I can assure you that the association I have the privilege of representing will at all times gladly cooperate with you in the interest of safety, and will appoint members to serve on joint committees for the purpose of dealing with any special problems; in fact, I believe there has already been one such committee appointed.

Mr. Phillips Responds to Mr. Parvin's Address

CHAIRMAN WHITE: I am sure that we have all derived much benefit from Mr. Parvin's address. I could say many nice things about it myself, but I am going to call on Mr. D. G. Phillips, of the Wabash, to tell how much we have all enjoyed it.

MR. PHILLIPS: I know that you were all very much interested in Mr. Parvin's remarks about the ability of division superintendents to play poker and to shoot "craps," and you are right, gentlemen, when you presume the remarks he made were a challenge to meet him in his own room later.

It certainly does the safety superintendent a lot of good to have supervisory officials, superintendents, if you please, come here today, as this superintendent has, and assure us that the superintendents' association, that is the superintendents themselves, are now going into this safety movement and are going to do the very best they can to let us help them put the movement over.

We have gone along here for years listening to the eloquence of Isaiah Hale and the pleadings of Shedd and the cold mathematical facts presented by Tom Carrow, but we haven't reached anywhere near the point that we wanted to reach. Now as Mr. Parvin comes to us and tells us the superintendents are on the ground and that they are going to supervise this matter after these other fellows have done their part, I feel like just saying this one thing—Sheridan was 20 miles away, but Sheridan is now here on the firing line, and that 35 per cent reduction Tom Carrow mentioned is just as good as won.

CHAIRMAN WHITE: Of course, our first duty is to prevent accidents among our employees. However, we are not always successful in doing that, and the next best thing is to have competent physicians to look after these men and get them back on their jobs with us with as little delay as possible.

We are going to have the pleasure of listening to an address this

morning in which we are all very much interested, and I am sure that Dr. W. Louis Hartman, chief surgeon, Michigan Central Railroad, representing the medical section of the American Railway Association, will be able to tell us just what we want to know. I take great pleasure in introducing to you Dr. Hartman.

THE SURGEON'S VIEWPOINT ON RETURNING MEN TO SERVICE

W. Louis Hartman, Chief Surgeon, Michigan Central Railroad, Detroit, Mich., Representing the Medical Section, American Railway Association

In my short experience of 25 years in dealing with accidents I have found that practically 80 per cent of all accidents happen in the first two hours of the first half of the working day and the last two hours of the last half. Those accidents that occur in the first two working hours are due, in a large majority of cases, to the employee, having his mind concentrated on some subject other than his work. This is often due to the home environment or to something which has happened just prior to his leaving for work. He may be in financial distress, have illness in his family or have had a quarrel with some member of his home, and his mind is concentrated on that subject rather than on his work. Therefore, his mind is running single track and it takes from one to two hours to divert it from that siding and bring it out on the main track where he will concentrate on the work that is before him; the result is that, in the meantime, an accident is liable to occur.

To my mind, a great many of these accidents could be prevented if we could get closer to our employee's home environment and the problems that go to make up his mental attitude. Just how this could be brought about is a matter well worth considering.

The accidents that occur in the last two hours of the working period are largely due to over-fatigue, resulting from some physical or mental defect, and for this condition the remedy is at hand. The avenue that leads to the correction of these defects lies in seeing that the employee is not only physically and mentally fit, but that he is kept physically and mentally fit; and this is obtained through periodical physical examinations, whereby we discover any disabilities and through proper treatment and observation see that they are overcome. Merely making a periodical physical examination gets us nowhere unless we follow up the defects that are found and see that they are corrected. Of course, due to human equations, however cautious we may be, we will probably always have a certain amount of accidents, but there is no doubt that the majority of these can be avoided.

We will now deal with the man who has had an accident and is about to be returned to work. In my opinion, these men should often be given some light service until they are able to resume their regular duties, thus reducing the chance of an accident. In the case of an employee who has been injured and has had a long-drawn-out convalescence, my

experience has been in these cases that if his duties could be changed to those of a lighter capacity, his recovery would be more rapid than if he were allowed to wait around until such time as he is able to take up his regular duties. In the case of the man who is performing some light duties which will keep his mind occupied and away from his physical defects, the psychology is that he will be thinking of what he is doing instead of his defects, and therefore his recovery is more rapid.

It also shows him that his employer is trying to do something for him and is treating him as a human being, and this diverts his mental attitude to the channel where he is anxious to recover sufficiently to be able to resume his old occupation. While during this period he is perhaps not earning what his employer pays him, in the end he is an economic asset to his employer.

My experience has been that at times too little attention is paid to what the surgeon might have to say regarding returning the injured to duty. Due consideration should be given to what the surgeon has to say about the physical condition of the injured. There have been cases where men who knew nothing about surgery have put their opinions above those of the surgeon. These cases are few and far between, being perhaps brought about through lack of confidence in the surgeon. If, however, this is the case, my advice would be to change and obtain men to do this work in whom confidence would be placed.

Time of Disability Is Sometimes Underestimated

I am not going to leave the surgeon out of this matter, either; I am going to talk about him also. The surgeon sometimes underestimates the time of disability. This is often done through the surgeon's idea that he is helping his employers; but this is certainly a mistake, as it is more economical in the long run to over-estimate a disability than to under-estimate it. This you can readily see, for the reason that often if the estimated disability is made too short, an early and equitable adjustment is not made and later on becomes a more expensive proposition than if the proper estimate were made at the outset. I thoroughly believe in an early adjustment, as my experience has been that it matters not how honest the employee may be (and most of them are honest), his recovery is more rapid where an early adjustment is made than where the time is allowed to drag on without settlement.

One of the points that I wish to stress and which is all-important, is cooperation from the higher officials down to the man directly in charge of the injured employee. My experience has been that this has not been practised as thoroughly as it should be. Of course, we all realize that large corporations are considered by employees and by the public in general as cold-hearted and indifferent, and the belief is that all they are interested in is what they can get out of the employee; that they are blind to human kindness and the welfare of their fellow-man.

We who are more closely connected know that this is not true; therefore it is our duty to dispel this distorted idea in the minds of our

employees and the public and show them that large corporations have a heart and are not just looking to squeeze the last bit of service out of the employee in order to increase the exchequer of the company. By eliminating this fallacy from the mind of the injured, he will not feel that he is obliged to go outside and employ an ambulance-chaser in order to protect his interests and obtain what he thinks is right for his injury.

Whenever a man is sufficiently recovered that he can do light work, this should be provided for him, as I have said before, in order to keep his mind from dwelling on his physical condition.

On the New York Central Lines, this method is practiced and we find that it is an economic procedure. I can do no better than to quote the instructions recently issued by the vice-president of the New York Central Lines:

A Railroad Vice-President's Recent Instructions

"It is very desirable that the supervisory forces, especially foremen, retain an active interest in the return of an injured employee to his work as soon as he is able to perform satisfactory service, irrespective of the period of disability.

"It is an advantage to injured employees as well as the company, that the economic loss resulting from injuries be minimized as much as possible. In all injury cases, it shall be the duty of the employing officer, when the employee does not return to work on the day following the injury, to ascertain whether his injuries are of such a nature as to warrant further loss of time.

"No injured employee should be permitted to work when, in the opinion of the attending surgeon, the injuries are of such a nature that the recovery therefrom will be retarded in any way. This question is wholly one for the attending surgeon to answer.

"While the question as to whether an injured employee can perform satisfactory service is largely one for the department in which he is employed, due consideration must be given to the company's interest in connection therewith. Where satisfactory service can be rendered by an injured employee in a capacity other than that in which he is regularly employed, it is highly desirable to so employ him where possible."

It has been shown, since this practice has been followed, that the employee is more satisfied, and that it goes a long way toward convincing him as well as the general public that large corporations have consideration for the protection of their fellowman.

CHAIRMAN WHITE: We are greatly indebted to Dr. Hartman for taking us in hand for the medical department and telling us how that department can contribute to the success of our work.

I am going to call on Mr. W. A. Booth of the Canadian National Railways to express to Dr. Hartman our thanks for his very fine address.

MR. BOOTH: I am sure we all appreciate very much what our friend said to us this morning. I remember his saying something about the first two or three hours in the morning being perhaps the most hazardous for the men because they may have something on their minds that happened at home before coming to work. I believe my friend Jones touched on that a little yesterday.

I am sure it is very pleasing to this Council to have one of our medical friends come along, as also the superintendent that preceded him. It goes to show, I think, that the Council is bettering its programs each year. You know that, after all, these medical fellows are about the best in the land. I have a good deal to do with them. I know we all appreciate very much what Dr. Hartman has said to us, and I should very much like to move a vote of thanks.

CHAIRMAN WHITE: That completes our program for this morning. We still have some time yet, and I am going to open what might be called a round table discussion. I have been requested to ask Colonel Loree if he will say something more in connection with Dr. Hartman's address.

Colonel Loree Responds to Dr. Hartman's Address

COLONEL LOREE: Mr. Chairman, I don't know why I should be presumed to know much about the medical profession. I have been called doctor frequently but I think that is because I wear glasses. Nevertheless, I do think, in all seriousness, that we have paid much too little attention to the physical condition of the officers and employees of the railroads and that a very large number of what may be termed preventable accidents have been directly caused by the failure on the part of the management to be cognizant of that fact.

Dr. Hartman said this morning that within the first two-hour period and the last two-hour period of the working day occurred the majority of accidents, and I don't think that he will have to take any water on the assumption that that is the experience of all of us. The reasons advanced by Dr. Hartman as to the prevalence of accidents in those periods we must likewise concede. It is no kindness to the man, if you know that financial or domestic worries are occupying too much of his attention, to allow that man to continue in the service unless those matters can be properly adjusted.

I remember a case which was recalled by Dr. Hartman's paper, an experience of my own after I had been connected with the railroad. I now have the honor to be with, only a few weeks. We had an engineer of long experience and exemplary record, who, had to be summoned to the office for violation of the rules. They weren't serious derelictions and if they had come over an extended period, there would have been very little thought of it; but for a man who had gone on for years without any violation of rules, and then three coming to the attention of the assistant trainmaster, it seemed to be a matter of some moment.

Investigation was first made outside and then from questioning the

man, it developed that his wife was extremely ill. He had gone to a very large expense for doctor bills and he was trying, in order to save some money, to do the night nurse work, and the result was that when he went on duty in the yard during the day, he was totally unfit for the service.

When he had finished the third day, I said, "You can't work any more until your wife has been to the hospital and is well on the way to recovery," and I shall not ever forget the despairing look that appeared on that man's countenance. First of all, 30 days' pay is a serious matter, and that seemed to be about the last straw in that man's bundle, and it was quite a long while before he could listen comprehensively to what else had to be said.

But there was no use in letting him go on because he would either have killed somebody or else he would have been killed himself, and I think very often if we took the trouble to go thoroughly into the home life and the conditions surrounding the home life of the employee, we would more intelligently approach the problem, not only of the prevention of accidents, but violated rules.

As I said before, the two things that the vice-president has to conduct his work are loyalty and discipline, and I want to clarify exactly what was meant by that.

The Employee Must Have Pride in His Organization

By loyalty I had in mind first of all the individual's pride in himself. Any man who hasn't pride in himself starts very poorly. Then he must have pride in his ability to perform the work for which he is employed. He must have pride in the organization which employs him. One of the truest things ever said was written by Elbert Hubbard: "Don't continually kick about the organization that employs you. If it is as bad as it is, how can you afford to work for it?"

Loyalty embraces the sacrifice that the individual is willing to make his own predilections for the benefit of the organization of which he is a member. It is the trust and confidence that all employees must have in those who have been placed over them for supervisory purposes.

What is discipline? I know to the operating superintendent, and perhaps to most of the safety superintendents and agents, and I know to a great many general managers and others, the word discipline has meant suspension, adverse criticism, dismissal, and yet nothing is further from the meaning of the word itself. Discipline is exactly what is meant in the Greek—it means to teach.

There is practically no place on a railroad for punitive discipline. It is very seldom that you can afford either to lay a man off in suspension or sever his connection with the company. When you think that in every engineer that works on the American railroads the company has at least \$5,000 invested, it should be a long time before the superintendent or trainmaster would sever that man's connection. No superintendent that I know, if you handed him \$5,000 in bills, would throw

it out the window, and he has no more right unthinkingly to put an engineer out of the service. There are five per cent, roughly, of the employees of the railroads that are no good, that are unfit for railroad service. They may be very competent elsewhere, but for our service they are totally incompetent.

Discipline means to teach, not only teach the details and the technique of the profession, but it means to teach how to perform the service that is to be performed in a safe manner, and it is in exactly that connotation that the two words which I used to express the tools of the vice-president were used this morning.

DR. HARTMAN: You will pardon me for taking the floor again. There was one part of this that I really did not stress, that is, the last two hours of the working day. My experience has been by close observation that the majority of our accidents which happen during the last two working hours of the day, are due to over-fatigue resulting from mental and physical unfitness.

I have a case in mind (this is only one of many) where a man had been working for a long time and the last half of the day he was slowing up. His economic value was only about 20 per cent of what it should have been. After censuring the man and going down into his record more, we found he had not only been going down in his efforts, but he had been ruining material. We examined his eyes and found his trouble. We had his eyes thoroughly examined, glasses put on, and he gave us a day's work. That is only one case of many that I could cite. Therefore, it is important that we know that in our shops where we have a great many accidents, the eyes of our employees are normal. If they are not normal, they should be brought up to normal with glasses.

Round Table Discussion on "Train Service Accidents"

CHAIRMAN WHITE: Colonel Loree, I was especially requested to call on you to say something in connection with Dr. Hartman's address, and I am very glad I did, because we enjoyed very much your further remarks.

This is one session that I am going to propose we finish in accordance with the program and adjourn on time.

I am now going to open a round table discussion for about 30 minutes on "Train Service Accidents." I am going to limit each man to three minutes, and at 11:45 I am going to adjourn this meeting.

ROBERT SCOTT (Atlantic Coast Line, Wilmington, N. C.): May I accept your gracious offer just for a moment and put a question before this meeting that I have been asked? Something was said yesterday afternoon by Mr. Phillips, I believe, in connection with the wonderful reduction that his railroad has made in grade crossing accidents. The matter was brought out by the representative of the superintendents' association this morning, and it seems to me, as some of our fellow members have said this morning, it is a matter of much importance that

we find out how many railroads in our group have changed the grade crossing whistle signal. I propose, Mr. Chairman, that you ask every man representing every railroad here to give the name of his road if it has changed the whistle signal so that it can be recorded in the proceedings.

CHAIRMAN WHITE: You have all heard what Mr. Scott has said, and I will be glad if each representative of the railroads here represented will signify whether his road has changed the grade crossing signal whistle, and I am going to start off with my own.

Railroads Using the New Whistle Regulation

(The following roads have changed the grade crossing signal whistle:)

Illinois Central Railroad
Wabash Railway
Hocking Valley Railway
Lehigh Valley Railroad
Great Western Railroad
C. B. & Q. Railroad
M. K. & T. Railroad
D. T. & I. Railroad
A. C. & Y. Railroad
Ann Arbor Railroad

CHAS. E. HILL (New York Central Lines, New York City): The New York Central Lines have not changed the rule excepting through special instructions which will have the same effect. It will require the sounding of the last whistle to be prolonged until the crossing is reached.

S. M. GALATY (Chicago & North Western Railway, Chicago, Ill.): The Chicago and North Western have the same procedure.

J. J. HEAVEY (Erie Railroad, Huntington, Ind.): The Erie Railroad has followed the same principle on the western division.

MR. HILL: Mr. Chairman, I am not going to discuss the question at issue at this time, but may I just ask those who are here representing the various units of the New York Central Lines to stand so we may know how many are present?

(There were thirty-five.)

ISAIAH HALE (Atchison, Topeka & Santa Fe Railroad, Topeka, Kansas): It has truly been said that he who tooteth not his horn, his horn shall not be tooted.

CHAIRMAN WHITE: I want to say that I am not going to do any tooting this morning. I was requested early in the game to leave the great Illinois Central in Illinois and it is still out there.

Does anyone else want to say anything about train service accidents? We have a little more time and should benefit by some discussion here.

C. T. BAILEY (Oregon Short Line Railroad, Salt Lake City): It appears to me that in view of the fact that a committee has been appointed

to investigate the subject, any discussion should be postponed until the committee has reported.

CHAIRMAN WHITE: This is another case where the acting chairman has been misled in opening that kind of a discussion. Next year I think I will stay in my room out of sight until the time for the meeting.

MR. CARROW: A thought occurred to me this morning after the very able address of the surgeon of the Michigan Central, which I think is so important that it should not go into thin air, as most of our thoughts do. While I was formulating a tentative resolution, I heard someone mention adjournment, and I will therefore have to present the resolution I have in mind extemporaneously.

"Whereas, The diagnosis of treatments of injuries and disease by railroad doctors enables them to detect the physical and mental condition of employees that might be antecedent to accidents.

"RESOLVED, That it is the sense of this meeting that safety officers develop a relation with their respective company surgeons and doctors that will enable them to obtain from the doctors any information that might bear on the prevention of injuries to railroad employees."

I move the adoption of that resolution.

(The resolution was seconded and carried.)

ADJOURNMENT

WEDNESDAY NOON LUNCHEON

October 27, 1926

E. R. COTT, Toastmaster
Safety Agent, Hocking Valley Railway Co., Columbus, Ohio

ADDRESS

**W. A. McGonagle, President, Duluth, Missabe & Northern Railway
Company, Duluth, Minn.**

No Congress of safety officials would be worthy of the name, without paying tribute to the life work and the public service of Ralph C. Richards, of Chicago, Illinois, the Father of the Safety First idea. It occurred to Mr. Richards that there was a needless number of fatalities and a far greater needless number of accidents in the railway service, many of which could be entirely prevented by a persistent and consistent system of education; and so he started a campaign of "Safety First" that has spread like wildfire among the railways of the United States and among our manufacturing industries, until the present results are so startling as to cause us to wonder why we did not adopt this method many years ago.

Mr. Richards, notwithstanding opposition at first, carried on, and today, when our reports show the many thousands of lives that have been saved and the greater number of accidents that have been prevented, we have cause to remember with gratitude this splendid man who was with us for a time to assist in doing God's work on Earth, and has now been called to receive the final approbation of the Master—"Well done thou good and faithful servant."

Suitable tribute should also be paid to Judge Elbert H. Gary, Chairman of the Board of the United States Steel Corporation, for working out a definite plan of safety, sanitation and welfare among the constituent companies of the corporation, which plan has produced marvelous results in saving the lives and limbs of many of its hundreds of thousands of employees and has at the same time brought into effect the closest cooperation of officials and men, due to the friendly interest taken by the officers in the welfare of these employees.

It is a very great pleasure for me to be present at this, the Fifteenth Annual Congress of the National Safety Council, Steam Railroad Section. I have been in the railroad service for a period of 45 years and during that time have witnessed the tremendous growth of the great railroad industry; but so rapid has been the development of the railroads of the United States, that we have neglected to look around us to see the increasing danger to life and limb caused by the mad haste that we have all been guilty of and the indifference that has existed among our employees for the safety of their fellow employees and the public. We have rather assumed that it was up to the employee to look out for his own safety, if he cared to, and have not impressed him sufficiently with

his responsibility for conserving the lives and limbs of his fellow men.

Fortunately, due to the activity of Ralph C. Richards and the many others who adopted and practiced his suggestions, we are at last emerging into a period when it is a disgrace to any railroad executive to permit carelessness among his employees; and each and all of them, to a greater or lesser degree, are taking into serious account as a business proposition, as well as a humanitarian obligation, the conservation of human life and limb.

The need of the National Safety Council, as a clearing house for safety ideas and methods of accomplishing them, is becoming more and more apparent, not only to the railroads of our country, but to all industries, and to our national, state, city and even our rural governments. The total membership of the National Safety Council, now consisting of about 4300 railroads, industries and municipalities, is appealing and shows conclusively that the people of this country are alive to their responsibilities in regard to the conservation of human life, and are anxious to become associated with specialists along this line and follow those recommended practices that will give us the desired results.

National Safety Council Congresses Lauded

The National Safety Council is doing a noble service in bringing together in congresses like this, men from all walks in life, each giving the best that is in him for the welfare of all, with the single thought of eliminating the needless accidents that have sapped the life of our Nation and have to a degree disgraced our modern civilization. Let us therefore be up and doing to make our country, already the brightest and best country in the world, also the safest Nation for each of us to labor in, and so give confidence to all that each one of us is looking out to an unusual degree for the welfare of all the others.

In my opinion, each railroad in the United States and each and every industry should be active members in such national organizations as this one, and preferably this particular organization, in order to secure maximum benefit at the lowest consistent cost, of the safety work being fostered by the master workmen who compose the official roster of this organization. There is not and never can be any politics in this National Safety Council, nor can it ever be controlled by any particular religious denomination; on the contrary interest for the personal safety of all the people is the first consideration of the officers and employees. Its meetings are held in different centers in our country, so as to make it reasonably convenient for the greatest number to attend and thus get at first hand full information regarding recommended practices and take this knowledge back to our homes to assist in adding further safeguards to our employees and to the public at large.

The accident prevention problem on American railroads, from the standpoint of the railroad executive, is the particular subject assigned to me today. To you who are charged directly with the responsibility of organizing and directing safety departments, I wish to say that outside

of the credit you will receive for carrying out humanitarian ideas there also comes the assurance that it pays in hard dollars to save the lives and limbs of our employees. Too many of us in the past have hesitated as we comprehended the cost of organizing and maintaining safety departments, but my own experience has fully satisfied me that all the expenditures we have made in this department of the Duluth, Missabe and Northern Railway were warranted. The investment made has been a paying one, even measured commercially, and we are in position to recommend to all other executives the organization and permanent maintenance of a strong and effective safety department, which, from our own experience, we know will tend to unite in a bond of fellowship all the officers and working men of your companies.

Ten years ago we created a safety department on the Duluth, Missabe and Northern Railway, with Mr. A. V. Rohweder, who is now the chairman of your Steam Railroad Section, in charge, reporting directly to the president. His presence here today indicates that he made good in his department and that the National Safety Council recognized his special ability.

He attends all officers' meetings, is familiar with all subordinate departments, cultivates the friendship of all officers, foremen and employees and the men look upon him as one of the most important officials on the railroad. He has succeeded in cultivating a spirit of cooperation and friendship among the employees that has resulted in very great benefit to the company, and we have as a result of this cooperation a record that is very satisfactory from every point of view.

Various Safety Committees Are Active

We organized safety committees in every department and required our men to serve upon them according to their seniority, beginning with the General Committee, upon which the officers serve and of which the president is the chairman. We follow with the Shop Safety Committee, the Operating Safety Committee, the Engineering Safety Committee, the Ore Dock Safety Committee, the Coal Dock Safety Committee, composed of employees and officers in each department. Written recommendations are made by the men in every department, tending to eliminate dangerous practices, increase efficiency and improve appliances used. These committees meet regularly once a month and have made thousands of recommendations, the majority of which have been adopted by the General Committee. Only a small number have been rejected, (about three per cent), and the employees who make the recommendations are always fully advised as to the reasons for rejecting any suggestion. Those whose suggestions have been adopted are also advised and complimented for their assistance in promoting safer and more efficient operation.

Attendance of the president and other general officers at department safety meetings now and then, gives inspiration to the men to do their best. It is the same old story of "like master, like servant" and the

men are glad to know that their officers really mean what they say in urging them on in making new suggestions.

Safety dinners and picnics are given now and then, at which our own officers and some good speaker from the outside, are present to spur the men on to renewed effort. The successful work of the employees is given full credit at these meetings and the men always return to their occupations fully resolved that it was worth while to give their time and their thought in eliminating as far as possible the accidents that cause sorrow in their homes and loss of earnings possibly for a long time.

The accident record of the Duluth, Missabe and Northern Railway Company, based on the number of accidents involving the loss of one day's time or more for the years 1917 to 1925, inclusive, is as follows:

Safety Record Covering Nine Years

Year	1917	1918	1919	1920	1921	1922	1923	1924	1925
Number of Accidents.....	607	413	494	298	179	68	71	45	76

The tonnage moved for the year 1925 was 21,373,044 tons; our maximum number of employees was 3,349; our average number 2,701. In addition to the above, our records show that the severity of injuries has been greatly reduced.

The Missabe Road has operated from December, 1923, to date, a period of nearly three years, without a single death and without the loss of an arm, hand, eye, leg or foot to any employee or passenger.

In our Car Repair Shops at Proctor, where we employ 216 men on the average and repair an average of 1,898 B. O. cars per month, we have a record of operating over eight years without a single lost time accident where one day's time or more has been lost.

These records mean only one thing, namely, that it pays to work out an intelligent plan of cooperation in reducing accidents and it pays for railroad executives to lend a hand in helping employees to help themselves to the end that sorrow may be banished in so far as is possible and that employees may leave their homes for their work on our railways and in our shops with a reasonable assurance that they will not be maimed.

In conclusion I desire to state that our company has been repaid many times over for the cost of organizing and developing the safety work on our railroad; it has paid me in peace of mind to assist in working out an effective system for preventing accidents to our employees; and I am much prouder of our record in saving human lives and limbs than I am of the splendid low operating cost we have attained, much of which is the result of loyal and faithful cooperation of our officers and men.

It is my hope that all our railways, industries and municipalities may see the light of the new day and realize that we are indeed "Our Brother's Keeper."

WEDNESDAY AFTERNOON SESSION

October 27, 1926

L. F. SHEDD, Acting Chairman
Superintendent of Safety, Chicago, Rock Island & Pacific Railway Co.,
Chicago, Ill.

The meeting was called to order at 2:30 oclock by Chairman Rohweder.

CHAIRMAN ROHWEDER: On the third lap of cur program, the chairman of the Program Committee will preside. I want to say that Mr. Shedd, who worked out last year's program and this year's program, has done a real job. I never realized until this year the amount of work that is involved in the job of chairman of a program. Visualize for yourself the amount of correspondence it takes to get together the speakers on the program and then work that out with the National Safety Council to get it down in brief form and into your hands when you register here at the convention. That is a real job. And then to work it out so your time comes along about as you anticipated is a bigger job.

I want to pass one more idea along to you and that is that we have three very excellent papers this afternoon. These gentlemen have come here representing three associations, three national railroad associations, and they have given considerable time and thought to their papers, and I hope that you will make any notes that you might want to make so you can discuss them tomorrow at the round table discussion.

I am going to ask Mr. Shedd to adjourn this meeting when the regular program is over.

(Mr. L. F. Shedd, of the Chicago, Rock Island & Pacific Railway Company, Chicago, Illinois, took the chair.)

CHAIRMAN SHEDD: I am very happy, of course, like most fellows, to be permitted to sit in the active chair up here, but the real good that I get out of this is through the magnanimity of the fellow who has just stepped off the platform. This isn't a love feast but Art has again displayed his executive ability, his real leadership, by distributing some of the honors, as it were, among some of the older heads of the Section. I am speaking now of Jim White and myself; and then it was splendid of him to let Cott be the toastmaster today, for if there is anything in the world that Cott likes to do, it is to talk.

I am very glad to preside; but the thing that I am really glad about is that we have had such a wonderful session this morning, climaxed by that wonderful speech by Mr. McGonagle, that Godfearing gentleman who has the courage of his convictions and the courage to come here

and tell them. The further we go, the better it gets, and I am anticipating something fine this afternoon from this wonderful array of talented men whose names appear on the program.

ROBERT SCOTT (Atlantic Coast Line, Wilmington, N. C.): Mr. Chairman, before you proceed with the program, I wish to offer a motion to the effect that the Steam Railroad Section go on record as making a specific request of the *Railway Age* and the NATIONAL SAFETY NEWS to reproduce in full every word that Mr. McGonagle offered at our luncheon today. I so move you, Mr. Chairman.

(The motion was seconded and carried.)

CHAIRMAN SHEDD: We are privileged to have with us today a man who has done a great deal outside of the Section to make streets and highways over the railroads, as well as remote from them, safer in one of the great states. He comes from a city in the northwest that bears a decidedly splendid name. I am very glad to introduce to you Mr. F. W. Matson, Commissioner of the Minnesota Railway & Warehouse Commission, and also Chairman of the Committee on Safety of Railroad Operation.

THE MINNESOTA STOP LAW

F. W. Matson, Commissioner, Minnesota Railway & Warehouse Commission, St. Paul, Minn.

On April 24, 1925, the Minnesota Grade Crossing law was approved and went into effect. Without quoting the entire Act I will present some of the sections:

SECTION 2:

"The commission is hereby authorized and required to adopt and prescribe uniform warning signs for use at grade crossings in this state which will furnish adequate warning of the existence and nature of such grade crossings and to make regulations as to the place of installation. There shall be at least three distinct types of such warning signs, to-wit: a home crossing sign, for use in the immediate vicinity of the crossing, an approach crossing sign, to indicate the approach to a grade crossing, and a stop sign, which shall have the word "stop" plainly appearing thereon, to indicate the necessity to persons on the highway approaching the crossing whether in vehicles or otherwise, to come to a stop before proceeding over the grade crossing, according to the provisions of this act.

SECTION 3:

"At each grade crossing in this state hereafter established and at each grade crossing where and when the existing crossing signs are replaced the railway company operating the railroad thereat shall erect and maintain on the highway on each side of the railroad track or tracks and within a distance of 75 feet from the nearest rail, one or more of such uniform home crossing signs.

SECTION 4:

"At each grade crossing where, because of the conditions surrounding the same, the reasonable protection to life and property makes it

necessary for additional warning signs to be placed on the highway at a greater distance from the crossing than the home signs, such approach warning signs shall be installed. The commission is hereby authorized to designate any such grade crossings requiring such additional signs on either or both sides of said crossing. When any such crossing is designated by the commission as requiring such additional protection, it shall notify the railway company operating the railroad thereat and the public authorities having the care of the highway. Such railway company shall, within 30 days after such notification, furnish such uniform signs to such public authorities, and such public authorities shall erect said signs in conspicuous places on said highway on either or both sides of such grade crossing, as the case may be, not less than 200 feet from said crossing and shall thereafter maintain the same.

SECTION 5:

"At each grade crossing where because of the dangers attendant upon its use a reasonable protection of life and property makes it necessary for all persons approaching the same to stop before crossing the railroad tracks thereat, such stop signs shall be installed. The commission is hereby authorized to designate any such crossing requiring such additional protection as a stop crossing and shall notify the railroad company operating the railroad thereat of such designation. Within 30 days after such notification it shall be the duty of such railroad company to erect such uniform stop crossing signs in conspicuous places on each side of said crossing.

SECTION 6:

"Whenever any vehicle carrying school children, explosive or inflammable liquids, or passengers for hire, or any trucks or any vehicle having in tow any other vehicle or equipment, or any vehicle of the tractor or caterpillar type, approaches any grade crossing it shall be the duty of the driver thereof to bring the same to a complete stop before reaching the railroad track and before crossing said track to ascertain when such crossing can be made in safety.

SECTION 7:

"Before proceeding across the railroad track at any crossing marked with such stop sign, it shall be the duty of all persons controlling the movement of vehicles to bring such vehicles to a full stop and to ascertain whether or not trains are approaching such crossing."

The Commission appointed an advisory committee composed of experts on signs, crossing protection and road marking. This committee met several times and worked out specifications for signs to be used and suggested the following general rules for the selection of stop crossings:

"Crossings Outside of Municipalities"

1. Where the view of an approaching train within a distance of 500 feet in either direction from the crossing is obstructed from an observer at any point on the highway within a distance of 200 feet in either direction from the crossing:
2. Where the view of approaching trains within a distance of 1,320 feet in either direction from the crossing is obstructed from an observer at any point on the highway within a distance of 50 feet in either direction from the crossing:

3. Where a public highway adjacent or parallel to the right of way turns and crosses the right of way:
4. Where the smaller angle of the highway crossing is less than 60 degrees:
5. Where the highway crosses the tracks of more than one railroad company on right of ways which are parallel, the distance between the tracks, as well as obstructions, should be controlling features.

"Crossings Within Municipalities"

At crossings in municipalities, no rules as to distance and clearances can be suggested. The usual speed of trains passing through the towns, density of traffic, the location of buildings, their distance from the main lines and the practice of spotting cars adjacent to crossings must be given consideration in scheduling such "stop" crossings.

Each railroad operating in the state was requested to submit a list of the most dangerous crossings on their lines and ones which should be designated as "Stop Crossings." The Commission had printed a pamphlet containing the law, the specifications for the different signs to be used and the suggestions outlined above.

In June, 1925, the Commission started out inspecting these crossings and has now almost completed the work. There are about 13,000 crossings in the state and we have selected about 1,300, or approximately 10 per cent, as stop crossings.

Great care has been exercised in the selection of these crossings and many of the crossings suggested by the railroad companies have not been marked. In many cases a sign has been placed on only one side of the track, that is in cases where the view was obstructed from one side only. These trips have been made in a special train consisting of an engine and business car, stopping at each crossing and walking over the road from both sides. In some cases we have improved the condition of the crossing by re-locating the signs, ordering brush cut out or small buildings re-located so as to give a better view.

In municipalities we have met with local authorities, and with them have gone over each crossing, securing their full cooperation in the location of the stop signs and their promise of enforcement.

On trunk highways we have been particularly careful about designating any stop signs unless conditions were so thoroughly bad as to make it necessary for the protection of life and property. We have had a representative of the state highway commission with us on most of the trips and he has been of great help in locating and re-locating crossing signs and advance warning signs. We have also taken into account the amount of automobile travel over the road as compared with train movement and our general policy has been not to put up any sign we would have to defend. That is, we want conditions to show for themselves that the crossing is one that should be a stop crossing.

It is very possible that in picking out so many crossings we may have made mistakes, in fact we have taken down a few stop signs that

were ordered up, because we found conditions were not exactly as represented to us at the time we designated the crossing. Every one of these stop signs has been ordered in after a personal inspection of the crossing by a member of the Commission, together with the engineer or assistant engineer of the Commission, assisted by advice of the railroad officials and municipal authorities.

I do not know how it would have been possible to have exercised more care in the selection of these crossings. Where there was any doubt about the advisability of making a stop crossing we have not designated it, feeling it would be better to have fewer crossings designated until the vehicle drivers of the state become familiar with this law. We have had several requests for installation of additional stop crossings. I believe that as the drivers come to know what this law means in the way of safety for themselves, their families and property, that the observance of it will become general and requests will come in for the designation of more crossings to be marked.

Certainly we have not made the mistake that other states have in putting up these signs promiscuously at every crossing in the state.

The Commission is not charged with the enforcement of the law. That is in the hands of the local authorities. The results vary with the activities of the authorities in the different towns.

In some towns the law is strictly enforced, in others little if any attention is paid to it. The Commission receives daily reports from various sources of the license numbers of automobiles ignoring these stop signs. We keep two employees busy looking up the name and address of the owner and writing a courteous letter calling attention to the law and violation of it and asking the driver's cooperation in enforcing it. We get some very nice letters in reply and I believe this work is doing some good. Of course, the best way to judge any safety measure is by the results obtained.

The Interstate Commerce Commission's accident bulletin shows that in spite of the greatly increased number of motor vehicles in use in the state, the casualties at grade crossings are becoming less. For instance, records of accidents at grade crossings involving automobiles in 1924 in Minnesota, show that 39 persons were killed and 112 injured; in 1925, 34 were killed and 113 injured.

Casualties at Grade Crossings in Minnesota

The casualties at grade crossings in Minnesota where automobiles are involved show the percentage ratio per 10,000 automobiles as follows:

1924—Killed	.77	1925—Killed	.60
Injured	2.22	Injured	1.98

The adoption by all states of a uniform law empowering state commissions to designate dangerous grade crossings at which drivers of automobiles and other vehicles must stop, as recommended by the

National Conference on State and Highway Safety, judged by the results obtained in Minnesota, is highly desirable and should have the active support of this Congress.

In Minnesota the State Highway Commission, in connection with its road building program, is very active in re-routing trunk highways in such a way as to eliminate all grade crossings possible. In such work, they are meeting with fine cooperation from the railroads, and where crossings are necessary the Railroad and the Commission are eliminating the grade crossing by construction of overhead or underground crossings and sharing in the expense of such improvement.

When the State Highway Commission took over the trunk highway system in Minnesota in November, 1920, there were approximately 932 grade crossings in connection with the 7,000-mile trunk highway project. The highway department by the end of 1926, expects to have eliminated 557 of this number, 44 being replaced by overhead structures, 80 by under passes and 233 by re-location of the highways. Further crossings will be eliminated by these methods as the trunk highway projects are further extended. The policy of the State Highway Commission is to be commended and their good work has no doubt saved the lives of many of our own citizens and citizens of other states.

In connection with the operation of the new Minnesota Grade Crossing Stop Law, the city of Minneapolis and many of the small towns have passed ordinances requiring all vehicles to come to a full stop at each designated crossing within their limits. These ordinances can and will do doubt be rigidly enforced and the effect will be far-reaching in commanding obedience to the stop crossing law.

We expect to make Minnesota nationally known for its minimum number of highway grade crossing accidents. The splendid cooperation between all state departments and the railroads and the educational campaign directed to the drivers of all motor vehicles is beginning to bear fruit. It will take further time to accomplish full results, but our program has been continuous and our efforts in this direction are being rewarded.

Mr. Bentley Responds to Mr. Matson's Address

CHAIRMAN SHEDD: Mr. Matson, that was a very splendid paper and I thank you in behalf of the Section.

Sometime ago it was my privilege to introduce a gentleman who sat at my right, and I did so through a reference that had been written in an article in one of the leading magazines in the country. It spoke of him as a man who had attained more or less success financially, and it stated he was the fellow who shook the tree and caused the plums to fall. Now get that. It did not state he gathered up the plums that the other fellow had caused to fall from the tree, but he shook the tree.

The gentleman I shall give the privilege of responding to that very good paper, is the fellow who is shaking the educational tree from which

those splendid plums are falling which you and I are enjoying each month as they come from the A. R. A. Safety Section. I will be glad to have our good friend, Bentley, from way down south, tell Mr. Matson what we think about his paper.

L. G. BENTLEY (Chesapeake & Ohio Railway, Richmond, Va.): I am sure you must be wondering, even as I am, what words I could possibly select to convey to Mr. Matson our appreciation of this splendid paper so forcefully presented. I hope that what I shall say briefly will be taken on the strength of its sincerity and that I do correctly interpret your feelings toward Mr. Matson in telling him that I think he has brought to us one of the most encouraging evidences that we could possibly get of this expanding spirit of cooperation on the part of national organizations in this great work of saving lives.

Cooperation in Safety Work a Solemn Obligation

Aside from the saving of lives and the preventing of injuries to our own employees, the railroads of the country feel, and rightly, that there is no more solemn obligation, no more sacred work that they may perform, than that of cooperating in this work of preventing highway crossing accidents, those accidents through which not only the guilty suffer, but innocent children and women, who are in no sense chargeable with the action which caused the disaster. It is through the work of such men as Mr. Matson and the organization he represents, that the railroads are looking for the upholding of their hands in this splendid, all-absorbing work; and as an educational feature of this work, the thoroughness, if you please, of the method whereby this law was written and is being executed, the care to see that nothing was written that might have to be unwritten, that nothing was done but that which had received the most careful consideration, is worthy of any attention that this Section may see fit to give. Gentlemen, I know that I do correctly represent you when I say that we do sincerely appreciate your presence here today, Mr. Matson, and the wonderful message you have brought us.

CHAIRMAN SHEDD: Digressing just a little bit from this Section over to the A. R. A. Safety Section; I think we safety fellows don't care which horse we straddle as long as we keep on. We were pleased to know that the purchases and stores department has added its assistance and prestige as well to the A. R. A. Safety Section, and I understand that Mr. H. R. Duncan, of the Burlington, who has been requested to represent the A. R. A. Division of Purchases and Stores, is here, and unless he is extremely modest and doesn't care to do so, I would like to see how big and how good looking he is.

H. R. DUNCAN (Burlington Railroad, Chicago, Ill.): I am very glad to be here. Our section up to the present time has never taken up the safety movement, but it has now appointed a committee and I am a member of that committee. We are going to give our attention to the

safety movement. I am here to get as much information as I possibly can.

CHAIRMAN SHEDD: There is another man in the audience whom I would like every fellow to know. Over in the central west there is a state which I will characterize with the words, "What it purposes, it performs." We have a man here representing that splendid state from which the grasshoppers tried to drive the inhabitants. They were unsuccessful. Famine has overtaken it. They withstood drought and everything, but today, in my opinion, excluding my own state of Illinois, I think it is the greatest state in the Union, and I think Jesse Greenleaf ought to stand up and let the boys say "hello" to him.

(Mr. Greenleaf arose and the audience applauded.)

CHAIRMAN SHEDD: Mr. L. K. Sillcox, General Superintendent of Motive Power of the Chicago, Milwaukee & St. Paul Railway, representing the Mechanical Section of the A. R. A., has kindly consented to appear on our program and add his measure to its success. I take great pleasure at this time in introducing Mr. Sillcox.

THE MECHANICAL DEPARTMENT AND ITS RELATION TO SAFETY

L. K. Sillcox, General Superintendent of Motive Power, Chicago, Milwaukee & St. Paul Railway, Chicago, Ill.

The meaning of human life is experience. Responsibility alone brings experience. Individuality is developed by responsibility. Methods may change; the individuality persists. In law a person who is not responsible for his behavior loses his individuality, for responsibility is the functioning of an individual—a conscience—who promises, who stands sponsor for the acts of the person. The real individualist devises ways to encourage the individuality of those he employs and holds himself responsible for the results. This is the first charge on his enterprise; material prosperity comes second.

When safety is made a matter of serious study, two fundamental relationships come into view that are in themselves sufficient to cause the movement to be indispensable. These are, first, that safety is only one of the manifestations of a deep, thoroughgoing efficiency; and second, that safety is primarily a matter of the head rather than the hand and hence pre-eminently educational.

In mentioning the subject of sustaining interest in safety, the mind naturally turns to safety committees or to employees who have lost interest or who need to have their interest improved. It may be, however, that the loss of enthusiasm on the part of the employee can be traced to lack of interest on the part of the employer. Unless the latter has consistently and conscientiously kept up to date in the matter of safety, he can not lay the entire blame for lack of interest in safety on the employee.

One of the ways in which an employer can certainly indicate his sus-

tained interest in safety is by devising new avenues of approach, as well as by adopting devices and processes that are developed from time to time, and while this is not meant to indicate that all schemes brought to his attention should be made standard, it does emphasize the need for, at all times, being ready to listen to suggestions, the application of which will make for improved safety in the handling of the work. Such a procedure does, at times, represent the expenditure of considerable sums of money for new and improved equipment or new devices. Such a situation is inescapable in view of the contribution of the engineering profession to safety, which has been very marked, and the application of electricity and other sciences in the way of advanced forms of machinery and processes have aided safety very materially.

An employer who takes advantage of all these developments to add to the safety of his plant, is making a substantial investment toward maintaining the interest of his employees in this important subject.

It is interesting to observe figures shown in the 1925 report of the Director of the Bureau of Safety in the Interstate Commerce Commission, indicating the number of freight and passenger cars and locomotives inspected, the number found to be defective, and the percentage defective each year for the past ten years and from them see that the 1925 showing is better than in any previous year:

TABLE No. 1

Year	Inspected	Defective	Per Cent Defective
1925.....	1,214,170	41,426	3.41
1924.....	1,172,900	51,387	4.38
1923.....	1,162,629	96,024	8.25
1922.....	1,096,670	46,370	4.22
1921.....	907,293	47,040	5.18
1920.....	911,537	40,416	4.40
1919.....	1,078,361	38,551	3.57
1918.....	1,119,451	42,448	3.79
1917.....	1,166,759	41,378	3.54
1916.....	967,507	35,372	3.65

In addition, Table 2, a tabulation, for the period June 30, 1921, to 1925, inclusive, covering freight cars inspected and percentage found defective, passenger cars inspected and percentage found defective, locomotives inspected and percentage found defective, and the number of defects per 1,000 inspected, indicates substantial improvement in 1925 over previous years with respect to freight cars and locomotives; and as regards passenger cars the showing is better than that which obtained in either 1923 or 1924.

Furthermore, a study of the 14th Annual Report of the Chief Inspector of the Bureau of Locomotive Inspection to the Interstate Commerce Commission for the fiscal year ended June 30, 1925, as shown in Table No. 3, shows a 69.7 per cent decrease in number of persons killed as compared

to the previous year, as well as a decrease of 33.9 per cent of the number of persons injured.

In addition to the train service accidents already mentioned, it is well to take account of the fact that in the maintenance of equipment department, there were, in 1924, 540,000 employees, of whom in that year 221

TABLE No. 2

	1921	1922	1923	1924	1925
Freight cars inspected.....	865,858	1,046,964	1,117,355	1,123,258	1,167,980
Per cent defective.....	5.34	4.35	8.49	4.47	3.48
Passenger cars inspected	20,082	26,116	22,038	21,359	22,526
Per cent defective.....	0.87	0.97	1.27	1.54	1.19
Locomotives inspected....	21,353	23,590	23,236	23,283	26,664
Per cent defective.....	2.80	2.40	3.64	2.89	2.10
Number of defects per 1000 inspected.....	62.36	50.54	100.31	52.73	42.46

TABLE No. 3

Number of accidents, number killed, and number injured caused by the failure of some part or appurtenance of the locomotive or tender, including the boiler, by comparison, year ended June 30.

	1925	1924	1923	1922	1921
Number of accidents.....	690	1,005	1,348	622	735
Per cent increase or decrease from previous year	31.3	25.5	117*	15.4	12.8
Number of persons killed.....	20	66	72	33	64
Per cent increase or decrease from previous year	69.7	8.3	118*	48.4	3
Number of persons injured.....	764	1,157	1,560	709	800
Per cent increase or decrease from previous year	33.9	25	120*	11.3	12.6

(*Increase.)

were killed and 53,311 injured, representing 15 per cent of all fatalities and 43 per cent of all injuries to employees on duty.

The officers of the mechanical departments of American railroads are fully alive to the importance of overcoming these accidents. On every railroad there is a complete safety organization providing, through the general foremen, foremen, assistant foremen, gang leaders and other supervisory forces, full and complete safety supervision and training of maintenance of equipment employees, particularly new and inexperienced men, to the end that maximum safety may be assured and a 35 per cent reduction in casualties by 1930, which is the safety goal of the railroads, may be achieved.

The result can and will be accomplished. The following methods are being used to awaken and sustain interest in safety:

Methods of Persuasion:

- Inspiration
- Education
- Information
- Group Rivalry
- Prizes
- Lessons from actual accidents
- Recognition of meritorious acts.
- The personal touch.

Methods of Compulsion:

- Rules and Regulations
- Discipline
- Physical safeguard
- Safe Maintenance
- Improved design or method

Each railroad has a safety organization working through committees, staff meetings, etc., to develop to the utmost the features listed under "Methods of Persuasion," and to impress the value of rules, discipline, etc., listed under "Methods of Compulsion."

It is well to recall the extent to which these results are attributable to the elaborate character of the equipment and the careful attention paid to rules and regulations by the railroad managements and employees. It is true that occasionally an accident happens, though its results may be quite out of proportion to the seriousness of the accident in itself. Indeed, some of our most serious accidents have been, so far as cause and circumstances are concerned, of a relatively minor character, while others, more alarming in their nature, have been attended with few or no serious casualties. Results are, indeed, somewhat a matter of chance, in that they are governed by circumstances as much as by cause.

An important point to be remembered is that every accident which occurs induces careful study of each factor involved; and this in itself, both in road practice, shop practice, and from the standpoint of design or rolling stock and locomotives, as well as the specifications and inspections covering materials entering into the same, by reason of standardized procedure and exchange in views made possible by the American Railway Association, has resulted in a very real and fundamental way to make possible the advance in practice which is evidenced by government statistics, as well as from daily experience on each railway system.

CHAIRMAN SHEDD: Mr. Sillcox, we are surely indebted to you for that paper, giving us so much new and interesting data, and which you so ably presented. That is all I am going to say about it. However, there is going to be more said about it by one of the best looking young fellows in the Section. I say young because he is considerably younger than some of us, and who by the way, comes from a very splendid railroad, the name of which is reflected in two of America's beautiful streams—the Delaware and the Hudson.

I am glad to give Mr. J. E. Long an opportunity of replying to your very splendid paper.

J. E. LONG (Delaware & Hudson Railroad, Albany, N. Y.): Mr. Chairman, that introduction was even better than we arranged for this noon.

On behalf of the members of the Steam Railroad Section of the National Safety Council, I want to express our appreciation to the Mechanical Section of the American Railway Association for sending so distinguished a representative to our meeting today, and our thanks to Mr. Silcox for his most interesting and instructive address. There is considerable food for thought in his paper and I know that each one of us here will want to take a copy of it home to give it the careful study it deserves, for, as you know, the food we take into our bodies is of little value unless properly digested, and by the same token the mental food we receive is valueless unless mentally digested.

We know that accidents are only a small portion of the mechanical officer's many duties and responsibilities. Mr. Silcox has told us how important a part it is, and we know how vitally necessary it is for every railroad officer to get squarely behind the safety work if it is to be a success.

I wish again to express to Mr. Silcox our grateful appreciation for his intensely interesting and important contribution to our meeting today.

CHAIRMAN SHEDD: You know it has been said in certain writings that they builded better than they knew. I say this with all respect to the engineering department. Some of these fellows had the impression that the engineering profession were not much in sympathy with us; but they were susceptible and came across, and we are very glad, I assure you, to know that the engineering societies have taken such a deep interest in safety because "well planned and well begun is half done." We are very glad to have Mr. E. R. Lewis, Principal Assistant Engineer of the Michigan Central Railway, of this grand and glorious city, and who, by the way, is representing the American Railway Engineering Association, with us here. He will add another strong link in this chain of successful things that we have forged here today. I am very glad to introduce Mr. E. R. Lewis.

STARTING POINTS

E. R. Lewis, Principal Assistant Engineer, Michigan Central Railway, Detroit, Mich.

The American Railway Engineering Association, which I have the honor of representing, consists largely of chief engineers and other officers of the principal steam railroads of North America. We pioneered in the field of safety for many years before any specific safety organization was effected. It has ever been the duty of the civil engineering

profession to protect their men, their structures, their equipment, their machines and tools with all possible safeguards.

We are strong for organized safety. We know the difficulties, we are familiar with the inertia to be overcome. We deeply appreciate the great strides made to this end by the National Safety Council, and we desire to afford every means within our power to further the objects for which this Council stands. Our "Manual of Recommended Practice" includes safety rules which are the results of the labors of our committee on rules and organization extending over a series of years, during which the best thoughts of supervisory officers, railroad executives, and writers of railroad rules for employees were collected, reviewed, reconciled, revised, combined, and finally adopted as standard.

General Notice Prefacing the Rules

The rules are prefaced by a general notice. Our general notice to maintenance of way employees reads as follows:

"To enter or remain in the service is an assurance of willingness to obey the rules.

"Obedience to the rules is essential to the safety of passengers and employees, and to the protection of property.

"The service demands the faithful, intelligent and courteous discharge of duty.

"To obtain promotion, capacity must be shown for greater responsibility.

"Employees, in accepting employment, assume its risks."

To this list of precepts, the Michigan Central Railroad Company, with which I am employed, adds this specific warning by way of emphasis:

"When in doubt, employees must take the safe side and run no risk."

Many years ago I learned to respect that last extraordinary warning—written so forcefully by Colonel Webb, then chief engineer, that no employee could mistake its meaning nor doubt its intent. It leaves the heedless no excuse.

The 1925 Transactions of the Steam Railroad Section, presented at the National Safety Council Convention in Cleveland last autumn, are so replete with valuable matter relating to safety that the ground seems admirably and exhaustively covered. Improvement and standardization of safety devices are attracting the necessary attention. I judge that in-so-far as the human element is concerned—and it seems responsible for some 90 per cent of our accidents—the chief problem now confronting this Council consists of ways and means of impressing on all the people, the precepts of the gospel of self preservation. Since self preservation is the first law of nature, the assignment sounds perfectly easy. As a matter of fact, it is quite the opposite. We have progressed greatly, yet we may well adopt the motto of that great British empire builder, Cecil Rhodes, "So Little Done, So Much To Do."

As a member of the American Railway Engineering Association I would like to present two thoughts, born of our experience in and out of committee work closely related to safety:

First, we are handicapped in Steam Railroad educational circles by two conditions, the foremost affecting the present personnel; the other affecting the prospective employee.

Railroad employees are busy men and women. They have many exacting duties with the ultimate object of selling transportation. They must work fast and think fast. Most of them must at the same time fight the clock and the weather, for schedules are schedules. They must see and hear and remember and remedy many things, under many conditions. They must protect the company's interests and deal with the public. You who drive automobiles (and who does not in this automotive age) well know that no driver is a safe or a good driver who does not keep his eyes on the road and his mind on his job. No good driver is a safe driver who drives when he is impatient, or nervous, or overtired, or in any but a calm yet alert and normal condition of mind and body. If you really and properly drive a car you will see and think meanwhile of little or nothing outside the driving limits.

Safety Lies in the Least Dangerous Course

Many railroad accidents are due, I believe, to lack of concentration on safety; due to the employee considering other duties and problems while in charge of a hand or motor car or other moving vehicle or machine. There are many other accidents attributable to the employee's lack of power of mental concentration. No person is safe who can not, or will not pursue always the least dangerous course with his whole mentality focused on the danger to be avoided. The individual must be awakened to the absolute necessity of exerting his will to concentrate before he can be educated. The first requirement of salesmanship is to get the attention of the prospect. Our problem is then, to impress safety, preferably in some attractive manner, on the attention of the people.

The other handicap, affecting both the employer and the prospective employee, is lax method or absence of adequate means of employee selection. It is becoming harder every year to "hire and fire" employees. This probably is as it should be. An impersonal attitude on the part of the employer is likely to be interpreted as an affront by the employee, and is to be avoided if possible. The trend toward the co-partnership viewpoint comes nearer that Justice on which this world was founded and endures. Because men can not now and should not be indiscriminately discharged with or without cause, we should be very particular as to whom we hire and how we hire them. Employers preferably should have special means for the examination of applicants for all positions and such means should be used to select employees only after a strict measuring up to standard requirements, physical, mental and moral.

Once on the payroll, the employee should not be lost sight of by the employing examiner. He should be made to feel, without any inference of espionage, that having entered the service with a clean bill of health, it is up to him individually to retain that state of being, for the em-

ployer's benefit as well as his own and that of his fellow workers. By example and precept he should in like manner educate his family in safety. Selection then is our most efficient safeguard, with education of employees made easier because the selected worker is more readily impressed with safety teaching, having the intelligence to understand its importance.

Most of the technical societies have recognized the value of instituting student chapters and of seeking in various ways the cooperation of college and university authorities to interest the youth of the land in the technical activities of their elders with a view to applying for student membership. This trend suggests the second thought I would leave with you, namely: educate the young people to practise safety.

I would go farther back than the university, farther than the college, the high school or the common school. I believe that the way to get the best results from teaching safety is to reach the infant class. By the time a child is old enough to go to kindergarten alone, he or she should have the precepts of the safety primer by heart and should be drilled in the practical rudiments of resisting danger. A child so schooled will make the safest and best railroad employee.

There are various organizations through which a great deal has been and is being done along these lines for boys and girls, notably the Boy Scouts and the Campfire Girls, which can not be too highly commended. The self sacrifice of the scoutmasters and other volunteer officers of these training corps is most commendable; for they sacrifice not only time but their personal funds in many cases, for transportation of troops, and many other incidentals. Boys are eligible as scouts at the age of twelve. The training is, of course, moral, mental and physical. It is of inestimable benefit to the youth of the land, our future men of affairs.

Children May Be Trained to Become Safe Citizens

But the Boy Scouts and the Campfire Girls are of an intermediate grade. An applicant must have had certain preliminary teaching to be or to want to be a scout. It is this early training of children that you and I through the mothers and fathers and teachers of America must direct to obtain the greatest safety results. We forget less of what we learn in childhood than thereafter. Details fade, but principles inculcated in early youth endure through life. The extent of good in this project is illimitable—children trained to be safe citizens, observing, careful, methodical, efficient, honest, physically, mentally, and morally alert and upstanding. It would indeed be a pleasure to select railroad employees from such promising material.

What a glorious objective and how sure of attainment, if you, the members of this section and of other sections and kindred organizations, will only put this thought across to the entire people and keep it before them! This assignment means diligence and perseverance, unremitting toil in the face of apathy and obstacles; but it is sure

to meet with less opposition than most great movements and just as certain to be among the greatest, because no one can doubt that it will be of greatest good to mankind. This, gentlemen, is our opportunity. What are you, what are we, going to do about it? Let us plan well our campaign and carry on, for the future safety of transportation and of the millions of patrons who depend on its services.

CHAIRMAN SHEDD: Mr. Lewis, on behalf of the Section and personally, I want to thank you for your very able paper and the way you have presented it; and I am going to call on a gentleman to say a little more about it. In this gentleman you will immediately recognize both oratorical ability and a desire, as well as further ability, to say good things to folks who deserve them. Mr. Cott will say something more about Mr. Lewis' paper.

SECRETARY COTT: I have been honored, Mr. Lewis, with the privilege to respond to your address. I presume, first, because I came from the maintenance and construction department of a railroad. There is a happy relation (perhaps you don't know of it) between our association and the association which you represent because we have a good old friend in the person of Mr. Arthur Ridgeway, now chief engineer of the Denver and Rio Grande, who formerly was in charge of safety and has left us to go into your ranks and into your association. Mr. Ridgeway was well loved by all of the older members of the Section and is remembered by them.

You remarked early in your address that an engineer very seldom talks, it is the silent profession. I presume, however, that you are an engineer, and in spite of that, you did a very good job of talking. I can't say anything about your ability as an engineer, but I am sure that your association had every confidence in you when they selected you, and they took the safe course when they made that selection.

It has been said that an engineer is trained to look at all sides of a proposition and sometimes he doesn't see the heart of it. Your paper is a splendid presentation of the subject and got down to the heart of the matter at hand; we thank you, sir, for being privileged to listen to you and being able to take home a paper in which there is food for thought.

DISCUSSION OF MR. LEWIS' PAPER, "STARTING POINTS"

F. W. Mitchell, Director of Personnel, New York, New Haven & Hartford Railroad Company, New Haven, Conn.

I find a deep sense of satisfaction and pleasure in making the response in this safety conference to the representative of the American Railway Engineering Association because it is to the engineering departments that we are indebted for much that has made our accident prevention work more potent and our machinery more effective.

We recognize, therefore, an obligation and acknowledge with apprecia-

tion the help that our safety work has received by the contribution of improved standards and design, and more careful scrutiny of conditions of maintenance, training the human element, and all other features of accident prevention to which the engineering departments have given strength and stability by their substantial support and constructive effort.

These are features that are so fundamental in their relation and so far reaching in their moral effect that I feel like saying without qualification, that too much emphasis cannot be placed on their importance.

A limitation that is short of the best that these departments can provide or maintain has a very distinct and active tendency to promote a like limitation in the character of the personal effort of the employees who are brought into contact with such conditions and examples.

An interesting phase of safety has been referred to by Mr. Lewis in connection with the effort to instill the principles of safety into the minds of the children, even down to the earliest years of their comprehension of its importance and value.

What will develop from this instruction yet remains to be demonstrated, for our industries have not as yet begun to enlist in large numbers the products of this comprehensive effort.

Accidents from Carelessness May Become Rare

With this as a background, however, and with better machinery and standards for protection, we may certainly hope for a day when accidents from carelessness of employees and many other forms of human failure may be a very rare occurrence in the course of our experience.

I am reminded of an incident that happened in one of our safety meetings when a supervisor of many years' experience, in contemplating the present spirit of safety and contrasting the conditions of former years, due to the lack of the organized effort, said with evident conviction of the truth of his statement. "Why, if we had been taught safety years ago as we now are, we wouldn't be having accidents at all today."

Let us hope his estimate of the present effort and his vision into the future prove true. It is not an unreasonable expectation, and faith is a very necessary element in bringing it about. "From Faith to Light" is a most practical sentiment, as witness the telephone, the radio, and the heavier than air flying machine.

Let us then continue the spirit of cordial cooperation, not only in our engineering departments, but in all departments, and let us confidently expect progression in safety in no less measure than we have expected and experienced other achievements. To this end, too, we must heartily endorse the suggestion presented by Mr. Lewis that careful attention should be given by all our railroads to adequate and well organized methods for employee selection.

Because it has been my experience to be closely associated for some time not only with accident prevention work but also with the examinations, revision and development of rules, and investigation of previous records of applicants for employment, re-employment or re-instatement, I

feel that I can speak with a most intimate knowledge of the actual conditions that obtain and the dangers that are invited when there is inadequate provision for safeguarding this feature, or when any laxity creeps into the effort to carry out the requirements of such provision in an efficient manner.

These also are features that are fundamental in their relation and far reaching in their effects. They are important factors affecting every department of our operation. In closing this response to the thoughts presented by Mr. Lewis I can find no more fitting words than those he used himself, and I therefore join with him in sentiment and program:

"Let us plan well our campaign and carry on for the future safety of transportation and of the millions of patrons who depend on its service."

CHAIRMAN SHEDD: I hope I made no mistake in my introduction. They say it is proper for the chairman to exercise certain prerogatives not appearing on the program. I am not going to make a speech.

I understand that we have had sitting through all of these sessions a gentleman who started his railroad career as a fire boy. He handled the scoop for many years. He was promoted to fireman, then to a freight, then to a passenger engineer. He was afterward promoted to road foreman, and today he is superintendent of automotive power of a very splendid railroad, the Michigan Central. I would like to have Mr. J. F. Jennings stand up and let us have a look at him.

Many Safety Devices Are Employed on Railroads

J. F. JENNINGS (Michigan Central Railroad, Detroit, Mich.): You know I have a great deal of confidence in your chairman, and I thought he was a man of his word. Every expression that he made was handled in suitable English, but if my recollection is correct, he told me he was going to adjourn the meeting at the close of the papers.

I never laid any stress on being a public speaker; in fact it rather embarrasses me to get up in front of a bunch of men and try to say something pertinent to the discussions that are carried on; but from what the boys tell me when they come in and see me alone, I surely have a command of the English language.

The safety first movement is one of the finest movements that has been introduced in many years and the mechanical men can appreciate it from the numerous safety devices which have been applied to railroads. The locomotives of today are made as safe as it is possible for human intelligence at this period to do. We try to preach safety in our shops, and I must confess that the safety agent is a frequent caller at my office and he is one of the fellows in addition to the vice-president who finds a lot of fault with me. You know, the only thing he ever gave me aside from criticism, was a cigarette at the luncheon table today.

In all seriousness I appreciate the safety movement and I believe that any safety agent on the Michigan Central will tell you that I am back of him 100 per cent.

CHAIRMAN SHEDD: Mr. Long, who is chairman of the Resolutions Committee, has two resolutions that he would like to present, I will ask him to do this in deference to the wishes of your regular chairman, so I am not taking any prerogatives not mine.

Mr. Long: "BE IT RESOLVED, That the Steam Railroad Section, National Safety Council, in convention assembled, hereby extends to Mr. W. A. McGonagle, President of the Duluth, Missabe and Northern Railway, grateful appreciation for the inspiration of his presence and participation in the program."

"BE IT RESOLVED, That the Steam Railroad Section, National Safety Council, in convention assembled, hereby extends to Colonel J. T. Loree, Vice-President and General Manager of the Delaware & Hudson Railway, appreciation for his attendance at the Fifteenth Annual Safety Congress and his valuable contribution to the program."

I move these resolutions be adopted.

CHAIRMAN SHEDD: May I suggest that we have these adopted by a rising vote?

(The motion to adopt the resolutions was seconded and carried by a rising vote.)

ADJOURNMENT

THURSDAY MORNING SESSION**October 28, 1926****D. G. PHILLIPS, Acting Chairman
Wabash Railway, St. Louis, Mo.**

The meeting was called to order at 9:40 o'clock by Mr. A. V. Rohweder, Chairman.

CHAIRMAN ROHWEDER: You will observe on the program that we have reached the point where we can discuss some of the things that have been told to us in the last few days. The acting chairman of this morning's program is Mr. D. G. Phillips, of the Wabash, and he will give you the detailed arrangement of the program.

(Mr. D. G. Phillips, Wabash Railway, St. Louis, Mo., took the chair.)

CHAIRMAN PHILLIPS: You will note the program this morning is divided into two parts. The first hour is the hour when the safety inspectors and the safety agents talk. That means that Bentley, Scott and Hill are to keep still the first hour and give their boys a chance.

I don't know of any meeting that I could preside over that would give me more pleasure than a meeting of safety agents and inspectors, because, to be honest, they are the fellows who do the work.

We are going to let you talk about anything you want to this morning, but there is one subject that I know you would like to talk about the most. I know you would like to talk about the safety superintendent. You would like to tell how he blames you for all bad records and takes credit himself for all good records, and how whenever he has a hard job on hand, he sends you out to do it, and all that sort of thing. I know that is what you would like to get up and talk about, but we are sensitive fellows and in order that we may go away from here having a good taste in our mouths, don't abuse us too much.

I am going to tell a story that indicates how much any person can do in safety. It is a story that every inspector and every superintendent can find good occasion to use.

About a month ago in St. Louis the local safety council, of which I have the honor to be an officer, started broadcasting 15 minutes every night in the week except two, on safety. He have a man there known as "Safety Sam." He broadcasts over the radio somewhat after the fashion of the Chicago man who tells bedtime stories.

We are organizing a safety club in St. Louis, of children who listen to Safety Sam in Safety Town, and we are asking them over the radio to write letters to Safety Sam, asking the children to become members of Safety Sam's club, and we send them a button and a pledge. The pledge is about crossing streets and railroad tracks.

This has been going on about one month. Thousands and thousands have already written letters asking to become members of that club and some of those letters are wonderful.

We received a letter from a little boy which read about like this:

"I am a little boy 11 years old. I am very much interested in safety. I want to become a member of your safety club. Won't you send me one of those buttons and one of those pledges? I listen to you over the radio every night. Safety Sam, I like to hear you talk.

"I am an invalid. I have been in bed for five years. I can't even sit up. About the only company I have is the radio. People like you don't like to talk much with a sick boy."

That letter appealed to us. We thought of that poor little boy lying there on his bed for five years, who wanted to do so much for safety; the last person on earth you would expect to be interested in safety. He never will get out of that bed, fellows. The letter appealed to us so much that Safety Sam and his wife and another member of the Council went out to see this boy. They paid him a visit and they found conditions just as he described. He was an invalid in bed. He was so interested in safety, and we all felt what a shame it was that that little boy who couldn't do a thing in safety should be so interested in it when others were not. But how mistaken we were.

Influence of a Little Invalid Boy for Safety

Safety Sam went back there again the other day, and here is what that little boy has done, the boy can't raise his head from the pillow. He has organized a safety club out there. He now has 515 members of that safety club. His sick room is the headquarters, and he has the best boys' and girls' safety club in the city of St. Louis.

We fellows really ought to be ashamed of ourselves when we say we can't do anything. It brings to mind the old saying, "Where there is a will, there is a way."

But this is a meeting for safety inspectors. We are going to have to limit your time of talking to three minutes. You heard those speeches yesterday. Who will be the first safety inspector to get up, the men who do the real work in safety departments?

C. W. HAMMOND (New York Central Lines, New York City): For the last two or three years it has come to my notice that the New York Central Lines have been sort of clogging the docket, as it were, so for the last year or so we have kept rather quiet. However, I would have you know that the New York Central is still making progress. I believe it was a D. & H. magazine that I saw the other day which said, "Progress is a good deal like riding a bicycle, because when you stop you have to get off."

There is only one thing in my mind this morning with reference to equipment that I would like to speak about. Many of you were present, I believe, two years ago when I had the pleasure of discussing a paper written by a United States inspector. His subject was "Proper Maintenance of Equipment." I told at that time that I thought our inspection of our equipment was nearly 100 per cent, but we should have proper equipment to inspect.

I would not have you believe that we do not have proper equipment on the New York Central Lines because we haven't a car in freight service today that is not either all steel or steel underframe, but we do find today that many of our railroads are equipping their brakes with dish brake wheels which causes a very dangerous condition because of the fact that you can not get 100 per cent braking power.

We have eliminated the dish brake wheel on the New York Central Lines, and the only ones I know of that are being installed are those put on by some foreign railroads.

Those of you who have been in the game realize what I am talking about. When you elevate your brake over 45 degrees, you are not getting proper braking power and that is one of the causes of a great many of our complaints among the switchmen, more especially those who have to ride the cars over a gravity hump.

Trouble Through Wheel Being Mounted Wrong

E. D. SWIER (Belt Railway of Chicago, Chicago, Ill.): We experience a good deal of trouble with brake wheels of that kind on our clearing yard common. We have had that subject up a good many times and we have been told by the Master Car Builders' Association, which I believe is a section of the A. R. E. A., that the dish wheel was never intended to be mounted that way, that is with the dish up. The dish is supposed to be down, and where cars are made and equipped with the dish up, it is contrary to the standard plans of the car builders association.

When the wheel is mounted with the dish down instead of up, it is just as good and probably a better braking proposition for the use of clubs on gravity yards, as the ordinary flatter wheel.

W. L. BOSLOOPER (Michigan Central Railroad, Detroit, Mich.): Were I to talk about the dish brake wheel, I would merely have to reiterate what Mr. Hammond said, because I have been working around humps and on humps for the last 24 years.

There is something else I want to call to your attention, that is the matter of the continuous operating lever.

We have had a great many papers read at meetings of the Safety Section of the A. R. A. and Steam Railroad Section of the National Safety Council regarding the number of employees struck and run over by engines and cars.

In the operation of a hump, you are going to run across a great many operating levers that are not what you term defective; however, the knuckle locks stick in such a manner that it is necessary for the man doing the cutting to go between the cars to do it, with the result that he sometimes stumbles and is run over. I believe that should be taken up for consideration by the mechanical section of the A. R. A.

CHAIRMAN PHILLIPS: I would like to say that is one proposition that I am thoroughly sold on.

A. C. HARTLEY (Michigan Central Railroad, Detroit, Mich.): Mr. Boslooper has spoken of the continuous operating lever which could be used in case the lock sticks. I have had a lot of experience with locks sticking and it is my candid opinion, based on quite some investigation, that if our car department would drop a little oil on the knuckle locks, it would last from two to three months, and particularly when cars go to the repair track. If the knuckle lock were oiled, it would save a lot of running in between cars. I believe this should be given consideration. We have given it some consideration, but we haven't perfected it up to this time.

J. R. McCAMPBELL (New York Central Lines, Indianapolis, Ind.): I want to approve what Mr. Hammond and Mr. Boslooper have said about the brake wheels.

We have another feature about brakes that has caused a lot of accidents on our railroad. I refer particularly to the stirrup at the bottom of the brake staff. We find our hump riders report that a chain will not go around the staff.

This is a matter that has been given a good deal of consideration but the problem is not yet solved and we are having quite a bit of trouble from that source.

Practical Discussion of the Crossing Whistle

C. D. SHEFF (New York Central Lines, New York City): The question was brought up yesterday among some of the officials in regard to the crossing whistle. I would like to hear something from some of the practical men assembled here today as to how they feel about the change in the crossing whistle. Personally, I have had considerable experience as a locomotive engineer and I have always been a great stickler for the rule. The standard rule requires two long and two short whistles approaching a crossing, and I believe that signal, if properly given, is the best yet. I would like to see the thing discussed fully today.

We have tried out on our line, and pretty generally so, 13 second whistles. If we are running 60 miles an hour approaching a crossing (the whistling post is supposed to be located 80 rods from the crossing); we are making 88 feet a second, and that would bring us down within 176 feet of the crossing, and I believe if that was carried out, the engineer would be giving a pretty reasonable crossing whistle.

CHAIRMAN PHILLIPS: I would like to ask you one question. How does that rule work on 10 miles an hour?

MR. SHEFF: We have to take into consideration the speed of the train, of course, but we try to get them to use two long and two short. The idea is to get the whistle up close to the crossing, not to it or over it, but near the crossing. We can't afford to blow a whistle over the crossing because there are still a few horse drawn vehicles and if we should frighten the horse, we would have to pay.

H. M. WILLIAMS (Missouri Pacific Railroad, St. Louis, Mo.): I have been running an engine 44 years. I have struck 10 automobiles in which

seven people were killed. Some years ago we started on the Missouri Pacific to instruct the engineers to begin whistling back 80 rods from the crossing and finish up the whistle, no matter what rate of speed we were running, when we got to the crossing, and we have cut down a number of accidents due to that manner of whistling.

From my experience as an engineer, it is my opinion that if you keep your whistle blowing up to the crossing, you are going to attract the attention of the car driver.

The grade crossing for the last hundred years has been nobody's business. The railroad company built it. They said to the people who drove over it, "Look out for the cars while the bell rings or the whistle blows." That was when we had the ox-cart and the horse and buggy. We haven't done a thing in the world in the way of changing that thing. Every single county superintendent of highways, county judges that I have talked to, I have asked to put up a sign 300 feet from the crossing on the highway.

Adequate Warning to the Man Approaching the Crossing

Everything in the world should be done to warn the man who is approaching the crossing that the crossing is there, and I say frankly that the collision of a locomotive and automobile is a very foolish accident and the most easily avoided accident that could happen. Therefore it behooves us all to get in touch with the road departments, the highway departments all over the country in the different counties and cities and do something to make the crossing considered a dangerous place.

Another thing, the different roads are trying out different whistles and locating the whistles in different places. I believe the Wabash is trying out something of that sort. Some roads have changed the whistle to a short and a long and something else, but I really believe if we stick right with the old road crossing whistle that the people have known for so many years and continue it right up to the crossing, it is going to do a whole lot toward cutting down collisions at grade crossings.

Another thing we want to take into consideration is the fact that we must get in touch with the people. The crossing is as much their business as it is ours; therefore let's get together and do everything, so when we come back next year to this convention, wherever it meets, we will be able to show that we have done something towards avoiding these terrible road crossing accidents.

CHAIRMAN PHILLIPS: Remember this meeting is open to every man. If there is any engineer, fireman, brakeman or conductor present, even though you are not an official safety agent or inspector, for this morning I want you to consider yourself in that category because we would like to hear from enginemen right now.

B. G. CHAMBERLAIN (Big Four Railroad, Indianapolis, Ind.): There has been a great deal said about the whistling and I agree with Mr. Shéff because I have had several years' experience myself; but there is one thing that I want to ask. It is a question that we have not solved

and which has caused one death and two or three personal injuries due to the men going back over the tank to measure water.

You don't have that trouble on some of the railroads where you have the water pan, but we haven't any. We have long runs and we have to figure the water.

I understand some railroads have effective devices to tell how much water we have in the tank without going back. We have tried several of those on the Big Four but they proved unsatisfactory, and I would like to hear from someone as to what they are doing on the railroads in that connection.

CHAIRMAN PHILLIPS: Will someone answer the gentleman's question?

RICHARD EDLESTON (Michigan Central Railroad, Detroit, Mich.): We have been working along that line on the Michigan Central and I might say our plant foreman at Jackson has a very good idea that can be applied on all roads, that is, two long rods reaching up above the tank, down to the base of the tank, with a float similar to those used in toilets. This float comes up with little brass plates fastened to the brass chain and as the water rises, it indicates per foot what you have in the tank. This is set inside of a superheater float and registers practically every inch of water in the tank without the fireman or engineer leaving his seat box.

Measuring the Water in the Tank

LOUIS H. COLLETT (Santa Fe Railroad, San Bernardino, Cal.): On the Santa Fe they have a system of measuring the water in the tanks with a quarter inch or half inch hose fastened with a straddle on the side of the tank, the width of the tank.

Some master mechanics have placed it on the inside of the tank and as it is fastened up to the top of the tank, they pull it up or down; without going back it gives you the water right in the front of your injector hose where it is located.

J. A. CLANCY (N. Y., N. H. & H. Railroad, Boston, Mass.): I thought it might interest you to know the impressions of a safety inspector and the developments which he believes are under way, at least at these sessions.

As I see it, we are going to replace all the safety inspectors with psychologists, scientists and members of the medical profession. Of course that is only my idea.

In 1922 we were all up against the same proposition with our labor trouble, and at one of our places we had a psychologist hiring men. We had three or four engines waiting to have the valves run over, with trains being held up. The machine shop foreman was nearly crazy trying to get these engines away, and the psychologist telephoned down to him and said, "We have a fellow down here who can do anything on an engine. Come right up."

When the foreman came in the psychologist was asking questions— if he was married, if he had a family, if he lived with his family, if he went to church, if the children went to Sunday school. The foreman

couldn't stand it any longer and he said, "For God's sake, ask him if he can run over a set of valves?"

We wouldn't do that today. We have a personnel department on the New Haven.

We are starting something that might interest you. We have 29 shops and engine houses and we are going to put a flag up at the first of each month and leave it up there until we have an I. C. C. accident and then we are going to take it down. We believe it will stimulate a lot of interest and add to our safety work.

By the way, we have one engine house that has a meeting every Saturday morning. We have gone to this particular house over 1,000,000 hours and we are still going. We started in November, 1919.

This flag that I referred to reads, "No accidents this month," and of course we pull it down when we have an accident and put it up the first of the following month.

Problem of the Brake Step on Box Cars

MR. BOSLOOPER: I have another matter that was also called to the attention of a safety inspector meeting some years ago and as I understand, went to the Committee of Direction of the A. R. A., and I have heard nothing of it. That is the abolition of the brake step on box cars. That is one of the most dangerous things that we have to contend with, especially in yards where there is gravity, not only on the humps, but as I say, in these yards of gravity where you have field men, car jumpers as you call them, to spike the first eight or 10 cars that go in under the clear track. In cold weather when the brake step is covered with snow and ice, there is where you find a great many falling from cars and being run over.

CHAIRMAN PHILLIPS: Are there any conductors and brakemen here? I would like to hear about the end step business.

L. L. GALBRAITH (Santa Fe Railway, Richmond, Cal.): That is something which the men in the yard in train service have been trying to put over for a long time. They have taken it up at different times in their organizations and I think it is a very live subject. When you do something along those lines, it will be the means of reducing the number of accidents in train and yard service.

J. J. HEAVEY (Erie Railroad, Huntington, Ind.): I want to concur in what is being set forth by the Michigan Central man and the other gentleman. I want to illustrate that. We have had on my territory two serious accidents due to the brake staff within the last 90 days.

One of those men was an old, experienced switchman of 27 years' experience; the other was a young man just entering the service. I think it is of vital importance, especially for the Committee of Direction to try to make a standard which will be adopted by the Bureau of Standards to do away entirely with that brake staff.

Another thing I would like to hear about from some of the men present is pusher and helper service. We have had serious accidents on our

railroad due to pusher service. I think we ought to consider that from an unsafe operating standpoint. If there is anybody who has anything to offer whereby their railroad has minimized or eliminated the pusher service and helper service by the double heading process, I should like to hear it.

CHAIRMAN PHILLIPS: We have time for three more speakers only and we want three new men to talk.

A. R. TILMAN (Santa Fe Railway, Albuquerque, N. M.): Before we get off the question of the end platform blocks, let us remember that we do not necessarily have to raise the brake staff any higher than at present.

From my practical experience I find it is better to have the present height above the cars and your brake pole on top of the car rather than on the end of the car on a platform. That will not necessarily mean that you will have to raise your brake staff any higher than at present, which I understand was the objection raised some time ago.

MR. ROWLAND (M. K. & T. Ry.): I would like to ask that gentleman just how the pusher accidents occur?

MR. HEAVEY: By the train parting while in motion.

MR. ROWLAND: How do they part when they have a man pushing?

MR. HEAVEY: An air push. I am a living example of the accident. My right leg is off due to that operation. The train parted with 85 cars and the pusher engine walked right into the caboose, a wooden frame caboose.

Methods Employed in Pushing Trains

MR. SHEFF: We are at the present time pushing trains up to 50 miles with a pusher behind the caboose and we have done that for the last five or six years successfully. We do, however, couple the air through on pushers and we have never found that it was an unsafe practice. We consider that a steel underframe caboose is able to stand as much as a steel underframe car, and we are doing that successfully every day in the year; we haven't to my certain knowledge had an accident in more than two years. Of course, we don't cut the engine off from the caboose while running.

F. TINMAN (New York, Ontario & Western Railroad, Childs, Pa.): Speaking of the pusher service in relation to handling heavy freights, we operate pushers of the Santa Fe type and we make the practice of coupling the air through the entire train. Sometimes we use two pushers, sometimes more, but the air is coming up entirely through the train, engine, caboose and all. I can say we have had no accidents due to the pusher coupling onto the trains. We handle trains of 100 cars, empty trains, and up to 75 loads, and we are operating pusher service in safety due to the fact that the entire train pushers know our coupling throughout the land. We stop at the top of the hill to cut off the pusher; wherever they cut off, the trains stop.

I. R. McCLARREN (New York Central Lines): I just want to tell a story. It will be very fitting here.

There was an old bachelor who once gave a dinner and he bought a lot of watermelons to serve to his party and he told his chef to fill them with good whiskey, and he did. He served the watermelon. He noticed that everybody ate up all their watermelon and no one said anything, but the particular thing he did notice was that they put the seeds in their pockets.

Let's put the seeds in our pockets of what we have heard here today.

H. R. COLE (Erie Railroad, Jersey City, New Jersey): The pusher operation that my predecessor has outlined as prevailing on the Erie does not prevail in its entire territory. In our New York region in the anthracite territory and heavy pusher on the main line, we operate the caboose behind the pusher, and some of the pusher units consist of two to five engines, stopping at the top of the grade and attaching the caboose at the rear of the train at that point.

The Safety Special on the New York Central Lines

J. R. McCAMPBELL (New York Central Lines, Indianapolis, Ind.): I want to state briefly that the New York Central has recently run a safety special over the entire line, consisting of locomotive and three cars. Our General Safety Agent, Mr. Hill, had the officials bring all the employees in groups to a proper meeting place to address them on the subject of safety, and I want to tell you that nothing in this whole work is creating the interest in safety as much as the trip. We have meetings of 200,000 to 300,000 employees on the company's time. Every agent on the New York Central Railroad is requested to apply safety in his work every day.

CHAIRMAN PHILLIPS: The time is now closed for the first hour's session. The next hour's session, you will notice, is labeled "Round Table Discussion." This lets all these fellows in who have been talking as well as the safety superintendents themselves. This round table discussion just adds the bosses, as I called them a while ago, to the list of talkers and it doesn't mean you other fellows are to keep still at all.

I am going to make a three minute speech to start with to tell you about something we are doing on the Wabash which I think is a fine thing. Perhaps some of you are doing the same thing.

On the fourth or fifth of the month I know in my office every injury that occurred during the previous month, and the time lost.

It is done solely for the purpose of having a record to send out to the men while it is fresh and while they are most interested in it, because those are the records you are interested in. If you get the record sent out the fifth of October for the month of September, you are very much concerned in it and you receive it in time to stimulate you for your October record.

We have this rule. In every mechanical department and in all the operating and maintenance of way departments the day a man is injured

a telegram is sent to the division superintendent or master mechanic and that will cover all the employees. A telegram is sent stating that this man was injured on this date. Within three days this man must be visited by his foreman and at the end of three days another telegram must be sent whether the man has returned to work or not. You can go into any superintendent's office or any master mechanic's office on the Wabash (and I know there are other roads doing this) and he can tell you the lost time accidents up to that date.

Here is the principal reason we have for doing that. We believe that supervision is the one thing that we need. There can't be good supervision unless the head of the department knows exactly what is going on in his division, and when he gets these reports showing a man injured today and another report on the day he comes back, he has before him the information that will enable him to supervise.

One of the speakers a while ago told one other thing that we are doing in connection with our accidents. At the first safety meeting after an accident has occurred (of course an investigation is held right at the time), the master mechanic at the mechanical meetings and the superintendent at the other meetings has that man's foreman in that safety meeting. He asks him two questions and he wants to be prepared to answer them. The first one is, "What had you done prior to this accident to prevent it, to keep it from occurring?" After that is answered he asks this one—"What have you done to prevent the recurrence of that accident?" Every foreman on those divisions where that rule is now in effect knows that he must answer those two questions and he must be prepared to answer them satisfactorily or else be reprimanded.

We have an hour meeting now and we want to hear from just as many as possible. We will use the three minute rule again. Let's start on the subject I mentioned; I would like to hear some further talk about platform, and also about the loose covers on the bunkers of refrigerator cars, which are causing a number of serious accidents.

The Psychologist Has a Valuable Place in Industry

JOHN BURNS (New York Central Railroad, Collinwood, Ohio): I think it is a very poor man who will not say a word in defense of his own dog when somebody criticizes him. Regardless of whether the dog is good or not, he is my dog.

I have heard some ridicule of the psychologist. A great many of our boys can't remember my name and they call me the psychologist. That is my dog. I would like to give you my impressions of the value of the science of the human mind practically. If you know the reaction on the human mind when you are talking to a supervisor whose job is at stake, you know something of value, you have a club you can use. If you know the reaction of the employee when his job is at stake and he is possibly sacrificing it by careless practices, you have a weapon.

You know some men are susceptible to flattery. I will not quote this literally but practically. Shakespeare said, "Flattery is the food of fools but most wise men will take a bit." If you know that, you will use flattery, and you can get a good result with some people. If you will study the science of the human mind and its reaction in our daily life, that is psychology.

The most wonderful story that I have heard since I came here is the psychology of the helpless little child and what he did for safety. Hundreds and thousands may be influenced by the psychology of a child. Don't laugh, joke or ridicule psychology; there is something in it.

CHAIRMAN PHILLIPS: I would like to say one word. I don't believe any man can be a successful safety agent, a successful master mechanic, a successful superintendent, unless he is a real psychologist. With all our laughing about this matter of psychology, when we get right down to it, fellows, we must know our fellow men before we are able to do anything with them. We all agree with that. We didn't mean to ridicule at all, because we all know that we must be psychologists if we want to reach the other fellow.

Discussion of the Length of Brake Chains

F. A. HOBBLE (A. T. & S. Fe Railway, Topeka, Kansas): My brother brought up the question of the stirrups at the bottom of brake staffs. I think he only told half the story. The balance is the excessive length of brake chains and if a movement could be put into effect whereby brake chains, particularly on line cars, could be shortened, the handling of cars in switching could be made much safer.

With regard to the cut levers, with due apologies to those whom it may touch, it seems to me the abomination of all cut levers is the rocking tie and we in one instance had a train broken in two three times at one station, with people climbing through the cars, and we have had injuries on account of it.

WM. LENDERKING (B. & O. Railroad, Baltimore, Md.): It seems to me this matter of chains being too long on a brake staff can easily be corrected by having proper inspection in the yards as trains come in. We find that occasionally, but through inspection we correct it.

J. A. McNALLY (Wabash Railroad, St. Louis): Two weeks ago yesterday at a point about 90 miles west of here we had a fireman killed on account of a hatch cover from an E. X. P. L. car coming loose (that is, out of its position on the car), but still fastened to the chain. The chain seemed to be a little longer than the usual chain that is used to hold them up there. In passing a freight train on a double track, this came off, or had been off (the investigation didn't determine), and struck the windshield in front of the window, knocked the brakeman unconscious and struck the fireman on the skull and he died on the way to the hospital. On further investigation we found that cars delivered to the Wabash at Kansas City and other places had the hatch covers lying on top of the roof, some of them with the pin gone which is supposed to

hold them up there, others with the little lug missing that fits at the end of the cover to hold these hatch covers on, and very few cars that were properly covered and secured.

I presume these cars traveling from Kansas City and Omaha to New York pass over some of your railroads and you may have had experience along that line, but I think it is something that we should all take up and see that there is proper overhead inspection; where these cars are iced and re-iced, they should be given the proper inspection and these hatch covers properly fastened. I believe it would be well for all of us to take the subject home and see if we can't eliminate an accident like we had here.

C. T. BAILEY (Oregon Short Line, Salt Lake City, Utah): I would like to ask if that isn't a matter of supervision on the part of your terminal forces? I think that could be largely controlled by proper supervision at interchange points.

E. P. GOLDING (M. K. & T. Railway, Dallas, Texas): Isn't it a rule when cars are emptied that hatch covers are placed down in the bunkers? Isn't it the rule on your railroad?

CHAIRMAN PHILLIPS: We are speaking of the condition in which we find the cars. The rule is there should be a proper hasp on there and it should be fastened. We have gone into the matter and we are not receiving refrigerator cars in proper condition and are not delivering them in the proper condition. We are just as guilty. We couldn't find a train leaving or coming to us that had covers fastened properly on all cars. On lots of them the hasps were broken and gone.

MR. COLE: Is the trouble that is experienced with loaded or empty equipment?

Problem of Swinging Hatch Covers an Old One

CHAIRMAN PHILLIPS: These were loaded and had been re-iced.

All of our progressive railroads, including the Pennsylvania, the Santa Fe, the Union Pacific and others, are beginning to have a lot of double track and this is making the matter of the covers swinging over the sides very important. I might say that I attended a firemen's convention three years ago in this same town and a number of firemen asked me at that time if I wouldn't get after that very proposition, and there were firemen from every road in the United States there.

MR. HEAVEY: I think we handle about as large a set of that class of equipment as most railroads, and it is my experience that the vast majority of those hazards are on empty equipment returning from the eastern points.

CHAIRMAN PHILLIPS: I just referred to that one accident. I agree with you on that.

MR. HEAVEY: We have made an investigation on the Chicago starting point and we have minimized materially by overhead inspection and a follow up. You will find that the trouble exists in the old equipment. It is not the hatch plug that creates the trouble; it is the hatch cover, and we also find on investigation that it isn't all attributable to the

unloading of the car, the re-icing of the car or the terminal inspection. We find in many cases that the condition exists or is made by trespassing on side tracks. We find our own employees are the worst violators in the summer time. Our train service employees at many points will go into those bunkers to get ice and they don't follow up the teachings of this organization as propounded for 15 years that I know of. They don't think about the other fellow. They get the chunk of ice and they throw it on the ground and leave the hatch cover loose. We have had one serious accident at Kenmore, Ohio, from a commercial standpoint as well as the human material standpoint. It was very serious. Too much can not be said; too much interest can not be shown by this organization and the section of the American Railway Association as to promoting the very best terminal inspection that we can get on our empty equipment returning from eastern shores.

CHAIRMAN PHILLIPS: We are going to have to change our program just a moment. We have with us four of the finest singers in the world without any question. Pride causes me to say that one of them is from the Wabash. They will now sing to us.

(The Pullman Porters' Quartet sang several songs amid applause.)

Appreciation of the Pullman Porters' Quartet

SECRETARY COTT: Boys, I don't know that I can voice in words our appreciation of your singing because music touches something deep down in your heart and brings you a little nearer that which you have always wished to be but never reached; every time that is stirred, it makes you just a little bit more like what you want to be.

I am sure when we go away from the inspiration of this meeting with the addresses and talks we have heard, we will carry back with us a memory of something that was stirred by your singing.

As a little evidence and token of our appreciation we have some pieces of paper here that Uncle Sam passes around which our Section wishes to give to you. I am also delegated by our chairman, Mr. Rohweder, to present to you a box of cigars, with the compliments of Mr. McGonagle, president of the Duluth, Missabe & Northern Railway, in whose presence you sang.

CHAIRMAN PHILLIPS: We have just a half hour left and let's use it.

J. E. LONG (Delaware & Hudson Railroad, Albany, N. Y.): Your almost silent partner for 12 years would like to say a little on this ice bunker proposition. I concur in everything that has been said about proper and thorough overhead inspections at interchange points and terminal points, but someone mentioned the question of train crews getting into ice bunkers.

I am going to tell you how we have helped that situation very materially. We put ice boxes alongside of our caboose so that it is a lot handier for our trainmen to get ice from those boxes than out of refrigerator cars. We fill our locomotive ice bunkers before the engines leave the round house.

If you are going to get at the bottom of troubles, you have to go to the bottom, and unless you are giving your train crews facilities for getting ice legally and honestly, they are going to get it the other way. I don't think any of us should blame a trainman for getting ice anywhere if he can't get it where he should get it.

J. H. AMOS (Missouri Pacific Railroad, St. Louis, Mo.): Gentlemen, this is my first attendance at a meeting of the National Safety Council. I feel that you may think I am a trespasser.

It may seem harsh for me to say this, but I have been in the business of dealing in blood and bones for 25 years. This great profession which I represent should stand in close relation to you gentlemen, to your association. There should be no secrets between our departments and the departments over which you preside.

The Leak Stoppers of the Great Railroad Systems

When I was a boy, a young man, I lived on a farm. It used to be my job at threshing time to take the straw away from the old fashioned straw carriers. It often occurred to me that the straw would come from the straw carrier onto the stack. What a tremendous waste it was when the grain was not properly separated by reason of the defective machinery of the threshing machine.

Gentlemen, when you fail to keep your machinery in proper condition, the grain comes through the stacker onto the straw stack and it is an absolute waste. You are the leak stoppers of the great railroad systems of this country. When you fail to stop the leaks in your shops and on your works, we of our departments are the beneficiaries.

I believe that we should keep in close touch with you gentlemen and you should come to us and we should go to you. We should seek your cooperation, not ask it. You should seek our cooperation. We are experts on the causes of accidents and I am sure that you gentlemen can obtain some valuable information from our departments just the same as we can obtain valuable information from yours.

I am going to take some of the seed that has been sown in this convention into my pockets and sow it among our employees and among our departments for future benefit and use.

J. W. BORRIS (Pullman Company, San Francisco, Cal.): Mr. Chairman and members of this wonderful conference: I am very glad to be here to look into your faces and obtain so much information.

I was glad to know that you didn't have time, you were too busy with the different departments, to say a thing about the porter. So I want to ask one question which will bring to your attention the porter's place in the great safety movement. Did any member here present make a safety convert? While you are thinking about that, I want to express our thanks to our director, Mr. Guilbert, and Mr. Carry, our president, for the opportunity to be present at this wonderful conference.

But our problem comes when we leave our homes as porters and come to the Pullman home where there is one porter with a safety message

and 40 passengers who do not know much about safety. We have to spread ourselves over the whole group like a mother bird, and try to get them from one end of the country to the other safely.

During my spare moments I have collected the emblems of as many roads as possible and put them away. I have done that for two or three years. Not long ago there was a little white girl about nine years old who saw those emblems and she became interested, as a child will, and began to question me. I told her, "These are the emblems of the great railroad systems. I am going to a conference and these are to be represented there, and these railroads will talk about the safety problem." The emblems were loose; she went to her aunty and got a pair of scissors, and using my paste, she pasted those emblems on this page. She worked on that two days, and in that time I told her all about swinging out of the door and swinging on the seats and putting her fingers in the door, and all about safety. I found out her father had been connected with a railroad.

A Little Girl Interested in Safety Ideas

I had a greater task for her. I took out the central page of each of these folders, the map which shows the relation of railroads. She cut them out, put them on this sheet and colored them with crayons. I told her that somehow I would get this before our conference. She wrote down her name, age and address, and I am going to ask that she be sent some kind of token, something to show that we have actually made a convert to safety in this little girl.

Among the Pullman porters we have a *Pullman Porter Messenger*. It is to spread the message of safety. I happen to be the editor, and I am in a position to offer you one or two pages, if necessary, if you will send us little safety messages. I ask you to cooperate with us as porters, that you do what you have said, namely, help us to educate the public to safety.

SECRETARY COTT: I move we get the name of the girl and send her safety buttons.

(Mr. Botts furnished the information.)

CHAIRMAN PHILLIPS: I just want to say there is one thing we white fellows can't do. We can't go home and tell our wives, "Don't do this or that!"

C. F. LARSON (Missouri Pacific Railroad, St. Louis, Mo.): I am very glad to follow my former superior, Mr. Amos, under whom I worked a number of years in the claim department of the Missouri Pacific Railroad, and I don't know what the relation is between the safety work and the claim work on other railroads, but I know that on the railroad represented by Mr. Phillips, it is very close. I know that on the Missouri Pacific it has grown very close. The claim department's investigation of accidents is frequently much more thorough, going into the legal phase of it more than the operating department, and I have always been able to get from the claim department of our railroad certain facts that are not brought out by the operating department.

If there are any railroads here that do not have that close relationship between the departments, I would recommend that you get as close as you can to the heart of the claim department.

We had a division or shop on our road that had been making a miserable record with personal injuries for a long time. The management found it necessary to change the master mechanic on that division, not because of the personal injury feature, but because of other reasons, and probably that was one of them.

A very active master mechanic was put in that shop who discovered this situation, and for two or three months instead of getting better it grew worse. He called all of his supervisors in (it is a large division, covering more than 500 miles of jurisdiction), and put the matter before them, and they mutually agreed on April 1, 1926, that every foreman who had a personal injury among the men under his supervision would pay a fine of one dollar. The fund accumulated rapidly for about two months and then suddenly ceased. They had promised me that the month they cleaned their slate and had no more injuries they would give a banquet at a prominent hotel on that division and I should be the honor guest.

An Active Master Mechanic Stopped the Accidents

As I said, in two months the fund ceased to grow because the injuries ceased on that division. On the first of August I went there and we had a glorious feast and that division has not had a reportable injury from that day to this. That master mechanic was changed from that shop to one of the largest shops on the first of October and he has instituted the same program, and I understand that he will have practically a clean slate this month. Other shops have caught the fever and it has followed all over the road.

Some of the railroads are having trouble with their maintenance of way employees. I am happy to say that the largest reduction we have made on our system, which has reduced us from 39 men, a million man-hours, to only 24 at the last quarter, has been primarily among our maintenance of way employees; and if anyone has an idea of ridiculing psychology here, I want that stopped, because we have a maintenance of way engineer on the Missouri Pacific who is a psychologist.

On our Joplin division we have not had a reportable personal injury about the brake and building department for three months. We have one division of our railroad that went through an entire month without a reportable personal injury.

F. W. MITCHELL (New Haven Railroad, New Haven, Conn.): The New Haven Railroad has the high tension current, 7,000 volts, and we don't like to have them swinging the fire hook and hooking onto that because when they come down, they stay down. We had to devise some other means of storing the fire hook than putting it up on top. We have 11 foot, 10 foot and nine foot hooks and we use a superheated flue, five feet in diameter, that is built right into the tank. When they get through, they slide it right back into the tank.

CHAIRMAN PHILLIPS: I am sorry to say that our time is up. I never enjoyed anything as much in my life. All my 29 years of experience I have wanted to preside at some kind of a meeting besides a prayer meeting, and, Mr. Rohweder, I want to thank you for that opportunity.

(Mr. A. V. Rohweder took the chair.)

CHAIRMAN ROHWEDER: We have two or three things that we want to get out of the way before 12:00 o'clock. One is the report of the Committee on Resolutions in connection with train service accidents. Mr. Bailey, of the Oregon Short Line, is chairman of the committee and we will ask for his report at this time.

MR. BAILEY: In conformance with the desire of this Section, after that resolution was passed your committee convened and in the short time we had before us tried to look this situation over; we found it to be a rather large subject for us.

A committee to function properly and to determine remedies that should cover the train service accidents on our American railroads, has a big job on its hands, and as we discussed that among ourselves yesterday, we are recommending to this organization that a permanent committee of that character should be established and that this committee be given the opportunity of making a survey of the records of past experience so that in time it will be in a position to make a real concrete report to you with suggestions or recommendation as to remedies available.

Report on Analysis of Train Service Accidents

Fortunately, through a report that came to the committee's hands yesterday, taken from the Interstate Commerce Commission records in Washington over a spread of years, we were able to look the situation over in a general way, and I am going to give the Section the benefit of that report, indicating the enormity of the proposition.

Train service accidents, as reported to the Interstate Commerce Commission, are subdivided into 10 separate causes and these causes, as the reports come to the Commission, are tabulated. To gain any idea of the necessity for close study, you must have a spread of time and an accumulative period to get that result.

This analysis of train service accidents is subdivided under 10 separate heads. Under the particular heading, "Coupling or uncoupling locomotives or cars," in the past six years there have occurred 10,572 deaths and 11,121 injuries. The sum total of those two items are but 3.95 per cent of the total train service accidents.

Coupling and uncoupling air hose—there were 2,776 deaths and 2,971 injuries. That composed 1.03 per cent of the total number of accidents; and so on down the line through the various headings.

You can see that any attempt on the part of a small committee on snap judgment to make recommendations worthy of consideration, would be futile. We are therefore recommending to this Section that a permanent committee be created to study the question of train service accidents and be prepared to make a report at your next annual session, during the

interim of which the committee might be able to arrive at some satisfactory recommendation. I am making that proposition to you now.

CHAIRMAN ROHWEDER: What is your pleasure in connection with Mr. Bailey's recommendation?

Z. B. CLAYPOOL (St. Louis-San Francisco Ry., St. Louis, Mo.): I move you that this be accepted as a progress report, the present committee to be made permanent, and they report at the next convention.

(The motion was seconded.)

W. L. RICHARDS (Union Pacific Railroad, Omaha, Neb.): I would like to amend that motion so the committee will be enlarged to include at least seven members.

(The motion was seconded, and the amendment carried; the question was then put to a vote and the motion as amended was carried.)

CHAIRMAN ROHWEDER: Has the Resolutions Committee any further report, Mr. Long?

Further Report of the Resolutions Committee

MR. LONG: Your Resolutions Committee wishes to submit the following resolution for your consideration:

"BE IT RESOLVED, That the Steam Railroad Section of the National Safety Council, at their Fifteenth Annual Safety Congress, extends to Mr. Victor Parvin, Superintendent of the Ann Arbor Railway, and a representative of the American Railway Association of Railway Superintendents, Dr. W. Louis Hartman, Chief Surgeon of the Michigan Central Railroad and representing the Medical Section of the American Railway Association, Mr. F. W. Matson, Commissioner of the Minnesota Railway and Warehouse Commission, Mr. L. K. Silcox, General Superintendent of Motive Power, Chicago, Milwaukee & St. Paul Railway, and a representative of the Mechanical Section of the American Railway Association, Mr. E. R. Lewis, Principal Assistant Engineer of the Michigan Central Railway and representing the American Railway Engineering Association, the Pullman Quartet, and all others who in any way contributed to the proceedings, sincere appreciation of their able and effective participation in the success of the program."

MR. BAILEY: I move the adoption of the resolution.

(The motion was seconded and carried.)

CHAIRMAN ROHWEDER: I want to call your attention to one thing in connection with Mr. Matson. On our program we didn't show Mr. Matson's full title. Mr. Matson is not only a railroad and warehouse commissioner of the State of Minnesota, but is also a Chairman of the Safety Committee of the National Association of Public Utilities Commissioners. Many of you gentlemen know you furnished a large amount of material in connection with safety on American railroads that was sent to Mr. Matson and presented in his annual report at Cleveland, at the meeting of the National Association of Public Utilities Commissioners.

We have now arrived at the part in our program which, as Charley

Scott said last night, probably is most pleasant, and that is passing the job over to someone else. I want to ask Mr. Long, who was elected secretary of this Section, to come to the platform, and I will ask Mr. Cott to turn over to him the office of secretary of this Section. Mr. Long has served the Railroad Section as chairman of the Membership Committee and has done a remarkable piece of work.

(Mr. J. E. Long took the secretary's chair.)

CHAIRMAN ROHWEDER: As you know, the man who has been secretary for the past four years has been elevated to the vice-chairmanship. If there is anyone in the Steam Railroad Section of the National Safety Council who understands the ins and outs of the Council's activities and a man who has been responsible for a good part of the work done here and the work done in the past year, it is Emerson Cott, of the Hocking Valley, and I take pleasure in installing him as Vice-Chairman of your Section.

Chairman Rohweder Hands the Gavel to Chairman White

Before passing the gavel over to J. D. White, of the Illinois Central, as your new chairman, I want to express my appreciation to each one of you for the remarkable attendance we have had this year. Mr. McGonagle commented on that yesterday. I think it was probably the highest tribute that could be paid to our Section: the ~~fact~~ ~~that~~ ~~it~~ ~~was~~ ~~the~~ ~~highest~~ ~~tribute~~ that did and going back to your properties is going to have a wholesome effect. It will have on my particular Railroad, ~~because~~ I know as well as you do that a great number of conventions are ~~not~~ attended by the membership as they should be, which has always been the opposite in connection with the Steam Railroad Section and the A. R. A. Safety Section.

I also want to ask for the incoming chairman that you express to him your opinion of the program that we have had here during the last three days. As I told you on Tuesday, it was more or less of an innovation; it was an idea that we were putting the cart before the horse in not getting hold of our supervisory and executive officers and getting them to come in and properly understand what we are trying to do in the Steam Railroad Section. The remarks of the men of the purchasing and stores department of the A. R. A. certainly carried out in a very fine way the idea I have had for a long time, that we have simply been hanging up a sign to the various departments on our railroads, "Keep off the grass—this safety job belongs to the safety men."

I think if we get them in here and have them tell us what they know about it and what we ought to do, which they did yesterday and which they will do even more if they can discuss it at their annual conventions and feel that is part of their job, we are going to get a lot farther than we have in the past, when we go back and report in a hit or miss fashion that "I said so and so," or "some member of this Section said such and such a thing," it doesn't make near the impression on your officers as a statement from the man representing their association.

At this time I take pleasure in passing the office of chairman of the

Steam Railroad Section over to our good friend, J. D. White of the Illinois Central, who served this Section during the past year as vice-chairman:

(Mr. White took the chair.)

L. F. SHEDD (Rock Island Lines, Chicago): May I have just a word? I would like to suggest that we do one thing, either as the first act of the new chairman or as the retiring act of the last one, and that is that we remember that dear, good fellow who was thoughtful enough of us to send us a telegram and regarding whom we should be thoughtful enough to reply. I refer to that dear Christian character, John Broderick of the B. & O. We all remember him at Salt Lake. We remember his enthusiasm, his interest.

Therefore, I move you, Mr. Chairman, that we have our secretary send a telegram to John Broderick expressing our appreciation of his remembrance of us, returning our remembrance for him, and adding further that we wish him Godspeed for an early recovery and the regaining of his health and strength, and that we look forward to having him with us some time in the future.

Officers of the Section Are Present

CHAIRMAN WHITE: I believe it has the approval of everybody here, and I take it upon myself to ask the secretary to send such a telegram.

I am going to call on Robert Scott to tell us what he thinks of the past administration and the way these meetings have been conducted.

MR. SCOTT: Ever since we started this society with our big big job has been to get the other fellow interested. There is a tremendous lot of work. We have been here in Detroit for two or three years now. We have attended these sessions faithfully. We have obtained a wonderful bit of information out of the programs and I want to say that it is one of the most interesting programs that has ever been put on for the Steam Railroad Section of the National Safety Council.

I think the chairman of this Section and the chairman of the Program Committee and the secretary and all of those who have had anything to do with it are entitled to our thanks. We have had representatives of other departments come here and tell us that they are with us in our work and that's what we want to know. Don't you gentlemen wish that your president had been here and sat at the speakers' table yesterday and had said the things about the safety department of your railroad that was said about Arthur Rohweder's railroad safety department, which is being so ably managed under his direction?

You gentlemen have no doubt read Mrs. Shelley's story. It was a story about a young student in physiology who, it seems, set about visiting the graveyards and hospitals, gathering bits of human beings and putting them together. He created a monster that finally set upon him and devoured him because he couldn't put the conscience there.

Gentlemen, we are living in a wonderful age today, this age of fast-moving trains, this age of powerful automobiles that are speeding up

and down our highways and our streets. Let us not create a monster that is going to turn upon us and devour us.

We must go out and bring the average mind up by education and by training so that these people can take care of themselves against this monster that the scientists are creating today in this busy world of ours.

To my mind the chairman who has just left the platform has done his bit in contributing in a large measure to that wonderful work in which we are engaged. I know what it is to be chairman of a busy section like this for 12 long months. I know what it is to undertake to pull off a meeting like this, and my sympathy has been with Mr. Rohweder throughout.

There is only one criticism that I will offer and that is that Mr. Rohweder has been just a little too modest in presenting himself before us at these meetings. Mr. Rohweder, I, personally, thank you and I am going to propose a rising and a rousing vote of thanks to you for the splendid manner in which you have conducted this work during the past year and at this, our Fifteenth Annual Conference.

(Mr. Rohweder was given a rousing vote of thanks.)

CHAIRMAN WHITE: We have another ex-chairman here and I would like to let him say what his opinion of Mr. Rohweder's term of office is.

More Time for Round Table Discussion Suggested

CHAS. E. HILL (New York Central Lines, New York City): Mr. Chairman, as usual, after Mr. Scott has completed his remarks, there is nothing left to be said. I have sat in a great many meetings of this character and at no time have I been any more impressed with the genuine, sincere manner in which this particular meeting has been conducted. To my mind it has been constructive and that is why we come to these meetings.

I don't know of any class of men who know more about putting in long hours, tedious hours and hard work than railroad men. There is no body of men within the entire United States that forms a more composite part of the real citizenship of this great country of ours, and when we gather here together and rub shoulders and exchange ideas and give the benefits of our experiences to our fellowmen and coworkers, we are doing something that is really worth while. I believe that the character of program that was outlined by the chairman of the Program Committee through the aid of the chairman of the Section, is one that has been productive of great results.

The only suggestion I might have to make would be that we have more time for round table discussion. I think it might not be amiss to suggest this for your consideration, inasmuch as you called upon me, that you set apart the second day and give the boys out in the field, the men whom we are depending on to get results for us, a greater opportunity and permit them to talk about the vitals that go to make up the casualty records of our various railroads. Let them tell us of the experience and troubles which they encounter, so through these experiences we may be able to profit.

I wish to express to the outgoing chairman my deep appreciation of the manner in which he has conducted his office. He has done it admirably, and I want to say to the incoming officers that in so far as I possibly can help, you will have the continued support of the railroads that I have the honor of representing to make the next meeting as much of a success as is possible.

CHAIRMAN WHITE: I hope as many nice things will be said about me one year hence as has been said about Arthur Rohweder.

We have about 100 railroad members of this Section. That means, I figure, about 300 men that can and will attend these annual meetings. I want to say again that I very much appreciate the distinction that has been conferred upon me to serve as chairman for the coming year, and I am going to do my level best to make myself worthy of the compliment; but I want you to understand that this is not a one man's job, nor a three men's job, but it is a job of every man in the room or who may attend here or who is in the safety department of the 100 railroads that are members of this Section. I want your cooperation, every one of you. There are no secrets in the safety department. If you have anything to say and can't see me, write me. I want your help and I know I am going to get your help. I want this year to be one of the best years for safety we have ever had, and we will meet some place one year hence even better than this year and have a fine meeting. As I said before, don't forget I want your cooperation.

Committee on Secretarial Expense Is Authorized

D. G. PHILLIPS (Wabash Railway, St. Louis): Mr. Chairman, in order to express our appreciation of the institution of what was known as executives' day, I move you that we recommend that the incoming administration consider again having an executives' day next year. I think we ought to express our appreciation of this executives' day program.

T. H. CARROW: I would like to amend that motion by letting it remain as a suggestion.

CHAIRMAN WHITE: We will take care of that, Mr. Phillips. Thank you very much.

MR. ROHWEDER: Your vice-chairman made a very definite recommendation in connection with the secretary's job. I was secretary of this Section for two years and anyone who has had the privilege, or rather the work, of serving as secretary, knows that to do the job right, it is a real job, and I felt at the time I was secretary that some assistance should probably have been given.

We have a little different situation on the D. M. & N. than they have on the Hocking Valley and a lot of other railroads. We had the money to go ahead and do the things with, but some day you are going to get a secretary who can not do that. It is a question of whether one railroad should be burdened with the expense of doing the work that is required of the secretary for this Section.

Therefore, I move you, Mr. Chairman, that a committee be appointed

to investigate the suggestion made by your retiring secretary, Mr. Cott, looking toward the possibility of taking care of the clerical expense, or other expense, in connection with getting out a monthly news letter, which is an important thing if put out properly.

In addition I want to say this. A great number of the members of this Section from time to time get up into the great Arrowhead country of Northern Minnesota; in fact, some of the executive committees of this Section have met in that country for the past two summers. That invitation is not only open to the executive committee but to any one of the railroad safety officers or any of the railroad subordinate safety officers. We would be glad to have you come up there at any time. We have a fine climate in the summer with all the facilities in the world for fishing and getting away from the heat. I am extending that invitation to you on behalf of Mr. McGonagle, President of the D. M. & N. Railway and myself.

(The motion was seconded and carried.)

CHAIRMAN WHITE: I am now going to call on the Pullman Quartet to sing one song, after which the meeting will come to a close.

(The Pullman Quartet sang "Home, Sweet Home.")

ADJOURNMENT

Taxicab and Fleet-Owners Section

New Officers of the Section

CHAIRMAN: J. T. SMITH
Yellow Cab Co. of Philadelphia, Philadelphia, Pa.
VICE-CHAIRMAN: J. ROBERT CLAIR
Checker Taxi Co., Boston, Mass.
SECRETARY: J. E. DOBBS
General Necessities Corp., Detroit, Mich.

Committees

POSTER: HARVEY D. WOOD, Chairman
Yellow Cab Co., Chicago, Ill.
STATISTICAL: RUSSEL REEL, Chairman
Yellow Cab Co., Des Moines, Iowa
PROGRAM: HENRY J. MINEUR, Chairman
J. M. Horton Ice Cream Co., New York City
ENGINEERING REPRESENTATIVE: F. C. SINGLETON
Standard Oil Co. (Indiana), Chicago, Ill.
EXECUTIVE COMMITTEE (The Officers and)
DALE HARMAN
Yellow Cab Co., Kansas City, Mo.
LEE L. MILES
Louisville Taxi Cab and Transfer Co., Louisville, Ky.

October 26, 1926

DALE HARMAN, Chairman
Manager, Yellow Cab Company, Kansas City, Mo.

THE Taxicab and Fleet-Owners Section of the National Safety Council convened in the Ladies' Parlour of the Hotel Statler, Detroit, Michigan. 10:00 o'clock, Mr. Dale Harman, manager, Yellow Cab Company, Kansas City, Missouri, chairman, presiding.

CHAIRMAN HARMAN: I think for the first few minutes we had better have a little get-together-and-get-acquainted meeting. I would like you to take one of these registration cards and each gentleman stand up and

give his name, residence, and classification of business. In that way we will get started off and know who is here and what to expect.

(Each man then arose and gave his name, business, and city.)

The first order of business this morning is the report of the different committees.

First we should have the report of the secretary, but he is absent and will possibly be here later on. The next is the Poster Committee. Mr. Wood, can you tell us about that?

HARVEY D. WOOD (Safety Director, Yellow Cab Company, Chicago, Ill.): Mr. Kinney asked me to apologize for not having much to report at this time. In fact he has been rather inactive as to that committee, and therefore, has nothing to report.

CHAIRMAN HARMAN: I rather feel that the Poster Committee of our division, gentlemen, will possibly be very much neglected, as fleet-owners and cab operators haven't got very much to post, but you will see a very good display of posters at the different hotels where the various meetings are being held.

Section Should Have Great Variety of Posters

MR. WOOD: Mr. Chairman, I would like to say that as far as posters for the taxicab business are concerned, the field is pretty much destitute. We have a very limited supply of taxicab posters.

I would like to see this Section get out a great number of good taxicab posters. I believe it is a good medium for getting our story over to the drivers, and I have found, after going up to the National Safety Council, that they have probably not more than 15 posters that apply to the taxicab section.

CHAIRMAN HARMAN: Have any of the men present anything to say on this subject? I would be glad to hear from you as to what you may be doing in your respective lines of business on posters for the benefit of your drivers. I will naturally assume that fleet-owners are all interested in drivers the same as the taxicab man. That is, the educational work in the taxicab business is the driver and the safety of his driving.

J. T. SMITH (Asst. Gen. Mgr., Yellow Cab Company, Philadelphia, Pa.): In looking over the posters sent out from month to month by the National Safety Council, it is a pretty hard job to find one that applies to the fleet-owner, and I think the next committee that is appointed has an opportunity of doing considerable good work for our division of the association.

I think this National Safety Council is realizing more and more the importance of the highway end of the Safety Council and if we can emphasize that and work on them, we can get more in the way of posters.

F. E. SHEARER (Standard Auto Accident Co., New York City). I was talking with a broker in New York City. Some of you gentlemen may be familiar with the insurance proposition there. There are fleets knocking around the city, trying to get insurance and can't. This broker had a lot of trouble trying to keep his risk insured. At the present time he is as much interested in the safety work as in the brokerage business.

He had one poster which struck my attention particularly. The poster was a regular blue print. It said, "Yes, a driver can be a gentleman." That poster was a favorite poster with all the drivers where it was displayed.

This man is spending about three per cent of all his premiums on safety work, keeping the risk which he has in New York City insured.

CHAIRMAN HARMAN: I might say for myself we have a garage with about 250 car capacity in Kansas City, and we have framed these posters gotten out by the Safety Council, such of them as pertain to traffic for our garage, and such as pertain to shop accidents to our shop. We have adopted a frame.

You know the size of those posters, two and a half by four feet, and we have made a line of those clear around our entire building between the windows.

Two or three weeks ago, when our schools opened, we took those particular posters down that pertained to slow driving around the schools and put them up on either side of the garage where the cabs go out and come in, in an effort to get before our drivers the message. "Now is the time to drive slow and protect our children around the public school."

Experience in Building Posters on Safety

HENRY J. MINEUR (Safety Director, J. M. Horton Ice Cream Co., New York City): I got into the ice cream business about a year ago. Before that I had been safety director for a plant in Brooklyn. I hadn't been very much interested except by association with the Brooklyn Safety Council.

I found there wasn't much to help the fleet operators in their safety work. A great many had tried to carry a campaign purely with literature. They didn't go further than to post notices or what few bulletins they got, and there was no personal contact, no follow-up.

We made up quite a number of posters affecting the public, and combined in some of the posters the public hazard as well as the hazards to employees, and I dare say we have, during the last year, put out 40 of our own posters, and they are designed for practical fleet-operators.

It is true, in the ice cream business at least, that some of them are having difficulty in placing their insurance. The reason is, as I mentioned, there is no systematic safety work. The posters from the Safety Council dealt mostly with public accidents and very few dealt with injuries to the employee insofar as automobile operators are concerned.

We found some of the posters put out by the Council to be very effective, so much so that some of our fleet-operators have wanted to take them home after they were put on the board. I think that is an indication they were interested.

We don't use a poster the second time if we can help it, unless it is especially good. We keep our posters on the boards for about two weeks and we have four boards on which we put posters dealing with the oper-

ation of automobiles. One of these is located in the drivers' room and other places.

In addition to that we have the pay roll envelope system. We don't run them every week. We run them once every two weeks or we might run one every three weeks or once a month. During the last year, or the first nine months of 1926, we have been very successful in cutting down our outside accidents as well as our inside accidents. Roughly we have averaged about 10 less automobile outside accidents, a little greater number of inside accidents, and about nine lost-time accidents for the month. Those are all monthly figures, and it shows that the posters together with your follow-up work really do some good.

I agree with the previous speaker that the Council ought to get together and devote more time and consideration to the operation of these fleets. I would be glad to send to the Council those posters we have made for our own use.

Methods of the National Safety Council Poster Division

MR. WOOD: I am afraid we don't appreciate the fact that the National Safety Council will give us only as we give to them. In other words, we can only get out of the National Safety Council what we put into it.

The Poster Committee, being as inactive as it was last year, didn't get any posters out and consequently we haven't any posters. If the gentleman over here had been on the Poster Committee last year and contributed to the committee his 40 posters, then we would have 40 posters. But inasmuch as there were no posters contributed, we have no posters. That is the way it goes.

I happen to know some of the members of the Public Utilities Committee, and they have got out some 48 posters during the past year, and as a result the members of the Public Utilities Section were privileged to receive 48 posters during the year.

So you see we must remember that the National Safety Council is merely gathering that data from us fellows and distributing it around to the other members. I was very glad to hear the gentleman say he was going to send them in. I think we should nominate him on the Poster Committee.

S. J. STEINMANN (Indemnity Insurance Co., Philadelphia): I am of the opinion that what is known as the general bulletin should be used just as well as an automobile bulletin. In posting bulletins there is a whole lot in following advertising principles. Too many people post bulletins and they will post them promiscuously and you will never get your message home.

My personal experience has been that no matter how many boards you have you should post the same bulletin on every board, and a bulletin isn't worth the paper it is written on after everybody has seen it.

The gentleman from New York brought out a point—personal contact. If you follow up with pay roll inserts and a little letter to the employee if he is married, addressed "Mr. and Mrs.," you will do a lot of good.

I feel that is the paramount thing in safety work—personal contact. Many an organization has fallen down due to the fact that they have overlooked that little personal contact feature.

F. C. LYNN (Kansas City Public Service, Kansas City): This matter of supply of posters from my observation is rather unlimited.

I had the experience of going down to the public schools and talking safety, two weeks ago, and found down in the second and third grades the children were making safety posters that carried just as good messages as some of our high-priced articles.

I don't think it is necessary to have a poster that applies directly to the work in order to get the message over. Any of the good safety posters put over the message.

The problem, as we all know, is to get the boys to read the poster, not get the poster. Here is a practice we followed out. The board was blank every other day. In other words, the bulletin board had the poster on today. Tomorrow it had nothing on it.

We capitalized on the psychology that every workman is anxious to have the superintendent or general manager or the president speak to him, and also on the fact that every general manager and superintendent is anxious to speak to the employees if he has something in common that he can quickly pass a few words.

When the general manager or any of the other officials walks through the plant, he says, "Jack, what was on the bulletin board yesterday?" Every day, every employee being anxious to impress the management, he was wide awake so he could answer and it put over the safety idea as no other sales argument could possibly do. It struck me as being the best kink in connection with bulletin boards that I have ever heard executed.

One Reason They Have a Good Safety Record

F. B. HENRETTA (Yellow Cab Co., Roanoke, Va.): My former experience was in railroads. My principal duty was safety. I found that secrecy is the greatest impelling force. My present system is a poster that every man carries in his pocket every day, a form of merit and demerit.

Every time one of our men checks in the checker will say, "What is rule so-and-so? Let me see your card." Then he has to dig out the card. If he doesn't answer correctly, he gets a very small demerit.

The record of each of those men is kept secret from the others. I look over these records and come around and say, "John, your record is getting bad." He will say, "How is Tom's record?" I will say, "That is none of your business. Pep up a little. Your record is getting bad."

We haven't had a serious personal injury. Our insurance company told me that it was one of the nicest records in the United States.

CHAIRMAN HARMAN: We only leave the poster up for our school or new man. I don't know whether you men have the labor situation to contend with, but we are always taking on new men. We have a school

of instruction which we have to put these men through. Even if they are expert drivers, for our particular line of business they have to be schooled.

So we have these posters around our garage, almost entirely around the building, and they are all numbered and our instructor has a little talk on each poster, as to why we are trying to put that message over to him. Some may be automobile-wrecking or running down a child on the street. We retain the posters in our garage and keep them bright and clean so the man doesn't know the oldest from the newest, but as they come from the Safety Council they are put up there before they lie around outside.

Furnish Practical Experience for the Posters

J. E. DOBBS (General Necessities Corp., Detroit, Mich.): I am very much in favor of the poster, providing we can get a consistent supply of posters pertaining to the fleet-owners, so that we can run our bulletins with some result, because I do believe that the posters play their part in the safety game; but as Mr. Smith over here stated, it is so hard to find one that relates to the fleet-owner's business.

I think the body here could furnish plenty of hints to the Safety Council as to what kind of posters they want. I know in my line I see a lot of rear-end collisions for instance, and the excuse is, the man in front stopped suddenly. I think we could bring out a suitable poster to cover that.

In another case a truck driver backs his truck without ascertaining if it is safe, and in the meantime a child or another vehicle will come up.

Different things like that could be brought out on these posters, such as making left-hand turns improperly, the picture of a collision, bringing out the result of that collision, and different features like that.

CHAIRMAN HARMAN: We can get those posters through the National Safety Council if we can get a committee here to function in such a way that they will give this information.

MR. MINEUR: Mr. Chairman, I would like to say the special posters we made up, would not be very useful to the National Safety Council. Our poster is on cardboard. I think the size is 15x18 and we have them in different colors. We have all the colors of the rainbow, so wherever a bulletin is changed, it stands out prominently.

MR. WOOD: The National Safety Council takes them and paints up a poster. Ordinarily they just furnish a picture and the artist has to work that picture into a bunch of wording.

MR. MINEUR: We have no picture, just wording.

MR. WOOD: I think Mr. Hemman of Armour & Company, Chicago, has a great deal of experience with fleet-owners. He has been connected with the stores of Chicago for a good many years.

L. D. HEMMAN (Armour & Co., Chicago): I believe my story will be better told tomorrow. I will say I believe in pictures more than slogans. I notice you can always get a crowd around a picture.

CHAIRMAN HARMAN: The next committee that we should get a report from is the Publicity Committee, but Mr. Gibson of the Pittsburgh Transportation Company, is not present. I feel that publicity in a general way comes under the same heading as this poster and bulletin work.

We will pass on to the Statistical Committee, Mr. Reel of Des Moines. He is unable to be here. I don't feel that the Taxicab and Fleet-Owner Section of this National Safety Council is old enough to have very much statistics to work on. We have our individual statistics, and I don't know how one of those would apply to the others or how an ice cream company might be interested in some other company like the Standard Oil Company fleet.

Has anyone anything to offer on the statistical end of it?

Mr. Wood: I think we have a whole lot to come. You are not in the taxicab business, are you, Mr. Dobbs? You mentioned running into the rear end of the truck. Probably 40 per cent of our accidents are that kind. So we really have a great deal to come. Any kind of a vehicle operated by a driver is confronted with the same traffic problem.

CHAIRMAN HARMAN: The traffic problem is the same, no matter what company you represent.

More Publicity Needed for Accident Prevention

MR. MINEUR: Mr. Chairman, I think all fleet-operators have the same thing to contend with. I think there is one thing that is common to all of us. That is the question of publicity. Why can't we get the newspapers of the United States to take an active hand in publishing pictures on safety? If the pictures carry the message, why can't our newspapers give one picture a day on the question of operating automobiles?

CHAIRMAN HARMAN: That is a very good idea, getting it into the newspapers. Our newspapers are very free to give printed articles, but they are not much on giving illustrations of any safety work.

The next committee is our Program Committee.

J. T. SMITH (Yellow Cab Co., Philadelphia): I have no report except that program outlined as announced in the booklet.

CHAIRMAN HARMAN: We have now a Round Table discussion on "Safety Devices and Their Maintenance." I want you to feel perfectly free to talk now.

F. E. SHEARER (Standard Auto Accident Co., Detroit, Mich.): I would like to have some gentleman's opinion as to whether he thinks a public bus carrying 30 passengers, for example, should be equipped with a speedometer?

The reason I ask is that in New York I ran across a large bus line, 100 buses. The speedometers in these buses were either not operating or had been taken off. In taking that matter up with the president of that company, he said, "We don't want our passengers to become nervous. If we have old ladies riding, we don't want to make them nervous when they see that speedometer picking up."

"The speed limit is 30 miles and the driver is responsible for anything that happens over that. The maximum speed on an open road is

supposed to be 36. It actually is 45. To my experience, there is no actual sense of speed on an open road at 45 miles an hour."

He suggested that speedometers be placed on the steering post where nobody but the driver could see them. The objection to that was the driver will always paint his side of the story to make it appear as favorable as possible for himself.

I would like to have someone else's opinion as to whether there should be a speedometer on a bus.

J. E. DOMIS (General Necessities Corp., Detroit): I think there should be a speedometer. My wife was on one of those buses one day and was very excited and nervous when she got home, telling how fast this bus drove. I think the people who ride have a right to know whether that bus is going 90 miles an hour or 15, as they are supposed to be. I think it is a good chance for anybody riding on that bus to observe from a safety angle and report that driver.

Keeping Drivers Within the Speed Ordinances

MR. LYNN: Down in Kansas City our transportation department takes this attitude on speedometers, that unless we can give a man a bus with a speedometer, we can not hold a man responsible for observing the traffic regulations. If he exceeds the speed laws or any of the regulations, the company pays his fine, but he gets a letter in that case. If the speedometer is working and he gets into any trouble, that is entirely up to the operator.

Not only are we trying to keep men within the speed laws by means of speedometers, but we set the governors on the coaches so they can not exceed the speed laws, and they are tested by tachometers once every 30 days, actually tested on the road by the transportation department. So we have three angles from which we are trying to watch the operation.

We have one express line that is supposed to give high-speed service inside of the city limits. If a man has a limited schedule, we insist on his being there on time, and the tendency is for him to get there, and that is the reason it is necessary to take all these precautions. The schedule is 25 miles an hour and he has to run 25. Naturally the tendency is for him to go over speed.

From the mechanical standpoint, I can't see but what every businessman would be vitally interested in giving the man not only a speedometer which is working, but also a governor, because the expense goes up about as the speed. I think it is a good chance to save a lot of money.

MR. MINEUR: We have about 40 men in our garage. We don't have speedometers on all our trucks, but we do have them governed down from 40 to 35 miles an hour, particularly on large Pierce Arrow trucks. We find that any speed above that, when they are carrying a load of ice and ice cream, which brings the gross weight up to about 40,000 pounds, is detrimental to the operation of the truck. It runs to ruin in no time. We have them checked by inspectors that do nothing else

but inspect the vitals of the truck at the end of each day, and no truck moves the following day on which they find anything wrong.

F. B. HENNETTA (Yellow Cab Co., Roanoke, Va.): I want to do away with all speed laws and run under control. Now the railroads all over the country run on that rule—under control. You know and everybody knows that a bus running 60 miles an hour sometimes is perfectly safe and under control. Another time it may be running six miles an hour and it is dangerous. If they make the rule 10 miles an hour and a man is running six and kills somebody, whose fault is it?

If we find anybody not running under control, punish them severely. Run under control! Right in our town now our men have a rule to run under control. Never mind city limits. There are four different speed laws on Bond Street, and nobody thoroughly understands them. The trucks are allowed to run 10 miles, taxis 15. One car is allowed to run six miles around a corner, another eight, and there isn't any sense to it at all. Run under control and don't mind the speedometer.

FRANCIS MCGUIRE (Eastern Dairies, Inc., Springfield, Mass.): We had considerable trouble with the buses on speedometers. It seems the average person who rides in those buses takes great delight in finding something they don't like, generally speed.

Quite a large bus operator has a speed limit. The fastest rate of speed is 30 miles an hour. If there are two infringements, they discharge the driver.

Keep the Vehicle Always Under Control

The average bus companies realize they must abide by most laws. They realize it is their bread and butter and do not do anything objectionable, so as to bring criticism on the buses.

I think a man would be safe at 35 or 40 miles an hour with a bus load of passengers if he only uses the speed where he knows it is allowable and safe. But when we talk about six and 10 miles an hour, it is out of the question.

I think bus operators work out their own salvation. You see them on the road pull over when they hear a horn. Their speed is reasonable. I think they are very near perfection.

CHAIRMAN HARMAN: I have thought of your suggestion to run under control. I have railroaded for a good many years myself, and will have to confess that running on a railway with a clear right of way, or at least your right of way handed to you, is much different from an automobile down a state or national highway where there is no speed limit; and I think the thought of control is leaving the matter entirely too much to the man.

If your man knows what speed is, then you might leave it to control, but I will venture to say there won't be two men in 10, if you cover the speedometer and put them out on a clear five-mile strip, who can tell how fast they are driving.

I don't think the question has ever been asked me by a passenger as to why we didn't have a speedometer.

I can recall several instances in my own case where I have had a splendid driver but with a lot of speed. One was a good business-getter, bright, energetic, enthusiastic in his work, but every day I would get a report that he was exceeding the speed limit. So I took him in my own car. It was summer time and I took him out on the boulevard.

I tried him three times in 10 miles and at no time did he guess how fast I was going within five miles. It showed he did not possess the faculty of judging speed. Many men would judge the speed within a mile or two per hour, but there are some men who can't. Eventually we took it out of him. He is with me today and has made a splendid driver. I am simply giving that as my own experience.

Speedometers Should Be Placed on Every Bus

MEMBER (Aetna Life Insurance Co., Hartford, Conn.): It might be in order to leave speedometers off the taxicabs. I think it is a grave mistake to consider leaving them off the bus, and I would seriously question the insurance of any fleet of buses where I found the owner had left off the speedometer or put it out of operation, simply because he was afraid some of the older passengers might become frightened. I should think, looking at it from a psychological standpoint, he would be concerned as to what the public would think, because we all have to cater to the public, and if the public is convinced you are operating a safe line, they will patronize it.

I happen to know something about the bus line running between Hartford and Springfield, and I know that they are making a very serious effort to break up any speeding by their drivers. I have talked with their officials and find that it is to their interest as far as the public is concerned to get the public to patronize that line, and they know the public won't patronize it if they feel the drivers are going to exceed the speed limits at all.

So I should say, regardless of whether speedometers or other safety devices are used, owners of automobile fleets should be interested in doing such things as will incur the good will of the public.

MR. LYNCH: I wonder if this meeting would be interested in knowing some of the safety features incorporated in our buses in Kansas City, which we have to have in order to operate double-deck buses with one man. The dead-man steering wheel stops the bus in case the man lets go of the steering wheel, and the doors are interlocked with the brakes and a few things of that kind.

CHAIRMAN HABMAN: It is all safety device, whether you consider speed or the man getting hurt. I would be glad to have you give them your experience.

MR. LYNCH: The problem of course was to make money with buses, and we figured we couldn't do it with two men. The next problem was to make a safe, double-deck bus carrying 63 people, only operated by one man.

Naturally on the hills of Kansas City the first thing was air brakes.

The next thing we decided to do was circulate the passengers, bring them in at the front door and let them out at the rear door, with one operator in charge. We made the doors automatically controlled by means of door engines. With only one man on the bus, of course we never wanted the doors open except when the bus was stopped, so we interlocked the brakes with the doors.

The man opens the front door by taking his foot off the heel rest. At the accelerator or pedal is an ordinary cup. He sets his heel in that and that rests on a valve stem of an air valve. When he takes his foot off, that cup raises up about three-quarters of an inch and permits the air to go in and open the front door. The air that comes in through this heel rest is only permitted to enter when the brakes are applied. When air is in the brake chambers, it is then relayed in the heel rest.

Any time a man is coasting down a hill, he can take his foot off the accelerator and the door will not open, but when he comes to the curb and makes his stop the next thing is to turn to greet his passengers. As he turns about, the door opens as he looks toward it. It looks rather uncanny as you sit there and watch. As he turns back around to start, he naturally reaches for the accelerator pedal with his right foot, so when his foot hits this heel rest, the door closes.

Control of the Bus Doors is Always Insured

There is no danger of anybody jumping on or off at that door except when the bus is stopped. The door is closed before the bus is moved.

For example, the rear door is handled by means of a treadle on the floor in front of the door, just the same contrivance, only instead of a heel rest, a big plate on the floor. He uses this in letting the passengers out. As soon as they are off, the doors close automatically. The driver doesn't have to pay any attention to the people. His attention is entirely with collecting fares from the front.

The door closes when the brakes are released irrespective of the passengers, so it is impossible for a passenger to alight from the coach at the rear except when the coach is standing still. There is no danger of getting hurt that way.

Now one other feature that is incorporated is the dead-man's wheel. Some of you electric operators know a dead-man's control. It is the same on the steering wheel. The steering wheel is composed of two portions. A man holds it with either hand. Whenever he lets go of the steering wheel with both hands, it drops down three-eighths of an inch and strikes an air valve, which drives the air into the brake chambers and stops the bus. You can be driving 30 miles an hour and get up out of your seat, and the bus will stop like that. You can fall dead, or be drunk and go to sleep, and the bus will absolutely stop. You might be in the center of the street, but there is no danger from a man going to sleep.

There is another thing we had to take into account. The doors are automatically closed. Suppose, for example, there was an accident which injured the operator. It had to be arranged so that the pas-

sengers could free themselves. So when anything happens that causes a man to drop his steering wheel when the brakes are not set, the air that goes into the brake chambers also goes into the door on the opposite side and equalizes the doors so the passengers can walk up and pull the doors open and get out to safety.

In order that one man might have control of the entire coach, it was necessary for him to know what was going on in the upper deck, so after some four or five months we finally arranged a periscope which is right up in the ceiling of the coach, and a man just glances up there and gets the entire picture of the upper deck. After he has the picture, it doesn't do him any good unless he can say something, so we have a loudspeaker at the side. If he sees somebody on the upper deck standing up while going under a viaduct, he says, "Sit down, Rube," or something of that kind.

This seems like a vision, a dream, but when I tell you that we have been operating there for a year and are still operating you will know that it is possible.

Discussion Regarding the Use of Bumpers

CHAIRMAN HARMAN: I appreciate that talk very much. I am sorry we didn't hand this subject to you to talk about. He has given us some very good ideas. He happens to hail from my town and I know they are operating 90 buses and while they are new, they have been very successfully operated as far as accidents or public hazard are concerned. They have been very successful, and no doubt it is due to these many devices.

J. T. SMITH (Yellow Cab Co., Philadelphia): What about bumpers and headlights?

CHAIRMAN HARMAN: Mr. Hilmes, have you got your fleet fully equipped with bumpers?

MR. HILMES: No.

CHAIRMAN HARMAN: Can any fleet-owners give us any ideas on that?

I can say this for a cab operator, we have them on all our taxicabs. I only put them all on since the first of April, and it has stopped the mashed fender. I can't say that it has stopped any particular accidents, because I don't know that it has.

MR. SMITH: How about the severe injuries and knock-downs?

CHAIRMAN HARMAN: We have had very little of that now or before. I can't say any measured amount of the success could be contributed to the bumpers, but with us from the financial point, the fender maintenance was excessive, because they were always nicking the fender against some other car. The bumper has practically eliminated that.

MR. SMITH: We have 276 out of 1,100 cabs equipped with bumpers, but our figures do not separate the bumper-equipped cars in any way. In the beginning, before we had bumpers at all, we were of the opinion that in case of knock-downs the injury with a bumper would be a great deal greater than without the bumper, the way it would strike a person and throw him.

GLENN ROYER (Columbia Casualty Co., New York City): With a bumper on a vehicle, it would appear you are going to fracture or break when you strike, but in investigation of about four knock-downs where the headlight or fender struck a person, they were much more severely injured than by bumper knock-downs. You would be surprised to know what a fender can do to a human body. A headlight will make a very bad accident, but your bumper has considerably more to give than you would think. Furthermore, it presents a plain surface and you don't get the mangling.

I believe in modern traffic you want your bumpers on account of the radiator problem. A punctured radiator would pay for a good bumper.

MR. MINEUR: On all our cars we have rear bumpers. Rear bumpers on the trucks are bumpers enough.

Drivers Inclined to Depend Too Much on the Bumper

MR. HILMES: Seven years ago we had bumpers on all our cabs. We will recall at that time they weren't as up-to-date as now. We took them off for two reasons; because they were always getting broken, and after investigation we found that the driver depended too much on the bumpers, with the result he struck a lot of things, and people, which he didn't strike after we took them off.

However, we are very much in favor of the bumpers that are designed now. Only last Saturday night the bumper on one of those cabs saved not only the cab, but a lot of other things. The cab broke away and started to cross the viaduct, and hit the rail on the other side. If that bumper hadn't been there, it would have gone through the rail.

MR. WOOD: This isn't a commercial bumper at all. It is a piece of plate steel about four inches wide and pointed on two brackets, which fasten to the spring to the manifold. Of course that type of bumper would not have as much flexibility as a commercial type of bumper, but it serves the purpose as far as saving fenders and radiators is concerned.

CHAIRMAN HARMAN: Can anyone here give us any experience on governors, which are naturally a safety device, as speed control from the mechanical end of it?

MR. HEMMAN: Governors have been very peculiar and hard to get to function properly, but there is a governor on the market now that is a vacuum type and will give power, but I have found on all light-weight vehicles where power is not a necessity you can make a governor for 10 or 12 cents by cutting a gasket out of bronze or copper and perforating it with 16 holes to give the desired volume.

I have used that eight or 10 years on trucks and it has served its purpose well. I don't know any reason why it couldn't be successful in taxicabs or buses, and that will only control your engine on your direct drive. It will give you full velocity on your lower gears or hill climbs.

CHAIRMAN HARMAN: Do you use governors in your fleet in general?

MR. HEMMAN: Everything is being equipped with governors practically all the way through. They are also sealed with our own seal and monogram and traveling mechanics inspect those every 30 days.

GLENN ROYER: (Columbia Casualty Co., New York): I had an experience with a driver of a heavy Mack. He had a through run from Philadelphia to New York City. I talked speed with him for a while and he finally admitted the truck was governed but he was driving at night and early morning and made remarkable time.

I doubt very much whether you can answer your whole problem until a governor is devised that actuates from car speed instead of motor speed. I think that is where you come out.

On the proposition of speed, if we can go back for a moment, railroad companies do not govern their equipment, at the present time, although they have made efforts. Some have put speedometers on their engines so they can give their men a top speed, but our friend from Virginia here opens up a very interesting subject when he says, "Drive under control."

Be Able to Stop Safely if You Have to Suddenly

Last night I made a statement to some drivers in these words, "Drive them so you can stop them if you have to."

Your speedometer certainly has a place on deluxe buses, running on modern, concrete highways between cities where top speeds of great velocity are possible, if a man has no speed judgment; but to give a man an arbitrary speed limit means nothing when you analyze accidents, because a car might be perfectly safe at 40 miles an hour on a straight pavement when dry, and immediately dangerous when the pavement is coated with ice.

In trying to get drivers to come down and use that judgment, I have found this effective. Tell them their speed is directly contingent upon the effect of the brakes and their brakes are not effective unless they can friction between the pavement and tires. Therefore, regardless of the inspection the garage gives you, in the first block you are traveling apply your brakes and see what you can do. When it begins to rain or snow, do the same thing occasionally.

How many of us have had this experience? We drive for maybe a hundred miles on straight, smooth roads, making good time. Rain or snow comes and we don't use our brakes. Then an emergency occurs. We are driving at top speed, we don't know what the pavement is, and slam into it.

If you test your brakes occasionally during the day, I think you will get that control judgment that you want, and the thing more or less solves itself without a speedometer.

CHAIRMAN HARMAN: The next thing on the program is a paper by Mr. F. W. Parks, C. H. Cowdrey Machine Works, Fitchburg, Mass.

BRAKE INSPECTION AND MAINTENANCE

**F. W. Parks, Sales Manager, Cowdrey Brake Tester Organization,
Fitchburg, Mass.**

It is rather difficult to present a paper of this sort without giving the impression that it is concealed advertising. Because of certain experimental work conducted at the North Broad Street Garage of the Yellow Cab Company of Philadelphia, your chairman invited me to discuss this subject here today.

Our organization has conducted experimental and research work for several years. We have had occasion to test the brake performance of several thousand cars. It is from this background that these observations are drawn.

"There has never been a science in any subject until a measuring means has been developed." Brake inspection and maintenance has never been on a scientific basis comparable to other parts of the motor vehicle, such as the power plant, or the lighting and starting mechanism. There is a very good reason for this. There are many scientific units of value in common public use in connection with the motor vehicle. The motoring public has adopted engineering terms, such as miles per hour, horse power, candle power, watts, volts, amperes, etc. But there has never been any such accepted unit term for describing brake performance.

Before the motoring public can adopt any term or name to describe brake performance, automotive engineering must first determine performance standards, and give a name to the unit that describes that performance. To be sure, deceleration is a term used among engineers but it is apparently too deep for general use.

As a result of this situation, brake performance has from necessity been described in terms of personal impressions, such as bad, fair, good, etc. But these are merely general terms and mean nothing definite whatever. You are all familiar with the result of this situation in practice, a driver reports to the shop that his brakes need attention, based merely on his personal impression. So a mechanic repairs and readjusts the brakes until they pass his own personal impressions of efficiency. And you all have seen many examples of the conflict of these two personal impressions. How chaotic this state of affairs would be if it existed completely throughout our every-day life. Suppose the butcher had no scales on which to weigh meat; or the druggist no scales on which to compound prescriptions!

The motor vehicle is such a comparatively new development of civilization that most engineering attention has been directed toward making it run—cheaper, quieter, faster, etc. You will find many instruments on the vehicle pertaining to running it, but not one instrument of any sort to indicate whether it will stop.

Our accumulated data enable us to submit to the automotive industry the accompanying "Table for Grading Motor Vehicle Brake Performance."

We are adhering to the practice already established by the Bureau of Standards and adopted by several states, that all brake performance be interpreted as from an initial speed of 20 miles per hour. We also concur with the resolution of the Eastern Conference of Motor Vehicle Registrars, that all brake tests shall be made by using an instrument especially designed for the purpose, rather than the "painted line across the road" method, which is admitted to be grossly inaccurate.

The Mathematics of Brakes

For the first time in the history of the industry, so far as we know, we have established mathematically the theoretical relationship which exists between motor vehicle weight, retarding force, and deceleration, and have actually measured the retarding force. Our equipment measures it in pounds of road pull, and at each wheel separately. The sum of the readings obtained at each braked wheel is the "Total Retarding Force" for the corresponding pedal pressure.

We have prepared charts by means of which stopping distance may be predicted. These charts are remarkably accurate when used in connection with our machine.

Greater Safety with Less Expense

Let us assume that we are dealing with the brake operation and maintenance of a fleet of 100 two-wheel brake taxicabs. For city traffic, perfection can not always be maintained, so let us set as our bogey a grade mark of C-2.

That is to say, if every cab in our fleet can stop in from 35 to 40 feet from a speed of 20 miles per hour without appreciable slewing on a clean, level, dry, smooth, cement roadway, our braking systems are in good operating condition for two wheel brake cars. If we can keep within this bogey, our accident record should be materially reduced. Also if we can do this, we will automatically and unconsciously accomplish other highly desirable results.

But how are we to go about it? First, so long as it is the driver who takes the responsibility and who does the complaining to the repair shop, let us settle with him. Suppose we locate a brake testing machine near the garage door, so that each morning as he drives out he may stop for a few seconds, apply his brakes, and take a reading of both wheels without leaving his seat.

Let's not go into the science of it all with him, but just assure him that if each wheel on his cab reads within a certain green space on the dials of the brake tester corresponding to from 750 to 850 lbs. of road pull, his cab is O. K. for the day. His brakes are then equalized, and at a point which will give him as good brake performance as he has a right to expect from a two wheel brake cab. That is, he will be able to stop

GRADING TABLE
for
MOTOR VEHICLE BRAKE PERFORMANCE
From an Initial Speed of 20 Miles Per Hour

Stopping Distance	Comment	Grade
Between 15 ft. and 16 ft.	Commercially perfect for 4 wheel brakes	A-4
Between 16 ft. and 18 ft.	Excellent for 4 wheel brakes	B-4
Between 18 ft. and 20 ft.	Good for 4 wheel brakes	C-4
Between 20 ft. and 25 ft.	Fair for 4 wheel brakes	D-4
Between 25 ft. and 30 ft.	Poor for 4 wheel brakes	E-4
Over 30 ft.	It's no longer a 4 wheel brake car	F-4
Between 30 ft. and 32 ft.	Commercially perfect for 2 wheel brakes	A-2
Between 32 ft. and 35 ft.	Excellent for 2 wheel brakes	B-2
Between 35 ft. and 40 ft.	Good for 2 wheel brakes	C-2
Between 40 ft. and 45 ft.	Fair for 2 wheel brakes	D-2
Between 45 ft. and 50 ft.	Poor. Brakes need attention	E-2
Over 50 ft.	Vehicle unsafe on highways	F-2

in 35 feet from 20 miles per hour on a clean, dry, level, smooth, cement roadway with a vehicle weighing about 4,200 pounds.

But now, having given the driver a yardstick by which to approve or condemn his brakes, we must give the shop the same equipment. We have removed the guesswork from the driver's seat by setting a standard. Therefore, the brake mechanic must have the same standard. That is the only way we can prevent unnecessary disagreements regarding brake performance, between the drivers and the mechanics.

Here's where our troubles are likely to begin, and they may obtain for a few weeks. There may be a few traditions to break down and bad habits to cure. Of course, it's better to have one man in charge of all brake work, especially if he can be made to see that his is the most important end of the cab. He has been led to believe, through shop tradition, that the rear end is the greasy, dirty job, while a transfer to the front end has meant social advancement to him. Unfortunately, too, in many shops, advancement to the front end has carried with it a raise in pay.

Where there has been no single mechanic on brakes, and all hands have had a try at it, one may find some wonderful attempts at improvements in original hook-up design. With eight mechanics in one garage, left to their own devices, it takes but a few months for them to make startling brake changes, particularly in lever positions, for the entire fleet.

Once get this condition of mal-adjustment into a fleet and it ceases to be a joke. For the cost of tires, brake lining, and shop labor can be increased very decidedly by such mal-practice. But do not blame the men; blame the management. Put one man in charge of brake work. You have one man responsible for the stock room, why not for brakes? Establish a standard practice, and hold your man to that practice; make

changes in that practice if and as you see fit, but do not permit him to do so unknown to you.

For the first month this program may cost you more than formerly. The drivers will have to have a new toy and may be persistent in their criticism of the new method. The brake gang may run into a snarl on many cabs, and may spend considerable time correcting difficulties that required many months to accumulate, and previously went unsuspected. The brake testing machine helps them to locate eccentric drums; bell-mouthed drums; levers out of parallel on cross rods, and out of position at drums; worn pins, sleeves, and bushings; warped bands; worn cams; linings loose on rivets and so forth. The first few weeks may prove to be quite disheartening.

But once the fleet has been through the correcting process, easier sailing is ahead. Each job now takes much less time. The brake foreman knows in just what position he will find his leverages, because no one has attempted to improve upon them behind his back. He can now get along with fewer men. And in the end this is what should develop:

Results of the Brake Testing System

1. Accident record shows a drop.
2. Money outlay in the settlement of accident cases decreases accordingly.
3. Money outlay for repairing rolling stock due to accident decreases.
4. Tires last longer, due to better brake equalization.
5. Linings last longer because of better brake equalization.
6. Tie up of rolling stock for repairs due to accidents and brake lining jobs shows a decrease.
7. Fewer arguments regarding brake performance between drivers and shop.
8. General body repairs due to chassis strains caused by unequalized brakes reduced.
9. This equipment and system of standardized brake inspection and maintenance practice might have quite an effect in court in winning accident cases, as proof of exceptional care.

Many taxicabs are equipped with disc wheels, which many garages insist shall be removed for each adjustment of the brakes. When brakes are adjusted with the aid of our machine, we find that this waste of labor can be eliminated except in a few of the worst cases.

In advocating a more scientific and standardized practice for brake adjustment and maintenance, we are not recommending an increase in expense. Returning to our example of the 100 cab garage, the cost of operation would be about as follows:

First time through the fleet, three men, one hour per cab to correct mistakes.

Later, one man to adjust and maintain brakes in good condition;

average time, one-half hour per cab including relining. This would pass each cab over his machine once each week.

For small fleets the drivers' daily inspection machine may be eliminated and the dual service performed by one machine.

Savings from the Financial Standpoint

From a financial standpoint, it hardly seems necessary to defend standardized practice in our case of the 100 cab garage. The cost of equipment should be saved several times over each year.

Take the tire bill as just one example. For 100 taxicabs the yearly tire bill is somewhere near \$24,000, I am informed. Better equalized brakes will undoubtedly increase the life of tires. Better brake inspection will undoubtedly eradicate those egg-shaped drums which lock in the same spot at each brake application, thus wearing out tires. The amount of tire bill reduction would vary widely in different garages, dependent upon a number of local conditions. But it is only necessary to reduce the tire bill six per cent to pay for the necessary brake testing machine equipment in one year.

Take another example for illustration of the financial soundness of the investment; the stopping performance of the fleet. If we test scientifically the stopping ability of 100 two wheel brake vehicles, we find that only a few can stop within 35 feet from a speed of 20 miles per hour. The balance of the fleet performs all the way down the scale even to 100 feet stopping distance. In almost any fleet tested, the number of vehicles which should be ruled off the highway is surprisingly large.

Now, obviously, this inability to stop must affect accident records. If one vehicle can stop in 35 feet and another requires 95 feet or even 55 feet, then the probability of accidents will be reduced if all are brought within the 35 foot performance. Some fleet operators pay out one and one-half per cent of their total income in settlement of accident cases, which is an appreciable sum. Reducing this to one per cent might pay for the machine equipment in one year. At the same time, the reduction in number of accidents affects cost of repair and cost of rolling-stock tie-up.

It seems almost fundamental in any mechanical operation that the labor cost of doing work right the first time, and knowing that it is right when it is done, must be cheaper than hit-or-miss methods. Most fleet owners are paying more for a poor result than this recommended method of brake adjustment and maintenance would cost them. The payment is in added costs elsewhere, and may slip by unnoticed until carefully investigated.

Better work at less cost is the slogan which has made the automotive industry of the United States what it is today. This slogan may be well applied to the important problem of brake adjustment and maintenance.

CHAIRMAN HARMAN: I want to thank you for your very interesting report, and would like to hear from anyone who has any questions to

ask on this brake adjustment, or any comments to make in connection with this report as rendered.

HARVEY D. WOOD (Yellow Cab Company, Chicago): I would like to ask Mr. Parks what he has to say in connection with wet brake-lining. Of course I understand the machine doesn't keep your brake drums dry, but assuming that your car does go out of the garage with the brakes properly adjusted, the car gets out and gets into the wet, and naturally it is commonly known that you haven't then got the braking power you had when dry. How can you deviate from that standard scale you have laid out?

MR. PARKS: You can't. That is to say, any such routine doesn't change outside conditions a bit. The brake-testing machine is merely a yardstick.

Now in setting up a standard you must first define the conditions under which that standard is to operate and must assume a clean, dry, level, smooth, cement road. If that road becomes dirty, oily, wet, and is up-hill or down, you have altered the conditions. So far as wet brake-lining is concerned, you have again altered the condition, because it is a well-known fact that different brake-linings have different characteristics when wet.

So all we may do is to assume certain definite conditions, set a standard, assuming definite conditions. We have still got the weather conditions outside, which I was hoping someone would mention in this previous discussion.

Ability to Stop Within the Clear Coast Ahead

Dr. H. C. Dickinson, of the Bureau of Standards, has made a suggestion. I can't give the wording of his proposed rule exactly. It was to this effect: the driver of a motor vehicle should have the privilege of driving just as fast as he can drive so long as he is able to stop within the clear coast ahead. The clear coast ahead was defined as that distance in the direction the vehicle was going which had no obstacle that did not have a legal right to be there.

That answers the question so far as this wet brake-lining or wet street surface is concerned. If the driver can't stop in the clear coast ahead, he is not driving cautiously.

The machine doesn't do anything that could not have been done before perhaps. It merely offers a mechanic something he didn't have before to measure the result of his work.

MR. HENRETTA: I think that gentleman made a very clear and nice advertisement of my argument—under control. It would be too bad to let a subject like that go without clinching it. I believe it ought to be advocated by this body, some uniform system of compelling people not only to carry a driver's permit for themselves, but carry a brake permit for their car. In other words, to have their cars tested either by a municipal body or someone from each place who wants to enter into it to that extent and issue those permits.

MR. PARKS: I might explain that in Massachusetts there is a regula-

tion, a state law, and the registrar may designate brake service stations and the signature of those brake service stations is acceptable to the registrar.

A vehicle may be condemned by the inspector. They don't necessarily have to go to that inspector. Another inspector will do, provided the operator can bring in a certificate from one of them.

MR. ROYER: I am not going to endeavor to quote from memory, but someone said, a motor vehicle should not be driven at a speed in excess to that from which it may be stopped within its assured clear course ahead.

Now we have a battle with this brake proposition which is impossible for us, because our men were forced to go around with portable instruments.

When the boys get a bad reading there may be one of a number of causes and they try to analyze that thing by going over the system. Presently you will find one wheel will drag and the other revolve with the stream pressure. That requires an adjustment, of course.

Brake Adjustment With and Without Passengers

The way they endeavored to get at that with light and medium weight vehicles was to try to get a wheel drag, and you can see which wheel requires attention. That is immediately dangerous. If one of the wheels happens to be in powdered grit, sand or pebbles, any dirt like that alters it, and you may not get a positive knowledge of what you can draw.

For the benefit of those who want to get into that end of it, be sure you try your drag test on a perfectly smooth, clean surface. You can sweep a section of the garage and get it.

There is one question I would like to ask. You state you would inspect these brakes when you got out to the garage. When you get that bus full of passengers, what effect would that have on the brake?

MR. PARKS: You have raised a very interesting question. You remember the example taken was that of taxicabs, the relationship between the rate of the vehicle. In that case the ratio is so small it is practically ignorable.

That is not true, however, in the case of buses. There is one case that I can tell you of. At the 15th and Cumberland Street Garage of the P. R. T. in Philadelphia we had to devise means for putting an imitation load in order to adjust the brakes under loaded conditions, and it is unfortunate, but true, that at least certain types of braking mechanisms have been so designed that the braking effect is entirely different when empty than when loaded, particularly when the live load bears such a heavy proportionate ratio to the proportionment of the vehicle, as in the bus.

In the case of a cab weighing perhaps 4,450 pounds you have about 600 pounds of load, so that small increase may be ignored.

MR. ROYER: I have tested this one particular instrument that we have and I have tried with several drivers. I have a big, heavy driver,

and going over 20 miles on hour on a good, smooth pavement, he would try his brakes and he could stop that bus within about 32 feet. I get a little man under the same conditions and he will try these brakes and can't stop in 45 or 50 feet. It proves we have to get a minimum if we are testing these buses and get an average-sized man.

MR. PARKS: I might add that pushing the brake equalization effect on four-wheel brakes materially alters the amount of pedal pressure necessary in order to produce the maximum amount.

I have in mind one particular case from a very authoritative source, which I am not permitted to quote. There was a case of a small, four-wheel brake car with 180 pounds pedal pressure, and with the ordinary distribution of retarding force such as given by a good brake mechanic by the sliding on the floor method spoken of. That vehicle was stopped in 24 feet in the speed of 24 miles an hour. That is not particularly good for a four-wheel brake car.

The following day the same car and the same man, with the car driven only a mile and a half, had its brake readjusted and the retarding force properly distributed on the four wheels, and it was tested again. The stopping distance came down to 18 feet and the pedal pressure from 180 pounds to 160 pounds.

Bus Operation on the Hills of Kansas City

MR. LYNCH: The brake situation is one that is very close to my heart. I have a rather hard problem in the brakes on the buses in the hills of Kansas City. We have run some interesting tests and experiments. One test was 7,000 miles long and the temperature of the brake drums was read every six miles. We were after a lot of things besides brakes. We found without any apparent reason your brake equalization will shift from wheel to wheel. In other words, as the bus rides along you might start out with an equalized brake and in an hour's time in 15 miles the brake will be on the right-hand wheel. In 15 miles further it would be on the left-hand wheel, without any change in equalization so far as the mechanism goes, because they were air brakes with the same pressure between the lining and the brake drum. It was the matter of a little drop of oil or grit from the road, throwing the equalization off. The brake temperature would drop from 600 down to 300 and the other would go up in proportion.

The total amount of energy in those brakes was constant. We would run 15 miles an hour and stop.

I have come to the conclusion that this brake problem is something that we are all talking about, but doing nothing about. The first thing I did when I got into Detroit was to call my good friend at the Timken Axle Company about brakes. He said, "We know less today than we thought we knew five years ago."

It seems to me the big problem is brake lining. When you get a brake lining that is right, you will then be able to forget your brake problems and it looks like a brake lining is going to be something along

the line of a metal brake, something that is not affected by moisture, by oil, or by gravel or road dirt that flies up into your brake drum.

There are some very promising products on the market at the present time that look like they are going to solve the major portion of our problem. There are some linings that look like we can adjust our brakes and expect to forget them for 25 and 30 thousand miles without any more attention.

I am absolutely disgusted with the present brake linings. I don't think you can do anything at all toward equalization with those linings. In this chart that you gave for performance of four-wheel brakes, you had particular reference to the passenger car, I presume, Mr. Parks?

MR. PARKS: Yes.

Two-wheel Brakes vs. the Four-Wheel Brake

MR. LYNCH: What bus carrying as much as 75 per cent of the load on the rear axle, with two-wheel brakes, will give you almost the same performance as four-wheel brakes? The sliding of the tire is the limit with which you can go. Suppose you have four tires in the rear. It is going to change it materially when you go to talk about buses and trucks in performance.

MR. PARKS: It has been our experience in such buses as we have had opportunity to test so far that it doesn't vary materially from that statement.

You made a statement a moment ago that due to the increased weight on the rear axles and increased surface content that you could get nearly as good performance in two-wheel brakes as four. Personally, we haven't seen that happen. Our experience is rather limited, however, but I am inclined to believe that I would like to see it done, if it is going to be done.

MR. LYNCH: That gets into the next paper anyhow.

One other question is the question of load. If you can obtain a brake lining where your connection or friction is constant with air brakes, you can take care of your load without any consideration from the driver at all. You can use a variable load brake which will give you the same retardation irrespective of the load.

MR. HENRETTA: The question came up about a 300 pound man with his foot on the pedal. Your brake efficiency is retarded. Would it be feasible on that pedal to put a resistance coil spring, so you could only get the maximum pressure required on the pedal?

MR. PARKS: I don't know, because I never heard the question raised before.

MR. HENRETTA: It could be arranged. That would be on the principle of the loaded and empty brakes. The same principle could be applied to the pedal, I believe, with maximum resistance coil on the pedal.

MR. PARKS: The previous speaker raised a point. I thought you gentlemen might be interested in. It is a bit startling, but you take an inclined plane of glass. (Some of you may have heard this before.)

You take a miniature automobile of the four-wheel brake design. Don't have any pedals, but just adjust each wheel of the miniature automobile, incline your sheet of glass at an angle greater than an angle of repose, so the miniature automobile will slide down.

It is an interesting thing that it will slide straight with any two wheels locked excepting the two rears. You may lock the two front wheels or the two wheels on either side, or diagonally crosswise, and the car will slide straight down this piece of glass. But if you lock the two rears, it will turn around.

It so happens that problem was submitted to the Bureau of Standards some months ago. It is now public property. I understand they are now doing some experimental work to find out why that rather curious situation exists, but it would seem to imply that the two rear wheels are the least two wheels that need brakes.

As far as I personally am concerned, if I were having a car built for myself and was only going to have two brakes on it, I would prefer they would be on the front wheels. If I were building a four-wheel brake car, instead of having the brake effort adjusted on this small ratio commonly mentioned in the advertising matter of automobile manufacturers, I would prefer to have 60 per cent in front and 40 in the rear.

We believe this has been more neglected than any other part of the automobile, and are inclined to believe that the next five years will see a great deal of progress in this connection. I heard one man say that the ordinary external brake was a mere modification of the type of brake in use 2,000 years before Christ by the Egyptians.

The Pavement a Big Factor in Brake Control

MR. HEMMAN: We have various kinds of brakes for four wheels. You have your tires to contend with. A taxicab driver has a puncture. He may throw on a new tread, which throws his brakes out of equalization.

Have you ever taken into consideration your pavements? I am not familiar throughout the states, but in Chicago we have creosote pavements. I don't care what tires or brakes you have, you can't stop when it is wet. Let's stop that kind of pavement.

The next thing is asphalt. In Chicago we have granite-surface pavement in all our parks, and I don't care what brakes you give me, I will stop, unless the pavement is coated with ice. I will go through all our boulevards and stop and not skid.

Probably 25 years ago when we had dirt roads and macadam roads, sprinkling wagons were all right. They settled the dust. But now with sanitary pavement, I don't see any use of the sprinkling wagon. But they come around in Chicago and flush these pavements, and the taxicab driver puts on his brakes and skids across the pavement.

In the asphalt district, Mr. Sprinkling Man goes along and sprinkles. One of the members of the family is out with a light-colored dress, and he comes along and throws water all over her clothing, and you get a cleaner's bill.

I think that is good food for thought, and if we get behind it we can eliminate that, because I believe in a good city they flush their streets at night.

CHAIRMAN HARMAN: I think it would be commendable at one of our meetings to recommend that to the National Safety Council as a consensus of opinion, and that fleet-owners and taxicab men and bus owners exert their efforts to do so.

MR. MINEUR: I think it is generally agreed that the braking equipment is a very important factor. The man who operates the brake is by far the most important factor.

In New York City, if we get in touch with them, we can find out their system of checking up on brake workouts. They go out every once in a while on the highways and stop trucks and automobiles indiscriminately and ask to test their brakes. That is a very unscientific way to get at it, but some of these fellows, to my knowledge, had defective brakes and have been advised to report to one of the state agencies for examination later on to show that those brakes have been adjusted.

A Semi-annual Brake Test in Kansas City

CHAIRMAN HARMAN: In Kansas City we have a semi-annual brake test brought about through the traffic officials, and the local Safety Council has always rendered 70 per cent of the service. Where there is one policeman, there will be five members of our Safety Council who will go down. It is a voluntary proposition. The policeman stops the man and says, "We would like to have your brakes tested."

In certain cities at certain hours of the day, they will make these tests. The only thing you have is a ticket to put on the windshield that shows you have had your brakes tested. If a man's brakes are very much out of adjustment, the officer recommends to the owner that he go some place and have his brakes adjusted, as he may get into trouble.

MR. HENBETTA: We have a test system in Roanoke of that kind, and are handed a certificate, but after hearing this gentleman discuss it scientifically, I found we don't know anything about what is done.

S. J. STEINMANN (Indemnity Insurance Company, Philadelphia): In connection with brake troubles, I was wondering whether or not there is anything in the material used in construction of the brake drum itself, that is, hard metal or soft metal? I have heard some discussion on it at a prior time, and am wondering if anybody here knows anything about it.

B. D. DEWESE (Safe-T-Cab Corporation, Cleveland, Ohio): On that particular subject I think the brake lining fellows are now making better lining. Therefore, the brake drum fellows are doing a lot of experimenting.

We are just now getting so-called steel drums and low-carbon steel drums and having them decreased. What the results are, they claim they don't know. They are trying to keep brake drums from wearing

out too fast and trying to make them expand evenly under heat. That is one of our brake troubles.

CHAIRMAN HARMAN: Has there been a test made along the lines suggested by Mr. Lynch in his bus operation, for the pleasure or small car? I don't know what you call it, but it is something like the metallic substance they use in the brake lining on a railroad train or a carburetor.

MR. DEWEESE: The American Car & Foundry, I understand, has been conducting those tests for years and I have seen some interesting experiments in metal brakes on automobiles, with reasonable success.

They have failed to overcome that one great thing we all know about, in other words, metal contact. They have had a little difficulty in applying those in such a way they don't get shattered. Any who have had brakes shattered are pretty well scared.

CHAIRMAN HARMAN: What is the general consensus of the meeting on the gentleman's suggestion here about our offering a resolution to the National Safety Council on street-sprinkling in larger cities?

MR. WOOD: I so move, Mr. Chairman, that this committee pass a resolution to the National Safety Council to be incorporated in the minutes of this meeting to the effect that the resolution should be worded later, but to carry out Mr. Hemman's thought, that sprinkling of the streets during the daytime should be discontinued.

MR. ROYER: Don't we want to put some words in about the undesirable pavement surface?

CHAIRMAN HARMAN: I would be very glad to appoint a committee to write a resolution of that kind. I would like to make Mr. Hemman chairman of that committee, and Mr. Royer is on the same committee. I will also appoint Mr. Steinmann. These gentlemen will be a committee of three to present to the session tomorrow morning a resolution on sprinkling and pavement surface.

I have been delinquent in selecting our Nominating Committee. We will do that now. I will appoint the following:

Mr. L. D. Hemman, Armour & Co., Chicago.

Mr. J. E. Dobbs, General Necessities Corporation, Detroit.

Mr. F. B. Henretta, Yellow Cab Co., Roanoke, Va.

Mr. H. D. Wood, Yellow Cab Co., Chicago.

ADJOURNMENT

WEDNESDAY MORNING SESSION

October 27, 1926

The meeting convened at 9:45 o'clock in the Small Banquet Hall, Statler Hotel, Detroit, Michigan, Chairman Harman, presiding.

CHAIRMAN HARMAN: The first thing on the order of business is a report from our Nominating Committee of which Mr. Wood is chairman.

HARVEY D. WOOD (Yellow Cab Company, Chicago, Ill.): Mr. Chairman and Gentlemen of the Taxicab and Fleet-Owners' Section: The Nominating Committee submits for your consideration the following names as officers for the year 1927:

REPORT OF THE NOMINATING COMMITTEE

Chairman, J. T. Smith, assistant general manager, Yellow Cab Company, Philadelphia, Pa.

Vice-Chairman, J. Robert Clair, director of safety, Checker Taxi Company, Boston, Massachusetts.

Secretary, Joel E. Dobbs, safety engineer, General Necessities Corporation, Detroit, Michigan.

Poster Committee, Harvey D. Wood, safety director, Yellow Cab Company, Chicago, Illinois.

Statistical Committee, Russell Reel, statistician, Yellow Cab Company, Des Moines, Iowa.

Program Committee, Glenn Royer, Columbia Casualty Company, New York City.

The Executive Committee is as follows:

Dale Harman, general manager, Yellow Cab Company, Kansas City.

Lee Miles, president and general manager, Cab & Transfer Company, Louisville, Kentucky.

CHAIRMAN HARMAN: One section of the committee has been omitted here, as you may have noticed. That is the Engineering Committee. This committee will be as in the past appointed by the National Safety Council office.

It seems our committee has covered the situation very thoroughly, and if I can get a motion from the floor, we will elect these men in a body.

(The motion was made and seconded and carried.)

The next thing is to try to bring up the unfinished business of yesterday. I know Mr. De Weese is here, and would like to have him come forward and read his paper on "Advantages of Four-Wheel Brakes."

ADVANTAGES OF FOUR-WHEEL BRAKES

B. D. DeWeese, Safe-T-Cab Corporation, Cleveland, Ohio

I haven't prepared any formal paper because I believe that round table discussions are much better in bringing out the valuable points. Also I am very timid about discussing four-wheel brakes because one gentleman said here yesterday that the head man of the Timken Detroit Axle Company said he didn't know anything about it, and last year I talked to the vice-president, and he didn't know anything about it.

Therefore, I think if we start on the premise that the engineers are rather in the dark on the question of four-wheel brakes, we can pry out the points a great deal better than to assume any system of four-wheel brakes or two-wheel brakes is the final answer. I don't believe that is true. As far as this meeting is concerned, in fact the whole meeting of the Safety Council, the question we are interested in is, is this four-wheel brake device, regardless of its type, a safety device?

In other words, we want to know what a vehicle equipped with four-wheel brakes saves in the hands of the average man more than a vehicle equipped with two-wheel brakes. I think that is the big question we are interested in. If it is, regardless of some slight mechanical differences or some slight extra cost of maintenance or something of that nature, it should be adopted.

Now let's start from that point. Is it a safety device? You all heard the paper yesterday by Mr. Parks, who has unquestionably gone into the theory of braking a great deal more than I expect to touch on it, and he pretty conclusively held out that a four-wheel brake car will stop in one-third less distance than the rear-wheel brake car only. It is pretty well determined that a four-wheel brake car, unless you have that ability to lock the rear wheels, regardless of what else you do, will skid less than a rear-wheel brake car only. Those are two points that are also fairly well established.

Out of about 45 builders now (I am speaking of the pleasure car field more than the commercial car field) about 37 or 38 say four-wheel brakes. There are conspicuous examples that do not equip. We can mention them, because it is no secret. Some of them are Lincoln, Hudson and Dodge, probably about three of the largest users of rear-wheel brakes only. On the other side we have the vast General Motors organization, who are almost universal in their acceptance of the four-wheel brake principle. They don't use them on their lightest cars. They wouldn't say they wouldn't be a good thing to put on there. I think they would answer, "Well, we don't need them."

But Mr. Willys at Toledo doesn't even agree with that, and he is quite a figure in the industry. He says, "I just got out the Whippet and it has four-wheel brakes and should have."

That is the way the controversy has been going on for some time, but I think the general impression in the industry is that we are headed

directly for universal adoption of four-wheel brakes. I don't think there is any question about it; the public is going to take care of that.

Let's assume now that last year we built four million motor vehicles. There wasn't a large percentage of those equipped with four-wheel brakes. This was because the Ford, Chevrolet, and such vehicles in the light class naturally dominated the production. On the other hand, in the heavier cars there was a very notable percentage equipped with four-wheel brakes.

Let's leave that for a minute and go out on the street. First we have to look at this thing. If it is a safety device, we can argue about that one way or the other, then we have to jump over and take facts as they are on the street.

You all know, if you drive rear-wheel brake cars now, if you are going along behind some fellow who has advertised, "This car is equipped with four-wheel brakes," you have to lay off pretty well. That is equally true for the truck, bus, or taxicab. If you are on Michigan Avenue, Chicago, you are going to have to go 35 miles an hour or whatever they tell you to go. Over on Carnegie Avenue, Cleveland, we have them go 35 miles an hour at certain times of the day. If you go down there, you have to keep up with the procession or get off the street. Therefore, you fellows who are going to drive rear-wheel brake cars only are going to have to use more vigilance than the others.

The Question of the Law in the Case

I think that is the biggest factor we have to consider in commercial operation, that we have to run our vehicles over the same highways and same congestion as the pleasure vehicle. Therefore, the pleasure fellow is going to force us to do something we may not want to do.

Let's take for a minute the law of the case. Mr. Newcomb, of Cleveland, who is a very able lawyer along the lines of accident cases, having made a great study of them, prepared a thesis on this subject about two years ago for the Columbia Accident Company of Cleveland. It merely deals with the four-wheel brake as a safety device in the law from this angle: that the taxicab is a public vehicle and the bus is a public conveyance, therefore, under the law they become common carriers. The law of the land says a common carrier must have a brake on each wheel.

Mr. Newcomb says: "Let us assume that two years from now (that is today as this was written two years ago) we have an accident. We go out here and your taxicab is going along at the rate of speed allowed of 35 miles an hour, and is following, let us say, a Nash. Mr. Nash equips his car with four-wheel brakes, and due to some obstruction ahead, he has to stop quick and jam on the brakes, and you go into the back of his car."

You know the mental alertness of two people is not the same. There is no such an equality of mental alertness. That has been entirely elim-

inated, because we can't find two people who will do the same thing in the same way.

Then take Mr. Newcomb's example: suppose you go into the back of the car and kill a person on the back seat. Mr. Newcomb said if he were going to take the case of the person who was killed, he would say:

"Gentlemen, I am going to prove statistically that the great majority of motor car manufacturers have already adopted this safety device. I am going to prove that the car is better under control with that than with any other device. Here is a common carrier. Here is something that is transporting passengers for hire, the same as the street railways and steam railways.

"This vehicle is not equipped with a safety device. Therefore, they have not used that due diligence and caution which the law says they must in order to avoid this accident."

So that deals with the law side of it. I think you are going to find some judge some of these days is going to say, "Well, you didn't take every precaution. You didn't have this commercial vehicle properly equipped with all the safety devices that are available."

Two General Types of Automobile Brakes

I don't know whether you are interested in types or not. I am not here to discuss types. It so happens I was with the Columbia Accident Company during the battle of the brakes. You remember we had paid advertisers, one fellow for and one against. It pulled the subject out in the open and created a lot of interest and bad feeling. I remember I almost had a fist fight with a friend of mine over four-wheel brakes.

We will have just a brief discussion of types. We have two general schools, that is, we have a mechanical school and the hydraulic school. Probably Fred Dusenbergh, in Indianapolis, was the foremost exponent of the hydraulic principle in this country. He actuated his brakes by oil or glycerin, as the Hydraulic Brake Company does in Detroit.

The mechanical school is divided into two parts. You might say we have the Isotta Franchini type. It comes from the foreign car, actuating front brakes. Brakes are attached to the front axles. Then we have Benedict's. They both conclude now that internal expanding brakes are the thing to use.

You might say the Cadillac, Buick and Nash are among the foremost exponents of four-wheel brakes on pleasure cars, and they don't agree that you should use the internal brake all the way around. I think the Buick used the external brake, and Cadillac used the external rear and internal front and Nash does the same thing. Pierce Arrow used the Isotta Franchini enclosed brakes. I like to think of enclosed and exposed brakes.

In my experience with four-wheel brakes, I have never as yet seen an enclosure, meaning a method of enclosing a front brake, which was entirely fool-proof. By that I mean so that water or grit could not get in. Grit can get in a very small space and so can water. We can

use enclosed brakes with shutters on them so we can keep a certain amount of those materials out, but they will get in; and if we make a good enclosure, they stay in after they get there.

So that is the problem of the engineer. He turns around and makes a wonderful, nice, enclosed brake and then drills holes in it to let the stuff that gets in come out. I don't care whether the brake is external contracting or internal expanding; I believe some sort of water sheds would be a good thing. You can take an external brake and put something on it and when you go out for the average drive you won't be troubled with a whole lot of water.

Of course the truck fellows and the bus fellows and the taxicab fellows have been very slow and backward about taking on the four-wheel brake, but they have not been condemning four-wheel brakes. Their principal reason has been mechanical difficulties. While we want our commercial vehicles as near fool-proof as possible, we don't want them laid up. We say, "Two brakes give us enough trouble. If we had four, that is twice the trouble." So we have been very careful about equipping our commercial vehicles with four-wheel brakes. But it looks as though we are going to be forced to do it whether we want to or not.

Another thing, I think the public is going to force the passenger carrier to do it. For example, I believe this condition is going to come around in the taxicab business. I believe if one operator says, "I am not going to have four-wheel brakes—I don't need them;" and another gets four-wheel brakes and advertises them to the public, it is going to cause the first fellow to lose business, because the public as a whole is beginning to believe four-wheel brakes are safer than rear-wheel brakes only.

The Taxicab and Bus Business Highly Competitive

I think the taxicab and bus business is highly competitive and will continue to be. I think, though, from what I have seen of the four-wheel brake in commercial car operation, we needn't look for any more expense than we can look for on the rear-wheel brake because longer wear of lining and those features will offset any adjustment.

Personally I don't believe it is true for this reason: wear and strain on braking mechanism is caused by leverage and pressure. On a four-wheel brake job, naturally pressure per square inch is considerably reduced on each brake drum and the wear of the lining is considerably less. There is quite a variance of how much less. I have heard all the way from 25 per cent to 75 per cent. Of course that is a hard thing to determine because conditions vary radically. I think as a whole you can say we are not going to have any more trouble with the four-wheel braking systems as worked out today than we would have with a rear-wheel braking system.

There is one more point I might bring up. The coming of the four-wheel brake has improved brakes generally. We have a lot better rear-wheel brakes than ever before. There is no doubt about that, and those

fellows who are going to stay with the rear-wheel brakes are going to continue to try to improve them.

There is another economy. I believe with the coming of the four-wheel brakes and balloon tires, the chains on the light vehicle will be practically eliminated. You don't need chains because you are going to skid on brick. On the four-wheel brakes if you put chains on your rear and apply your brakes you have the same skid that you would with rear-wheel brakes only. It gives you the same tendency to skid as before. It has been pretty well proven that four-wheel brakes and balloon tires eliminate chains except for Ford driving.

Now if there are any questions, I would be glad to have you bring them up, but that is all I have to say on the subject.

Two Papers Taught a Lot About Brakes

CHAIRMAN HARMAN: Mr. DeWeese has surely covered this situation thoroughly, and we want to thank you for the able talk you have given us. Between Mr. DeWeese's talk and the talk given us yesterday by Mr. Parks, we have learned a lot about brakes.

F. B. HENRETTA (Yellow Cab Co., Inc., Roanoke, Va.): I would like to ask Mr. DeWeese's opinion on one point. He brought the taxicab into a kind of close place there in the eyes of the law. In his opinion, would it be all right to use the service brakes in the leverage, leaving your emergency for the rear?

That would give you less tendency to skid by using front brakes for service and would give you the benefit of the four brakes for emergency.

MR. DEWEESE: That has been brought up a great deal. You don't get the advantage then of four-wheel brakes. That is the only thing against that. But for a service brake, I think the brake on the transmission is going to be eliminated entirely. We have to have two chains in our brake, but as Mr. Parks said yesterday, he would rather have a front wheel brake, if he is going to have any and can not have four-wheel brakes. That is absolutely true, and anyone with experience would say so, especially if he was on a slippery street with rear-wheel brakes.

This is true except in the turn. In the turn you have the so-called semi-releasing front. We have a semi-release brake and don't get a lock. When we lock a front brake on a severe turn your tendency is to go straight ahead. That is the reason for this 60 proposition or 75 or 65, meaning less leverage on the front than rear.

However, frankly, except on a severe turn, you can go out and lock all four wheels, turn the front any way you want to and there is no effect on the car at all, if you have a good system.

There is one thing I fall in though, and that is brake equalizers. I had a talk yesterday with Mr. Carrow. He is a famous French engineer who invented the paro brake which is pretty generally adopted, and now Mr. Benedict is carrying it on under the name of Benedict's.

I asked Mr. Carrow, "Why don't you equalize your brakes?"

He said: "Here's the answer. After 14 years fooling with that brake, my theory of braking is, if you cut out all equalizing, stiffen up your brake mechanism and your brakes so as to cut out so much spring, then adjust your brakes just as equally as you can; and then because they don't happen to be 100 per cent right, you leave them alone and let them wear down, after they wear themselves equal, they will become very good and stay that way a long time."

We put that into effect. It is a new idea and it is absolutely true. Mr. Carrow knows exactly what he is talking about. As a rule there is too much fussing about brakes. If we have good brakes, if we will adjust them so they are reasonably equal and then leave them alone, we will soon have a condition where they will wear in and we will have much better brakes. Equalizing really accentuates that.

They talk about equalizing systems, but there is one thing we have never been able to do—equalize the effect of the tire on the footing, and until you can equalize that, any talk of equalizing is bunk. You have the pressure on four tires exactly the same, and still if one tire is soft or one tire on the wet footing, you have no equalization.

There is only one system. A man by the name of Smith invented a brake starting from the tire on the footing. That was on the Ford for about a year, and it comes as near doing that as anything I ever saw. It is absolutely controlled. In other words, if you are on a slippery pavement and your tendency is to lock, your resistance is built up there.

Two Fundamental Objectives to Strive For

H. W. HEINRICH (Travelers Insurance Co., Hartford, Conn.): I have been very much interested in the papers read and the discussions, but it strikes me we have as yet in this Section discovered no one particular goal towards which we should strive to get the results we want.

The chief goal I have in mind is not the things we have been so far discussing. It is not four-wheel brakes or two-wheel brakes, for if they are not used, they are not effective in stopping accidents. Speedometers, if they are not watched, are not effective. It is the same way with a number of other operations.

The two fundamental things in my opinion for the chief objectives this division might aim at are two things discussed yesterday. One, I believe, was the clear space or course ahead, and the other was the business of driving under control. But in those two also there lies a fundamental that has not been talked about.

Take for instance driving under control. If two men, both having their cars absolutely under control, approach an intersection point at right angles and are both driving 20 or 25 miles an hour, and their cars are so physically constituted that they can not stop within the proper distance, if they both insist on right of way, they will get it, and it will take them right away to the hospital.

It is not the business of brakes or cars particularly that should constitute our chief objective, but the driver himself. That is all vague.

That is general. Everybody might say, "I will admit it is the driver." We all know that. We have heard of education and safety campaigns and things like that.

Now I just want to mention that one point. If that is our objective, to make the operation of any and all motor vehicles safer for the driver and passenger, and for the public in any order of importance they may stand, then we must know what, in the business of operating vehicles, constitutes the chief causes of accidents. I know it with respect to my own limited experience, but do we know it here, and if not, shouldn't we find it out? Shouldn't we determine what that big thing is?

The Reckless Driver Can Be Cured

We have determined what that fundamental cause is that lies back of four-wheel brakes and back of the car operation, back of everything, and it is the driver. The driver can be cured. It has been our experience that it is not the custom to hold the man who supervises that car personally accountable for an accident when he hits anybody else. There may be occasions when he is to blame, as when he leaves his car improperly parked, but he has a chance to claim that it was the other fellow's fault. When he hits anything, he should and can be held personally accountable for that accident. The driver comes back and says, "The darn fool ran right in front of me!"

The driver is personally accountable and you can make him stay on the job and be happy, in spite of it. That is one big, specific remedy that will cure this business of accidents.

Let the head executive talk to the driver and prove to him that he thinks it is fair to hold him accountable. Let the chief executive tell him that he himself is sold on safety, wants it, is going to have it, that the man's job depends not only on how he runs his car and the revenues and commission he makes, but on safety as well as production.

If the chief executive will do that, and spend a little time on it, he will create that spirit in the drivers through having contact with the big men, that spirit of being on their toes and mentally and physically alert so they are efficient producers.

CHAIRMAN HARMAN: Thank you very much for those remarks; and I believe we are coming to that in our Friday program. We have Dr. Viteles, of the University of Pennsylvania, here and he is going to give us an extensive talk on that and he has had the training of men from the psychological standpoint as well as actual standpoint.

If there is no objection, we will follow Mr. DeWeese's talk on brakes with a rather free-for-all talk from everybody on the use of chains. I would like to have Mr. Wood, of Chicago, talk on that, as they have been doing a little experimenting in Chicago recently that will possibly be new to some of you.

HARVEY D. WOOD (Yellow Cab Company, Chicago, Ill.): The Yellow Cab Company of Chicago decided about six weeks ago to experiment without chains on the wet street. The principal purpose of the experi-

ment was to find out how important a factor chains are in preventing skidding accidents.

I refer only to taxicab operation, because the elements here have to do only with that particular industry. I might start back a little.

In Chicago, and everywhere else I suppose, when they start sprinkling we have a general order go out to all our stands and garages for "Chains on." It is a universal, general order. All our taxicabs, 2,500, put on chains, and they keep those chains on until orders come out "Chains off." Regardless of whether the streets are dry or not, it is uniform.

They found, as many of you men have probably found out, too, when it starts to rain there are, in a city like Chicago, about a million people that want taxicabs all at one time, within the same minute almost. That, in other words, is your biggest period.

Now take 2,500 taxicabs and tie them up for a space of time, at least five minutes. A man is pretty good if he can get two chains on the rear wheels in five minutes. Take 2,500 taxicabs and multiply that by five minutes and you have an awful lot of lost time at that peak period when everybody is clamoring for a cab.

Interesting Experiment With the Chain Problem

Skid chains are not the cleanest things in the world, neither are tires under those conditions. Ordinarily streets aren't just what they might be at that time. We all like to keep our drivers looking as spick and span as possible, and usually when that man gets through putting on his chains he is not only besmeared with mud and dirt on the outside, but his temper probably is not the best to receive a customer and treat him with the courtesy we like.

So with that thought in mind, they decided to experiment, and the deciding factor is going to be (because it is still an experiment) whether or not accidents as a result of not using skid chains will compel us to go back to the use of them.

We have had very pleasing results. As a matter of fact, immediately after this order went out, we had two days and one night of rain. Chicago always gets her share of rain, and so we had a real crucial test; and I am glad to say that during those 36 hours we had less accidents than we have had during the same period of dry weather.

Now there isn't anything unusual or startling about that when you consider accident statistics, because if you gentlemen attended the General Session yesterday in the Ballroom of the Book-Cadillac, you saw in those statistics the larger percentage of our accidents are during dry weather and in the daytime. Now what does that mean? To me it means this, that in the daytime and dry weather the ordinary driver drives faster than at night and in wet weather. We all know that speed is a big contributing factor to accidents.

In other words, a man hasn't his car under control, an unexpected emergency pops up, and with the physical mechanism of his car, it is impossible to stop before that occurs.

I have talked to a number of ordinary drivers and they feel this way

when the streets get wet—I will give it to you in their language—"We used to get those chains on and we felt we were all wet. We could get back in the car and away we could go on asphalt and concrete or creosote at the same speed as on a dry street without chains. Then an emergency arrives, and an unexpected thing happens, we strike on our brakes, our chains serve as skates and we skid right into them. Now we feel a little creepy. We know we haven't chains. Now we feel we haven't anything there to hold us, and we go along a bit more carefully."

It has been that thing alone that has cut down the accidents during wet weather. I haven't brought any data along as to the number of accidents or comparative figures or charts, which I would like to have and am going to get a little later on, but generally speaking, our experiment has been very satisfactory.

Now we don't expect to do away with chains entirely. It is obvious that during snowy weather and slushy streets you must have chains in order to get anywhere at all. That is to come yet this winter. We of course will use our chains during snowy weather or when there is snow on the streets, but for wet spells and rain we found so far the experiment has been very satisfactory.

CHAIRMAN HARMAN: Would be glad to hear from anyone now on the chain. We want a general discussion.

Further Discussion on Use of Chains

B. D. DEWEESE (Safe-T-Cab Corporation, Cleveland, Ohio): Here is one point. If you have a dry street with a lot of dust and oil on it and it starts to rain, that is the worst time. It is only a matter of five or 10 minutes until the surface of the street is again at the point where the friction between the tire and footing is not as good as it was on the dry street but much better than when the rain first started. It is true in cab operation. If the driver didn't instantly put them on, in five or 10 minutes he would be beyond the point of the greatest danger.

CHAIRMAN HARMAN: I might say that I am the second oldest Yellow Cab operator in the United States. The rules and regulations have been rather universal with us.

In our city our main arteries and our boulevards are all a pavement that is oiled about twice a year, in the spring and in the fall, and when it starts to rain the streets are just covered with bubbles of water.

We heard of this move in Chicago to go without chains as a safety precaution. I went so far as to have our board of directors meet and see whether they sanctioned my opinion. We couldn't think of doing it in Kansas City and didn't attempt it. We have a few old drivers that feel they have the privilege of breaking a rule. We even got after them, because we were afraid they might go without them.

We use the chains there. Mr. Wood's talk on how much loss of time there is, is very true, but we have our men educated almost to the point that when it starts to sprinkle, before the rain has really begun, they have their chains on.

I would like to hear from the fleet-owners, too.

J. T. SMITH (Yellow Cab Co., Philadelphia): Lots of times you have some very peculiar ideas as to how things are going in the way of accidents. We took off chains during May in Philadelphia, and for a while I thought the accidents were in far greater numbers than they had ever been with the use of chains, but I had some comparisons made. I have taken July, 1925, and August of this year, July being with chains and August of this year without chains. In July, 1925, we had 3.3 collisions per 10,000 miles. In August, this year, we had 3.2 per 10,000 miles without chains.

There is one thing that comes out. We find that in collisions without chains they are less severe. A man naturally drives with more caution without chains than he does with chains and the collisions are less severe.

As far as costs are concerned, I might say that the accident cost per 10,000 miles on rainy days in July amounted to approximately \$175 for 10,000 miles. In August the cost for 10,000 miles amounted to approximately \$110, backing up that statement that they are less severe and less expensive.

Experience With Use of the Rubber Chain

MR. WOOD: I am purely an accident prevention man and have been trained to look at everything from the accident standpoint, but we have estimated in Chicago that if we can go ahead without chains, it will save us the cost of chains and the wear of tires to the amount of \$200,000 a year.

MR. HEINRICH: Some talk has been made recently on the use of rubber chains, and the claim has been presented along this line, that there is no appreciable rumble or jar of the car. The chains can remain always on the car, and will give the approximate braking effect in all kinds of weather that the steel chains give.

If anyone knows anything about them I would like to hear it.

L. D. HEMMAN (Armour & Co., Chicago, Ill.): I never use skid chains and never allow them to be used. I believe during the snowy season you need a shovel. You don't need a skid chain on a solid tire. It is like a man with a sledge hammer.

There is a rubber skid chain put out by the Goodyear Tire Company. I got a set of them and that is all we had this spring. I put them on the rear of my car. I drive a Cadillac coupe weighing 4,600 pounds. I put them on at the start and left them on. You can't hear them. I put four men in the car, pulled out in the road in a foot of snow, and went right through. But at high speed on a slippery pavement, if you slap on your brakes so you lock your wheels, you slide forward. You get no side-sway. They must have been on the car fully three weeks, and you can't notice any wear on them at all, and I imagine the amount of service I gave them would wear out about three sets of the metal cross-chains.

CHAIRMAN HAEMAN: We gave a test to a pair of Goodyear rubber chains and found they were all right in rain, but in snow in our town

where it is hilly, they were absolutely no good. The cab actually stuck in the snow with these chains on.

What has been your experience, Mr. Toye? Have you had any experience down in New Orleans?

JOHN L. TOYE (Yellow Cab Co., New Orleans): We tried one set, but we are thinking seriously of doing away with chains altogether. We have a level city.

HENRY J. MINEUR (J. M. Horton Ice Cream Co., New York): I might say we have discontinued the use of chains on our lighter trucks and cars. We find that stressing the point that men should be more careful during rainy weather has produced good results. Our experience has been particularly good during or after rainy weather. We have had better experience than during dry weather. On large trucks during snowy weather we use chains.

MR. WOOD: I would like to suggest that we appoint a committee to make some technical tests to determine the coefficient of friction produced by using steel chains on a tire on ordinary wet streets, asphalt or concrete. I would like to suggest that such a committee be appointed to report some real information on that at our next session. I personally don't believe that ordinary steel chains give you much friction on a wet asphalt street.

C. F. COWDREY, JR. (Cowdrey Brake Tester Organization, Fitchburg, Mass.): I think that suggestion should be that test be made with straight pneumatic tires and balloon tires also.

CHAIRMAN HARMAN: I think your suggestion is very good. The chair will appoint a committee, which will be announced at the last session, to get some actual facts.

FRANCIS MCGUIRE (Eastern Dairies, Inc., Springfield, Mass.): I would like to ask the members if any of them have had any experience with steel cables in place of chains. We have been experimenting with them and some of our men like them very much. I can't really tell you a thing about them, as to what results they are giving.

CHAIRMAN HARMAN: Is there anything further you would like to say on the chain situation? If not, we will start with the day's program.

We will now hear from Mr. L. D. Hemman of the Armour Company of Chicago.

LIGHT TRUCKING

L. D. Hemman, Automotive Department, Armour and Company,
Chicago, Ill.

Automobile accidents cause many injuries, deaths, and tremendous property damage, and how to stop the growing number of these accidents is a great national problem. The loss in money due to automobile accidents is an immense economic waste that is a tax on automobile owners. The bright side of the present situation, however, is the knowledge that most accidents can be prevented. This is especially true of the commercial vehicle in fleets where a control and system can be used.

Safe and sane operation will give fleet operators a better standing in the community, because frequent maiming and crippling of people and damaging property is not a good advertisement and does not create the impression of efficient business management. It will also help to keep the fleet owner's cars in commission, thereby saving him considerable loss from lack of use.

In operating the safety plan it is essential that some one person be in an executive supervisory capacity. Through his hands all communications and materials pass. Reports should be rendered to him and he should be held responsible for carrying out the measures decided upon. However, one person's attention will not make a safety plan work successfully. The enthusiasm of everyone having anything to do with the fleet and its operation should be enlisted.

Safety Plan Depends on the Morale of the Drivers

The success of a safety plan very largely depends upon the morale of the drivers. If they are not sold on the idea and do not give it their whole-hearted cooperation the maximum effect can not possibly be attained.

Drivers should be appealed to from these angles.

Aside from a saving effected by reducing the number of accidents, the fleet owner will find many other savings made when his organization is working for efficient fleet operation.

In February, 1917, I took charge of the delivery system of "The Fair," one of Chicago's large popular department stores. While I have no intention of passing any comment on conditions there, I will say, however, that it was their belief that their service was not only costly, but the poorest in town.

Now, having set myself to the position, and having taken the time to make a fair survey, I came to the conclusion that an educational program was needed more than anything else. Their equipment was good, consisting of 78 trucks and 265 horses. The motors were all of good make, but running wild. The shop was good and handled by good help. We were having considerable trouble and expense due to careless driving and no follow up, especially with our larger vehicles; that is, the furniture and bulk trucks. Due to the height, we were constantly having bodies pulled off or wrecked from being driven into overhanging obstructions such as branches of trees, fire escapes and low viaducts.

The first step taken to remedy this was the installation of governors to control speed; then we attached an enameled sign to the lower windshield frame, just in front of the driver that read: "WARNING! 95 per cent of all accidents are due to carelessness. This truck needs 12 foot clearance. Be careful of overhanging obstructions.

I am pleased to say that this solved that problem. We then started holding weekly meetings at the various branches. While this gave fair results we were not wholly satisfied, so we then made a ruling that whenever a driver had an accident or complaint registered against him that he must appear at my office before reporting for work on the following

day. This naturally lost him time for which he was reimbursed if found not to blame. When he appeared at the office we would go into the accident thoroughly. We had a table in the office showing a miniature layout of a street and a street crossing and with two toy autos which enabled us to go through the circumstances of the accident just as it happened. From this procedure we endeavored to determine the negligent party and this was also an aid to the driver in preventing a recurrence.

Drivers were required to make out accident reports in detail of all accidents, however slight, and we classed an accident as any occurrence that happened other than regular performance. These reports, along with any complaints, were registered alphabetically in short form in a small book for ready reference, and would at a glance give the complete record of any driver.

We now changed from weekly meetings locally to monthly meetings. These meetings being held at the main garage the first Monday of each month. In attendance were the drivers and their helpers from each branch, accompanied by the branch superintendents so that they could also get our ideas and follow them through the month.

Picking the Jury Was an Important Point

Now, at these meetings we selected a jury, the jury being picked from the drivers and each branch being represented on the jury. To be eligible for jury service it was necessary that a driver have a clear record for at least one year, this meaning that he had no accidents or complaints registered against him. With the first of these meetings we were naturally anxious that the report of the jury should be fair and in accordance with our ideas. We therefore appointed on that jury as foreman the cost clerk of our repair shop. This man was above the average of intelligence, an organization man and well liked by all.

In opening these meetings the first order of business was roll call, after which court was opened, the jury selected and offenders of the preceeding month were brought to trial. Acting as a judge and clerk, I read the accounts of all accidents and complaints from the book mentioned and commented upon each, asking the offending driver for his explanation and then the jury retired. In their absence the meeting went into general session and with the assistance of the shop superintendent we discussed all happenings and complaints, endeavoring to sell the men the idea that they were salesmen, not mere drivers, and that as a company representative the impression left by them on any client should be a pleasing and lasting one. Also, that in driving through the streets they should remember that each pedestrian as well as motorist was a possible customer of the store and that through courtesy and safe driving they should lead the public to understand that the name "The Fair" really meant courtesy as well as quality.

When the jury returned the foreman read the findings. Penalties exacted by the jury ranged from a day to a week's lay off; assessment

of damages for the accident anywhere from 25 per cent to the whole; and among the verdicts of guilty there were some with recommendations of leniency; as in one case verdict read, "We, the jury, find the defendant guilty as charged, but being possessed with the knowledge that his wife is now in the hospital we feel that he can not afford a lay off or fine, so we therefore recommend that he be let off this time with a reprimand."

The jury's report being all in, sentences were then imposed and the meeting adjourned to the shop where trucks and their separate units could be seen by all. Here the shop foreman explained the causes of different sorts of wear and breakage.

Ability to Drive Had to Be Demonstrated

At time of employment no man was allowed to take out a company truck until he had first demonstrated his ability to the shop superintendent, and the shop superintendent's word was final whether he worked for the company or not. This had the tendency to have them take care of their equipment, as they knew that the shop superintendent had costs to meet and that if they did not help him meet them they would be out of a job. We also gave them to understand that they in turn had a right to refuse to drive a truck not fit for service because of bad breaks or steering apparatus, and that the company would back them up for refusing to take such a truck out on the road.

We now adopted the National Safety Council program of placing safety posters in garages and slogans below windshields, changing these regularly.

Now, while we made careful selections in purchasing our equipment and necessary supplies for their maintenance, operated a good efficient shop, governed our speed, made regular monthly inspection of our equipment and kept same well adjusted and lubricated, it is my belief that our big improvement and saving came from our educational campaign and safety meetings.

The first full year's operation of the program as outlined reduced our operating costs \$100,000 over the preceding year, and in 1924 we spent \$20,000 less than was expended in the year 1916, when everything was considerably cheaper.

One other change we made was in taking from the hands of attorneys the handling of our property damage claims. Instead I had our C. O. D. investigator make an investigation of all accidents, getting signed statements where possible. Our average losses in full settlement of all property damage claims for the past four years was under \$500. The investigator also attended all trials, as having gone over the ground and talked to witnesses he was well fortified to act as prosecuting attorney or witness for the defense, giving both sides of the case as soon as heard.

Starting with 265 horses and 78 motors, of which 50 were electrics, I have left that organization with 100 motors, 30 of which are electrics; I added 22 cars to the fleet and traded off 20 electrics on gas trucks. In

making this change we also dispensed with 200 horses. I do not mean that the changing of 20 electrics to gas and the adding of 22 more made it possible to eliminate 200 horses; it was, however, one of the important factors.

I have now, since June 1, of this year, been located with Armour & Company in charge of operation and maintenance of their vast fleet of cars numbering over 3,000, and am endeavoring to work out something with this organization similar to that at "The Fair." I have started with the installation of governors which is about complete. I have also started having accident reports sent direct to my office so that personal contact can be had with all drivers.

We are now putting in full operation the National Safety Council's plan of placing safety posters in all garages and loading docks, and are placing metal card holders just inside and below all windshields directly in front of the driver which hold the safety slogans. We are adding to the slogans on safety others on the care and lubrication of machinery parts which are changed four times monthly:

Following are some of these slogans as distributed monthly:

January

1. Drive as you would if the boss were sitting on the seat beside you. *Grease universals.*
2. Drive safely or not at all. *Test oil in transmission and differential.*
3. Remember! Reckless driving is not a Demonstration of Skill. *Change oil in motor.*
4. Do not stop or start suddenly. "Save Gas and Oil." *Grease each week.*

February

1. Even a pedestrian has a right to cross the street. Give him a chance. *Grease universals.*
2. Children are thoughtless! THINK FOR THEM. *Grease pack wheel bearings.*
3. An accident while backing up is not an accident. It is a deliberate act. *Change oil in motor.*
4. Remove that Switch Key! No idle running. *Is transmission or differential leaking?*

March

1. In case of accident use discretion and be courteous. Remember a soft answer turneth away wrath! Sell the name "ARMOUR." *Grease universals.*
2. Strictly observe traffic signals and warning signs. They are not put there to amuse the children. *Change oil in motor.*
3. Don't ride that brake! *Is differential throwing oil in brakes? If so, check your level; undoubtedly too much oil in bowl.*
4. Never release clutch unless you are going to stop or shift gears. *Grease each week.*

April

1. Accidents don't just happen. There is a cause. *Grease universals.*
2. Don't stop or start suddenly. "Save Gas and Oil." *Test oil levels in transmission and differential.*
3. There are a lot of drivers, but not many careful drivers. Get the safety habit. *Change oil in motor.*
4. The right of way isn't worth dying for. Life's too short anyway. *Grease each week.*

May

1. If you have a smash-up everyone will seek to blame you for it. *Drain transmission and differential.*
2. Your truck can cause more destruction in one minute than you can pay for in all the rest of your life. *Grease universals.*
3. Remember! Every person you meet, whether afoot or astride is an Armour customer. Do your bit to keep them "Armour Sold." *Grease pack wheel bearings.*
4. Be careful today and live to enjoy tomorrow. *Change oil in motor.*

June

1. An accident is as dangerous for you as for anyone else. *Grease universals.*
2. Always handle yourself under the eye of the public so that the name "ARMOUR" when seen on a truck spells "COURTESY" as well as "QUALITY." *Change oil in motor.*
3. When in doubt always stop! *Is differential throwing oil in brakes? If so, check your level; undoubtedly too much oil in bowl.*
4. If you owned this car how would you handle it? *Grease each week.*

July

1. Don't be a road hog! Sell the name "ARMOUR". *Grease universals.*
2. Don't ride that clutch! *Test oil levels in transmission and differential.*
3. Don't cut corners. *Change oil in motor.*
4. Don't dream while you are driving. *Grease each week.*

August

1. Keep your eyes and ears open! *Grease universals.*
2. Approach all corners slowly. *Grease pack wheel bearings.*
3. Better be late than sorry. *Change oil in motors.*
4. Children at play may not hear your horn. *Is transmission or differential leaking?*

September

1. Oil and Grease cost less than Parts and Repairs. *Grease universals.*
2. Keep radiator full. *Change oil in motor.*
3. Do not overload. *Is differential throwing oil in the brakes? If so, check your level; undoubtedly too much oil in bowl.*
4. Spread your load over body so as to keep proper balance. *Grease each week.*

October

1. Grease Universals. *Oil and Grease and proper driving will get results for which we're striving.*—W. H. S.
2. Drive carefully! You may meet a fool. *Test oil level in transmission and differential.*
3. Your horn is alright but remember you can not blow them off the street. *Change oil in motor.*
4. Turn corners slowly. *Drain transmission and differential now! Wash out with kerosene and refill with Zero Test compound. Cold weather is coming.*

November

1. A safe driver has no accidents. How are your brakes? *Grease universals.*
2. You have no right to take a chance; the other fellow may have to take the consequences. *Grease pack wheel bearings.*
3. When you find it necessary to use horn, also use brakes. *Change oil in motor.*
4. Coast up to all stops, but never down hill. *Is Transmission or Differential leaking?*

December

1. THINK! Before you take the chance. *Is Differential throwing oil in brakes? If so, check your level; undoubtedly too much oil in bowl.*
2. Never leave truck on an incline without blocking a wheel. *Change oil in motor.*
3. In descending steep hills, shift to first and leave clutch in! Never out. *Grease universals.*
4. You can't stop quickly on slippery streets. *Grease truck each week.*

CHAIRMAN HARMAN: I want to thank you for that paper.

Along the line of weekly meetings, sometimes we feel we can't have them, but in my business where we have 400 or 500 cab drivers, if we don't have a meeting every week or every other week, they want to know what is the matter. I can see better driving on the streets following these meetings.

J. E. DOBBS (General Necessities Corp., Detroit): Our program is pretty much the same as Mr. Hemman's, which brings out in my opinion, that a great deal of the fault and cause for accidents lies with the man. We must educate the man as to what is the right thing to do in driving a truck on the streets, get them down to the office and investigate the reports, and keep right on top of the man.

When an accident happens, I get the man down and I find out in questioning him that he did something which, to his best knowledge and belief, was supposed to have been right. In the course of argument I convince him that he was wrong. In that case, the man was wrong, he was the cause of the accident, and it wasn't bad brakes or slippery pavement or anything else.

I think poor judgment and lack of education are the greatest causes for all accidents.

WM. F. YORGER (Public Safety Superintendent, St. Louis Safety Council, St. Louis): I have to leave this meeting, and I have just a few words to say. I have been engineering the St. Louis Safety Council, and there are a few things I want to leave with you men who operate taxicabs and with you fleet-owners.

I don't know what your connection is with your councils in different cities or whether you have them or not, but I want to say, one of the most important things in your business is to eliminate that liability cost to which you are all subjected. The second thing is to get the people to use your service.

Now the Yellow Cab Company of St. Louis came to our council and said, "We need you." Here's what they do and it has been the secret of their success. They have a meeting of their cab drivers. They meet every second and fourth Thursday of the month. At that time such men appear before them as the Coroner of our city. These speakers are all furnished by the Council. That is our service to them, also the direction of streets.

The Cab Driver Can Be the Ideal Driver

They are the men who are confronted with these different problems. They are shown where the taxicab driver is looked upon as the ideal driver of the city, that he is the man the public looks forward to, that when they step into his cab they want to know they are going to get to their destination safely, that they are going to get there with the least bit of trouble, and that there is a man behind the wheel who knows his business and knows the traffic laws and how to operate a motor vehicle properly. Those are the things that will help in bringing business to their company, which is a very good one.

There was one thing I wanted to take up before I left here. You mentioned your block streets, your wooden blocks. I can't see any reason why any city of any consequence should sprinkle those streets. There is where you call upon your Council. We have taken that up in our own city. Our wooden-block streets are not sprinkled. We have these large sweepers and that work is done at night in order to get off the dust. That is the only reason you sprinkle your streets anyway. However, those conditions are local, because the sprinkling problem is part of your city administration duties.

Now then, your city may have a contract. Ours has one which runs into next June. If that is eliminated the sprinkling conditions are eliminated and it will result in the flushing of the streets.

You can go to a taxicab driver and say, "Let me show you something. When you are driving 60 miles an hour, do you really know how fast you are going? Just take one-half the speed you are driving. If you are running at 30 miles an hour by your speedometer, you are driving 45 feet a second. If you are riding at 25 miles an hour and you apply

your brakes, if they are in good condition, you can't stop in less than 35 feet.

Those things brought out to your driver, showing him how to reduce accidents, reduce the liability cost of the company. In reducing that liability cost the whole thing reverts back to the driver.

The Yellow Cab Company of St. Louis found out that it was the only means by which they could eliminate the accidents, to such an extent that now every driver that goes throughout the month without an accident has his dues paid in the local union by the Cab Company, which means that one particular cab company pays out \$1,250 a month; yet they save a lot of money.

MR. MINEUR: There is a point that I might leave, and that is to eliminate that claim of the driver that the company was wrong or some outside force was responsible for the accident.

We have a trouble card that the driver is supposed to turn in every night if anything is wrong with his particular car. That places the responsibility on him. He drives the same car day after day.

CHAIRMAN HARMAN: If there is nothing further on this subject, I believe we have time to go into the bus operation. Mr. Brown, of Philadelphia, is with us and will give us a little talk on "Bus Operation and Heavy Trucking."

SAFE BUS OPERATION

**N. T. Brown, Vice-President, Philadelphia Rural Transit Company,
Philadelphia, Pa.**

Mitten Management has been operating in Philadelphia in coordination with the street car and sub-way-elevated lines of the city, a fleet of motorbuses to the number of about 400, in addition to which we operate an intercity bus service with Philadelphia as the hub, and reaching to New York City on the north, Washington on the south and Atlantic City on the east. All our buses are of the gas-electric type, which was developed by Mitten Management engineers in cooperation with the engineers of the General Electric Company and the Yellow Truck & Coach Manufacturing Company after several years of research. The gas-electric principle thus developed has been generally adopted by manufacturers and operators, and in our opinion is the feature which has made the motorbus entirely applicable to city transportation.

P-R-T motorbuses have had an enviable record of safety, and it is about this particular phase of operation that I wish to speak.

The gas-electric bus is superior, in our opinion, to the mechanical drive from the standpoint of safety. The smoothness of operation during the period of straight-line acceleration produces practically no jar as compared with the uneven advance of the mechanical drive. The significance of this feature is at once apparent when one considers the large number of stops per mile in city transportation service and that passengers are continually walking in the aisles toward vacant seats when the bus is accelerating.

The elimination of gear shifting enables the operator to keep both hands on the wheel and his entire attention on the traffic through which he is driving. The conservation of human energy because of the elimination of approximately 5,000 shift operations per day is helpful in preventing accidents, since the driver is more alert than he would be if he was compelled to shift gears, thereby more slowly reaching the point of physical exhaustion.

The gas-electric bus is provided with three separate and distinct brakes. The foot and hand brakes are common to the ordinary type of motor vehicle, and in addition there is a regenerative electric brake. In making a stop, the operator uses both the foot and hand brake at the same instant, doubling the safety factor. The electric brake is used in emergency, being especially valuable in controlling the bus on a down grade, its effectiveness being in direct ratio with the vehicular speed. That is, when the bus is moving slowly, the braking power is slight, and increases as the speed of the bus increases.

The Handicap of the Brilliant Headlight

To protect against rear-end collisions because of frequent stopping, each bus is equipped with a rear stop-light. A tell-tale light is mounted on the dash in a position to be readily observed by the driver, so that he may tell at a glance whether or not the stop light is in operation, and govern himself accordingly.

The constant bane of every motorist is the brilliant headlight which blinds him at every hundred yards along our roads and our city streets, and many accidents are caused because of carelessness in the focusing of these lights. The headlights of P-R-T buses are kept properly focused in accordance with the state law, and recently we have installed safety lights which can be played on the edge of the road, allowing the upper headlights to be turned off entirely, and eliminating even the slightest glare in the eyes of the approaching driver, at the same time lighting up the side of the road so that there is no danger of ditching the bus.

We have installed in our central garage, a brake testing machine, by means of which brakes are scientifically and equally adjusted, so that the pressure is the same on each wheel when the brakes are applied. The machine indicates the weight of the pull on each wheel, and instantly records any inequality of braking power, as well as whether power is being lost due to dragging brakes, when the brakes are in the off position. High points on the brake lining and drums, and similar brake failures are also indicated. Equal distribution of braking force on both rear wheels has eliminated the hazard of skidding on wet pavements.

It is thus possible for us, by regular test of every vehicle, to assure ourselves that brakes are at their maximum efficiency at all times. Since good brakes are a vital factor in the prevention of motorbus accidents, their mechanical perfection, at all times, is vital to successful operation.

Adequate inspection of a large fleet of motorbuses is a requisite, not only in order to make every vehicle safe at all times, but in order that

maintenance may be kept at a high standard of efficiency. Inspection of buses is regular and frequent, and every mechanical detail is tested by expert mechanics.

Nor is the importance of trained personnel lost sight of. In fact, we recognize that the human factor is probably the greatest of all in the prevention of motorbus accidents. Drivers are employed only after passing rigid medical examinations, and after meeting equally rigid standards as to weight, height and age. These men are thoroughly trained in motorbus operation before they are allowed to operate in regular service. Because of this care in the selection and training of men, we have succeeded in building up a force within the past two years, which in appearance, in courtesy, in skill, in operation and in general efficiency has won the plaudits of the public of Philadelphia, and numerous comments from visitors to the Sesquicentennial this summer bear testimony to the esteem in which this operating organization is held because of the high standard of its personnel.

The bus is no longer an experiment. It has come to stay. It has a definite place in the coordinated transportation system of the great city. It finds a field of increasing usefulness in intercity and interurban service. It is encouraging to see that street railway and steam railroad managements are coming to a realization of the fallacy of attempting to thwart the progress of a facility which has so thoroughly met the popular taste by contributing a great share to the speed, comfort and safety of modern passenger transport.

In addition to these factors of safety as outlined, there is maintained in the central office a system map, the duty of one man being to place a pin on this map showing the location of each accident which may have happened. These locations are then analyzed, with the idea of determining whether or not any of the factors contributing to the accident hazard can be removed; for instance, possibly the moving of the traffic officer from one side of the street to the other, or the changing of traffic regulations at this location, or the removing of a billboard or shrubbery which may obstruct the view of the driver approaching an intersection. We have found that this has materially helped to reduce the number of accidents.

Discussion Following Mr. Brown's Paper

CHAIRMAN HARMAN: Mr. Brown, I want to thank you for your able talk on this subject, and if there is anyone who has any questions to ask, I know Mr. Brown would be delighted to answer.

F. C. LYNCH (Kansas City Public Service Co., Kansas City, Mo.): I was quite interested in Mr. Brown's paper, particularly with reference to the safety features of the gas-electric. I operate a few gas-electric buses. In fact, I think that I have the only insulation in the United States where the exact duplicate equipment is in service, both mechanical and gas-electric. In other words, the first bus that comes will be on certain routes, exactly the same as to body, engine, chassis.

I can't say it appeals to me that gas and electric are any safer than mechanical. I don't know whether Mr. Brown intended to convey that impression. There is a certain handling of the mechanical which is desirable.

In other words, when a man is moving along in traffic with a mechanical job in low or second, he can control his speed very nicely by the position of his foot on the accelerator and creep along with the traffic, as you all know. The gas will come along and the engine will help him to brake, and it makes a very nice handling proposition for traffic.

If you use gas-electric and are on a slope and trying to creep along, you are continually going from brakes to power and power to brakes. As Mr. Brown says, you have no retardation from your engine similar to your retardation in your mechanical job. At your low speed, if your resistance with your propelling motor is set so that it is practically a dynamic brake, it doesn't have any effect in the traffic and it makes it mean to handle from that standpoint.

MR. BROWN: In answer to the gentleman's question, we do believe that the gas-electric bus on a wet street is superior to mechanical driving. When we constructed our first gas-electric bus the accelerator pedal was on the right foot, which was customary with all automotive equipment. It wasn't very long after that we discovered we could add a safety factor to the vehicle by moving the accelerator pedal to the left foot, therefore, using power and brake, the same point of efficiency as you use engine compression. In other words, when the vehicle starts to slide and the rear end starts skidding, it was a touch of the gas and a touch of the brake.

I have never been able to find any vehicle that will skid as long as the wheels are revolving. I discovered that some years ago. If I could keep the wheels on the street car moving, I had no sliding take place.

So we put our gas pedal under the man's left foot. I won't say it is safer, but I believe it is easier to handle in traffic, due to the fact that the man has both hands on the wheel and his eyes ahead of him, and at no time does he have to shift any levers. He has his left foot on the gas, his right on the brake and both hands on the wheel, where I believe they belong.

CHAIRMAN HARMAN: We are very fortunate in having Mr. Brown here today as well as Mr. Smith and the gentleman who talks to us Friday morning on the training of drivers, for there is hardly another concern in the United States so situated as they are in Philadelphia, where one company operates street cars, interurban cars, city buses, interurban buses, taxicabs and airplanes. Therefore we are able to get a lot from people who have experience in all of the transportation lines that we are interested in.

I will appoint Mr. Hemman as chairman of our Committee on Sprinkling. The idea yesterday was to get a resolution up to the National Safety Council to give us such assistance as they could.

ADJOURNMENT

FRIDAY MORNING SESSION

October 29, 1926

The meeting convened at 9:55 o'clock in the small Banquet Hall, Statler Hotel, Detroit, Michigan, Chairman Harman, presiding.

CHAIRMAN HARMAN: I find after our Nominating Committee made recommendations which were adopted, that Mr. Glenn Royer feels he will be unable to attend and asks us to accept his resignation. It was rather difficult to get all of the original committee together. Some have left town and some we couldn't find.

I don't know that this is in order, but if there is no objection, the chair will appoint a man to fill that vacancy. I will take it for granted you all agree with me, and in place of Mr. Royer I am going to appoint Mr. Henry D. Mineur, of the J. M. Horton Ice Cream Company, New York City, to fill the vacancy.

I will introduce this morning Dr. Viteles of the University of Pennsylvania, at Philadelphia.

THE SELECTION AND TRAINING OF TAXICAB DRIVERS

Morris, S. Viteles, Ph. D., University of Pennsylvania, Philadelphia, Pa.

Possibly the most important single psychological factor in accident causation in the taxicab business as well as in any other transportation business is the differences in ability among men driving cabs. If all men were alike there would be no place for an employment office in any industrial organization. The employment office could be replaced by a policeman whose only duties would be those of keeping the applicants for employment in order and of sending in to each department the numbers called for by that department.

Unfortunately for business administration, all men are not alike. The very word "selection" implies that they are not alike. That they are not alike is a matter of common observation, as often made by the man on the street as by the scientist weighing the nature of these variations in his laboratory.

However, there are marked differences between the man on the street and the scientist in the way in which they describe human variations, in the methods used to uncover them, in the fineness of the differences observed and in the way they are explained and utilized. The layman is satisfied to talk blithely about how alike and unlike people are, using the term "likeness" and "unlikeness" very loosely. The scientist, with a punctilious regard for exact phrasing, speaks of "individual differences" and "variability;" and assigns a very definite meaning to this and similar concepts.

The man on the street depends on a casual observation of differences; the scientist insists upon controlled conditions and specially designed apparatus. For example, we all know that some men work fast and others more slowly. The layman is satisfied to use the term "sluggish" or "slow" or "fast" or even "as fast as lightning" in describing these differences without attempting to measure them with any degree of accuracy. The scientist recognizes that the same sorts of differences exist, and he sets up a tapping key in series with an accurate timing device and an exact recording device. He examines 20, or 100 or 1,000 subjects and finds that the rate of tapping varies with age, sex, mental stimulation etc. but that even under the same conditions the rate of tapping of practiced adults of the same age varies from five to 14 taps per second (See Whipple), and that these figures indicate persistent, characteristic individual differences. He calculates central tendencies and variations from the central tendency and in the end is able to state exactly to what extent the individuals differ in this trait and to suggest, perhaps, the cause of these variations. He not only insists upon accurate recording but he measures in the most refined units of time. Whereas the layman uses the term second or minute or even five minutes almost interchangeably in referring to small units of times, the scientist measures time to the thousandth of a second and describes individual differences in terms of these units.

Testing the Efficiency of the Mind

Making use of these exact instruments and refined methods, he has found, for instance, that men differ in the number of digits they can recall after a single repetition—that some adults can recall only five, others as many as 12. He discovers that after a single reading of a paragraph some adults recall as many as 12 ideas and others as few as one, whereas the greatest number of individuals tend to recall four. In so far as movement is concerned, experiments demonstrate that the time taken by an individual to react to a visual stimulus may be as much as twenty-thousandths of a second longer than that to an auditory signal, and, more important perhaps from the point of view of selection, that the time differences in response among individuals to the same stimuli may be as high as half a second, and that the differences increase as the complexity of performance increases.

In the matter of imagery, it is found that some men have clearer and brighter images of objects they see than of sounds they hear. Some can not form an image of or carry a tune; others can not see in retrospect a beautiful vista but can form clear, bright images of tunes and movements.

The scientific selection of taxicab drivers or workers in other fields of transportation or industry, involves merely an application of this scientific method in analyzing and measuring such individual differences. The differences to be measured in the case of the taxicab drivers are more complex, more varied than those of rates of tapping or speed of memorizing, but they can and have been submitted to similar analysis and

measured in ways which make it possible to separate the unreliable from the reliable driver.

The complexity of these underlying factors is demonstrated by the fact that many men who have made outstanding success in one or another profession are unreliable drivers. For example, I know a surgeon under whose care, in case of need, I would place myself without a moment's hesitation, but in whose car I would be as loath to drive, were he driving, as in the car driven by a low grade imbecile. So far as his ability under the distracting conditions of traffic is concerned this man grades very low. To say this is not to reflect upon his ability as a physician. It is merely to say that the two are complexes or different ability. It is in the analysis of the nature of these complexes and in their measurement that the psychologist is contributing in one way toward the reduction of a mental hazard in accident causation.

Examples of Psychological Research

An example or two may suggest the nature and accomplishments of psychological research in this direction. Reaction time in car operation has been studied by two investigators—Moss and Allen—who find that the average time taken by a driver to place his foot on the brakes in response to an auditory danger signal is 0.54 second—or, in other words, that the average person traveling 30 miles an hour would go 22 feet before he began braking the machine after hearing the danger signal. However, some drivers in the group showed a reaction time as low as 0.31 seconds, others a reaction as high as one second. The importance of such differences in selection are self-evident, particularly since variability in performance seems to increase with reaction time.

Differences in accuracy and certainty of response under the complex distracting conditions of the street—as measured by specially designed apparatus—have been recorded in a number of investigations. An apparatus of this type, designed by me and at present in use in the selection of motormen and cab drivers, shows a variation ranging from zero to 50 in the number of incorrect responses to four signals presented in haphazard order, and a significant relationship between the accuracy and speed of these responses and performances on the street after employment. Detailed descriptions of this apparatus have been published elsewhere, but the facts, for example, that in one case the number of motormen discharged because of accidents decreased from 14.1 to 0.6 per cent following the use of this test, and that in an investigation by another observer (Snow), using apparatus designed by him, a pronounced decrease in accident rate followed the application of tests—are extremely suggestive.

Other individual differences influencing accident rate, such as age, years of experience in driving, education, etc., could be mentioned and experimental results cited. But those given above are sufficient to demonstrate the nature of individual differences affecting accidents and to indicate the specialized technique devised by the scientist for their measurement.

As a practical problem the employment manager, or foreman, and the

psychologist interested in selection, are doing fundamentally the same thing, using different methods. Psychology in selection is not a cabalistic art by virtue of which the psychologist evolves a mystic formula of perfect selection out of his inner consciousness. He starts with a common-sense recognition of differences, which is the property of all of us, and merely develops a technique and an improved method for analyzing them and for making the measurement of them more accurate and reliable. At best even the psychologist's method is imperfect enough, but it is a little better, in the same way as the dietician's mixture of carefully weighed foods for the diabetic patient generally proves a little better for the patient than his haphazard choice, if not as tasty.

Selection, however, is not the only way of reducing personnel accident hazards. To even the most optimistic vocational psychologist the possibilities of improved selection seem limited by the inherent weaknesses of test procedure and by variations in the behavior of mankind other than those of ability and temperament. He knows that the adjustment of the employee is determined by many other factors than the ability to perform the job, and that even if the selection instruments were perfect, accidents would still take place and labor turnover for this and other reasons still appear on the monthly reports of the employment manager.

Improvement and Training Are Logical Steps

This point of view reflects no discouragement with psychological tests and other improved methods of selection in industry. It is merely a frank recognition of their limitations. It still recognizes the importance of selection in accident prevention, and the justification of further research in this direction. It merely implies that it is necessary to go a step beyond improving selection in the process of pairing workers satisfactorily with jobs.

Improvement of training is the logical and necessary step beyond selection. It is so important a step that the speaker feels justified in devoting the major portion of his time to a consideration of the psychological factors of importance in training.

For the purpose of this paper the term "training" will be used in a rather broad sense, to cover not only the formal instruction given as a preliminary to placement on the job, but with reference also to the continuous and uninterrupted process of education by means of which workers are kept adjusted on their jobs.

It is no exaggeration to say that the administration of personnel is largely a problem of training personnel to meet changing and higher standards of accomplishment. Training, in this sense, is a continuous process, to each phase of which the factors determining the efficiency of routine preliminary training are equally applicable. From this point of view, the day to day campaign for the reduction of accidents is nothing more than the education of the worker in the avoidance of accidents.

Training, whether of the preliminary or follow-up type, should be based

on a recognition of certain elementary principles underlying human behavior. It should take note of the tendencies towards behavior which develop accident hazards, and be directed toward the elimination or reduction of these hazardous tendencies. One such tendency, a tendency given inadequate recognition in the vast majority of industrial training courses, is associated with habit formation.

The operation of any motor vehicle involves a number of habitual responses which must be set during the training period. Learning to drive a car consists largely of learning to perform a number of movements in a certain series with a minimum amount of attention and effort. Safe driving is habitual in character. The safe taxicab driver, for example, is the one who always slows down in approaching a street corner; who always looks back before turning; who always maintains a safe braking distance between his car and the car preceding him, etc. He does it always because it is habitual; he does it without stopping to figure it out—to decide that it is the best thing to do.

Establishment of Desirable Habits Essential

The desirable driver makes a habit of avoiding bumps; he makes sure that passengers' fingers are safe before closing the door; that no one is leaning against the door before opening it, etc. The tendency toward the appropriate behavior is so firmly established that the driver performs it as naturally as he lifts his fork to his mouth in eating.

To establish desirable habits so firmly is the prime function of the training course. An application of the principles governing habit formation which have been worked out in the psychological laboratory, can contribute considerably to the achievement of this objective. Experiments in the laboratory have shown, for example, the influence of a factor described as "habit interference" in the formation of habit. The exact nature of this factor can be illustrated by a simple experiment. A subject is asked to sort 80 cards, containing 10 cards each of eight suits. Each suit is in the form of a design, that is, a square, a triangle, a circle, an ellipse, etc. Copies of each of these designs are arranged in a given order on the table before the subject, and he is instructed to sort the cards on to the table, placing each card of each suit on its appropriate design as quickly as he can.

If he is given ten trials there will be noticed a marked decrease of time on each trial, starting with perhaps as high as 300 seconds for the first trial and diminishing to 80 or 90 for the last. The time decreases because the subject remembers better in each trial where the card is to be placed. The card is seen and the hand is moved in the proper direction more and more quickly until, in the last trials, the subject need pay no attention to the movement of the hand. It moves automatically in the right direction. A habit of movement has been established.

The designs on the table are now rearranged, so that the square appears where formerly the circle had been; the triangle in place of the ellipse, etc., and the subject is instructed to sort the cards again. The interest-

ing and significant thing is that in the first two or three trials of sorting to the new arrangements, the times are almost invariably longer than the time taken in each of the first two or three trials in sorting toward the original arrangement. This is because the subject must not only make the proper response, but he must resist the tendency toward the habitual response which has been firmly established in the first ten trials, and which tends to interfere with the formation of the new mode of response.

The fact of such habit interference is largely overlooked in industrial training. There is a failure to emphasize the standard procedure and the continuous repetition which are the only safe methods for the formation of safe habits of operation. The well established principle that the accuracy with which a certain action is performed is decreased if antagonistic actions are practiced with it is almost totally neglected.

Habit Interference vs. Habit Formation

I remember very well a training course in street car operation which I took as a student apprentice as a preliminary to the analysis of the duties of this job. In this course, after a day of preliminary instruction in the school room, the student was sent out to learn operation on the road under a so-called line instructor. Each day there was a different instructor, and each showed a personal preference in the way he handled the controller, the air brake handle, and other mechanisms involved in operation. One day, for example, I was taught to take a short bite of air, another day a long bite; one day to speed up at one rate, another day at another rate; one day to open the door with the right hand, another day with the left hand, etc.

The total effect of such differences in training from day to day is to stress habit interference instead of habit formation, and to leave the student, at the end of the training course, unprepared to meet the conditions on the road with a set of firmly established habits providing the only safe avenue to safe operation on the road. The effect of such training is to decrease the accuracy of response and to increase the time of response in a way that interferes with safe operation. The potency of such improper training in accident causation in street car operation can not be overestimated.

The same holds true of taxicab operation. It is extremely important in cases in which inexperienced applicants are hired and taught how to drive, and perhaps not equally so, but still extremely important, even when experienced drivers are hired. There are still a thousand and one details of safe operation of extreme importance in accident prevention which the private driver must be taught prior to placement on the job, and, which, in the case of all drivers, must be reinforced by continued emphasis after placement. Slowing up at street corners, signaling to other vehicles, to pedestrians, loading and unloading procedure are a few of the many examples which could be cited.

Without attempting to discuss in detail ways of handling this problem, it seems important to note that the assignment of a man to a single

instructor does not adequately meet the problem. There may be variations in instruction on the part of one instructor, unless he is carefully selected, carefully supervised and a definite program and standard procedure in training also developed.

Looked at from the point of view of drivers, training should have the same objective, and should be approached from somewhat the same angle as is the intensive drill in the use of bayonets in the case of soldiers. The object of such intensive bayonet trial is to set up habits of response so certain that action occurs without preliminary thought on the part of the soldier. If the soldier had to think before parrying a thrust he would be struck while the thought processes were still going on. To think, in this sense, is to choose between possible actions. As a matter of fact the soldier has not the time to make a choice. The movement on his part, in a certain direction, must follow immediately upon the movement of his opponent and be appropriate to that movement.

Careful Drivers Are Habitual and Automatic

In the same way each taxicab driver must be trained so that in so far as daily operation is concerned, so far as safe methods of driving are concerned, they will be entirely habitual and automatic, and, at the same time, free from the possibility of contradictory movements which will place him and his passenger in danger. The chief value of a safe driving campaign in which, for example, drivers are urged to give the right of way at intersections, lies in the further fixing of safe habits of driving. In one company, with which the speaker is familiar, the beneficial effects of such a campaign continued for months after it had closed. Habits had been fixed.

This emphasis on habit does not imply, of course, that there are no circumstances in which the driver must use judgment; must think quickly. It merely assumes that the chief factor in safe day to day operation is safe driving, and in this sense dependent upon the establishment of habits of operation associated with safe driving.

There is another psychological principle, perhaps less well known than the one discussed above, that may well be considered in preliminary training and equally well in the more intensive educational or safety campaigns. This is what is known by the psychologist as the principle of ideo-motor force. It states simply that the presence of an idea in the mind leads to action—that thought, in other words, produces action.

A simple illustration of this principle is found in an experiment occasionally used as a parlor trick. A small ball is slung on a piece of string about 12 inches in length. The subject is told to hold his hand out at arm's length, with the end of the string in his hand, the ball, therefore, swinging at a distance of 12 inches below his hand. He is instructed to close his eyes and then to think either of a pendulum swinging to the right and left or of a pendulum swinging backward and forward. The experimenter watches the movement of the ball, and from this movement can tell whether the subject is thinking of right and left or of backward and forward. For, curiously enough, when the subject is thinking of

right to left the ball swings in that direction, and when he thinks of backward and forward, the ball moves accordingly.

The explanation of this apparently mysterious performance is simple enough. The idea "left to right" in the mind of the subject is accompanied by contractions on the part of the muscle responsible for this movement, contractions small enough to be unnoticed by the subject, whose attention is centered elsewhere, but marked enough to set the ball in motion.

The same principle can be illustrated by asking the subject to hold his arm straight out in front of him and to think of right or left. The appropriate movement follows the thought of right or left, and the subject's thoughts can thereby be "divined."

Other apparently mystic phenomena can be readily understood if this principle is known. For example, a few years ago a gentleman appeared in Philadelphia and laid a wager that he could find an object hidden anywhere in this large city. His conditions were straightforward enough. The object was to be hidden anywhere in the city. He was to be placed, blindfolded, in an automobile, alongside of the one who had hidden the object. The automobile was to be driven through the city slowly, the only requirement being that at some time during the trip the automobile pass the place at which the object was hidden.

An Interesting Experience in Mind Control

The conditions were accepted. The gentleman with this uncanny ability sat in the automobile with his hand lightly placed on the arm of the one who had hidden the object. As the automobile passed the spot at which the object had been hidden the experimenter called a halt. He stepped out of the automobile and instructed the one who had hidden the object to move around the pillar—for that is what it proved to be—in a crevice of which the object had been hidden. They walked around the pillar together, the experimenter still holding his hand on the arm of the one who had hidden the object. For the second time he called a halt, with the announcement that the object would be found on the side of the pillar at which they had stopped. The object was found there.

The explanation of this is likewise simple. This experimenter knew something about ideo-motor force. He knew that as they approached the place at which the object was hidden there would be small muscular contractions in the arm or in some other part of the body of the one responsible for hiding the object. His hand, lightly placed on the arm of this person, detected the small muscular contractions accompanying the thought of the hidden object, and it was by this means that he was able to locate this hidden object and many others hidden at different times by different observers.

What is commonly known as kleptomania is a pathological exaggeration of this same tendency in an individual. The sight of an object awakens the idea of taking the object and the appropriate movement is performed. In the case of normal people the force of this idea is over-

come by inhibitory tendencies. The abnormal kleptomaniac is incapable of conquering the idea which sprouts into the appropriate action.

If you observe a crowd at a football game you will likewise notice the influence of the same factor. When the ball is moving toward the north the crowd lists to the north; when it is moving south the list of the crowd is in that direction. At an exciting prize fight ideo-motor force may take on a dangerous form in the shape of an excited fan who accompanies his shouts of "slam him" with appropriate movements of arm and body—to the danger of those sitting around him.

Studies of the types suggested above, both of normal and abnormal individuals, show the extent to which the presence of an idea prompts a movement. A consideration of this factor is of utmost importance in the choice of material and methods for the training course. It shows, for example, the superiority of positive over negative suggestion in training and in supplementary safety campaigns; and the superiority of "do" over "don't" in instruction and discipline. It suggests the need of presenting only those positive ideas and images which will lead to safe action, and the extreme importance of avoiding the negative idea which leads to action appropriate to it rather than to safe performance.

In the light of this principle it seems preferable, for instance, to show pictures of how the right thing is done rather than pictures showing the wrong way, for the idea to which the picture of the wrong way gives rise may result in action appropriate to it. The ineffectiveness of "don't" in the safety code and in the driver's manual of instructions likewise becomes evident. Such "don'ts" may create the very tendencies toward wrong action, a guard against which it is the purpose of training to erect. Negative suggestions set up a mental hazard, positive suggest a tendency toward behavior which gives the driver strength in his struggle of mind over accident.

Further Mental Factors May Be Weighed

Many other mental factors can be weighed with profit in selection and training. Thus, for example, the attitudes of the instructor and supervisor, as they affect the emotional attitude of the driver, deserve serious consideration in a training and supervisory program. An impolitic approach on the part of the instructor may awaken an antagonism, a feeling of unwillingness to cooperate which may seriously affect the attitude of the driver toward cooperation. Unjust censure on the part of the supervisor on the street, or criticism at the wrong time, or sarcastically worded, can produce an emotional blow-up which may be the direct cause of a serious accident.

The extent to which emotional attitudes of these sorts influence accidents may be seen in the experience of one manufacturing firm in Philadelphia. Because of the difficulties of guarding machinery, the accident rate remained high in one department of this company. It was found, moreover, that it was much higher among new employees than among experienced workers. At one time there was occasion for lay-off, and naturally men more recently hired were laid off first. It was

expected that paralleling the lay-off of new men would occur a noticeable reduction in accident rate in this department. As a matter of fact the accident rate went up, the direct cause of the rise being the feeling of uncertainty created in the minds of the men who remained at work. Each one was worried that he might be the next to be laid off. The effect of this worry was to distract attention from the job, to create an uncertainty in response that resulted in a marked rise of accident rate.

This is merely an example of a situation which arises in other forms in taxicab operation and which is subject to control. Other factors which might be discussed are laws governing retention as they can be applied in training, factors influencing attention, the effect of fatigue, etc., but time is limited, and it seems "good psychology" to close—to avoid fatigue and the emotional blow-up on the part of an audience which constitutes as great a mental hazard to the speaker as do some of those discussed above to the driver.

Discussion Following Doctor Viteles' Paper

CHAIRMAN HARMAN: We appreciate your talk very much. It was most interesting. Has anyone any questions?

F. C. LYNCH (Kansas City Public Service Co., Kansas City, Mo.): I just want to ask one question. That is, do these characteristics of the men change? In other words, does the time change in which one man will react to a visual signal? The way I feel this morning, I might not get by the examination. Other mornings I might feel better. Over a period of years does that change?

DOCTOR VITELES: There is no doubt the conditions of one's body and other conditions do affect results from a test study such as this. There is no doubt that reaction changes in men, but the change occurs within a narrow range and beyond that range no amount of additional training, no amount of improvement will induce reaction. It is those limits we are trying to measure.

In other words, in the east, instead of measuring response in two or three minutes, we use half an hour to train a man. We give him 15 or 20 minutes, as much time as he needs, then we test the response. If we tested him in two or three minutes, we would not get an accurate estimate of that man's abilities, because he might not feel well in the morning, etc.

In measuring tapping it is found they vary with mental stimulation, but no matter how much you urge men, one man will tap faster. One man will start at 12 and increase to 14, but there is still that difference between the man who taps seven times in normal conditions and the man who taps 12 times.

CHAIRMAN HARMAN: I presume most of the taxicab operators here are aware of the fact that many of the large cab operators are using a mechanical test, that is known as the fear action test. It is an electrically operated machine. I regret to tell you that I am very poorly informed on it. We have just purchased one in our business in Kansas City, and it is installed. I expect to take a man from Chicago back to Kansas

City to put it in operation within the next couple of weeks. The Doctor no doubt can describe that in detail.

DR. VITELES: Ours is quite different. The test we use in Philadelphia is a test that I designed for the selection of street car motormen six or seven years ago, and the principle is quite different from that which Dr. Snow uses. For instance, Dr. Snow depends on one single performance lasting a half second. In my opinion, that can not give an index. We take a half hour, and in that half hour we give him a set of four signals coming up in haphazard order.

In other words, that reaction of fear is only one very small part of the bigger program of trying to test his ability to drive under ordinary conditions.

MR. LYNCH: I would like a little information. Is it going to be possible for you to start an educational campaign among the fleet-owners that are not large enough to have a Doctor of Psychology on their staff? Are you going to be able to give them enough so they can actually employ the men on a scientific basis such as you are doing?

Psychological Tests of German Boys

DR. VITELES: I think what we would have to do is what they do in Germany. In Germany no boy is accepted as an apprentice to learn a trade unless he passes psychological tests. The union manufacturers have combined to insist upon the psychological tests as preliminary to apprenticeship.

Germany knew that in order to compete with the allied nations, she would have to produce more economically than the allied nations, and she decided the best way would be to get the best man to do each job.

There are some small plants which can't afford to have a psychologist. They have a central testing bureau and send the apprentices to the testing bureau. Three or four plants use the same bureau.

CHAIRMAN HARMAN: I might say, Mr. Lynch, in answer to your question, the National Association of Taxicab Owners, to which most of us cab-owners belong, is really the starter of this method of training the cab-drivers. For the benefit of the fleet-owners, we appreciate the fact that we are training men for the driving of one particular class of public service—taxicabs. While there is a difference, a Green or Yellow or some other kind of a car might be used, they are all standard gear-shift, about the same size and weight, and are handled in the same line of traffic. We appreciate the fact that the fleet-owners here are dealing with trucks to a large extent, some small-sized, some medium and some large-sized.

I think in the Hoover investigation of traffic conditions the principal object of some of these different tests was to be brought into the licensing of drivers in different states with the object of having a code of rules that not only a driver of a public car would be subjected to, but also the driver of an individual car would have to take a certain test. It might not be as rigid for my wife or my son or myself to drive my

own car as it would be for a man that was going to drive a government mail truck or an ice cream truck or a taxicab.

Did you get the same idea, Doctor?

DR. VITELES: Exactly. As a matter of fact, I may add to that I was on a sub-committee to the Hoover Committee, which hasn't made any report. A series of tests were to be used in connection with the licensing of drivers.

J. E. DOBBS (General Necessities Corp., Detroit, Mich.): I would like to ask about the psychological test. After testing a man, can it be determined definitely that a man is potentially hazardous, or whether it is just a chance that he doesn't come up to the test required, and by eliminating this group, you may eliminate the majority of accidents, but be unfair to the individual?

My question is whether we could determine that this particular man is potentially hazardous to put on a truck?

DR. VITELES: Well, of course, that is the most important objective to the test, to separate the unreliable or hazardous drivers from the safe drivers. Now in test construction we first analyze the job, then construct the test. Then we give that test to a number of new men. The test is not thought to be of any use until it has been proven that the ones who fail the greatest number of tests are the most hazardous drivers, and the ones who pass have the least accidents.

Not Perfection But a Start Toward Perfection

The question you ask is whether or not the test can do that perfectly, or whether it is unfair to some individuals, whether for example it is fair to one-third of the individuals? The test is not perfect. The employment manager who turns a man down may be more unjust, and generally is more unjust, than the psychological test, because his standards are not well-established. He is using standards that have not been checked. We are using standards that have been checked, and our standards are undoubtedly more reliable than the average employment manager. We hope to achieve this perfection.

It is better to be unjust to a few men than to a whole group of men, and cause death to a little child in the streets. There is enough justification to be unjust to a certain group of potentially safe drivers. It is not perfection, but a start toward perfection.

S. H. HILMES (Yellow Cab & Baggage Co., Omaha, Nebr.): Your men on the streets with your instructors, does one instructor take them through the entire course, or do you go to a certain point with one instructor and then turn him over to the other?

DR. VITELES: Now I will have to make a little confession. I can answer that question definitely in this way: the analysis I reported here occurred in the case of the Mid-Western Electric Railway six or seven years ago, when they started psychological tests of that kind. As a result of my experience, the course of instruction was changed so that a man gets his experience with one instructor for three or four days, long enough to set those habits.

The same thing is true with a street railway with which I am not associated. They have a better-organized school. They keep a man in school with headquarters instructors for four days, but one man stays with one instructor. Every procedure is standardized so that all the instructors are teaching the same procedure.

The taxicab and bus course hasn't been so well organized. The company with which I am connected is not as well organized as it might be.

MR. WOLFE (Travelers Insurance Co.): I was very much interested in what the Doctor had to say on reaction and can see very well where a man seeing the images quickly has a certain reaction, but I can't quite see how callousness is associated with these tests. For instance, you might put a man through the test and show he reacts very promptly, yet he may be very much more callous than a slow thinking man. Of course, I can still see how even a callous man, because of his quick reaction, can avert an accident, yet if he wasn't callous, he might not have been quick enough to avert an accident due to callousness.

A Clever Device for Testing the New Driver

DR. VITELES: This is a very important point. There are two answers to that question. There is a little device for measuring carelessness, but I don't know how it is working. The device is simply this: two little trains running in a track five feet square. The two trains run in separate tracks but the two tracks intersect, at three points. One of these trains moves at a high speed, not under the control of the driver. It moves automatically and every once in a while changes its speed.

The other train is controlled by the driver, and he is instructed to move that train as fast as he can without bumping the other train at intersections and without going off the track. If he goes too fast it will go off the track.

We give him one trial of two minutes. He can drive around about 22 times. The automatic train moves 22 times in two minutes.

We give him a second trial, and say to him, no matter what he did, "You did very well. I want you to try it again, but you made one mistake before, you didn't go fast enough, so I want you to try it again and go just as fast as you can. But remember, no accidents!" In other words, we try to establish the attitude of mind of speeding up in the hope we will distinguish between the careless driver and the reckless one who is willing to take a chance when given an opportunity, and the one who says, "No, I am not going to speed up, because I want to avoid accidents and collisions."

We find one man will react by refusing to speed up and say, "I would rather go slow," and others will quickly drive all over the place.

There is still another answer to the question. The man who is able to drive, who has quick reaction, even though he is careless, is still a better bet than the slow, unreliable fellow who may also be careless.

In the case of taxicab drivers, if we want to know if a man will use good judgment in handling passengers—whether he has a sense of dis-

tance which will help in parking in a small space, whether he uses good, common-sense judgment as a whole, whether he can speak well enough—we use the 30-minute paper test which we find very successful. We find the men tend to leave the job sooner when they make low scores.

MR. WOOD: I know that Doctors of Psychology vary a lot in their opinions on that subject, but I want to give you men the benefit of Dr. Snow's experience in Chicago.

Dr. Snow had three major tests: first, the intelligence test; second, fear reaction test by this mechanical machine; third, what is known as carelessness test.

During the past winter he selected 1,000 men to whom he gave all three of these tests, and he kept a card on these men, that is he kept a record of their accidents. He had on that card the man's name, age, nationality, and whether married or single. He also had on that card the man's score in the intelligence test. He had on there his nerve reaction test, and he had his score in recklessness test.

The Intelligence Test Found of Least Importance

Now strange to say (I don't know whether we ought to make this public; if not, we will strike it out of the proceedings), during the summer Dr. Snow has had two men, graduates of the Philosophy class in Northwestern University, compiling data that have been accumulated over a period of months on these thousand men to determine the merits of this test. Dr. Snow, as well as the rest of us, was very much surprised to find the intelligence test was of the least importance. In other words, a man may fall down completely on the intelligence test, but stand up well under the fear reaction test, and do exceptionally well in the carelessness test, and not have any accidents.

On the other hand, he may have a good score in the intelligence test, but fall down on the fear reaction test and make a poor recklessness test and have a good many accidents.

So in comparing the two, he found the intelligence test was of the least importance in selecting drivers for taxicabs.

For the carelessness test he uses a big block with a metal plate covering it that is raised about a quarter of an inch above the block of wood. Now the plate is cut up into a mass or puzzle. I have tried to work this with my pencil.

At the corners are little brass-headed tacks imbedded in the wood. The applicant can't see them. They are connected electrically to a recording machine something like a stock-ticker that goes off in measures of seconds or a given measure of time.

The applicant is told, as the Doctor said here, that he is to take a metal stylus, or pencil, and he is to start in at the beginning of this puzzle. It is almost apparent how he can get through. He is told that he is to start out and go through that line as rapidly as possible, and that the speed with which he goes through there is going to be one of the important factors as to his efficiency in the test, but, as the Doctor

also mentioned in his test, he is not to have any accidents. Accidents will determine largely his score.

He goes hurriedly through this thing, and the thing to test is whether or not he goes through the corner, so the time between these two points is measured in this instance. If he slows up here and goes very carefully around here, the time interval between the contact with these two metal points would show he was careful in going around this corner. Still on the straight-a-way he would speed up and not slow down until he got to the corner here where eminent danger existed.

That is the carelessness test, and so far he found that to be most valuable. The men who passed this test made a good record with less accidents than any other fellow.

DR. VITELES: May I say a word in connection with the fact psychologists don't agree? This paper test, which I call the intelligence test, is not really a psychological test.

We find it also shows no correlation in the accidents on the part of the drivers. If we were considering accidents alone and had to discard a test, we would throw the paper test out in a minute. It does show beginnings of significant correlation between score and earnings and between score and general fitness. They are very important to the taxicab operator and it is for measurement of these rather than the measurement of the accident tendency of the man, we are using our paper test.

How Shall We Develop the Safe Driving Habits?

J. T. SMITH (Yellow Cab Company, Philadelphia): I think there is one thing we can't overlook. We have our drivers' organizations. Now how are we going to develop these safe-driving habits? Everybody seems to admit that good driving is by habit.

I think everybody that was at Cleveland last year will remember hearing Admiral Simms talk on "Habit Formation," and how he compared that in the Navy with driving contests.

In one of our recent contests we allowed it to run over a period of eight weeks' time, this showing courtesy at crossings, complete control at crossings, signalling intentions. The reason for running it that length of time was to develop habits in a certain percentage of our men. Some wouldn't do it once probably during the entire contest. Other men would be inclined, without knowing it, to develop the spirit of the thing and the habit of automatically slowing down and automatically signalling.

In Philadelphia we have hard-boiled supervision of our operation. We write up a man for fast crossing, too fast for safety, and a man is penalized according to our merit plan. Too fast a crossing is a rate of speed in excess of 15 miles per hour. We have 40 supervisors, 20 on days and 20 on nights. The city is divided into districts with 40 men observing driving at crossings, etc., and the men have to answer the reports made in regard to their driving. It automatically develops that habit of slowing down at crossings.

The community safe-driving school is a factor in helping to develop the habit of better driving.

CHAIRMAN HARMAN: I happened to think of something in connection with my own everyday duty. I am getting ready to start the psychological test of men and this has baffled me.

Andy Waite is one of the old-time cab operators, and I know he will agree with me that the principal cab operator is the man that produces the most revenue. Mr. Henretta will agree with that, too, providing he is normally safe and courteous.

I have two men, one is 45 years old and will weigh 225 pounds, and is about as ignorant as a white man can be. He has been in my service 285 months and has not had an accident. The hardest thing we have to do is to keep him neat in his appearance. He is a slovenly fellow and is slow in movement. He and another young man vie for honors every month in the amount of revenue they collect, and the amount of miles they cover, and the least expense in the operation of their respective vehicles.

Apparent Contradictions in the Statistics

The other man is a young man, possibly 32 or 33, and he has been with me practically the same number of months. He is very bright. Why he is driving a taxicab, I don't know. He is snappy, young and quick.

There are your two extremes; and yet they are the money-producers of our company, having about 320 to 340 drivers. One fellow is nervous and flighty, always in a hurry. You have to watch him in breaking speed laws, and yet he never has an accident, and never does break the speed laws.

DR. VITELES: I am afraid you will get very tired of me before I am through, but I can't help saying something in that connection. I was almost ready to jump on my feet when the chairman said the most important thing was to get revenue, until he added, provided they are safe and courteous.

We made a study in which we compared 25 per cent of the best earners among men hired in 1920 with 25 per cent of the poorest earners. Now we found that the best earners had no more accidents than the poorest earners, and that the poorest earners had no more accidents than the best earners. The fact of accidents seemed to be entirely distinct from the fact of earnings. We found the best earners averaged a few more reports on recklessness than the poor earners, but they had no more accidents.

The hiring of men for the avoidance of accidents isn't tied up definitely with accidents. We find, for example, that by analyzing an application blank and assigning a definite score for each item on the application blank, we will be able to throw out the poor earners. We have checked it up on another group, and it worked successfully. We have made an intensive study, but the accidents and earnings do not conflict at all.

CHAIRMAN HARMAN: Gentlemen, I am afraid we will have to pass on to the next. We are going to be crowded for time, and the three subjects this morning I feel dovetail pretty much. Mr. Truett is the Director of Safety in the city of Baltimore, and he comes to me from the president of our National Association of Taxicab Owners, Mr. W. W. Cloud. I take pleasure in introducing Mr. Truett at this time.

COMMUNITY SAFE DRIVING SCHOOLS

John H. Truett, Director, Baltimore Safety Council, Baltimore, Md.

The preceding paper has treated thoroughly the subject of selection and training of drivers. It is unfortunate, however, that the methods treated in this paper can not, at this time at least, be applied to the individual driver. The value of this selection and training among the owners of commercial and transportation fleets has passed the experimental stage and is now recognized as a necessary fundamental practice leading to safe and efficient operation.

This especially applies to those companies that are public carriers. Their business would be seriously affected if a feeling existed among the public that they could not entrust their lives in these conveyances without a reasonable assurance that they would be carried safely. Therefore, it is not only a humanitarian duty, but also a business duty to have as safe drivers in our fleets as it is possible to select, and then increase and maintain this safety by training and supervision.

We frequently hear the uninformed and reckless observer say that the taxicab or truck drivers are the most careless upon our highways. This opinion is based on hurried observation of isolated cases and in some cases is by persons who possibly have never ridden in a taxicab, much less a truck.

Persons highly trained in a special line often can do things that others could not do without disastrous results, as, for instance, a diver can dive from heights without taking chances that would mean almost certain death for the untrained diver. The worker in a large steel mill must be trained and after training can spend his day working among the many gears and machines with comparative safety. Put an untrained man in his place without guidance or supervision and he is in great danger. This also applies to the experienced chauffeur; what ordinarily would seem to be taking a chance to the uninitiated is not a chance at all. The driver's training has taught him to judge distances and he has, in the majority of cases, a machine that is in perfect operating condition and has it under control. Therefore, we should not be guided by gossip, but facts; and what are the facts? Taxicabs of responsible companies are rarely seen in an accident, especially a bad one.

How then can the individual driver be reached to make him more careful or as well trained as the commercial driver? How can the interest in safe driving be held constant among the commercial drivers who slip occasionally?

The program of local Safety Councils includes a Safe Drivers' School. A stage is created to promote an educational program that could not be created in any other way. Progressive employers know the necessity for occasional talks to their employees. These become stereotyped and lose power if coming from our own organization over a long period. You could not hope to have a man in public life who is interested in accident prevention, or some other good speaker, visit many of the companies and give their employees an inspirational and educational talk. but this can be done in a large group meeting as an activity of the Safety Council, at the same time bringing into this training field as many individual drivers as possible. Such speakers as the head of your Police Department, Traffic Court and other judges, coroners and automobile administrators can talk to your men on such a program and it can not help but broaden the education of drivers as well as give them material for thought in careful driving, as a stimulation to what you, as employers, may be doing.

A Safety Council is a non-sectarian, non-commercial, non-political body, whose objects have no element of controversy, and it can promote a safety program for you that would not be possible of achievement by any other interest or organization.

Just a word of the experience of the Baltimore Safety Council would possibly be of interest.

Safe Drivers' Schools in Baltimore

Five sessions of Safe Drivers' Schools have been held since organization of the Council, under the leadership of Mr. W. W. Cloud, president of our largest taxicab company. These meetings are held at night from 8:00 to 9:30 p. m., usually in a large school auditorium. The program consists of a speaker on some safety subject, technical or mechanical instruction, moving pictures and entertainment. A well balanced program should be about 25 per cent safety and 75 per cent entertainment. Some cities have gone so far as to have boxing matches to secure interest in attendance. Others have used new comedy films and vaudeville acts. Certificates of graduation are issued to those attending a large percentage of the meetings. The Baltimore experience has been as follows:

Number registered in schools..... 6,515

Number of certificates issued..... 2,597

This is an average for each session of 1,300 registrations and 520 certificates issued.

This record is for white schools; separate schools were held for colored drivers, which, of course, were much smaller than the white schools, and the end is that we have reached this number of persons who operate dangerous machines upon our highways with an educational program, the necessity for which is apparent to anyone who uses the streets of our great cities.

The standardized cab companies have gone far in improving driving conditions on our streets and highways, through their careful selection

and training of drivers. The majority of these organizations maintain schools of instruction, first requiring applicants for drivers' positions to pass an examination as to their physical and mental fitness. Some also use psychological tests which help eliminate the hazardous applicant who otherwise might successfully pass.

You, the operators, are more familiar with this than I am, but I understand the practical experience along the lines of several of the large cab operators of Chicago and Philadelphia have satisfactorily reflected the advantages of this highly scientific procedure.

Much has been written and spoken on the subject of engineering methods of handling or treating street and highway traffic problems and the adoption of safety mechanical devices. All of these when properly applied and adopted are helpful, but the consensus of opinion of those who have carefully analyzed and studied the subject is that safety education is essential; without it we are apt to blunder along, paying in costly ways for our experience and in the end accomplishing little.

In this work of education, some of your companies are cooperating splendidly, have affiliated with their local Safety Councils and are prominent in their activities. This is not only helpful in a general and national way, but it brings to the individual company local prestige and a broader conception of the subject of safety.

Let me urge upon you operators not only the great importance of the Safety Council work, particularly as it can be applied to the education of drivers of motor vehicles of all kinds, but also your duty to your local Council which will heartily welcome and sincerely needs your support.

I would like to add that on the program of the local Safety Council in our home city we had quite a bad experience. We analyzed the situation in Baltimore as to fatalities where trucks were responsible in comparison with passenger cars. We found it very high.

We invited all the truck operators to a luncheon in a hotel and put the problem before them. We said, "We would like to prepare some kind of a program," and suggested a program of competitive campaign. We have in that campaign 31 companies who have entered so far, and they represent close to 2,000 trucks.

We started that campaign the first of April, this year, and I am glad to say, gentlemen (whether it is luck or not, we have no yardstick to measure), but we have killed 15 less people in Baltimore this year than last.

Safe Driving Contests in Kansas City

CHAIRMAN HARMAN: Before going on to the next speaker, I see the Director of Safety of our Local Safety Council in Kansas City back there, Mr. Julian Harvey. Mr. Harvey, I would like to have you tell these gentlemen about our experience with this truck proposition in Kansas City.

JULIAN HARVEY (Director, Kansas City Safety Council, Kansas City, Mo.): Giving credit where credit is due, I would like to say that I

stole the idea from Mr. Truett, and we experienced the same results in Kansas City that he has.

We started a contest along this line the first of August and had sixty-odd fleets, representing 2,000 motor vehicles. We are asking for information from these various concerns, which is very easy for them to give. The interesting fact has been the very general and ever increasing interest in this contest on the part of the individual fleet-owners.

To illustrate, a concern in Philadelphia, affiliated with our organization, sent someone into my office to inquire as to the details. They said they had seen the effects of it in an organization which was contesting; the head of that organization told them of that effect, and they wanted to know how they could come in and participate in the contest.

Remarkable Interest Shown in the Safe Drivers' School

I don't care how old we get we always like the spirit of contest, and I believe there is a wonderful opportunity along this line. Within the individual plants we encourage the holding out of some sort of reward to their men for careful driving.

Last month in Kansas City the concern which leads in the contest operated 2,338 truck days without a single accident of any kind. That represented a good many thousand miles.

I think it would be well for you, if you are doing anything of this kind, to see if something can not be done along this line, because it is one of those many things we must do and keep after constantly if we are going to control our accident situation.

CHAIRMAN HARMAN: Mr. Truett, I want to thank you for your most able article on this subject, and assure you we appreciate it.

I am a bit afraid I delved into your subject in a small way day before yesterday in describing some of the methods we have pursued in order to get a larger attendance of public car drivers in Kansas City; and I can say for Mr. Harvey and his organization in Kansas City, they have done wonderful work.

I recall very distinctly three years ago I went to one of the first meetings we had and there were between 500 and 600. I went to our next to the last meeting and the crowd was estimated at between 2,100 and 2,200, so you see how we have grown in Kansas City in getting these drivers to attend these meetings.

I don't think there is a cab operator or a fleet operator that can spend his time to any better advantage than to get his drivers to attend these meetings and to get them interested.

We hold a picnic every year for our drivers and shop men, office men, and everybody and their wives and families. When I got over to this meeting, which was held in the Street Railways Auditorium, I felt I was at one of our own picnics. There were some of my drivers there whom I didn't see how they could have got off to be there, but it had been arranged and they were there with their wives and children and having a general good time. We had a wrestling match one night, and a boxing

match one night, and are getting ready to prepare for entertainment next year.

I am fitting up a gymnasium in our garage to encourage the athletic proposition, to get the drivers enthused so they will go to these drivers' schools with more enthusiasm and do more good.

We will now hear from Mr. Barney Graves, of the Green Cab Company of Cleveland. I know from the standing of the Green Cab Company in that city and from my long acquaintance with this man's boss, that he has something good for us.

STIMULATING AND HOLDING THE INTEREST OF COMMERCIAL DRIVER ORGANIZATIONS IN THE GREATER SAFETY MOVEMENT

Barney Graves, General Manager, The Green Cab Company, Cleveland, O.

The results of any safety campaign for commercial drivers depend very largely upon the general morale and relation of drivers to the company. Before drivers can be expected to cooperate in any campaign for accident prevention, they must be thoroughly sold on the general policies of their company and also on their job. An employer who does not have the confidence of his men will always find it hard to secure their cooperation in avoiding accidents. On the other hand, if the drivers like their work and are interested in the welfare of the company, it is comparatively easy to get worth while results from a safety campaign.

In my experience with cab drivers I have found that any lack of interest shown by them is due largely to their lack of knowledge of the duties of the "present day" cab driver. In other words, many drivers think their only duty is to drive their cab and collect their fares. This class of driver will soon find his job very monotonous. He is on the same plane as the livery driver of the past and, instead of being a modern salesman of transportation, is merely an order taker.

We, of the Green Cab Company, of Cleveland, all realize that our drivers have been responsible for our success and we do not hesitate in telling them so. Instead of our schooling stopping with new drivers when they have passed their examinations and driving tests and are assigned to their cabs, it has only started.

As soon as they start to work, we set up a ledger sheet for each of them and figure their profit or loss weekly. These records are then recapped at the close of the month and posted to a permanent record. This enables us to determine at any time, whether any driver is an asset or liability. His average revenue per mile is taken as the selling price and the previous month's cost per mile as his cost. If he shows a profit for the week which is absorbed by cost of an accident, he is considered a liability to the company.

We then divide the drivers into four groups, based on the amount of profit they made, and their rate of commission is based according to

their profit rating. Each driver who shows a loss is then called into the office, we analyze his case and explain to him the cause of his loss to the company. The two principal causes are "dead mileage" and accidents.

After installing this system of individual driver's records and analyzing each case with the driver, we found that over 50 per cent of the unprofitable ones were showing a profit within a month.

This close personal contact with each of the drivers, whereby you compliment him on his improvement and caution him in his mistakes, certainly gives him more pride in his work and places him in a more susceptible mood for any campaign or work you want to carry out.

Safety Campaign Must Be Well Planned

Before trying to sell drivers on the "Greater Safety Movement," the first great step is to see to it that each and every official and executive of the organization is sold on safety and promises 100 per cent cooperation in selling safety to the drivers. If only the safety director is trying to put it across, he surely has an up-hill pull, for it is impossible to sell anything without first being sold on it yourself. Team work is very important, so if all the officials from the president down want accidents stopped and will pull together and organize a well planned campaign they are bound to get results.

On February 1 of this year the Cleveland Safety Council started a series of monthly meetings for commercial drivers. All companies employing drivers were invited to participate and all of us were more than pleased with the results obtained from them. Mr. Carl Smith of the Cleveland Safety Council certainly deserves a lot of credit for these meetings, for he spared no effort in making every one interesting to the drivers, and the drivers, instead of losing interest, looked forward to them from month to month.

This was due not only to interesting lectures but to well planned programs consisting of good vaudeville acts and prizes given by the different companies to the lucky admission tickets. The opening meeting in February was greatly responsible for the interest shown throughout the season. At this meeting, Dr. Charles Herbert Rust, of Worcester, Mass., gave a wonderful safety talk. His subject was "I Wonder."

There were 160 companies who participated in these meetings with an average attendance of 1,000. The Green Cab Company won first place in attendance and the Cleveland Railway was second. Almost everyone would get a lot more out of this safety work with drivers if they would only put more into it. These schools and meetings require money, and with insurance rates so high there is no better investment for a cab operator than a subscription to safety work.

At the beginning of this series of meetings, we decided to start a safety campaign of our own. We had approximately 500 drivers on our payrolls at this time, so we divided them into eight teams of approximately 63 men each. Each of our drivers has every eighth day off, so the division was made this way, which meant that one team was off every eighth day.

We then called a meeting of all drivers and all executives, starting our meeting with a short entertainment by our company orchestra, and then explained the details of our plans to them. Each team elected a day captain and night captain from among their members. The captain's duties were to supervise the driving of the men on his team and cooperate with the safety director of the company by reporting all cases of careless or reckless driving. Team members were identified by a distinctive button bearing the team number, which was worn on their uniform caps. The captains wore a special button with their team number, so the men could distinguish them.

Cash Prizes Offered

The company set up \$1,000, divided into first and second prizes, \$600 for the winning team and \$400 for the second. The team costing the least amount for all accidents, personal injuries, property damage and collisions, was to receive the difference between cost of accidents and \$600. The second winning team was to receive the difference between the cost of accidents and \$400.

The contest was to last for one month. The winning team was also offered a banquet and theatre party and the second team a theatre party.

At the close of February's contest, there were many drivers on losing teams who had no accidents; so in March it was announced at a drivers' meeting that all drivers who would continue throughout March and April without any accidents, and who were on losing teams, would be given a real surprise and treat by the company. This announcement held the interest of our drivers more than anything we ever did.

Method of Determining Winners

An accident was defined as "any occurrence which requires a report of loss to person or property" and failure to report an accident barred any driver from participating in the reward and also might cause immediate dismissal.

Each week all accident reports, regardless of how slight, were taken by the claim adjuster and assorted against the teams, together with the approximate amounts set up against each team required to settle claims of personal injuries, property damage or damage to our cabs. Even broken windows and dented fenders were charged against the teams. After the standings were determined, they were posted on a conspicuous bulletin board. These were posted at least weekly.

Results of Campaign

The total cost of accidents for the winning team for February was only \$324.59, which included everything from a scratched fender to personal injuries. A banquet was held at the Hotel Cleveland, after which each driver on the team who had no accident received his check. This was followed by a very interesting and complimentary talk by Traffic Judge Skeel. This was followed by a theatre party.

The total reduction of accidents for the first month's contest showed an actual saving of 61 per cent over January, and street conditions were even worse, as we had a sheet of ice on the streets almost the entire month.

The March winners only cost us \$411.95, and April winners, \$302.50.

So much interest was shown during this three months' contest, not only by the drivers, but also by our executives, from President A. F. Waite down to the men on the wash rack, that after the first month's eight of us who were executives of the company, each drew a team and did our best to win the prize.

Three Months Winners

The safety department's records showed that at the end of three months, 132 drivers had not had a single accident. These drivers had covered over 750,000 miles during this period.

We then took this bunch of drivers for a day's outing and dinner at one of Cleveland's prominent road houses, where each was presented with a Green Cab safety button by the company and a white gold signet ring by our insurance company. The boys prize these presents more highly than anything we have done for them.

All the time and money we spent on this campaign certainly proved a good investment for us and was responsible for a decrease in labor turnover.

Profit Sharing the Keynote to Accident Prevention

The climax of creating and holding the interest of commercial drivers was reached in July of this year, when at a special drivers' meeting, Mr. A. F. Waite announced to all the drivers that he had decided to make every man a partner in his business, with the result that now the company is still The Green Cab Company, operated and controlled by the same management, but any time you ride in a Cleveland Green Cab, you are riding with the owner of the cab.

This has resulted not only in cutting accidents approximately 50 per cent below our previous campaign record, but also has given Cleveland the best cab service possible, with much more courteous treatment, and has resulted in the drivers making about three times as much money for themselves.

CHAIRMAN HARMAN: I want to thank Mr. Graves for that most able article.

Has anyone any questions he wants to ask the young man from Cleveland?

J. E. DOBBS (General Necessities Corp., Detroit): I would like to ask him how they arrive at the settlement of the claims, the adjustment of the claim, for instance?

MR. GRAVES: Of course in Cleveland it is compulsory that we carry insurance. We had in mind our future insurance rates as well as our safe driving, and we work very closely with the insurance company. They furnish insurance to adjust these claims, and the policy is to

settle every claim as quickly as possible. With his past experience he is able to estimate.

The same thing holds true in damage to the other fellow's equipment. In case it can't be settled right away, it is only estimated. But at the close of the month, before the final results were posted, I personally went into it with the claim adjuster, going over all the reports of the month.

HARVEY D. WOOD (Yellow Cab Company, Chicago): I would like to introduce this resolution:

Whereas, During the fifteenth Annual Convention of the National Safety Council, the attendance at the Taxicab and Fleet-Owners Sectional Meetings has been greater than at any time in the history of the Section, and

Whereas, It is believed that this increased interest has been largely due to the tireless efforts and personal attentions on the part of the officers of said Section, be it therefore

RESOLVED, That the members in attendance at this Section, now in convention, extend their hearty thanks and deepest appreciation to their retiring chairman, Mr. Dale Harman.

(It was moved, seconded, and carried that the resolution be adopted and made a part of the transactions.)

(The audience arose and applauded.)

A Suggestion to Concentrate Section Meetings

CHAIRMAN HARMAN: I appreciate that very, very much.

I believe most of our larger fleet-operators have had an opportunity to say something within the past three or four days, and I know the cab-operators have. I feel we have dominated this meeting, but this is possibly due largely to the fact that we touch the public a little bit closer than the fleet-owner. We get our money from him, while the fleet-owner does not at all times, at least not directly. I know Armour Company get theirs in a roundabout way, and so does the ice cream man, dairyman, etc.

I would like, before we adjourn, to hear from my friend, Andy Waite, of Cleveland. He didn't get into town until yesterday, and while one of his young men has given us an able paper, I would like to have Andy come up and say a word to us.

I might say that this man has, in my opinion, been batted around more in the taxicab business than any man I know of, and still he is always on top.

A. F. WAITE (Green Cab Company, Cleveland): That is characteristic of the taxicab business, I think.

I haven't a thing to add to this meeting. I think Mr. Graves has presented our situation over there as we had it last winter. We found this close cooperation with our men did a lot of good.

There is one suggestion I would like to make, Mr. Chairman, to be passed on to the management of the Safety Congress. I would suggest

that these sectional meetings, at least this Section, be held all in two days. I believe it could be done. It is almost impossible for a taxicab operator to spend a whole week away from his home town. I was unable to get here until last evening. I wanted very much to be here before.

I think if that were taken up with the higher officials, it could be arranged that we could have this all within two days and we who couldn't spend the whole week would get the benefit of the meeting. I would like to have that passed on.

CHAIRMAN HARMAN: I would like to hear from some of the other members on that subject. I rather agree with Mr. Waite. There are other branches of the council meeting both morning and afternoon, and I believe we could accomplish all our work, and if any member would like to stay three or four days, he would have an opportunity to free-lance and attend other committee meetings in which he might be interested.

HARVEY D. WOOD: I notice Mr. Rawson here, who used to be an officer of the National Safety Council. I would like to hear from him.

An Advantage in Attending General Sessions Also

MR. RAWSON: It was my privilege to have a small part in organizing this Section.

There is no reason in the world why this Section should not have its meetings just exactly the time it wants them; but there is this suggestion which is thrown out to all sectional officers in considering such matters, and that is that the Taxicab Section is probably interested first in its own particular business, and second, in the safety movement.

The Executive Committee recommends that they try to hold their meetings in the mornings, so their delegates may attend the general sessions in the afternoons.

The National Safety Council has two or three sections which are very largely attended. Sometimes they run 400 and 500 in attendance at one session. They have so much business that they meet all day long for three and four days of the week. I am thinking of the Steam Railroad Section. With the exception of those two or three sections, most of the sections try to arrange their meetings in the morning and attend general sessions in the afternoon.

I can appreciate Mr. Waite's point, the difficulty in staying away from a man's business so long, and I imagine it must be particularly hard for some who come from a considerable distance. But if it is possible, I recommend to you the desirability of trying to attend some of the general sessions also, so you may get some of the general pictures in addition to the very important subjects in your own business.

I hope I am not too presumptuous if I say that I feel a great deal of satisfaction in seeing you so well attended and hearing about your excellently arranged program for your meetings here. I know in the beginning we felt that the men in the transportation business were not quite as responsive as we had hoped they would be. It proves, I think, that there is need for the Taxicab and Fleet-Owners Section and it is very worthwhile to have meetings at the Congress.

CHAIRMAN HARMAN: I appreciate your little talk very much, and I want to tell you we are going to keep at this Cab and Fleet Section of the National Safety Council until it is going to be the predominating Section.

In fact, when I go back to this railroad proposition I see two or three old railroaders back in the crowd, and am apt to be one myself. I spent 23 years operating cars on rails, and I don't think they are in with the automobiles that haven't a track or train. Every automobile is covering 100 miles to the individual railroad car's one mile, so we are in the highway. I regret to say that in the Safety Congress the accidents of automobiles are largely in excess of railroads today, and it is for that reason that I think this Section of the National Safety Council should get back of it and get more interest in it, and get these men that are operating automobiles to get as enthused as the group we have here at this time.

Further Ideas Regarding the Section Sessions

MR. HEMMAN: It has been somewhat of a hardship to get away for a whole week to attend this convention, but I feel the time has been well spent.

Perhaps, as you said, the taxicab-operator has a little different contact with the public than the fleet-operator, still we have a lot in common, and I might suggest for the Congress next year that we all come in on the points we are interested in, and perhaps the taxicab-operators can have the first two days of the session and the fleet-owners have the last two days of the session, with the second afternoon or the third morning to take up those points that are of interest to both.

The taxicab men could come in on Monday morning and have their session Monday and Tuesday mornings, Tuesday afternoon the fleet-owners could meet with the taxi men and take up such points as would be of benefit to them.

If I have anything to say about it, we are going to have a lot of fleet-owners here next year.

MR. DOBBS: I think it would be a very good idea if a roster of everybody's name, address and occupation was passed out for every member here, so we could continue this meeting through correspondence instead of dropping it and going home until the next meeting.

I should like to write to Mr. McGuire and another man here who do the same kind of business I do and ask them questions on different points. If I were in the cab business, I would certainly write to Barney Graves and ask for his program.

I think the meeting should always start with a roster as soon as it gets going, so we can get these names in our minds and get better acquainted.

MR. HEMMAN: I would like to second that motion. We have 5,000 vehicles scattered in 48 states in the Union. I would like to get acquainted with the men throughout the country.

CHAIRMAN HARMAN: I think Mr. Hemman's suggestion is very good.

If we meet the first two days of the Congress, it would be all we would need, and the fleet-owners could meet the last two days. Then we could have a roster of every man who registers and those attending could take the names of any men who offer subjects that they would like to correspond about.

Our chairman for next year is here. I am sorry he wasn't able to be in one of these meetings before this one, but am glad to know that Mr. Smith will be able to take advantage of all that. No doubt we will reap the reward next year.

ADJOURNMENT

Textile Section

New Officers of the Section

CHAIRMAN: G. W. COOK

Travelers Insurance Co., Springfield, Mass.

VICE-CHAIRMAN: R. B. SHERMAN

United States Finishing Co., Norwich, Conn.

SECRETARY: HARRY C. WASHBURN

Fisk Rubber Co., New Bedford, Mass.

Committees

MEMBERSHIP: H. W. DONALD, Chairman

American Mutual Liability Ins. Co., Boston, Mass.

STATISTICAL: HARVEY SAUL, Chairman

The United States Finishing Co., Providence, R. I.

POSTER: IGNATIUS MacNULTY, Chairman

American Woolen Company, Andover, Mass.

PROGRAM: DR. GEORGE VAN EMBURGH, JR., Chairman

The Clark Thread Co., Newark, N. J.

PUBLICITY: DR. R. P. KNAPP, Chairman

Cheney Brothers, South Manchester, Conn.

ENGINEERING REPRESENTATIVE: W. H. HEINRICH

The Travelers Insurance Co., Hartford, Conn.

EXECUTIVE COMMITTEE (The Officers and)

BENJAMIN F. GRIFFITH

J. & P. Coats (R. I.), Inc., Pawtucket, R. I.

October 26, 1926

DR. GEORGE H. VAN EMBURGH, JR., Chairman

Medical Director, The Clark Thread Company, Newark, N. J.

THE Textile section convened at 9:20 o'clock in Parlor C. Statler Hotel, Detroit, Michigan, Dr. George H. Van Emburgh, Jr., Medical Director, the Clark Thread Company, Newark, New Jersey, presiding.

CHAIRMAN VAN EMBURGH: The first item on our program is the reports of officers and committees.

Mr. H. C. Washburn, Poster Committee.

**REPORT OF H. C. WASHBURN, CHAIRMAN, THE
POSTER COMMITTEE**

In submitting the report of the Poster Committee, I wish to call attention of members to the fact that the success of any committee must of necessity depend upon the full cooperation of all members of the Section, if favorable results are to be obtained. Form letters were sent out to every member in February soliciting material from which representative bulletins might be made up. Although the committee received many replies the response was not as general as we had anticipated.

In addition to personal letters the entire section was again circularized in May. From the replies received it was very evident that many of the members were experiencing difficulty in obtaining just the type of poster desired pertaining to the particular hazards of their plants. One or two stated that they were undecided as to the feasibility of continuing to order bulletins for use in their mills because of their general, rather pertinent, application, but few suggestions for improvement of the posters were received.

A Poster Committee can have no better source of material than from the Section members themselves, and if each will cooperate fully with the incoming chairman by sending in just one photo, sketch or suggestion, your committee will have material sufficiently diversified to make possible bulletins or posters applicable to all of the various operations in the textile industry.

However, the present committee received and forwarded to the National Safety Council material from which some fourteen posters were made up, samples of which have appeared recently in the NATIONAL SAFETY NEWS at the rate of one monthly, and I am informed that the Council has on hand at the present time material enough for the Textile Section to run several months longer.

CHAIRMAN VAN EMBURGH: I happen to be chairman of the Poster Committee the year before last, and I experienced the same difficulty that Mr. Washburn has met with this year. I met a good deal of lassitude, and when they said "We are not getting the posters we want," I came back at them and said, "Tell us what you do want, and we will try to prepare posters in such a manner as to re-stage the cause of the accident." They were not just exactly sure what they wanted. I hope that next year we can get a better crystallization of what they really do want, so that we can have these accidents, the causes of them, re-staged and published accordingly.

CHAIRMAN VAN EMBURGH: I think that Mr. Douglas and Mr. Lewelyn of the Membership Committee are not here. They have been working very hard this year. We have a number of new members who have come into the fold, and while they have accomplished a great deal in correlating the efforts involved in getting memberships, I think there is still a great deal more work to be done on that, and we will probably continue the next year with the same committee and see if we can not bring that to real productivity.

Are there any further committees?

B. F. GRIFFITH (Pawtucket, R. I.): Mr. Chairman, I would like to say something about the Publicity Committee.

CHAIRMAN VAN EMBURGH: Mr. Griffith is chairman of the Publicity Committee.

REPORT OF B. F. GRIFFITH, CHAIRMAN, PUBLICITY COMMITTEE

Gentlemen, Last year we got out one publicity letter. I was very much disappointed in the information that came to me. As you know, the success of the Membership Committee, the Statistical Committee, and practically all committees of this Section depends largely upon publicity.

I was quite severely hampered in getting out publicity letters, because I could get no information. I would like to recommend at this time that anyone who has one little item of information send it in, for no matter if they think it is of no importance to themselves, it may be of great value to the rest of the Textile Section. I hope that the chairman of the Publicity Committee this coming year will receive copies of letters of all the other committees, know what all the other committees are doing; and when it comes time for him to send out the publicity letter, to get the most effect from the membership from a collection of statistics and from the effect of all other committees, I hope that he will have this information so he can get it out on time and make the publicity letters of real value to the Section.

I think that is a wonderful source of information for the Textile Section. I know that I have plenty of items in the plant I am working for that I can put into publicity letters, but you don't want to write publicity letters all on your own information. You want the ideas of everyone else.

CHAIRMAN VAN EMBURGH: My experience has been that a great many of the people who are working on safety in the textile industry feel that they have done nothing startling or outstanding. I have talked with a great many of them, and asked for their ideas, and they say, "We are going along pretty much the same this year as we did last year and the year before, and we did not do anything unusual or startling. I don't want my name in any bulletins."

We want to know exactly everything that happens with regard to the safety record of their plant, and I never have come away from any other plant without taking with me something of interest, adding something to my experience. If the men and women doing safety work will only send the chairman of the Publicity Committee their thoughts, their records, their accident experience, they will give him something definite to work on.

Where we were scheduled to send out four or five letters this year, we had material for only one. I hope that next year we will come across with some real live matter.

Now, I would like to introduce the first speaker on the program, Mr.

B. F. Griffith, who is the safety director of J. & R. Coates, Incorporated, Pawtucket, R. I. Mr. Griffith has had four or five years of very hard up-hill work in which he has accomplished remarkable results. I have been particularly interested in the work he is doing, interested in seeing the remarkable drop that has occurred in not only his frequency but his severity rates.

THE KEYSTONE OF TEXTILE SAFETY

Benjamin F. Griffith, J. & P. Coates (R. I.), Inc., Pawtucket, R. I.

In the plant of J. & P. Coats (R. I.) Inc., of Pawtucket, R. I., recent and remarkable successes have been attained in a carefully planned safety campaign. This success has resulted in an actual saving to the company and to the employees. Concerns that are about to organize for safety (and those that are already organized) I believe should profit by the experience of others and I shall show what I believe to be the best form of safety organization and how it should be supported.

Textile hazards are less numerous and of a lesser degree than in many other industries. However, a relatively large number of serious accidents occur. It seems to me that textile manufacturers can and will, at a slight cost, prevent fully 75 per cent of all lost-time injuries, as soon as they realize that there is an actual saving.

When considering why accidents should be reduced and how to reduce them, it is well to pass the grim question of pain and suffering, as that we know and deplore, and endeavor to find a way to prevent injury as a sound policy of good business practice. Preventing injuries to industrial employees is a problem not easily solved in a single application of bulletins or speeches; but, as in golf, you must hit the ball and study its course down the fairway or across the green, and the next time you hit show improvement in your game.

Comparing a safety movement to the Roman arch, a foreman stands above as the keystone—on one hand absolutely responsible to the management for the prevention of accidents, while on the other hand the employees look to him for advice, for to them *he is the management*.

In any industry where production is systematically and economically arranged, the slightest break in process, causing spoiled goods, loss of production, etc., is reflected upon the good management of the department. I think I am fully justified in saying, also, that any accidents involving lost time in a department reflect in like fashion upon its management, and if proper instructions and safeguards have been provided by the plant management, then the foreman should be as fully criticized in the latter case as in the first.

In order to prevent injuries to his workers, the foreman must develop public opinion against accidents until carefulness becomes a habit, and he must instill serious interest and enthusiasm in the safety movement. New workers must receive from him thorough instructions in machine operations and general conduct relative to safety. This must be followed up during the new worker's period of training.

In recently reviewing accident causes in the textile industries, I noted a large number of cases that might be directly or indirectly caused by poor housekeeping, which is all too frequently the cause of accidents. I believe that the clean orderly room inspires carefulness on the part of the workers, as all persons have a certain amount of unconscious adaptability which raises or lowers them to the standard of their associates or associations. Good housekeeping is part of the foreman's

— COMPARATIVE DEPARTMENTAL ACCIDENT CHART —

job and if he can maintain his department in good order he not only prevents accidents, but will improve sanitary conditions and further assist in the freer movement of articles in the course of manufacture. Good housekeeping often opens our eyes to improved systems and more economical department control.

The man who advances to a foreman's position has been picked because of his interest in his work, his ability as a leader and his knowledge of processes. He gains his position because, in the judgment of the plant management, he has the equipment for the job. To the plant management, then, he looks for his instructions. The keystone of accident prevention is the foreman, but the responsibility of the management in a safety campaign can not be overestimated. When the plant management says, "Mr. Foreman, accidents must be prevented—it is part of your job," then accident rates will start downward.

Up to this point I have endeavored to show that part of the safety

direction of a plant which applies to the manufacturing organization. Besides the work of the foremen and managers in preventing accidents, there should be a safety committee organization. This organization should be apart from direct manufacturing control and its functions so carefully worked out that there will be a maximum effect from a most economical arrangement. I have found, after developing several forms of committee organizations, that the most satisfactory is one that is so arranged as to accomplish a two-fold purpose:

- First: To carry up from the employees suggestions regarding safety;
- Second: To carry down from the safety supervisor and management proper safety publicity and instructions.

In the individual departments of our plant we have what is known as the "Workers' Safety Committee," composed of representatives from each section. This committee meets with a chairman, who in turn is a member of the safety council. The safety council is composed of the general plant managers, the plant doctor, the head nurse, the employment manager, the workers' committee chairman, and the safety supervisor. Thus you see that every department and every position is represented in the council. This, I find, is the simplest and most economical form of committee organization, applicable, of course, to our industry.

The Safety Engineer Welds the Organization Together

At this point the safety supervisor steps in as a tying band to hold this organization intact and to provide for its smooth and sure functioning. Here we find him as a leader to the workers and an adviser to the management, confident in his convictions and persistent in his work, a man who in justice to himself, to the management and to the workers, does not accept nor try to accept any responsibilities for successes. The position he holds is between the plant management and the workers, and it is in this advisory capacity that the safety supervisor must act.

Foremost amongst the duties of the safety supervisor is the problem of keeping the committees active at all times and not allowing interest to wane. His ability to do this largely depends on his records and the influences he is able to bring to bear.

The records and reports of the safety committees should be carefully compiled. In the first place, the workers' committees should be required to submit reports of their monthly meetings with the safety supervisor. I have found it well to have reports of this type made on a standard form, outlining the procedure of the workers' committee meeting. This report should include such items for consideration as mechanical precaution, employees' interest, suggestions for safeguards, etc. When this is received by the safety supervisor, the meeting of that committee is checked off for the current month on his record book. At the end of each month, the safety supervisor submits to the general

manager a report of those committees that have not made a report, and if the committees have not met they must then give proper reason to the general manager. This assures a regular monthly meeting of each department workers' committee. From such reports the safety supervisor may write off, on individual cards, all safety suggestions. These suggestions should be investigated and the cards kept active until the necessary work is done or the suggestion is rejected.

The safety supervisor should supply the workers' committees with statistics and information for the successful conduct of their meetings and for their drive for fewer accidents amongst the workers. In our plant a condensed copy of the first aid report is forwarded monthly to all committees, showing details regarding accidents, such as:

1. Lost-time cases and causes by departments.
2. Lost time by departments for month.
3. Lost time by departments for current year to date.
4. Frequency and severity rates.
5. Infection cases.

In addition to this, a chart is made up for use at the meeting and for bulletin publication, showing the comparative standing of each department for the current year. This is the chart I have reproduced here and it is of the greatest value in arousing interest in safety, as it is abso-

lutely fair to all. The chart shows the percentage of increase or decrease in lost time for each department. In order to do this, the lost time of each department is taken for two years and a basic severity rate is set for each. The result is that each department sets its own rate, which is indicated in all cases by the zero line. The comparison of departments is on the percentage of increase or decrease in their own previous records. You will readily see that this eliminates the question of varying hazards between departments and any increase in accidents in a particular department can not be laid to increased hazards nor the influence of other departments. It is needless to say that the safety supervisor, in his own interest, does not use any more black ink on these lines than is necessary, as the chart is watched by critical eyes that will correct the slightest error or report the slightest doubt.

Augmenting the work of a safety organization, during the winter months it is well to hold safety meetings at night for foremen, at which accident rates may be discussed and outside speakers brought in to talk on some particular phase of safety. In addition to this, to assure good attendance at such meetings it is well to provide vaudeville entertainment, etc.

The Foreman Is the Key-man in Textile Industry

You will note that I give a chart here which shows a list of our evening meetings, together with the rate of lost hours and compensation payments. In supporting my theory that the foreman is the key-man or "The Keystone of Textile Safety," let me point out the effect upon accidents and compensation after properly converting the foreman group to safety and instructing them. On the chart you will see that after each meeting is held there is a resulting decline in accident rates and payments, and that all drops, although followed by some reaction, are for the greater part continual. Analogous to this, I have also found that the meeting of the workers' safety committee in each department has a direct and immediate result upon their accident rate.

With the establishment of a working safety organization there will result not only a reduction in lost-time accidents, as shown by my third chart, but an increase up to 100 per cent in the number of minor accidents reported. It is interesting to note what causes the latter, and the results. The cause is fundamentally the safety drive to have all accidents treated, as actually no greater number of minor accidents occur, but those that do are treated rather than neglected, and the number reported is therefore greater. The result is a complete reduction of lost-time infection cases, the development of confidence in the first aid department with its corresponding influence on the health of the workers, and lastly, the broader promotion of safety by the nurse through her confidential talks with the workers regarding their injuries. This increase in the minor accidents reported continues for some time until the safety movement reaches its point of saturation.

It has been the opinion of many practicing physicians and even of

those doing part-time industrial work, that a safety movement and health campaign is not wholly beneficial to their practice. On the contrary, I have found that while the plant or clinic physician may lose for himself and others the individual care of many accident cases, and while he may treat many medical cases at an agreed rate, he has not only the greatest opportunity to improve health in the particular plant and assist in the

—FREQUENCY OF MINOR ACCIDENTS—

—SEVERITY OF ACCIDENTS—

safety movement, but further through the increase in good will towards the first aid department he may assist himself and his associate physicians, and be a healthful benefit to the whole locality which that industry represents.

Cooperation by the plant physician is most essential in reducing the periods of lost time. This cooperation may come in many ways, for example, by having the physician give or secure the latest and proper methods of treatment, by his securing X-ray pictures of all doubtful cases, and by his deciding definitely the exact time when patients should return to work. It is often that much lost time in the future is saved by the good judgment of a physician in allowing a little longer rest for the patient. The physician is a professional man, and the employees learn to respect him. To him I shall always look for a good influence among our workers for safety.

With the success of a safety movement always comes a reduction in

compensation payments. Where concerns are self-insured, I have found that many exceptions are taken to the existing compensation laws, in favor of employees, in which more liberal allowances are made or compensation periods unnecessarily extended due to humanitarian ideas on the part of mill managers. In order for a safety campaign to be successful, the compensation laws of any particular state must be followed to the letter. I do not criticize charity gifts or appreciation payments, but these must be separate.

In summarizing textile safety, we return to the foreman as the leader who understands and practices the principles of safety as directed by the management, and a man who is familiar with the general principles of the compensation laws of his state. The reduction of accidents is due, finally, to the foreman's absorption of safety principles and his confidence in the movement. He is the one who is responsible for the production of his machines. He must also be a man who is the foundation of the safety organization, who stays generally in the background, yet he is the greatest safety asset—"The Keystone of Textile Safety."

The Management Must Be Wholeheartedly Sold on Safety

CHAIRMAN VAN EMBURGII: Mr. Griffith has characterized the foreman as the keystone of safety in textile manufacturing. I agree with him absolutely, but it has been my experience that you can not get that keystone to do very much unless you can get the management wholeheartedly sold, 100 per cent, or pretty close to that. I have talked with a number of foremen in industries, and they say, "I have got my job; it is to turn out production and keep the frames all running, keep the workers satisfied, and the management is not bothered very much about safety, and I have got hell enough here now without trying to find any more for myself. If my boss tells me I have to do it, then I will do it, but when you tell me I have to do it, why I have my job right here."

It seems to me that safety in any industry is very much the same as sunshine and light. If you can get the management to radiate safety and enthusiastically get in back of safety and then pass it on down the line to the superintendents or assistant superintendent, and finally down to the foremen, they will realize that if they don't come across and get results, they are going to be talked to; then they will get in back of the safety movement also. But unless you can sell the management, I don't know how you can do very much with or expect very much from the foreman. I have seen a number of meetings of the safety committee or safety council, in which the management sat in, degenerate into a sort of a routine, and everyone who came in was bored. They had their roll call, their reading of accidents, and—"why did this happen?" "Oh, Tom Brown's carelessness. He has been laid off and we won't have any more accidents like that." The cases are run through quickly, and the management says, "Anything further?" "No." Then the meeting is adjourned for one month, and everybody goes out with a sigh of relief, glad that is over with.

It is very unfortunate to find what happens unless the management is whole-heartedly sold on safety. I think that while I can agree absolutely with Mr. Griffith, that the keystone of safety is the foreman, the management, after all, is the big stick back of the whole affair.

There is another factor that Mr. Griffith spoke of that I would like to bring out. He said that they have a system in which the workers hand in suggestions for the improvement of safety in their departments or other departments they may be acquainted with. I would like to know to whom these suggestions are handed, and what is done with the suggestions after they are handed in.

I have known cases in which those suggestions have come into the hands of foremen, and the foremen have said, "If we report a condition of that sort, the superintendent is going to come down on my head. You know darn well that condition should never have existed. Why don't you clean it up? Or why can't you come to me and not put it in writing? If the fire pail is empty, tend to it, but don't turn in a written report. It is going to be a black mark against me and against my department."

Very often those reports are looked upon as personal by the foremen.

Then, I have known dozens of those reports to come through to the management and they say, "Has an accident of this sort ever happened?" "No, I can't remember one in three or four years." Then they say, "Oh, well, that is not likely to happen. We will just table that for a while and let it go."

Balancing Cost Against Accident Possibility

Or again, the question will come up, "How much will it cost to put a guard rail or a hand rail on this particular platform?" The engineer will estimate that it will cost \$5,000 or \$6,000. Then someone will turn around to one of the men who supervises that department and say, "When did you have an accident on that platform?" And he will say, "I can not remember one in five or six years." Then they will say "Oh, we will just let that go."

Workers have said to me, "I have sent through three or four suggestions, and nothing has been done on them. They have never told us whether they got them or why they didn't act on them." I think that where workers hand in suggestions, they are at least entitled to the courtesy of a reply.

That has been one of the things we have carried out in the plant I am associated with. If we believe that the suggestion is a favorable one, the work is commenced, but if we find for some reason that we do not want to act on it, the worker's suggestion is put on the bulletin board with a note right underneath it, telling why, at that particular time, the management does not feel that it is desirable to go ahead with the suggestion outlined.

There is another thing: if we want a reduction in our major accidents,—and by major, we mean all accidents that require losses of time in the shop beyond the season in which the accident has occurred, or one in which there has been some permanent disability—if the major accident

frequency rate and severity rate is to be reduced, we must insist that all accidents be reported immediately after they occur, no matter how slight. There are a number of very interesting phases to it that I have experienced.

When we started that many of the foremen said, "You are sending girls away from their rooms, away from their machines, you are taking 15 or 20 minutes of their time two or three times a week for tiny little scratches that we have never had any trouble with; I have never known a person in my department to have any real trouble with them. Now, they have to go down to the hospital and get it dressed. It has got to be a nuisance. They go on and work just the same. They pull out the sliver and suck the blood out and go ahead and work and it is all right." They say they never have any trouble, but every once in a while we get a severe infection, and those people who are working with them know just as well as we do what a tremendously harmful thing some of these infections can develop into, and what a tremendous compensation advantage it is when they have such a condition as that.

The Point of View is Influenced by Ignorance

I had one foreman say to me, "It seems to me you must waste a lot of bandages and dressings and ointments taking care of these little bits of scratches. It must be costing a good deal to run that first aid department. I wonder whether the company objects to it or not." But when you start having every case reported, your minor accident frequency rate is going to go up, and almost as surely the major accident rate is going to go down.

Now, one of the first things that I saw in our plant when I started it was that the foreman began to have a good deal against him. Perhaps he had, say, six accidents last month; and then, after the rule to report all accidents was put into force (because we had a case which developed infection as the result of failure to report immediately), the foreman began to have 50, 55 and 65 accidents counted against his department. He said, "Here I am helping the doctor, helping the safety work, and it is just boosting the frequency rate in my department. I am not going to be so keen about reporting anything if that is to be the result." So they began to hide cases again.

Then we had to divide it next into minors, sub-majors and majors, and tell the departments that the only cases we would count against them would be the major accidents; so that if they happened to have 150 minor accidents, in their department, it wouldn't be any detriment to them unless they are due to gross neglect or to the fact that a safeguard has been off when we go in there and try to straighten things out. The only ones that count are the major accidents, in which there is actual loss of time or permanent disability. That has done a lot to get the cooperation of the foremen in reporting every single accident immediately.

MR. GRIFFITH: In regard to your question, the matter of getting the

safety suggestions, as reported by the safety committees attended to properly: in our plant the reports of the workers' safety committees come directly to the safety supervisor. He has a card system in which he writes off that suggestion. He takes that card, and if it is for the maintenance department, he has an order for the job if it requires an order. If an order has gone through for the job, it many times requires an estimate. If it has not an estimate, why, it will go through and be approved or not approved.

The safety supervisor, if the order has not gone through the maintenance department, goes directly to the department and says, "Here, you are putting a suggestion in for something that needs to be done, and nothing can be done on that until you put an order in. If you are firmly convinced in your mind that this should be done, the management wants an order put in for it." The order is then put in, and the safety supervisor follows that order through the work department, checking up from time to time, he checks up in the estimate department to find out how it is going, and finally the estimate itself comes to the safety supervisor's department.

Routine in the Decision on Safety Work

He investigates that personally himself, with the order, and the estimate in his hand, to find out if the job, if possible, has been overestimated or if it really should be done. He passes the order back or the estimate back with his recommendations and, of course, this is either rejected or accepted upon the recommendations of all the different men whose hands it has passed through. If it is rejected, the matter is taken up with the safety committee that put in the order or put in the suggestion, and at that time we explain why it has not been accepted, if it has not.

I might say that I attend a great many of the workers' committee meetings, and the last workers' meeting I attended previous to the current month, they put in about six suggestions involving quite a bit of money, and the management asked them if they thought this work should be done. The mill manager was very emphatic in saying that he thought they would save money by doing these things, eventually. He approved of every single order, and when I got back to their next meeting, the work had all been done, greatly to the satisfaction of the committee.

ARTHUR BARLOW (Armstrong Corporation, Pennsylvania): For about 13 years I have been coming to the National Safety Congresses, and trying to see what I could get out of them that would be good for us, but I feel that I have been rather selfish in not trying on some occasion to tell what good we have got, and the results we have accomplished.

The talk this morning has been so closely related to the policy we follow in our factory that it has been inspiring to me to hear how successful you have made it, and it might be inspiring to you to hear how it has been with us.

For 14 years I have been the chairman of the safety committee of our factory, groping as one in the dark how we should get safety across to the workers. We began by forming a safety committee from the foremen's association, and arranging periodical inspections. We have a most enlightened and humane organization back of us. They were the ones to initiate the thing. As time went on, we found that as machinery began to be more and more safeguarded, those problems that seemed to us in our ignorance the only ones that should be tackled—that was guarding the machinery—did not bring about the corresponding reduction in accidents, which might have been expected. There was still something else to get to, and that was the education of the workers to take an interest in themselves.

Eleven Years of Successful Safety Contests

So we started—we are now in the eleventh year—safety competition. It is a very simple thing—we offered money prizes of very little value for the suggestions that were sent in. Our first idea was to offer a yearly prize by awarding points according to merit for the suggestions brought in, and those who had the highest number of points at the end of the year would get a gold medal and about \$25 or \$30. It was not very much, but the results were very, very satisfactory. We began to get quite a lot of suggestions, but the majority were of minor importance. Now, it struck me that we had here the keynote of the whole situation; directly you get a man interested in sending in something that affects his own comfort or safety or his well being, and you take him up and keep faith with him, and try to do the thing that he thinks ought to be done, then you have won a convert.

To make a long story short, for the month of September, out of a personnel of about 2,000 workers, we had 450 suggestions. The majority of those suggestions, I grant you, were of very minor importance, but the far-reaching effect of getting in 450 suggestions from a lot of men shows that you have aroused the intelligent interest of the organization, and they are working for and are interested in their own safety and welfare.

We call our competition the "Safety and efficiency competition"; we coupled that up and we give prizes for the best suggestion on it in each month, whether it relates to safety or efficiency; and if the quality of the efficiency suggestion warrants it, it is handed right to the factory executive for further action and greater attention.

Then, we run every year a first aid class. We are starting in a first aid class now, and we shall have to make some selective system, for we have not the means of teaching them all. We have the class held for one hour on Friday evenings, and the time spent in attending that class is paid for. We have an association of certificated members, many of them with medals and bars from the Red Cross. There is not a minute of the day, from Saturday midnight to the following Saturday midnight,

but there is someone in our factory that has had at least elementary instruction in first aid.

CHAIRMAN VAN EMBURGH: There is one point that Mr. Griffith brought out in his paper that has been of exceeding interest to me. He said that in arousing interest in his safety meetings for the foremen and the management, he had many times at his meetings staged a little vaudeville act or an entertainment of some sort. I happen to have been present at two or three of these meetings, and they were the most interesting things, I think, that I have ever seen in any safety work anywhere. Mr. Griffith knows, apparently, that you can do a lot more with people after you get them in a good humor.

At one of these meetings, he started off with a little entertainment, and the people just sat there at the start, because most of them were a little bit skeptical and wondered what this fellow was trying to put over on them now. They had a little vaudeville, a little cabaret, and after a while everybody got into the best of good humor. Then Mr. Griffith sprung the thing he wanted to get over. He turned around and said to the manager of the plant, "Wouldn't you like to address us?" Well, I watched that man's face, and the expression on it, but he did get up and he made an address. It went over. I think it was a wonderful thing to do. I have tried to copy it a little in my own plant.

Statistics Show at Least One Life Saved

H. L. CATES (Employers Liability Corporation, Boston): I was interested in one thing that Mr. Griffith said, and that was the fact that he had saved at least one life during the past year. I am sure that there is an interesting story behind that statement, and I would like to know just how it was that he accomplished that.

MR. GRIFFITH: I don't want to say how we saved that life. I am basing that expression, we will say, of saving one life and 16 serious disabilities on our previous experience through all the years that we have had statistics in our plant. We have had the rate of one death per year. Whether we have had two deaths one year and gone without an accident the next—we have gone at that rate. Our accident rate of 16 serious disability cases is only based on two years' previous experience, but the death rates we had for a number of years. This last year is the first time since I have been in this organization that we have gone without a death in the plant.

One of the best workers we have in the organization for safety—he is a foreman—was on top of a platform in our dye house, by the overhead pulleys and shafting where we had a platform across for the men to walk on. Some maintenance man had very carelessly left a board at right angles to the main platform. This man came along with his assistant, and he said to his assistant, "Don't step on the end of that plank, because it is a loose plank, you will go down." The next thing we knew, the man himself was down on the floor.

We have a system of getting a report right through to the first aid

department. We have got it on a special telephone line, and we got word to the nurse within about 30 seconds, and she came over there just in time to save him from going out as a result of the shock. He had multiple fractures and bruises, and we rushed him to the first aid department. We spent \$100 on X-ray pictures of that man, and we did everything we possibly could to save his life. The nurse was there in just one minute and approximately 40 seconds after the accident, and she had about 350 yards to cross, to come across the yard. The fact that we were so well organized, of course, assisted us a great deal, and we had a first aid car right by the first aid room.

Commenting on what Dr. Van Emburgh said about our meetings, I held such a meeting no later than Thursday evening. We had some 800 of our employees present. I talked for about 15 minutes, and I had another man talking for about half an hour; but I think that the one thing that impressed the value and importance of safety and got the whole big idea across for the evening was the entertainer we had.

He said that Pat and Mike were in a street car accident, and they were all bruised up and in pretty bad shape, and the claim agent came around and made settlements with them. Then Pat met Mike on the street the next week, and he said, "Well, what did you get out of it?" Mike says, "\$500." He says, "Well, that's funny, I got \$1,000 out of it." Mike said, "You got \$1,000; you were not hurt any worse than I was." "Well," he says, "I will tell you how I got \$1,000 out of it. I got \$500 for myself, and my wife and I were rolling down the bank, and I had the presence of mind to kick her in the face."

CHAIRMAN VAN EMBURGH: If there is no further discussion of Mr. Griffith's paper, we will go on to the next one that we have scheduled by Dr. Glenn W. Cook, the Travelers Insurance Company, Springfield, Mass. Dr. Cook is one of the past chairmen of the Section, and one of the most ardent safety workers in the New England states.

ORGANIZED ACCIDENT PREVENTION IN COTTON MILLS

G. W. Cook, Supervising Engineer, The Travelers Insurance Company, Springfield, Mass.

By organized safety in cotton mills we mean, that in addition to the usual efforts made by the management to prevent accidents, the employees are called upon to cooperate. Safety committees are formed, and they in turn review the accidents in the plant at periodic intervals, and suggest remedies. The safety committees also often make safety inspections of the plant.

A safety inspector is appointed who has entire charge of the safety problem in the plant, and who inspects the plant regularly and investigates all accidents. Various educational activities are carried on, such as bulletin boards, contests, etc., and safety literature distributed. Records are carefully kept of accidents and the entire force is stimulated to reduce accidents.

There are many varieties of safety organizations and many ways of getting the desired results. In any case, accident prevention becomes a plant activity in which the entire plant personnel is enlisted.

A safety engineer inspecting a cotton mill will find the physical hazards and the human element about the same as in any other industry, and consequently the problem appears the same. However, on outlining his plans for organized safety to the management, he will probably be reminded or warned that a cotton mill is different, with the inference that what is done in other industries to prevent accidents is either unnecessary or impractical in the cotton industry. It is necessary, therefore, to know what these real or imaginary differences are before a successful organization can be developed.

Inter-plant Visits Promote Progress in Safety

I called upon a cotton mill superintendent a few years ago and found him very much elated over the fact that he had just visited two other cotton mills in a near by city at the invitation of the managers. I inquired if it was not the custom for cotton mill superintendents to visit other mills and exchange ideas. He informed me emphatically that this was a thing simply not done in the cotton industry. This apparent secrecy in the industry, with the failure to exchange ideas, is a handicap to safety work and is probably the cause of the second handicap—complacency.

The safety engineer will often be met with the remark from cotton mill men, that the cotton industry is not a hazardous industry. This is true if compared with extraordinarily hazardous industries, but the insurance rates paid by the cotton mills indicate that they are about as hazardous as the average industry. What the cotton mill superintendent means to infer by this remark is that there is practically no hazard in the cotton industry, which is untrue, and this selfsatisfied attitude must be overcome if real safety work is to be done.

We know now that through organized accident prevention the cotton mill can reduce accidents in as great a ratio as any other industry, regardless of what the normal ratio of accidents in the cotton industry may be.

The real handicap to safety organization, however, is the type of personnel organization with which the safety engineer has to deal in a cotton mill. The agent, manager, superintendent, or as he is sometimes called, the master, is usually in complete charge of the mill. He is "the whole works." In few other industries is he in so complete control as he is in this one. Under him are foremen, called overseers, who in turn are in complete charge of their rooms or departments, such as carding rooms, spinning rooms, weaving rooms, etc.

The words "Agent," "Master" and "Overseer," are undoubtedly British, and perhaps the organization is patterned after English cotton mill organizations. I do not wish to criticize the system of management in a cotton mill, but merely to point out the handicap it presents to a safety

engineer. The superintendent in the average mill does not have the functional assistants usually found in other industries, such as an assistant in charge of employment, sanitation, fire, etc. In fact, these various duties are either handled by the superintendent, or delegated to the overseers in their own departments. The introduction of a safety inspector, with full charge of safety in the entire mill, is foreign to the system of management, as is the practise of holding committee meetings where the plant problems are discussed.

Organized accident prevention is essentially a cooperative enterprise, and it is doubtful if real safety efficiency has ever been accomplished in a mill in any other way. There is a part for the management, a part for the foremen or overseers and a part for the workmen, and it is difficult to introduce this democratic attitude into any plant which has always been managed by a military or line organization.

Safety committees are looked upon with suspicion, and the first meetings where the overseer and second hand sit in on equal terms are often made somewhat humorous by the absolute silence and tongue-tied attitude of the second hands. The superintendent hesitates to appoint a safety inspector who will go into the various departments and possibly interfere with the affairs or prerogative of the overseer. In turn the superintendent is not in the habit of receiving suggestions or advice from his operatives or mill hands.

The Experience of Three Cotton Mills

However, these difficulties are mostly personal and the result of a long established mental attitude. They can be overcome, have been overcome in specific cotton mills, and safety organizations established successfully in these mills have accomplished really remarkable results.

To demonstrate this, I will quote the experience of three cotton mills, one in Connecticut, one in Rhode Island and one in Massachusetts. In each case, they had been operating the same as the average cotton mill, with the idea, probably, that the cotton industry was not hazardous and therefore safety was not one of its problems. In each case this attitude was overcome and a safety organization established. A safety inspector was appointed who made weekly inspections of the plant. Safety committees were formed who reviewed the accidents in the plant monthly and worked out methods of preventing them. Safety posters and the various paraphernalia of organized safety education were adopted and put into use.

In the case of the Connecticut plant with 200 hands, the following results were obtained. In a six months period following the establishment of the safety organization, the lost time accidents were reduced in number from 15 to nine. The compensation accidents were reduced from 11 to three, and the hours lost due to accidents were reduced from 256 to 62. Since then, this plant, with a thoroughly organized safety organization has actually gone six months with only one compensation accident and 20 days of lost time.

In the case of the Rhode Island plant with 350 hands, the following results were obtained in a period of six months following the perfection of the safety organization. The lost time accidents were reduced from 10 to six, the compensation accidents from four to one, and the days lost due to accidents from 138 to 57. With added experience, this plant has also improved their record and has actually operated 10 months with only one compensation accident, seven lost time accidents, and 64 days lost time due to accidents. I believe that both of these represent striking examples of the value of organized safety work in a cotton mill.

The Massachusetts plant represents, in my opinion, the most cleancut demonstration of the value of organized safety, that I have ever seen.

Dividing the Mill Changes the Management

In December, 1924, a cotton mill employing about 2,000 hands was sold to two parties. The size and arrangement of the buildings were such that the mill could be divided into two equal parts. All the machinery and equipment were divided item by item down to the last waste basket. The help was also divided, nearly all remaining as they were. The overseers and the entire personnel of the management were divided likewise, so that when the division was complete, there were two exactly duplicate plants operating side by side and making the same product.

The first plant we will call Plant "A." This plant continued to operate as before and as the average cotton mill operates, with the usual effort towards safety and with the following results. During the first nine months there were 56 compensation accidents, and 1,294 days lost time due to accidents.

Plant "B" or the other half of this original plant, was purchased by a concern which thoroughly believed in organized safety. The plant was immediately organized for safety, using all the up-to-date methods, with the result that during the same nine months period there were only 14 compensation accidents and 212 days lost time.

In other words, Plant "B" had one-fourth as many accidents as Plant "A" and less than one-sixth as many days lost time. In nine months there were 42 fewer employees injured seriously enough to receive compensation in the plant where safety was organized. This plant, employing 1,200 hands, has since operated for nine months with only four compensation accidents and four months without a lost time accident.

These statistics, I think, answer very clearly the questions first, whether there is an accident problem in the cotton industry; and second, whether organized safety is worth while.

These results can be duplicated in any cotton mill, providing the management realizes that there is an accident problem in the cotton industry and is willing to approach that problem in a democratic way, realizing that it is a problem of the whole plant personnel, a cooperative enterprise, in which the girls on the spinning frames are as interested as is the overseer or the agent.

CHAIRMAN VAN EMBURGH: I think there has been very little of a democratic feeling in the management of the average cotton mill. Perhaps it is inheritance that has caused that; but I know of one large cotton mill employing about 5,000 employees where, up to the time of the organization of the safety committee, there had never been a joint meeting of foremen and superintendents. The attitude always had been to pit one man against another, not to let one superintendent know what the other superintendent was doing, to make the most out of each one of them and make them jealous of each other. When the first big meeting was held, 28 superintendents and assistant superintendents sat in one room, and a discussion was carried on. I happened to be present, and it seemed that everyone in the room was tongue tied for the next 20 minutes. Everyone was afraid to say anything. If one fellow had had experiences that might be of benefit to the others, he was afraid to get up and tell about them, or tell where he had made his mistakes, for fear of the consequences.

Changing the Plan to Hold Department Meetings

MR. GRIFFITH: Getting the men to talk in meetings, I have found very difficult. I have just started an idea that I think will be interesting to everyone here, although it is not new. We have been holding our safety council meetings, composed of our workers' committee, who are foremen or sub-managers in the plant, and I have acted as the president and conducted the meetings. Starting in with our next meeting we will have what we call "department meetings." Our council will sit intact as it is at the present time, and our carding and spinning department sub-manager or manager, will conduct the meeting, and he will give a short talk and tell of the accident hazards in his department. He will bring out all the particular points that he thinks will be interesting to the rest of the departments in the plant. I am sure, after having a little experience in this, that is going to be extremely successful, because when the safety supervisor gets up and talks, the rest of them keep quiet, they don't say a thing. When the general manager or managing director gets up and talks they all keep quiet, but when someone starts talking who is right on the level with the rest of the men, it is a different story. They are willing to come back at him, make comments, and suggestions and criticisms.

IGNATIUS MACNULTY (American Woolen Company, Andover, Mass.): I was much interested in the two papers, particularly Mr. Cook's. The organization he refers to may apply to any kind of a textile mill. He refers to the agent as being a supreme authority. Possibly no other industry has the authority placed in one man like the agent of a mill; but I think he will also recognize that the overseer in a large mill, where the department is very large, has a supreme authority. He is an agent for that particular department, but he is an organization that has not been mentioned today. The officer is not the only foreman. You have an officers' meeting. You have meetings of the help, but there

are two men that come in between them, and sometimes more essential than the overseer, and that is the second hand. He is very often the man that does the hiring and firing and the barking. The overseer does the barking, he is the director, in fact, between the operator and the management, and not always the overseer.

Now, I think it is hardly fair to the overseer that this great responsibility should be charged up to him, when very often it is not so. Theoretically it is so, you will say. But practically, in the ordinary every day work, it is not so. He is far and away above the help. He does not even discharge them; in many cases, he does not even hire them. The second hand does that. He is the manager to the average operative who is hired or fired or barked at, and he only meets the help, and they know the second hand.

There is another gentleman who is also very important, and that is the section hand. I know places where the section hand does the hiring; and where he does not do the hiring, he usually does the firing, and he does the barking for the other two.

Now, who calls meetings of the second hands? And who would take up a section hands' meeting? Nobody does it. I know people who are not a hundred miles from here who tried it. The overseer was not very happy about it. He was not very happy that the second hand would be called in in an advisory capacity; and when it was mentioned that the section hand might be called in and have meetings, and have points of contact, the second hand was not any too happy.

The Second Hand Is an Important Factor

What is the use of fooling ourselves? When you talk organization, you must talk organization either 100 per cent or not talk it at all. You must get more second hands into large plants. I agree with Mr. Cook that in the small plant of 200 to 400 people, these men do not have exclusive power, but you go into mills of 5,000 and 6,000, and sometimes 7,000, and the overseer is very far away from his help, and is by no means the direct contact. If you are going to get contacts established, you have to reach these other two foremen. They are as essentially foremen in the American firm as the overseer is.

The second hand is the essential, practical, every day foreman in an ordinary large plant, and the other fellow has his place. Now, we tried it, and we found a great deal of success in tackling the problem of the second hand and tackling the problem of the section hand, and making contacts.

Now, you notice that your accidents do not get very much less. Tom Jones and Mary Brown are having accidents. Why? Because you have not organized your human contact with the man who comes directly over them; he is not telling them about the machine, but telling them about the job, and how they should do that job, and the hustling that is required.

Now, I am not, understand, blaming anyone. The call of an industrial civilization calls for hustling. If you are an American, you are a hustler.

And it is during that hustling process—not the process of manufacture, but the process of hustling—that your accidents are taking place. You can invent all the guards possible and still have accidents, and you do have accidents in spite of those guards.

Now, you all said this morning that men were tongue tied, and a whole lot of other things were wrong with the safety meeting. Of course, you know the reason why. Each one of the speakers has stated that there is a certain amount of fear on the part of an operative who goes to a meeting, and the boss says, "Why did you bring that down?" "Well, we were told by the foreman." Do you know a boss that is pleased to go to a meeting and find that there have been suggestions made regarding deficiencies that he should have known existed. Of course, you don't.

Details of the Textile Plant Organization

I don't mean by that that the boss will fire me. I know a great many overseers who would not dream of firing anyone who would bring up a suggestion, but the help knows that he would not be pleased about it, so they don't bring it up. The suggestion is weakened at that particular point. Your help is not sold on the problem of safety, because he knows that the organization above him has not been linked up properly and that the section hand is afraid a little of the second hand, and the second hand is afraid of the overseer; and so, between the three, you have not got a complete link set up in your organization to establish an avenue of approach from the operator to the section hand. And then they both go to the overseer. I know cases where an overseer does not even know that his girls have been fired until, through an employment office, he finds that they have been discharged. Then, rather than follow it out with a very efficient employer service, he will not reinstate the girl for a few days or a few weeks, or maybe not at all.

So I just thought, Mr. Chairman, that I would inject in here the question of the overseer not being sufficiently the foreman in the room, that is all; and that we are simply beating at the air when we are taking a perfectly innocent man and saying that he is the key man, when he is not the key man. Some overseers are good fellows and are keymen, but the great mass of the key men are not the overseers, but the men who are subordinate to the overseers.

MR. GRIFFITH: Mr. MacNulty is a friend of mine, but I don't quite want to let him get by with all of that.

In the first place, perhaps I have not made myself clear in the matter of organization. We have no men in our plant that are called overseers, and yet we are a textile organization. Our managers are mill managers, when we speak of managers. Our sub-managers are floor managers, and our foremen are section hands or second hands. That is our crew. I am covering everyone right straight down, and there is a further subdivision of the second hand and the section hand in our plant, from

which these men are first selected for the safety committees, and all of this group sit at the foremen's meeting. In addition to that, I might say that I do know a great many bosses, or a great many men who are in charge of departments, who are mighty glad to bring in suggestions. I might have covered this point in my talk. If you can arrange your organization so that you can get your men to bring in suggestions, I think you have done something that is very remarkable, and I feel that in a way we have accomplished it in our plant.

We have what we call a sanitary inspector. All he does is housekeeping and safety work through the entire plant from morning until night. He reports directly to the safety supervisor, on conditions in the plant. Whether that is due to sanitation, safety or anything that applies to his department, if he sees something that would perhaps improve a system, he reports it to the safety supervisor. The safety supervisor in turn takes that matter up with the plant superintendent, not the managing director or the general manager, but with the plant superintendent. The result is that if the foreman or sub-manager or manager knows this is going on and felt they might get by without having it reported to them, they don't get by very long. Now, they feel that they would like to be the first one to report any condition in that department; and the result is that the bosses are reporting conditions and we are getting a great many of them all the time.

Get Along by Making the Help Like You

MR. COOK: Mr. MacNulty, I think, is pretty near 100 per cent right in his idea, on the key men in industry. The key man in the textile industry, and the key man in any industry is the foreman, or whatever you want to call him, but he must be the man that has direct, visual contact with the workmen; that is, the man that bosses them, and with his own eyes sees what they are doing. When you get a step removed from that, he is not a key man at all.

MR. MILLER (Wamsutta Mills, New Bedford, Mass.): I happen to be an overseer, and I want to say in regard to Mr. MacNulty, as far as my case is concerned, and my fellow overseers of the Wamsutta Mill, he is entirely wrong. I am the boss in my room, and I hire and I fire my own help, and I give my second hand the same privilege, also my third hand, so they will all have the respect of the people that work under them; but if anything is done, they have to report to me immediately, and, of course, I naturally back them up.

Now, in regard to safety, I think the best way to get along with your help is to first make them like you. You have to use diplomacy with them, you have to win their respect, and, naturally, when you do that they are going to work for you and your interests.

A careless girl or a careless boy is the one who has accidents. Now, a careless worker, I don't want them working for me if I know it, and I have got to be around my help to find out these things; I have got to know everything pertaining to my room and my activities at all times,

and I know where I stand. I could not run the department by sitting in my office and cocking my heels and staying in there.

To show you that this has proven pretty successful, Mr. Knight and I went through a year without a lost time accident, a whole year; and I think at the present time Mr. Knight has 250 hands or more, and I have in the neighborhood of 200.

The only way to do is keep at them all the time. It is all very well to go to a safety meeting and then come back in the room and forget it. You might as well not go. It is one of those things that you have to keep out of the rut. If you get into a rut, you are going to lose all you have gained. You have simply got to keep after safety like you do all other branches of your work, remind them of it all the time.

I will take a new girl and I will bring her to a girl and say, "Now, you look out for her, and watch that she does things right." She is instructed by myself, the second hand or third hand, whoever put her to work—but we have these girls looking out for one another. My help is mostly girls, and I had one trouble; I could not seem to stop them from running downstairs from away up on the top floor. The only way I have broken that is to send my second hand ahead when they were going out, or myself, or have a second hand bring up the rear. Well now, they have gotten into the habit of walking down the stairs, and they walk down now whether we are ahead of them or not. Safety grows, it is a habit, and it grows if you gradually drill it into them, but in order to be successful at it, you have to keep at it and keep out of the ruts.

Each Mill Has Its Own Individual Organization

We have safety meetings of the second hands, and we have third hand safety meetings, and we are only too glad if our second hand or third hand goes down with some suggestions. There aren't any of us that aren't big enough down there but that we want to see the credit go where it belongs, and we encourage that giving of suggestions, and we never have any trouble.

THE CHAIRMAN: I think perhaps there may be a little ambiguity, due to the differences in the organizations that exist in some of the mills. I happen to know that in Mr. Griffith's mill, his foreman, due to the type of organization they have, is pretty close to the key man—that is, he approaches very close to being a key man. In other mills, I know that the second hand or section hand is the actual contact man. I think that Mr. Griffith would be perfectly willing to have the interpretation on foremen made a little bit broader to include not only a foreman, but any man or woman who makes the actual contact, whether that person be a second hand or a section hand. That person is the key man, and while organizations like Mr. Griffith's mill and the American Woolen Company's mills, and the Wamsutta Mills may differ a little, I think the interpretation we should put on it is that it is the man that makes actual contact—and whether one person is in charge of his room and

holds the position of overseer or whether another person is in direct contact or not, is something that I would rather not take up here.

The next paper on our list this morning is by Mr. Lewis E. MacBrayne, general manager, Massachusetts Safety Council, Boston, Massachusetts.

HOW UNUSUAL RESULTS WERE ACCOMPLISHED BY A GROUP SAFETY CAMPAIGN

Lewis E. MacBrayne, General Manager, Massachusetts Safety Council, Boston, Mass.

The Massachusetts Safety Council has conducted, during the past few months, two inter-plant contests for accident reduction among industrial groups. One of them was among 11 textile corporations employing a total of 12,584 workers, in the city of New Bedford, Mass. That ancient port, once the center of the American whaling industry, is now famed for its textiles. It has a mill (it is no exaggeration to say) for every whaling vessel that once sailed from its wharves.

It is hardly fair to claim that any unusual results were obtained from this contest, although one corporation in the group had a clean record of no lost time accidents for four out of the six months. It was, however, the first inter-plant contest of a semi-public nature carried on among textile mills; and that fact permits me to observe, for a moment, the attitude of cotton manufacturers on the question of organized safety work. I am desirous of doing so because, in a way, these meeting machines serve as a broadcasting station by which we may reach, through the published proceedings of the Congress, and other agencies of publicity, a much larger audience than is here assembled.

The textile industry, while it is one of the oldest in the United States, is not yet fully sold as to the value of plant safety organization. There are two clearly defined groups of mill managers. One, brought up to view with suspicion anything that is carried into the plant from the outside, considers that its duty to the employees is done when it protects them with insurance. The other, alert to find and correct any item of waste that may enter into the cost of production, is ready to try out methods that have reduced accident costs in other industries, and even to experiment in new ones that may be better adapted to its own industry.

There is a prevailing opinion, on the outside of the textile industry, that the first group is composed of the veteran mill agents and superintendents, many of whom fought their way up from the ranks, and that the second represents the younger generation of mill managers, many of whom are graduates of textile schools. While it is true that the younger mill manager seldom fails to respond to the recommendations of the safety engineer, it is also a fact that some of the most effective safety work has been done in large corporations still under veteran management, and the agent himself has been the motive power behind such effort. So much for that.

It is my observation, reinforced by the experience of safety engineers

who are familiar with the details of textile plants, that there is some relation between successful mill management and good safety work. Usually the factory that is making money on its cloth is also making it on a lower cost of accidents, as represented by the payment of workmen's compensation. It has gone beyond the machine guard part of the problem, and made a study of the human element, which, as we know, is educational rather than mechanical.

No management is really sold on safety, when it limits its effort to guarding machinery. I have heard of one textile plant, employing 1,500 operatives, that has expended \$2,000 on machine guards within the past year, but it has neglected all recommendations relative to the instruction of workmen in personal habits of safety. It has no reduction in its accident experience for the year.

On the other hand, it is noticeable that the mill superintendent who is sold on safety, and looks upon his safety committee as something more than a gesture, puts over his program with 90 per cent of the overseers and second hands. The textile mill superintendent is seldom an office man. He usually spends the better part of the day in the plant. The overseers discover how he stands on most questions.

Returning now to the subject of my paper. We found, in the city of New Bedford, that inviting all the manufacturers to cooperate with us in conducting a friendly contest to reduce lost time accidents did not by any means guarantee that they would do so, even though the idea had the endorsement of all the insurance carriers. A letter, followed by a personal call, merely served to clarify the two groups to which I have referred. One group responded with quick acceptance, and welcomed the opportunity to stimulate the interest in their safety work. The other group declined curtly, and in one case indignantly, to be drawn into such a contest. This was regrettable, for not all of them were having a favorable accident experience.

Newspaper Publicity Was Enlisted to Good Advantage

The 11 corporations that entered were each designated by a key number and were so known to the others in the bulletins that we sent out from time to time during the contest. They reported to our office each month their average number of employees, the number of their accidents, and the days lost. The basis for the contest was their averages for the three months preceding.

To keep up the interest in the campaign we used newspaper publicity. 1,100 copies of a booklet entitled "Textile Mill Hazards," and later held a rally for overseers and second hands in the hall of the New Bedford Textile School. The program upon that occasion included musical numbers by mill workers, an illustrated talk on "Cotton Fibre" by the secretary of the National Association of Cotton Manufacturers, safety motion picture reels, and a round table discussion. The meeting aroused much interest and was reported by the press.

Originally we had proposed to carry on the contest for three months,

but at the end of that period it was unanimously agreed to continue it for another quarter. There were two reasons for this. One was that the safety committees in the several plants were genuinely interested. The second was that one plant, with nearly 1,100 employees, had established a clean record, three months without a lost time accident, and a number of people wanted to know whether it could possibly be done again. At the end of this first quarter only three of the plants had reduced their frequency, but six had lowered their severity.

To make the second quarter more of a sporting proposition, it was agreed that each plant should attempt to beat the average of the six months preceding, which of course included any gain made in the three months just ended. Quite naturally the plant that had made the perfect score found it difficult to better it, but it ended the contest with four clean months out of the six, with an accident frequency of 1.4 per 100 employees per year, and with only 18.7 days lost per 100 employees per year.

Good Records Made in the Contest

The plant winning the second quarter of the contest had more than 2,000 employees, but went 26 days without a lost time accident. Its rating for the three months was 1.1 for accidents and 27.2 for lost days. Another plant finished the contest with a score of 1.8 for accidents and 19 for lost days. There were five corporations in this second lap of the contest that recorded a decrease in both frequency and severity.

It is hardly fair to conclude, as I have observed already, that the contest gave us unusual results in comparison with what the plants had been doing in the way of safety work; but there were, nevertheless, some interesting conclusions. The two plants making the best records for the two three-months periods are both successfully managed. They sell a product widely known. One has a full time safety engineer of exceptional ability, and the other has an agent who has taken a personal pride in developing an effective safety organization within his plant. Both drew inspiration from the National Safety Congress held in Cleveland a year ago, and both have participated in conferences of the Massachusetts Safety Council.

All of which seems to bear out my contention that there is a relation between the well organized, progressive textile plant, and a safety program that gets results. A competent safety organization in these two corporations was merely a part of good management. Winning this or any other contest meant interesting the entire organization in lower accident costs.

Miss Brooks (Managing Secretary Paterson Safety Council): I am managing secretary of the Paterson Safety Council, and we have done a little work in the industry, and we find our most difficult problem to be getting the executives interested in safety work. The foreman is sold. We had a course in foremen's safety work last year that was very successful, but it seems to be very difficult to get his employer actively interested and backing up the safety work in the plant, and they feel that that is the first thing that should be done.

MR. MACBRAYNE: One method that we have to stimulate that is their chances to be on our board of directors of the State Commissioner of Labor and Industry, and he is very deeply interested in the relation of our work to industry. It gives us an unusual point of contact in getting at the state inspectors, and changing their attitude on their duties of inspection. We worked very quietly for three years. We would say to the state inspector, "Your job is not to go into this mill and find fault. It ought to be your job, after visiting 50 or 100 plants, to go to this one that is a little behind." That is, we are trying to sell the state inspectors the idea of passing safety information. Now, once or twice a year we stage a banquet at which some such person as the State Commissioner of Labor and Industry is the toastmaster or speaker, and at that meeting we endeavor to get in certain managers whom we want to sell on the general idea of safety. Usually the toastmaster, if he is not the commissioner, will be the head of some very large plant.

When It Is Plain the Management Influences Safety

Howard Coonley, who is one of the speakers at the banquet tomorrow night, is a member of our organization, and he is head of a very large industry operating in three different states. When Mr. Coonley presides at that meeting, these men who thought it was only a safety engineer's job and did not get very much higher, in a great many cases realize that the whole thing is hand in hand with management. Sometimes they will say, "We know such and such a secretary, they have eliminated all the falls by changing the girls from high heels to low heels." Then he checks up and finds that the secretary of that mill is interested in safety, and he probably is sold on whether he can have as good a plant as this man.

We always find that the big organization, with the management interested, is also holding its own in industry.

MISS BROOKS: May I ask, in those other shops, do they have active safety committees that meet on company time to discuss conditions?

MR. MACBRAYNE: Well, no. Practically all of the mills that entered into this did not have a complete organization. Generally speaking, the mills that would not come in have no organization, and the insurance carrier was very anxious to get them in in order to stimulate the organization. There were different forms of meeting.

CHAIRMAN VAN EMBURGH: I think keeping up interest in safety is one of the real jobs that any man or woman working for safety has got ahead of him.

There is a museum of safety at Jersey City, and the company with which I am associated has on two occasions been invited. We have taken these foremen, overseers, second hands and section hands, or anyone else who would like to come, in 30, 40 or 50 large jitney busses; we give our clerks a supper in the cafeteria free of charge and a little entertainment to fill in the spare time, and then fill the jitney busses

and drive them 10 miles to the city, take them all through the museum, spend a pleasant hour discussing the various features, then come downstairs to the large hall where they have been addressed. I have heard a great many remarks like "Say, that is fine, that's great, why didn't we do that before?" Well, we took them at their word, and we arranged for meetings at 5:00 o'clock, 5:15, but then they said, "Oh, gosh, I don't want to go to that, I have an appointment; if we have any more meetings, let's have them on company time."

We tried it during the noon hour, and found that that did not go very well, because the boys wanted to eat their lunches; they usually eat in about four or five minutes, then they want to play some soccer or the girls want to go upstairs and dance; they would rather do that than listen to any safety talks, so really I have been a little bit up in the air as to what these people do want.

I will say that when we have taken them to the museum, they have been whole-heartedly interested in it, and when we have given them talks on company time, they have paid the best of attention; but when you try to keep them after hours or at the noon hour, they don't like it.

I wonder if Mr. Roach would not like to say a word to us. Mr. Roach is deputy commissioner of labor in the state of New Jersey, and he has been one of the men who has done a great deal to help us with our safety work.

Section Enthusiasm is Observed and Praised

MR. ROACH: I was very much interested to notice the vigor and determination with which the debating is carried on in the Textile Section, quite at variance with some of my experience at some of the other sectional meetings.

It seems to me there should be no trouble where so much enthusiasm abounds on the part of the safety engineer, the overseer and second and third hands to arouse a similar enthusiasm on the part of the safety committees in the various plants in which they are located.

I agree with Mr. MacNulty in a great many of the things he says in regard to the difficulty of making a proper contact with the workmen, and of getting the safety committees and others entrusted with safety work in the plants to criticize plant methods and operations, that perhaps are the inheritance of many, many years in the locality; and I am conscious of this, that no well organized safety movement is worthy of that dignified term unless it has received the approbation and the moral and spiritual support of the plant manager, the chief executive who is, in the final analysis, responsible for everything that takes place in the plant.

Now, if the plant manager has no more than a casual interest in safety and says "Well, all the other plants in the textile industry seem to be doing something along this line, and you boys go ahead and organize and see what you can do"; and does not approach that subject with spirit and determination, I am quite sure, having a job to hold myself, that the men who are on that committee are not going to make any

very critical observations of plant practice within that jurisdiction. It can not be done, and it won't be done; and I tell you, gentlemen, that in many mills with which I have had contact, workmen and subordinate foremen, too, view and regard with a great deal of conscious irony these passionate appeals that are made to them to, "For God's sake work safe," when they are working under surroundings of excessive heat or dust or in uncomfortable work places that should not exist in this modern day of American engineering and industrial plant perfection.

It should not, and it does not exist in well regulated and properly conducted plants, where the plant manager really and honestly believes in the doctrine, "Am I my brother's keeper?" I mean in a decent, intelligent and purely democratic sense, stripped, perhaps, of the sob sister stuff that has more or less brought that kind of an expression into disrepute in these late and rather cynical days. I look with a great deal of interest and a certain amount of conscious state pride on the efforts that they have made in my friend, Van Emburgh's plant, to make the work places not only safe, but comfortable and make them so attractive that people want to stay in that plant; and that can not be done unless the plant manager gets the engineering department together and says, "Boys, what are the state standards on this?" And if you have not state standards of industrial practice to regulate industry, then I would say that whatever state you are in, whether it is in Massachusetts or Rhode Island or Connecticut or New Hampshire, you are living away back in the dark ages.

Develop Intelligent Standards of Practice

The first thing you want to do is to get the engineering department together and develop certain definite, intelligent standards of practice that are available for the direction of plant managers and departments of labor, and that they receive the approval of the American Engineering Standards Committee. Then you may find that instead of spending \$2,000 in the course of a year, it may be necessary, to make that plant right, to spend \$150,000; but if that amount of money is required, why shouldn't it be spent? Improved machines come in, old ones are scrapped, new processes arise that require the erection of new buildings, and new processes of manufacture. The old goes into the scrap-heap, the new comes in, with added production, reduced cost and improved quality in the product. And so it goes on with labor. Labor is production, tremendous production, and some of the more intelligent administrators of industry in our country have really discovered how productive labor can be when it operates under helpful, safe conditions of practice.

That is the message that I would like to leave with the Textile Section. I wish that all our mills in this country were connected with this sectional branch of the National Safety Council. I know that some years ago I was in the south, and I walked into a mill there, a fine, big, wonderful mill, rather crowded with machinery—one of the new types

of mills—and I saw one foreman in there with an air jet, blasting the dust, lint and dirt from the machines. As I was passing by, I spoke to him, and I said, "Well, that seems to me to be a rather rough practice in a place like this, to fill this place all up with dust in here, breathe it yourself and give it to the workers." He said, "Oh, you know, that's all right. It is a fine product here. We use nothing but first class No. 1 Sea Island cotton." That man really and conscientiously believed that that product was not harmful. We do not believe that a place in which they do that is a good place in which to work.

If you want your safety committees to do interested, enthusiastic work in your plant, get the big fellow at the top to come and say, "Here, I am going to be down at that meeting, and I want you fellows to go the limit to make that shop a safe place, irrespective of cost"; and then, when we have discharged the responsibility, we are going to make these factory fellows know that we want cooperation on their part. If you do that, I think you are going to get it.

CHAIRMAN VAN EMBURGH: Is there any further discussion on Mr. MacBrayne's paper, or on anything that Mr. Roach has said?

MR. GRIFFITH: I just want to make one comment on bringing the Commissioner of Labor in various states into it.

I had, you might say, practically sold the foreman on accident prevention. I had not sold the management. I had been told by the foreman that many of the managers say, "Go ahead, do something for safety," but they do not cooperate. I had the Commissioner of Labor of the state of Rhode Island address our managers and sub-managers and foremen, and I had the management of the plant well represented at this meeting. The Commissioner of Labor came there and he talked as the Commissioner of Labor of the state of New Jersey has talked today. He talked to the management of the plant before the foremen; and from that time on we have had very little trouble with the management.

I think that the Commissioner of Labor of any state has the statistics and the figures, and is a very great influence in any state towards the reduction of accidents and in selling the management of any particular plant.

CHAIRMAN VAN EMBURGH: Is there any further discussion? If not, before we adjourn, I will appoint a Nominating Committee.

If Mr. Cook will be good enough to serve as chairman of that committee, I will ask Mr. Harvey Sall and Mr. Griffith to serve with him, and have their report ready for tomorrow.

ADJOURNMENT

WEDNESDAY MORNING SESSION

October 27, 1926

The meeting convened at 9:30 o'clock, Dr. George H. Van Emburgh, Jr., presiding.

CHAIRMAN VAN EMBURGH: There was a report of the Statistical Committee yesterday that was deferred until this morning. I would like to ask Mr. Sherman, as the chairman of that Committee to report this morning.

REPORT OF R. B. SHERMAN, CHAIRMAN, STATISTICAL COMMITTEE

The report of the Statistical Committee, due to the nature of its work, which is very largely routine and clerical, must be brief. The compiling of the statistics, which are sent in by our members, is very properly taken care of by the National Safety Council, and there remains for the committee very little to do but endeavor to get more and more of our members to send in their figures, as the greater the variety of statistics we receive, the more comprehensive story the summary will tell.

An appeal was made this year by special letter to members and also in our *News Letter*, with the result that 32 members sent in their figures, as compared with 21 last year; a gain of 11 members, but still not enough, for out of 110 members of the Textile Section we should have more than 32 reporting.

I shall not attempt in any way to analyze these statistics. This, of course, must be done by each member according to his need and be left to each company to compare the experience of its own plant with that of the industry as a whole. The statement does, however, show a reduction in severity rate from .89 in 1924 to .45 in 1925.

The goal of this committee is to have 100 per cent of the members reporting, and with this goal in mind, our efforts during the coming year will be increased.

CHAIRMAN VAN EMBURGH: Are there any comments on Mr. Sherman's report?

MR. COOK: Although there are only 32 reporting it is interesting to note that the first year we asked for statistics, we had 17, and last year it went up to 32; and it is climbing all the time, and we probably will get a very good cross-section as we go along, of conditions in the textile industry.

CHAIRMAN VAN EMBURGH: I think at first the members of the Textile Section were rather reticent about reporting, for fear that their statistics would become known to other plants; but since we have convinced

them that nothing but a code number is used, they will feel a little more free in reporting their accidents.

The first paper this morning will be upon "Health Problems in the Textile Industry," by Dr. B. T. Knapp.

HEALTH PROBLEMS OF THE TEXTILE INDUSTRY

Dr. B. T. Knapp, Cheney Brothers, South Manchester, Conn.

It may seem from my title that I am conversant with such problems in all the textile industries, but I regret to say that such is not the case. I have acted as physician for Cheney Brothers, silk manufacturers, South Manchester, Connecticut, for the past seven years and this is about the only one of the textiles I have first-hand knowledge of. However, I assume that the health problems in the wool, cotton, jute and hemp industries are much if not quite the same as ours, with the possible exception of the factor of added dampness in some of the operations in the others, notably cotton manufacturing.

With us, the plant medical department is about 11 years old. It started first in a small way in 1914 with a nurse, then a doctor, nurse and clerk shortly afterwards. It has grown until today we have a personnel of 15, including three full-time physicians, three nurses, two laboratory technicians, X-ray technician, two dental hygienists, a physiotherapy technician and three of the clerical staff.

We extend the services of the various departments mentioned to all employees, during working hours, and if required the laboratory service is extended to employees ill at home, and also, of course, the nursing service. The doctors have never attended employees confined to their homes, unless the patient is a compensation case. The dependents of employees are offered the services of the clinical laboratory, X-ray laboratory and nursing service at cost, or below in some cases, but not the services of the physician; for thus we strive to live in amity with the practicing physicians in a town of 22,000 people.

The aims of the medical department are as follows:

- A. Care of all compensation cases.
- B. Examination of all applicants for employment.
- C. The treatment of all cases of ambulatory illness which apply for relief.
- D. Treatment of all out of work accident cases that apply for the same and are not employing an outside physician.
- E. Periodical physical examinations upon request.
- F. Attendance by visiting nurses at the homes of all employees confined there by any physical disability excepting contagious disease. This service is extended to dependents when requested at a small charge.
- G. Dental hygienist service which includes, besides prophylaxis, the taking of X-rays when needed.
- H. The general X-ray service which is routinely used in all compensa-

tion cases when X-ray is indicated, and is further extensively used in the diagnosis of internal diseases. Also it may be used by those injured out of work for the diagnosis of possible bone injury, foreign bodies, etc.

I. A state certified laboratory is equipped to do all tests done in any up-to-date laboratory at present. This laboratory service is also extended to the patient ill at home, in that, when requested by the family physician, the technician is transported to the bedside by the visiting nurse to obtain specimens for whatever tests are required.

J. Refractions of eye by a specialist of all cases whose vision is found to be defective by the Snellen's chart or otherwise.

K. Physiotherapy treatment directed by the physicians and under the administration of a trained technician is given those cases where it seems a necessary adjunct to the other treatment.

L. The furthering of propaganda for the prevention of disease by suitable talk, posters, health hints, etc.

The volume of work may be gauged by the following yearly report:

Total visits	35,265
Total compensation treatments	6,803
Total non-compensation cases	28,466
Total new compensation cases.....	1,228
Total treatments made by doctors in first aid rooms.....	13,169
Total treatments made by first aid workers.....	3,495
Laboratory cases	3,652
General X-rays	1,277
Dental X-rays	561
Employment examinations	1,025
Dental cases	4,152
Total calls made by nurses at home.....	7,263
Total new calls made by nurses at home.....	3,103
Actual nursing treatments.....	2,617
Periodical examinations	60

No natural raw silk is produced in America; therefore it must be imported from Japan, China or Italy, but mostly from Japan. It comes to us either as reeled silk from Japan, China or Italy, or as frisons and imperfect cocoons from China and Japan. In whatever form it comes it must pass through a great many processes before it is ready to ship as finished goods.

About 4,000 employees are necessary to manufacture the output of these mills. Their nationalities represent 16 to 18 nations, of which American born constitute 46 per cent, Irish 18 per cent, Italian nine per cent, Austrian and German six per cent, Swedish five per cent, Polish four per cent, and the balance scattered among Lithuanian, Scotch, English, French, Russian, Swiss, Canadian and a small miscellaneous group. Thirteen per cent are American born of American parentage, 33 per cent are American born of foreign parentage and 54 per cent are foreign born. Ninety-six and one-half per cent can read and write English, and only

two per cent are illiterate or unable to read or write either English or their native language. In the office force, 86 per cent are American born, nine per cent Irish, and the balance of five per cent are scattered among various nationalities with English and Scotch predominating. Of this group 22 per cent are of American birth and parentage, 64 per cent are American born of foreign parentage, and 14 per cent foreign born.

Our work covers a wide range of diversified occupations, numbering 371 in all, without regard to the sub-divisions which occur in many occupations. Some idea of the diversity in work represented within our organization may be obtained from the following list selected at random: weavers, cooks, mechanical engineers, winders, telephone operators, chauffeurs, dressers, chemists, doctors, spinners, locomotive engineers, cravat workers, teamsters, accountants, printers, electricians, engravers, warpers, carpenters, dental hygienists, loomfixers, laborers, clerks, inspectors, mill superintendents, dyers, twistors, painters, librarian, quillers, machinists, etc.

Contact Begun at Time of Employment

The first contact of the medical department with the employee is at the time of employment when every applicant, no matter what his station is to be, is given a physical examination. This examination is necessarily not an exhaustive one, as time does not permit, but every male applicant is required to remove the greater part of his clothing and he is systematically gone over from head to foot in about ten minutes, and by following a routine form it is possible to accomplish this examination in the time stated. With female applicants, examination is confined to the following: head (that is scalp), eyes, nose, throat and ears, neck, upper chest, including heart, the pulse rate and its other characteristics noted. The feet and ankles are examined. If the applicant, either male or female, is over 40 years of age, or if there is any indication, though they be younger, a blood pressure is taken.

Recently we have required routine Wassermann. Any other laboratory work that is indicated is done in our laboratory. The teeth of all applicants are examined by the dental hygienist and usually an appointment is made for a regular prophylaxis every six months or oftener; they are also advised as to needed attention by their dentist.

The applicant is then rated and if turned down for employment is told why, and told if it may be possible to change his rating in the future after needed medical or surgical treatment. All this is recorded on the examination card which is kept with the individual records in our files. We reject for various reasons about four to six per cent of applicants. Those who have objected to the routine physical examination for employment number less than one-half per cent of a total of 25,000 examined since 1916. Our labor turnover at present is about 25 per cent of the working force.

In fitting each applicant to the job he is being hired for we find a valuable aid in the book of hiring specifications, in which there is a photograph of each job, and beside which there is a list of the physical

requirements. Thus at a glance, after our examination, we know whether the applicant will fill the bill. Of course, the employment division also has a copy of the hiring specifications, and the applicant is carefully compared with the requirements before being sent to the medical division for examination. These hiring specifications are gone over from time to time by the plant physicians who visit each job and make suggestions regarding changes in these requirements.

Our next contact with the employee probably comes when he is injured at his work. These cases are handled as far as possible by the company physicians in the medical department. Cases requiring major surgical operations are referred to a consulting surgeon who takes care of them in conjunction with the company physicians. Our compensation cases number only a small proportion of the total cases seen daily. We treat only about one-half as many work accidents as out of work accidents, and the number seen would be still smaller if we did not require every employee injured, no matter how slightly, to be seen by the plant physician. Our redressings as far as possible are done in the first aid dressing rooms, with which each mill is equipped. Two physicians divide the eight mills, visiting them each day between 8 and 10 a.m. During this time they also treat any out of work accident that applies, and also refer any cases of illness that wish to be seen to the medical department.

Accidents Are Promptly Reported to the Foreman

A system requiring each employee injured at work to report his accident to the foreman within 24 hours after it happened, on pain of losing his first week of compensation, greatly aids us in keeping down the severe consequence of neglected injuries. Also our lost-time accidents are reduced by requiring the department head to find a job for the injured man unable to do his regular work. In case of injury to the lower extremity where a man is unable to walk, a car transfers him to and from work. I am indebted to Dr. Van Emburgh for many helpful suggestions regarding the operation of this scheme, which he has had in effect at the Clark Thread Company for some time. We find, as he did, that it is rarely that a man can not be given some work.

Fortunately our injuries in the mill are not as a rule major ones, but as we look after the employees of several public utilities controlled by Cheney Brothers, we do occasionally get some cases of severe accidents from the electrical department, sewer and water departments, and South Manchester R. R. In the industry proper, we do have many injuries of hands and feet, including many fractures, principally the digits, or an operative may have his hand caught in a machine. These as a rule are our most severe mill injuries. The flying shuttle is a potential source of severe injury. Fortunately, thus far, it has only resulted in contusions and puncture wounds, but is capable of great penetration should it strike the eye squarely. However, it seems impossible to so guard these machines so that the shuttle will not occasionally fly out. A laborer lost his eye just before I came away from a piece of steel from his pick.

With our system of prompt attention by a first aid worker—there are two in each mill trained by our doctors—our infections are comparatively few. Subsequent dressings are always directed by a physician, the nurses not being allowed to pass judgment on any case.

Injured employees are paid one-half the regular wage if they lose time, beginning the day of the injury if they belong to the Mutual Benefit Association, plus so much for each dependent child. If not members of the benefit association, compensation does not begin until the end of the first week, as required by the state law, and they receive nothing for dependent children. If they can keep at work and the time of convalescence is short they are paid full wage even though they are not on their regular job. If it is a long convalescence they receive the pay of the job that they are on plus one-half the difference between the regular and modified job rate; that is, the modified job usually means less pay.

Occasional Cases of Dermatitis Are Found

The only cases of occupational illnesses we have to deal with are occasional cases of dermatitis, caused by handling wet silk, usually in skeins. Sometimes a dermatitis arises apparently in susceptible individuals from the dyes also. Of course, we do occasionally have a machine worker who is affected by the oil he comes in contact with.

In all cases I can not help but feel that the individual is somehow peculiarly susceptible. They are usually very stubborn to treat and the first requisite seems to be to take them immediately off the job. Specialists are more or less on the fence regarding many of these cases, as they have declared to me that they are very difficult cases to testify about in court, and I am sure that they feel there is always some susceptibility on the part of the patient.

We may next see the employee for some illness, either an acute cold or intestinal upset, or it may be for some chronic disease that they consult us. We are usually able to do a great deal for these patients in the way of diagnosis, for, with three physicians, we can devote sufficient time to each case so that with our various laboratory facilities we can arrive at a diagnosis before a great while. It is only when the illness may make him a bed patient that we lose contact with him.

We are consulted by the employee for every conceivable type of illness, and I must say this takes the major portion of our time. The acute or subacute transient ambulatory maladies we are usually able to treat successfully in the medical department during working hours, but where we feel a case needs consultation with a specialist, as in some gastro-intestinal ailments or skin condition, or whatnot, we so advise the patient and give him the names of several consultants to choose from. These are usually Hartford men as they are near at hand.

If the patient indicates a desire to see such a specialist we then supply him with a letter to the consultant of his choice which includes a history of his case, the laboratory results, and whatever treatment we may have given him. He is also supplied with any X-rays that may have been

taken. A reply is requested containing the consultant's findings and advice, and whether or not he would like further laboratory work and X-rays. This when received is filed with the patient's medical record. By this cooperation with consultants we are able to keep in contact with the patient and follow his case to its termination. The satisfaction of this is apparent and ends much added interest to our work which would certainly be lacking were we merely allowed to look after compensation cases.

In conjunction with this purely medical side of the work, we run a chest clinic. Here cases that have been seen by the plant physician and are known to have or are suspected of having some respiratory or heart condition, are gotten together once in two weeks and gone over by a consultant in this specialty from Hartford. He comes to our medical department for the morning. He reads their X-rays, advises their treatment and indicates when he would like to see them again. All this is recorded on a special card.

Experience in Combatting Tubercular Cases

Of course, the primary idea in starting such a clinic was to have a check on our tubercular cases. These cases when they are found are advised to take treatment in one of the state sanatoria. In order to facilitate their leaving their work and going away without too great a financial hardship we operate what is known as our Tuberculosis Free Bed Fund. This association supplies the cost of the sanatorium treatment. In addition, if a member, they are paid their regular benefits from the mutual benefit association while away from work. The Tuberculosis Free Bed Fund receives its financial support from voluntary subscriptions from employees. This is taken up at irregular intervals, usually every two or three years as needed. Whatever sum subscribed is duplicated by Cheney Brothers. All employees are entitled to the benefit of this organization whenever necessary. Besides dependents of employees are given its aid if needed.

Our proportion of tubercular cases to all others is relatively small. We seldom have more than four or five cases in the sanatorium at once and not more than 12 to 18 cases in all under treatment or observation. When able to return to work they are taken back and re-examined at regular intervals. It is generally supposed that the incidence of tuberculosis is higher in the textile industries, but such is certainly not the case with us. It runs pretty evenly with the community at large and this is not excessive and, as you all know, has been constantly on the descent for the past ten years. There are eight counties in our state and we are fifth on the list as regards the incidence, there being four counties where it is more frequent than with us. This is rather remarkable when the location of the town is considered, as it is located in a very changeable and somewhat damp climate in the Connecticut River valley.

Before passing on to other problems I would like to mention our attitude toward cases of Lues and Neisserian infection. We do not penalize these cases that apply for treatment by a lay off or release, feeling if

we did so there would probably be many cases in the future which we would know nothing of, and hence we would have a greater menace. We do occasionally ask a man, if his appearance due to Lues is unsightly, to stop work for a short time, but provided he will take treatment and report regularly to us he is given his job back later. We administer our own salvarsan which the state supplies. The state also does all our Wassermanns, and I feel we have pretty good cooperation. In several instances our laboratory has demonstrated the Spirochaete from the initial lesion and these cases, under careful supervision from the plant physician, have been regularly treated with salvarsan, mercury or bismuth until cured.

Our X-ray department is of inestimable benefit to us as we not only use it for our compensation cases where bone injury is suspected or foreign bodies have to be located, but extend the services to employees for out of work accidents. For this a cost charge of the labor plus material is made. Also for diagnosis of disease this service is constantly used. For this no charge is made to employees and cost only to their dependents. Our X-ray technician is a graduate nurse and has developed a very fine technique. We have two X-ray equipments, one for general work and a small Victor unit for dental X-rays. We do nothing as yet therapeutically with X-rays, but hope to some day.

The Laboratory Is an Invaluable Aid

Thus far our dental department merely does prophylaxes. We have never employed a dentist, but I believe we may in time. However, this department renders distinct and valuable service in checking up the teeth of all applicants and doing prophylaxis on workers every six months or oftener. A great many of our troublesome or borderline cases of myositis, and myalgia are traced to focal infection which the dental X-rays disclose.

Speaking of focal infections, not infrequently where the tonsils are found to be the site of disease, and the patient is unable to employ a nose and throat specialist, we have removed their tonsils in the medical department. However, the status of these cases is always studied and no cases that can afford to pay an outside man is done by us. In order not to offend the local nose and throat man we first gained his sanction of this move.

In our laboratory we do all the usual work that is done nowadays including blood chemistry and basal metabolism readings. Such a laboratory is, of course, an invaluable aid to us in diagnosis, particularly when we occasionally have a small epidemic of malaria. For this disease, despite little mention of it in the literature, is still not uncommon in New England. One interesting epidemic our laboratory helped us out on a few years ago was trichinosis, which suddenly made its appearance among several of the Italian workers. In these cases most of them had eaten uncooked pork sausages, which must have been the source, as all the fresh pork inspected was found uninfected. Several of these cases ran a eosinophilia up to 40 or even 55 per cent. They all suffered, with

more or less severity, the gastro-intestinal and muscular symptoms of the disease and in the muscle fibre of one case the trichina was found.

In our eye work, besides the Snellens Test given each applicant at the time of employment, all are again given this test every two or three years, and cases found that need refraction are refracted by an eye specialist who comes to our clinic once a week and in a room fitted for his use these cases are gone over and prescriptions for glasses are given. By an arrangement with the American Optical Company, glasses are furnished slightly above cost. Besides the cases who need refraction, as found by the specialist at the time, he does his Snellens Test for any applicant who needs the same, or any case the plant physician suspects from symptoms as needing it, are also refracted. This work is paid for on a fee basis, so much for each case.

The Periodical Physical Examination Important

In silk manufacturing there are many operations that require close use of the eyes and it is of the utmost importance to the manufacturer that the eyesight be of the best if valuable cloth is not to be spoiled. Also, as can be readily seen, access to such a service very frequently clears up troublesome headaches, stomach trouble, cough, etc. In connection with eyes, the wearing of goggles in some of the hazardous jobs in the machine shop is, of course, the logical preventive measure, but in practice I find it difficult to get machinists to appreciate this fact, and it seems, except in some cases, very difficult to get them actually to do this.

We find our physiotherapy department, which we have had in practice for about two years, a very valuable and necessary adjunct to treatment. In the first place, the operatives, more enlightened nowadays than of old, know of this therapy and inquire for it. In the second place, many of our backs and extremities, both compensated or otherwise, are extremely slow in responding to treatment without it; also some infections, and these do well with the various means at our disposal in the physiotherapy department. Here, we have the usual appliances, deep therapy lamp, diathermy, ultra-violet, air and water cooled, whirlpool baths, etc. The department is in charge of a graduate technician who is also, of course, a masseuse. I feel that the time of convalescence is materially cut down in many of our cases by these means.

The periodical physical examination interests us greatly, and we only wish time permitted us to do it more routinely, as at present we extend it to everyone, but stress it particularly for the executives and foremen. We strive to make it very complete and comprehensive. We routinely X-ray all teeth, do a complete blood count, Wassermann, and a twenty-four hour specimen of urine, and whenever indicated, any other laboratory work, such as a blood chemistry, basal metabolism, quantitative urinalysis, kidney function test, etc. A complete report in the form of a letter is sent each person examined, explaining in simple terms any defects found and the remedy suggested. If a visit to a specialist is indicated, it is suggested in a letter, and a willingness to make appointment is expressed. The time for the next examination is stated and the man

is notified when that time comes. No charge is made for this examination. Many interesting defects have been brought to light, needless to say, and, of course, I know that this has been of extreme value to the worker. Also, it fits in very well with our constant campaign to make people realize the increased frequency and great danger of the so-called diseases of middle life or degenerative diseases.

By posters, health hints on pay envelopes, talks to foremen, etc., we are constantly striving to spread the gospel of preventive medicine. We try to direct them along the right road as to diet. So many of them are seemingly indifferent as to what they eat so long as it only tastes good. They prepare their midday meal very rapidly and eat it equally so, and I can not help but feel that many of our cases of chronic gastritis and worse have their inception here.

Again the question of overweighing in middle life arrests our attention. It is a difficult problem to get these people to realize the necessity of reducing. However, after a talk in which the dangers of overeating and overweight are pointed out we can sometimes get them to heed our advice. We also bend our efforts constantly to get them by exercise, fresh air, proper clothing, ventilation, etc., to build up a resistance to the omnipresent cold which is so costly to both the employee and employer.

There Is No End to This Preventive Work

However, in speaking of preventive work in general I want to stress the point that is known, but not always appreciated, that there is no end to any of this preventive work. It must be kept up continuously—a veritable bombardment of written and spoken advice must be rained on them at all times to keep constantly in their minds the necessity of such personal hygiene, that is, exercise, proper diet, fresh air, proper clothing and sufficient rest.

Much thought is being given now to the problem of old employees. When should they be pensioned, or if their length of service does not permit this, released? In the first place, in order not to have too great a number of elderly employees on the payroll at one time, it would seem wise, in order not to increase such a needless responsibility, to have an age limit beyond which an applicant for employment will not be accepted. Either this or it should be understood if accepted, that no responsibility would be incurred by the industry thereby. This may seem rather heartless, but there is really no reason why an industry should overburden itself with superannuated employees.

As to the old age pension, a man who has reached 70 years and has had 25 years of continuous employment with the company is eligible for a pension. With women, the age is five years less, that is 65 years. In pensions for partial incapacity, a man must be under 70 and over 65 years of age, or a woman under 65 and over 60 years of age; for total incapacity, a man under 65 years of age and over 55 years of age and a woman under 60 and over 50 years of age. In most instances where a pension

is granted for either a partial or total incapacity, 25 years of service is required. However, this requisite is sometimes waived in special cases.

Senescence, as we know, is a relative thing, as is shown by the fact that some reach physical incapacity for employment at 55 or 60 and even less, and occasionally if the required term of service is completed and there are extenuating circumstances, they are pensioned. With others who started with the company when in their teens, their term of service may be in excess even of that required, yet they are only 50 to 55 years of age. Almost invariably these workers wish to continue work. We have men at these ages who have been with Cheney Brothers for from 40 to 45 years who have no idea of requesting a pension now. We have several men over 70 still at work and one nearly 81 recently died. These men are all eligible for a pension, but prefer to work; and I believe it is an excellent thing for them, for how rapidly we age when taken suddenly from our usual work and left with nothing to do but await our end!

That accidents are more numerous among the old employees our records do not show, for the reason, I believe, that being long accustomed to their jobs they handle it with a precision and care not always found in younger men. Of course, whenever there is physical indication for retirement, and this may amount to an actual hazard in leaving them on the job, we recommend a pension.

The Old Age Problem in Industry

So in handling the question of old age in industry it seems to me the rational method is first, not to accept for employment those beyond a certain age. Pension those who are eligible if they wish it or if it seems they are no longer capable of doing their work, and allow the rest to work as long as they are contented, provided there is no hazard.

From my rather sketchy attempt you may gather that the health problems of the textile industry are in the main much the same as they are in all industries. We are constantly confronted with what for the past 15 years, I am glad to see, has come to be regarded as a necessity of striving to keep workers well and on the job; and the logical means to this end seems to be care, first, in the selecting of applicants for employment, placing the proper individual on the job that best suits him. Next, endeavor to keep him safe from accident while on his job by teaching and preaching safety first methods, rendering him immediate and continuous surgical care if he is injured until he is cured, offering the saner methods of treatment for his minor ills that he may speedily recover and have no complications, and interesting and advising him in seeking a diagnosis of his more serious ills, interesting and advising him in how to avoid the insidious diseases of middle life that spell early old age, incapacity and economic disaster. Thus by repeated periodical physical examinations and much emphasis on personal hygiene, together with reference to a suitable specialist when indicated, he may receive rational treatment and not fall into the hands of quacks and charlatans who abound.

Lastly, when he has arrived at the required term of service, study the individual and not his age, and allow those who are able, contented and willing, to work, and those who are not, to retire. And I can state that with all the various intricacies and detail connected with the daily care of the workmen of a plant whose population is 4,000, if you can do the right thing and all of it for each one who consults you, it is a problem in itself; and I can only conjecture how much more of a problem it must be to the physician in those industries which have, in addition to these problems, actual industrial diseases to guard against. Fortunately for us in the textile industry, there are few of these and rarely serious.

Further Discussion of the Dermatitis Problem

CHAIRMAN VAN EMBURGH: Dr. Knapp has mentioned that they have a number of cases of dermatitis or inflammation among workers handling wet silk and coming in contact with dyes. We have exactly the same problem in the manufacture of cotton thread. We find that many of our workers who handle green or red colors, or black colors in hanking, winding or spooling, will probably, after about two to ten days, begin to have little blisterlike formations appear on the hands. During the summer time it is particularly prevalent, and some of them have thought it was poison ivy, but we get it when there is snow on the ground, in the middle of the winter and at all times. There is only one thing to do for it, and that is to take them off the color and put them on white. That is a trade dermatitis for which the state laws holds us absolutely liable.

Whether or not tuberculosis is a prevalent thing in the textile industry is a question that has been discussed a great deal. I personally take exception to anyone that says the textile industry is chock full of tuberculosis. I don't believe it. I have gone into that problem very carefully in the past three or four years, have studied it and never have found a thing to substantiate it. I think the claim has arisen from the fact that in many of the textile industries the processes are attended by the formation of a good deal of dust and lint flying around in the air.

One has heard a good deal about breathing in dust from metals and materials causing tuberculosis. Where they see dust flying around in those departments, they think that must cause tuberculosis. I had the Board of Health in the city of Newark come down on me two years ago, and demand that we completely change one of our departments because a case of tuberculosis developed where there was dust flying around in the air. I looked through the record, and found that it was the first case of tuberculosis in there in 21 years, and I told them that, but the Board of Health said, "Well, it is dusty in there, and dust causes tuberculosis." Now, I will say that the breathing in of dust or the change of climatic conditions does irritate the mucous membrane. We have a great many cases of chronic catarrh. I find chronic catarrh a great deal more prevalent in those who work under dusty conditions than those who do not work under dusty conditions.

We examine all our employees' vision, because in the textile industry, good vision is necessary in order to turn out a good product. I have been amused when I have found people who were doing work where they had to see at a distance of 15 or eighteen inches, whose vision had been tested only as to a distance of 20 feet. We use the Snellen chart, with large letters at the top, and smaller letters as you go toward the bottom; you stand 20 feet away and you are supposed to be able to read with each eye independent of the other at 20 feet. That is called 20-20 or normal vision. That is good vision for far sight, but that is absolutely no guarantee that you will have good vision at 15 or 18 inches. I have seen many of those folks required to get glasses because they could not read at 20 feet, get glasses to use on a job where they have to see at a distance of 15 to 18 inches. Then the inspectors will go through there and see that they are working without glasses, and will say "Well now, unless you wear your glasses we will have to report you to your foreman, and you won't be able to continue to work here." I think that is manifestly unfair.

Little Difficulty in Getting Men to Wear Goggles

We have not had much difficulty in getting our mechanics to wear goggles. Up to a few years ago, we had a great deal of complaint about it. Many of our machinists and mechanics have to wear eye glasses, and when we compel them to wear a plain lens goggle it tilted the eye glass, bringing it too far up and distorting their vision. We had a lot of trouble in that but in the last two or three years we have fitted these people with super armor plate glass, ground to the same specifications as the ordinary eye glass, but there is the protection of the super armor plate. We find that these people not only use their goggles at work but they even use them to read their papers at night, because it saves them the price of a pair of good eye glasses.

DR. KNAPP: Who makes those super armor plate goggles?

CHAIRMAN VAN EMBURGH: The American Optical Company.

I think in most of the textile industries, we employ a very large percentage of female help. The standard of what to do with a pregnant worker is one that I have been very much concerned with. Those girls and women who are married and are working to help keep the home going, when we find that they are pregnant, how long are we going to let them work? We know that there are increased hazards that come with pregnancy. As the weight increases in the front of the body, the tendency is to throw the shoulders back to counterbalance the weight.

Now, those people immediately become an increased hazard from the stumbling point of view. They are not able to see the floor as well as they did before, they are not able to see the steps, they are much more likely to fall. The difference in their posture leads into increased hazards. Where shall we make those people stop work?

I have been interested in reading a number of articles by the Germans in which they say that a pregnant woman ought not to be permitted to

work after six months' pregnancy. I have also been interested in knowing that they say that women who work in the textile industry are particularly prone to miscarriage, and there are two cases cited in the literature in which it is demonstrated that this is the case. Fortunately, neither of these was cited against the company. I would like to know what Dr. Knapp's attitude is on that question of pregnant women in industry.

MR. GRIFFITH: I would like to raise a point in connection with that last remark. I have quite a lot of things that I want to speak about in connection with this talk.

We have had two miscarriage cases in our plant within the last two years. Of course, in one sense it does not make any difference, it is not considered as a compensation case in any way, or the work is not responsible for it. One case was six months and the other was about four, and they came out all right. I don't know whether it has anything to do with the work or not.

Eight Cases of Tuberculosis in Four Years

I also wanted to comment on the tuberculosis question. In our plant we have had eight cases of tuberculosis in four years. Seven of them were aggravated cases, the case had become arrested and they had been aggravated and they were all card room cases, all the seven. The eighth case was a card room case, and we found it was due to bovine tuberculosis. That case developed in a man who was on the farm, and we brought him in the plant and put him in the card room without proper examination at that time, and he threw it off very slowly. All those eight cases were aggravated cases. They had it for some time previous to the time they came in the carding room, and in every single case they had been employed there less than three months, and we were sure that the case was an aggravated case for that reason. They had it in a mild form when they came into the plant, and I have not, in my experience in the textile industry, found a case that you could lay directly to the conditions in the carding room. These are all aggravated cases.

I wanted to ask Dr. Knapp if he has any figures on the relation of old age to accidents?

DR. KNAPP: We have some, I believe, but I have not them with me.

MR. GRIFFITH: I have found that 76 per cent of our major accidents are to employees who have been employed two months or less. Eighty-six per cent of our accidents are to employees who have been employed two years or less. Practically the entire balance of our accidents, except for one or two per cent, are long-time workers, workers who have been there for years.

Why I wanted to speak about this, we have a system in our plant whereby an employee who has worked there a great number of years is entitled to a pension. We always give our pensioners, after they go on pension, a thorough physical examination. Now, we find two things: first,

that the pensioner will go on examination sooner if they are not in good health. They will die sooner, and it is costing us a great deal more to keep them in condition, medical expenses and so forth, and it is costing the company a great deal of replacement. I thought you would be interested to know that we are considering a plan where, after a person has been employed in the plant for 30 years, we start giving him a physical examination every six months, and at that time we take a complete history of what the case is, all the faults and so forth. We are doing this to extend the period of time that that prospective pensioner will be on the job. I am convinced that after looking through our records and finding out how long each person has been on pension after they have been pensioned, we will be able to extend the working life of the worker probably five years more than they are working at the present time. Instead of going on and pensioning at an average of 35 years' employment, we will have them going on pension after an average employment of 40 years. The result will be, we will be keeping a large group of skilled workers on the job; in addition to that, they will be earning more money all the way through and be in better health; and again, we will extend their life line just that much longer.

I would like to ask Dr. Knapp regarding the compensation being reduced for the first week. Is that allowed in the State of Connecticut?

Compensation After the First Week of Disability

DR. KNAPP: The state law only requires compensation to be begun after the first week of disability.

MR. GRIFFITH: Is that ever paid? In the state of Rhode Island after the insured person has been out four weeks, he is entitled to the first week's compensation.

DR. KNAPP: It is never paid in Connecticut. That, of course, is arbitrary with us. If they belong to our mutual benefit association, we pay them from the time they are hurt, but if they don't belong, we begin it as the state law requires, one week from the time they are injured.

MR. GRIFFITH: Well, then, how would you reduce that?

DR. KNAPP: In the first place, it is a means for getting those people to join their mutual benefit association. That is the first step that it accomplishes; and as I say, the first week's compensation, and the compensation which is paid in addition for each child—they lose both if they do not belong to the benefit association. But we do not pay them that first week unless they belong to the benefit association.

MR. GRIFFITH: The most important fact there is to get them to join the mutual benefit association?

DR. KNAPP: Yes, for their own good.

MR. GRIFFITH: Have you any figures on the relation of accidents to health of the worker that is insured? That is, have you ever made any comparisons there?

DR. KNAPP: We never have, and I don't think your statistics would be very convincing, because it is pretty hard to find any individual who

has not something the matter with him physically. In the rare case when you find an individual with nothing the matter with him, considering all minor ailments, and so on, that would be about one in 100,000, I think, conservatively.

MR. GRIFFITH: I just spoke about that, because I have noted cases where accidents have resulted from indigestion, slight dizziness and things of that kind, and I was wondering whether there were any figures on that.

DR. KNAPP: In regard to that, I can say this: I have had two cases that have been working on machinery, and we suddenly discovered that they were epileptics, and we took them off that work and put them on work that was not near machinery at all—much to their disgust, because they said that it was all right, and there was no danger. One man, however, fell one morning in a position near his machine. We had no idea that they were epileptics. One was a man, and one was a woman worker.

Personal Hygiene Influences People's Accidents

MR. GRIFFITH: What relation do you find between personal sanitation and plant sanitation and accidents? Do you find that as your sanitation increases, your accidents decrease?

DR. KNAPP: I have no figures directly bearing on that point. Personal hygiene has a great deal to do with some of these people's accidents. For instance, they come into the mill after they have stayed up half of the night, have danced until midnight and they feel tired and fatigued, not fresh, and they are more liable to have accidents and be careless while they are in that condition.

MR. GRIFFITH: I have had a little experience in watching our first aid room cases. We find not a great many major cases occurring on Monday, but we get a larger number of minor cases on Mondays, especially. We also find that after vacations, if we can get by the Monday and Tuesday after a week's vacation, we are doing mighty well without some serious major accident. I was wondering whether you, perhaps, had had that same experience?

DR. KNAPP: Well, Monday is always our biggest day. I don't think so much from accidents that have occurred within the shop, as from accidents that occur over the week-end, from playing football and things of that sort.

MR. GRIFFITH: Of course, we do not count those in, but we do find that a large number of minor injuries occur in the plant on Mondays.

DR. KNAPP: I think that is natural, because people have got their hands out. You know yourself, if you stop doing a certain thing for two weeks and take it up, you have forgotten some motion, you have forgotten something that you did mechanically when you were doing it right along.

MR. GRIFFITH: Commenting on the eye cases, plants which have routine eye examinations when the employee enters the plant perhaps would not

have as interesting figures as I have. We have examined our examiners all through the plant. We have quite a large number of examiners examining our thread in the different processes. As soon as it leaves the carding and spinning we have examination, and after it leaves the twisting, we have examinations. The result of examining all of those examiners showed that 23 per cent of them had eyes unfit for examination work. I had predicted that we would have a percentage a little lower than this, and I don't know whether I was believed or not. I did it just on a chance, from the experiences of other plants, and I found that we had 23 per cent with poor eyesight.

MR. COOK: I would like to ask Dr. Knapp the size of the personnel who handle his work?

DR. KNAPP: Fifteen in the medical department. We have three doctors, three nurses, two dental hygienes and two laboratory technicians. There are three clerks, a physiotherapy technician, and one x-ray technician—15 in all. It has grown gradually since 1915.

MR. COOK: And that is for how many employees?

DR. KNAPP: It is about 4,000 now. We have been up as high as, I think, 4,800. Of course, there is a store in New York, and we have a force there of about 350, but they are looked after by another physician.

Examination and Rejection of New Employees

CHAIRMAN VAN EMBURGH: In regard to the examination and rejection of new employees, we are taking five and six per cent. We have been able to place a few more than that in our industry, and our rejections are from two or three per cent. That is, two to three per cent are rejected because we feel absolutely that we can not put them out with safety to themselves or to the company.

I think there is a great deal more opposition to physical examination than one might imagine from the expression of opinions at a gathering of this sort. I have been on a committee to promote periodical health examinations among the doctors, and a great many of the medical men themselves do not believe in it.

There is no uniformity of feeling in favor of examination of new employees or periodical examination of old employees. I think it is a thing that we are going to come to, and I think the thing that is going to drive us to it the surest, is the fact that many of the industrial diseases are being made compensable—lead poisoning, mercury poisoning, benzol poisoning—there are seven industrial diseases in the state of New Jersey that are compensable. Now, most of those diseases do not develop rapidly as the trade dermatitis of the hand, due to dye, but they are diseases of long accumulation in which the person usually is exposed to the hazard for months or perhaps years before definite symptoms of the disease develops. Many of these people will wander from one plant to another. Perhaps three or four months after he comes to work for my concern, he develops a typical lead condition. We are going to be entirely responsible for that man's condition as it exists at

the time of the disability beginning. How much part we have played in the causation of his disease we are unable to say, but I should say very little; that most of this was coming from the place where he had been previously employed, and then accumulating the poison for a number of years. However, we are going to pay fully for it.

Now, there are a number of things that will show whether or not that man has intoxication with lead or with mercury, and those are signs that a doctor is going to be able to pick up.

When these diseases that are developed in industry, are made compensable, industry is going to find it necessary to protect itself by a lot more careful physical examination of employees at the time of their entrance into employment.

Rejections Are Influenced by Compensation Board Decisions

DR. KNAPP: While what Dr. Van Emburgh has said is so fresh in your minds, I want to say that one reason why our number of rejections has gone up is the peculiar decisions that are rendered by the Compensation Board, particularly in our state, but I guess in all states. You must remember that employees nowadays have been compensated for diabetes and tuberculosis and chronic nephritis that they have had independent of the work they have done. Nevertheless, it has been decided that they are compensation cases.

That is why our rate of rejections has gone up from four to six per cent.

As an illustration of some of the decisions that are rendered now, a man was compensated for who was killed on his way to his home from work. He did not take the regular railroad crossing to go to his home, but he took a short cut and a train ran him down and killed him. The Compensation Board declared that this man was striving to help his employer by taking that short cut home, in that he was getting home quicker so that he could get back quicker and be less tired.

Answering Dr. Van Emburgh's question about pregnancy, in the first place we make it a point when females are employed, to ask all married women if they are pregnant. As far as I know, we have never had a case of an abortion in the plant that is traceable directly to their work. I do not say that such cases have not happened, but they have not been traced to that. We urge them to stop work when they are six months pregnant, and we insist on their stopping work six weeks prior to the expected delivery of the child. As far as I know, that works out pretty well.

As regards the tuberculosis question, I will say that our cases of tuberculosis, strange as it may seem, have not occurred in the dusty occupations or in the damp occupations. One point that stands out in a survey of our mill is the fact that the highest percentage of health is reached in our dye house, which is probably the wettest and dampest and steamiest room in the whole mill. There are two factors that enter into that, however, and one is the fact that they are

all male employees there, and a pretty rugged type of individual is required for this work. It is handling wet yarn; yet there is no tuberculosis there that I know of.

Most of the tuberculosis cases we have had were in the weaving rooms. That is, in either the weaving of the broad goods or the silk, or the velvet weaving. It is not a dusty occupation, it is not a damp occupation, certainly; and yet, in the dressing rooms, where there is more dust, where there is this organic dust of the cocoons when they are opened, and gum and so forth, we don't have a great deal of tuberculosis there. But, as Dr. Van Emburgh said, I fail to see that the claim that textiles are chock full of tuberculosis can be substantiated. We have all the tuberculosis we want, but we do not have all that you might expect.

As regards the eye examination, I neglected to say that it is just as important that they be required for near vision as for far vision. When an applicant comes for employment, his vision is examined at 14 and 18 inches, and also at 20 feet, and he is not accepted unless he passes both satisfactorily.

In regard to objecting to examinations, Dr. Van Emburgh is exactly right. I know of a doctor himself who objected to examination. This doctor was going to be employed. It was by a rolling mill out in Ohio, and he objected to a physical examination; but the doctor went ahead and gave it to him, it was found that he was deaf. The point that is brought out by some physicians—that the periodic examination is not the thing to do, that it cuts down their practice—that is absolutely false, because as the Health Institute has shown, if you examine a worker frequently, he is going to go to his doctor for small ills, for things that he would not otherwise go to him for.

CHAIRMAN: The next speaker on our program this morning is Mr. J. M. Sandel, Director, Bureau of Safety Standards, Pennsylvania Department of Labor and Industry, Harrisburg, Pennsylvania.

PREVENTING ACCIDENTS FROM FLYING SHUTTLES

J. M. Sandel, Director, Bureau of Industrial Standards, Pennsylvania Department of Labor and Industry, Harrisburg, Pa.

An accident hazard in one of our oldest basic industries—a hazard that has been with the industry ever since power was used—has been successfully overcome. Most of the clothing we wear has been woven and wherever weaving is done a flying shuttle is employed. Everybody who has been in a textile mill realizes that the shuttles do fly from the looms, but the problem of guarding them had not received as much attention as other safety problems have.

It has been customary to erect a "target" or barrier opposite the end of the reed cap of the looms so that, should a shuttle fly, it would strike the target. Such a guard had been installed on many looms and the scars on this barrier tell of its effectiveness. Sometimes, however,

the shuttle will miss this barrier and strike a weaver of another machine. The effectiveness of such a guard was questionable because shuttles fly from the looms for a variety of causes, and the barrier has been improved by experiments and constant study until we now have a number of different types, with essentially the same features, for all kinds of looms except carpet looms.

Probably the first question that should be answered in connection with this subject, is whether or not it is necessary to provide guards for shuttles. The accident records over a period of time will conclusively show this necessity. A summary of 64 accidents due to flying shuttles which occurred in the state of Pennsylvania during the year 1924 shows the following:

Part of Body Injured	Number of Accidents
Head	2
Face or Cheek	8
Temple	3
Nose	5
Mouth or Jaw	3
Eye, or near the Eye	5
Neck	1
Ear	2
Hand or Fingers	15
Arm, Elbow or Shoulder	10
Chest	1
Sides or Back of Body	5
Foot or Ankle	4

These are not all of the accidents that occurred in Pennsylvania from this cause during the year and the other accidents did not cause the amount of lost time that those given above resulted in. It is easily conceivable that there were many other times when the shuttles flew from the looms and did not injure a person.

The accident records caused the Department of Labor and Industry to require that shuttle guards be applied on all looms. At the time of that decision, there were very few commercial guards available and the textile industry of Pennsylvania felt that they could do better than the commercial guard manufacturer and offered to get busy with experimental work to develop guards.

The results obtained by the industry are far and away ahead of what a commercial manufacturer would be able to secure and the work of installing the guards has widely progressed in looms all over the state, with the exception of carpet looms which are a special problem.

There is very little difference between the guards developed for silk, cotton, wool, and tapestry looms where one shuttle operates. The principal thought is that the guard is attached to the reed cap and extends the entire length of the reed cap over the shuttle and should the shuttle

fly upward and outward, the guard is designed to trap it and throw it into the box at the end of the loom. Shuttle guards for the plush looms are a slightly different problem since two shuttles are used and the spread between the different parts of the weave is much greater, but this has been successfully overcome.

Slide No. 1

The experimental work in developing the guards brought out all of the problems that would be encountered in any safety work. Production must be secured with the least amount of interference. There is no question but that the guard was a handicap to the weaver as he had been accustomed to working without one, but with a little practice the guard could be used. Material selected should be strong and sub-

Slide No. 2

stantial enough to stand a blow from a shuttle without parts breaking which will fall into the weave. It must be securely attached to the reed cap and not be dislodged in time by the vibration of the machine. Lastly it must enable the weaver to work at his weave when the loom is stopped.

The hardest problem was to secure the cooperation of the weavers. Many of them who were approached were aware that shuttles will fly, but even so it was a long time before they gave their cooperation heartily. Most weavers are paid on a piece work basis and they had their minds on their earnings when the problem was presented to them.

The guards have been installed in Pennsylvania long enough, by this time, so that we know what particular designs and features have

been found to be reliable; for example, attaching brackets and parts to the reed cap with screws is not satisfactory; through bolts must be used. Castings must be made of malleable iron instead of grey iron and rods over the weave which trap the shuttle must be steel rods at least one-quarter inch in diameter and riveted or welded to

Slide No. 3

the brackets. The space between the rods and the reed cap and the rods themselves should be less than the thickness of the shuttle used.

Slide No. 1

This is an improvement of the first design of shuttle guard that was approved by the Department of Labor and Industry. The rods can be moved back until they are flat against the reed cap when the loom is

Slide No. 4

stopped and weaver is working at the weave. The first forward motion of the reed cap brings the rods in position where they will protect should a shuttle fly.

Slide No. 2

This guard consists of steel rods bent to the shape that will give the protection and attached to the reed cap with through bolts. The rods do not meet in the center owing to the location of the filling fork of the loom.

Slide No. 3

This is also a stationary guard attached to the reed cap with malleable iron brackets. It consists of two rods and the rods are welded to the

brackets. The ends of the rods are turned down to deflect the shuttle to the box.

Slide No. 4

This is another guard approved by the department which enables the rods to be moved out of the way when working at the weave. Even in the other movable types, the first forward motion of the reed cap brings the rods in the protecting position.

CHAIRMAN VAN EMBURGH: Mr. Sandel's talk and illustrations of a way of preventing these projectile shuttles from getting out and injuring our employees is very well worth while. Up until this morning, I did not realize that there had been a guard perfected that would work as well as Mr. Sandel has indicated. Of course, we are going to have opposition on the part of many of our old employees to a guard of any type. Each of them sees an accident of that sort so seldom that he feels they are very unusual, but when you take the sum total of the experience of the industry or a set of industries in a state, we find it very considerable, as Mr. Sandel has indicated.

DR. KNAPP: I would like to ask two or three questions. In the first place, if the better guard he has pointed out is fool-proof, if it prevents virtually every shuttle from flying out? Also if he knows of any fatalities that have resulted from these flying shuttles? And if you don't think that the speeding up of production has increased the number of flying shuttles—that is, the speeding up of the looms for increased bonuses has not increased the number of flying shuttles? The faster a shuttle goes, the more apt it is to fly out.

Increasing the Speed Increases the Danger

MR. SANDEL: With the increase of speed there is, of course, an increased opportunity for flying out. Your warp does not lay so well on the race, and that is the place where we feel that the shuttle is deflected more than any other. We found one or two instances where the part of the loom that travels forward was not just right, and that the shuttle would fly out of the race, because both sides were not just uniform. But as to their being fool-proof, we can not say that what we have is perfect, but we feel that we are approaching something that is close to being perfect, and that we are past the experimental stage, and at a point where we really have something.

DR. KNAPP: Do you know of any fatalities from flying shuttles?

MR. SANDEL: None.

DR. KNAPP: I can easily conceive of a flying shuttle striking a man in the eye and giving him meningitis, and causing his death.

MR. WASHBURN: This is a subject that is somewhat of interest to me, from the fact that during the past few months we have been having a number of accidents in our plant, or rather in one of our three plants, due to the flying shuttle hazard. In investigating those accidents and coming in contact with those looms more than I had in the past, I got into position where I was almost tempted to keep away from the loom,

because they graphically demonstrated to me with what force one of those shuttles came out of the loom, and in this particular case they fixed the loom so that the shuttle would come out in spite of the guard which was on it at that time. Because of the fact that our work is on heavy material entirely, in fact, coarse weaving, that shuttle came out of the loom and was shot, catapulted, you might say, for a distance of fully 30 feet.

We have had a number of minor accidents due to glancing blows of those shuttles but I do know of cases in a radius of 50 miles from our plant where more serious accidents have occurred. In fact, in the next city to us only a month or six weeks ago, a smaller shuttle came out, struck a girl under the eye with such force that it forced the eye out of its socket, and it was necessary to remove the eye entirely.

Other Experience With the Flying Shuttle

These accidents caused me to make a special effort to see if I could not find out what improvements had been made in the present type of shuttle guard, and I got in correspondence with a number of different people relative to the matter. But I did not seem to find any marked improvement on the present type of guard. So we went to work on the matter in our own plant. The guards that we had on did not differ very much from what have been shown on the screen today, except possibly that they were not made of heavy enough material. But we have now improved the guard, in fact, made a new guard entirely, more substantial, bringing it closer down towards the warp, and have tested it out under all circumstances, so that we have practically come to the conclusion that it is fool-proof. The shuttle can not come out of the loom; they have tried it in every way, shape and condition; and we feel so confident about it now, that we are going to install it on every one of our looms.

It does not differ very much from any of these guards already shown on the screen, except that it has been extended somewhat, made more substantial, attached by bolts such as Mr. Sandel shows inside of the guards, and has been brought down nearer to the warp.

The weavers are very eager that they be put on the looms.

I would like to ask Mr. Sandel how low those guards came in the reed cap, how close to the warp, the lower end?

MR. SANDEL: That, of course, depends upon the size of shuttle you are using and the distance of the motion of your reed. We have to have the guards so placed that when the reed is in its farthest forward position, the bottom rod will be lower than the thickness of the shuttle, and if we pitch them forward on a slant from the reed cap, we feel that any tendency of the shuttle to leave the race as it goes across will be caught by the fact that the lowest rod is in that position.

MR. WASHBURN: Well, will there be no tendency to depress the warp and the shuttle, to get it underneath that guard if it was not down pretty close?

MR. SANDEL: I do not feel that we have encountered that at all. If there should be, the force of the shuttle would be somewhat arrested.

MR. WASHBURN: The shuttle does not always come out of the end of the guard.

MR. SANDEL: Oh, no, far from it. That is one reason why we found that they go all the way across the reed cap, but the general tendency is if the shuttle leaves the race anywhere along the travel, that it will strike the guard and be deflected downward, possibly in the end of the box, possibly under the loom. At any rate, the force is greatly decreased when it strikes anything, so that if anything should occur, it will be minor compared to what might happen.

MR. WASHBURN: How does this thing come down again? Does the weaver have to pull it down before she starts up her loom, or does it automatically drop? Is it heavy enough to drop?

MR. SANDEL: Yes, on any of the guards that are removable. It drops automatically. With those, the question of supervision comes in, to prevent the employee from tying on.

MR. WASHBURN: On that guard with the hinge, you say the first forward motion brings that down?

MR. SANDEL: Brings it down, and it locks there.

Many Accidents Due to Fault of Operation

MR. WASHBURN: Is there any possibility of the shuttle going far enough through or across to come out before that thing comes down?

MR. SANDEL: Well, there is. There is a possibility that the shuttle would fly out and meet the movable part of the guard on its way down.

MR. WASHBURN: That, possibly will answer the former question.

MR. SANDEL: Yes, that plus the fact that it requires supervision is one reason why the department does not favor that type of guard; but we have a number of them, nevertheless, where they have been installed in certain plants, and checked in those plants under supervision.

MR. WASHBURN: As I said before, we were having a great number of accidents in one of our plants, and after investigation we made special efforts to get in close touch with the weavers as to how they were doing the work; and we found that possibly half of all the accidents were due not so much to the fault of the machine, as to the fault of the operation.

MR. SANDEL: What you saw on the screen has been practically all silk looms. The silk mills have been foremost in this work in the state of Pennsylvania. The tapestry, cotton, upholstery, and velour have been a little slower, and we feel that the silk looms are now protected. There are only five cotton mills in the state, and we have been working with a corporation which manufactures cotton looms, and they have developed one guard that I spoke of and described; but the other industries are coming on a little slower. The department has not been pushing this, but we find that the industry has responded in a fine way, and we have been cooperating with the industry.

CHAIRMAN VAN EMBURGH: We will get along to the last paper of the morning by Mr. Ignatius MacNulty, of the American Woolen Company, Andover, Massachusetts.

MINIMUM REQUIREMENTS FOR SAFETY IN WOOLEN MILLS

Ignatius MacNulty, American Woolen Company, Andover, Mass.

In coming before you this morning, I am going to speak a few words first and then give you my slides afterward, describing the nature of the accidents and the way that we have of handling them in our mills.

Yesterday we had a discussion on the key man in the industry, and a little difference of opinion was expressed. I will touch a little on that question, and I want you to feel that while one group holds the view that an overseer is the key man in industry, and that is correct, there are other key men in industry, and those who believe that the overseer is the key man should not forget the other keys.

When Cohan wrote his play, he called it "Seven Keys to Bald Pate." If you only had one key, you could not unlock it, but if you had seven keys you could; each key fitted into one part of that key hole.

I notice that the fellows that wrote the Bible long ago mention that there were keys to the Kingdom of Heaven—not a key, but keys.

Now, you see, there is wisdom in a number of keys.

With that support behind my remarks, I want you to feel frankly that it does not minimize the key man, called the overseer. There is one key man that has been entirely eliminated or obscured in the problem of accidents, and he is also a fundamental key, and that is the state. None of you referred to the state. The old writer in the Book of Proverbs says, "Where no counsel is people fail, but where there is a multitude of counsel, there is safety." Now, the old gentleman that wrote that book certainly was a safety engineer.

Consequently, like Cohan, you might have other counselors, and say the gentleman who wrote that down had a very human touch in his knowledge. Therefore, you must not feel aggrieved when someone says that one particular group is not necessary.

Now, the state is that multitude of counselors. The state first lays down the foundation as to what regulation there will be governing life and limb in industry. If the state did not make those reservations, it would be very difficult to convert us to establishing those regulations, and to prove this, there is generally opposition when the state proposes new regulations—not always vindictive opposition, but opposition. Our state is a key man in industry. He represents public opinion, he represents the enforcement of law, he represents the well-being of the community; therefore, the state is the first key in the group of counselors in the industry; and don't forget that in advocating your various keys. File one of them down to fit in with the state law.

Now, there is another key in industry very essential, and that is the employer. If the employer is not interested in safety, the overseer can not be interested in safety. You left him out. The employer must be a safety man. He is in that group of counselors, a good employer, and the average employer today is a good employer. You have only to look back on the efforts that have been made in welfare lines since the war. You have had evidence here this morning from the point of view of the medical men, the efforts that have been made for the health and well-being of the employees.

The employers in those cases were certainly key men. They were men that were very much interested in safety in industry, in health in industry; so he ought to get emphasis placed on him.

If he is a good employer, he will first find out from the State Board of Accidents, Board of Labor and Industry, or whatever you may call it in your respective states, he will get in touch with them and have the inspector come and talk over the new regulations with him, so that he can apply them to his industry.

Every Executive a Keyman in Safety Organization

Then, after the employer, comes our friend the overseer that we love so much; but I want my overseer friends to feel that I was friendly to them, and defending and not criticizing them yesterday. It is not fair that the overseer should be asked to accept the entire responsibility as a key man. That he has his place in the key hole is true, but he is one of the other keys. Now, the overseer has quite an important function to perform. I think he is about the most important of the group, because largely—forgetting the difference in operation in foremen, and just accepting it on the pure principle of a foreman—he is the contact man, he is the man who usually comes in contact with the help, and knows them, and his attitude is known very clearly to his help.

And then you have the other key man, the fellow away down, the fellow on which you are all built up—the employee. There he is; he is the foundation stone in industry, he is the energy, he applies his human body to that machine, and sets it in motion. Before he steps in in the morning, your engine does not move. He gets right in the power house, workman No. 1, and touches something, and instantly powerful machines are set into motion. Surely he is a key man.

Now, here is your group: you have the state, you have the employer, you have the foreman, you have the workman, each contributing to the efficiency and safety in appliances. If you do not have those four counselors, linked up, you certainly do not have safety. If you do not regard the law, and you have litigation arise out of your accidents, then you are not paying attention to the state. If the foreman doesn't work in his employer's interest regarding safety, he is not a good foreman, and if the workman does not pay any attention to his foreman, he is not a good workman.

I thought I would bring these things before you this morning, to show

you just what I meant yesterday by the key man; and I know I have your friendship in that when you know that I am not criticizing anyone adversely.

Now, let us go back to the workman and see his attitude. I read in the papers that some great personage comes to the country and wears a peculiar hat, and the result is a great many people follow the shape of that hat. A peculiar color appears in a garment, and that color becomes the mode of the moment. A royal prince changed the line in his pants from the side to the front, as they have it in America, and immediately all the people in that country had their pants pressed the reverse way.

Now, why is that? Example; example; example. They were following the example of leadership, however funny it might be. It is a wonderful strength to follow the leadership of somebody who sits on high. We don't worry whether the high person is royal or not, so long as there is a highness in our human relationships; we accept that and follow it.

If the example that we follow, most of us, in our daily life, covers the colors and shape of our dress, the soles of our shoes and the color of hats, if we follow that in our ordinary social relationships, we shall surely follow something inside of the factory. Why? There are the same folks; the people in the factory are not different from the people in the highest places, they are the same people under a different set of conditions; and the same mentality, the same spiritual outlook is working in the factory that is working outside the factory.

Employees Are Keenly Susceptible to Executive Influence

If a man will change the shape of his shoes in 1926 from the shape we had in 1925, that same man working in a factory will follow the attitude, the shape, the desire, the atmosphere created by his foreman, by his employer and by the state. Of course, he will. And so, why should we not set up an example?

The average American boy and girl in the average city is the product of either the high school or the grammar school. Perhaps one-third of them will be high school graduates, and some will be grammar school graduates. They are reading today a morning paper and an evening paper, and the American newspaper today is more than a newspaper. It is a living magazine of impulses, describing human emotions and human activities. It is more than news. No paper is worthy of the name today unless it has a magazine section, a medical section, a section on psychology, and many others.

Your employees are reading those articles; they are developing their mental activities. You come into a mill and address a safety meeting at 11:00 o'clock today and you go back in the afternoon without responding yourself to the speech delivered in the forenoon—do you think you can do that without their knowing it? Why, of course; you have to sell them. They must buy it from your attitude. They know whether you are really interested, or whether you are talking to kill time. They

see these men intensely interested in the fabric. The overseer must be, or he would not be there. He must see that that fabric comes out as perfect as it is possible to do it. He must not make any errors, or very few, or he will be no longer in charge there. He must see that the physical conditions are as specified by law; that is his job.

Now, if that foreman puts the same intelligent effort that he puts into manufacture of the fabric, into the safety work—it is not alone the weaver, nor the spinner, nor the foreman's work, nor the workman's work, nor the bosses' responsibility; it is harmonizing and harmonizing by a complete effort right through the department for safety. Whatever the man does, he knows that unless he does that correctly he will not be employed there. If he has the same feeling regarding the relationship of safety, uses the same care and the same effort towards safety in that department that is put into the other thing, he will respond to the safety influence, and he will become a safety man.

One little word to my insurance friends. The insurance man's contention is that the accidents could have been prevented, should not have taken place; but that accident may happen in the street and the man is not arrested. A policeman does not always carry out his duties as he ought to. He does not do it to be vindictive. We have not lost confidence in our police department because very often an individual policeman will be guilty of a wrong act. We do not condemn the entire police department, neither do we very often discharge the man. He is reprimanded.

Both Doctors and Ordinary Workmen Make Mistakes

The doctors make mistakes. They are covered up once in a while, but they make mistakes just the same as anyone else, you see. But we do not disallow doctors in society, we do not disallow them in our social life. We realize they are human, and they are bound to make errors of judgment, and they change their point of view; and it is hard to get some doctors to move, it is hard to convince some doctors on a thing that is of keen business interest to them.

If that is so of the departments of Public Service and Medical Service, who are intellectual groups, why do you find fault with the workman not responding to his treatment? Can you find a criticism? Can you take a group of men and women—a group of medical men from anywhere—and put a standard up and find that those men and women will measure up to it? Of course, they won't.

I went to a show the other night, and I had to listen very attentively to the discussion behind me. "Is that right?" one lady said to the other; "are they real college men?" There was the instinct that did not realize the whole thing was make-believe. It was an exaggerated thing to her. Those two people working in a factory or mill or warehouse would be using the same intelligence. One would not notice a sign that you might stick up on the wall, and the other one would notice it. You put up a sign, "Wet Paint," and just sit there all day and count the Browns and Robinsons that will test it and touch it and see if it is wet.

That is the same mind, isn't it? Of course it is. Yet you find fault with him and say, "I don't believe you should have that accident." You have to recognize that you have a group of people of different mentality, different spiritual and different physical strength, and that the weak man and the weak woman in industry must be figured in as part of the job, as part of the whole life around us, and must not be found fault with. I emphasize that—fault must not be found with them; they must be recognized as an essential part, as fundamental as the man who is perfect.

Now, I am going to give you a few accidents that we have had here.

I have here 50 cases of mechanical accidents. I reduced the 50 to 27 specific cases; and out of the 27, 17 were females in mechanical accidents and 10 were males. Twelve of those accidents that were mechanical were due to cleaning machinery in motion. Twelve were females, and three were men.

Are Women More Prone to Accidents in Machinery?

Now, why is it that a woman is more prone to be injured in a mechanical accident than a man? You see, woman is particularly prone to take a susceptible attitude towards the machine, notwithstanding the fact that psychologists and some medical men say that woman is psychologically superior to men. They say that they are spiritually superior to us. Now, I merely mention that to show you that with this background she is more prone to touch the moving thing. Now, why is it? Why is it that a woman, more than a man, is fascinated with a thing that is in motion? But she is not; on the law of average, it does not show so. You take a little child and put a toy on the floor, you buy a toy that has motion—if you have the money at all, you will buy a superior toy—so that your little boy or girl will be attracted by the motion. You train the child to respond to something that moves. That child grows up physically, and it may not grow mentally as big and strong as it does physically, and you push it against something that is moving, and the inherited desire to feel and chase after a moving thing is manifest. You say, "That man should not have done it," but he does it, and he will continue to do it. We are guided mentally and physically to some extent by things we had when we were young. It is a fundamental thing in industry, and you can not change the facts.

Now, we could study and harness that thing and bend it to service, and not even fool with it; it is the finding fault with the thing that is a fact to which I raise my objection this morning. It is finding fault today. We don't find fault with the sun. The sun comes out in the middle of July and is intensely hot. What is the use of finding fault with it? I prepare myself for the sun. My house is so built that I can prepare myself for the hot days. I have windows open and screens put in. The same thing will apply to winter. Now, apply the same reasoning to your industry. Don't fight it; don't get angry at it. Adapt yourself, and find out the fundamental causes, and try to remove some of them.

So, the man who is careless—I don't know of one single case of a man deliberately going and getting himself injured. He reduces his earning power. All the arguments are against the man that is perfectly sane deliberately getting himself injured. Sometimes it may look otherwise, but it is not so. If we understand and sympathize with the weaknesses of the man, he will learn that he ought not to be careless and become a propagandist for you. But he knows that Jones has been sent down, he knows there is litigation about Jones' case, knows there are arguments that have made Jones very discontented. That has a reaction on those fellows. They talk to each other more than they talk to you and me. They have a peculiar viewpoint in the work room, a viewpoint on that room and the men in that room. That same group of men would not have the same point of view outside. Why? Because their environment outside is entirely different.

Now, all those things go to make up what we call accidents.

In looking over these instances we find out that age has nothing to do with it. Sex has a little. According to my list here we have them from 15 years of age to 45 years of age. We have them from four months' employment to eight years' employment, doing the same things, repeating the same things. It is not a particular thing peculiar to any one group of ages or any particular sex, or any particular length of service. How many overseers have you known that have been injured after they became overseers? I know quite a few men who have been overseers for 15 years. I know of a case where an overseer was killed doing a thing that nobody can convince himself the man was doing. He fell into a carding machine when the cards were being cut up, and he was killed.

There Are Fewer Mechanical Accidents Every Year

I merely mention that to show you that serious accidents are not confined to youth, to any particular sex, or to any particular class.

In our mechanical accidents we had 23 cases of those, and we reversed the figures: 17 of them were males and six were females.

It is a funny thing that this non-mechanical accident is the thing you have to face. The employer has reasonably solved the problem of accidents by following state laws, and improving machines as his business called for and as knowledge and humanity demanded.

The average employer has reasonably solved the problem of mechanical accidents. There are less of them every year; but we are not lessening a great deal the non-mechanical accidents. You will realize that yourself where you have a very close check on lost time, and induce people to come in and properly oversee the work. This is not a criticism; it is merely to bear out that those accidents are taking place. The accidents are there, constantly happening day in and day out—and why? For these reasons I am telling you, that we are trying to ask from a group of people something that we do not ask from the community that live around us, and of which we are a part, ourselves.

Why is it that we have more accidents at home, and there is not a word about it? More people are killed at home in a year than we kill in industry, and there is not a word about it. More people are killed on the highways of the United States by the common people themselves than the manufacturers of the United States kill in a year. I mean the man who drives an automobile is killing more people today—more of the common people. He is responsible for more violent deaths than the total industry of the country. If your industries killed anything like the number of people that are killed in a year by automobiles, there would be Federal investigation, your business would be tied up.

The Accident Follows Upon a Series of Mistakes

Not that I am advocating that they should go to jail, but the judge takes a commonsense view of it. He knows that the man did not vindictively injure or kill a pedestrian; he knows that there was a series of mistakes that entered into it. All those things are taken into consideration, and men use their intelligence. Now, if we used that in industry, we would come pretty near solving the problem of our accidents. We would certainly not be telling men to become discontented. The great thing in industry is to get men to feel that they must be contented with the effort made by the employer, by the state, by the foreman, by the insurance man—because he must be included in industry. He is part of our industry, he accepts risks that somebody else does not want to accept, so he is an essential part today of our life.

Now, if this group gets together and lets it be understood that an honest effort is being made to prevent accidents, and that there is no vindictiveness or anger or disgruntled feeling involved, we will come nearer to solving the safety problem, and we will lessen the attacks of the unthinking groups that want to put out of business legitimate business, and perhaps we will understand each other a little better.

I am trying to place before you not a mechanical thing, not a thing applying to the boss, applying to the overseer or applying to the workman, but the thing that applies to us all—that we are all key men, that we have all a little tongue of the key to fit the key hole in the lock, and to make it operate correctly. When we do that, we will come nearer to having an understanding of the employer with the workman and the foreman with the workman, and we will have a better spiritual outlook. If you do not get it from yourself and those around you, the unfortunate clergymen can not give it to you; you must get it in your human relationships with each other. You must have the feeling that that is part of the spiritual life also, that the industrial question is a responsibility; and maybe that explains the reason why so many people are dispensing with going to the Sunday services. People are not going because they are not getting the spiritual contact from their human relationships, industrial relationships, that they should get.

So, as the old writer in the book of Proverbs said, "There is wisdom in a multitude of counselors, there is safety."

(Mr. McNulty then showed a number of slides illustrating common hazards in industrial plants.)

CHAIRMAN VAN EMBURGH: Mr. McNulty has been very kind indeed. I think perhaps he has used a little bit of the psychology we spoke about yesterday morning. We think it has been very interesting.

Just one more thing before we go: The chairman of the Nominating Committee has handed me a slip with the suggestion that the chairman of the Textile Section for the following year be Mr. Glenn Cook; that the vice-chairman for the coming year be Mr. Sherman of the United States Finishing Company; and that the secretary be Mr. H. C. Washburn.

If there is no other suggestion, I would like to ask the present secretary of the Textile Section to cast a unanimous vote for Mr. Glenn Cook as chairman, Mr. Sherman as vice-chairman, and Mr. Washburn as secretary for the coming year.

I also would like to say that the request has been made, and we are going to try to act on it during the coming year, to keep all past chairmen of the Section on an ex-officio executive committee. That will give us the benefit of their experience, and perhaps will prevent our repeating a number of things that have been done before. We are trying this year to bring back into the ex-officio executive committee as many of the past chairmen of the Section as possible, and we will continue to do that.

I think the Section meetings this year have been better than any I have attended during the last three years, and I think we have had a great deal of good from them.

ADJOURNMENT

Woodworking Section

New Officers of the Section

CHAIRMAN: E. ROSS FARRA
U. S. Gypsum Co., New Brighton, Staten Island, N. Y.
VICE-CHAIRMAN (MANUFACTURING): JOHN B. GRIER
American Car & Foundry Co., Wilmington, Del.
VICE-CHAIRMAN (LOGGING): W. L. WALLACE
Edward Hines Yellow Pine Co., Lumberton, Miss.
VICE-CHAIRMAN (SAWMILL): J. I. THOMPSON
J. J. Newman Lumber Co., Hattiesburg, Miss.
SECRETARY: A. O. JACKSON
Aetna Life Insurance Co., New York City.

Committees

PUBLICITY AND NEWS-LETTER EDITOR: A. O. JACKSON, Chairman
Aetna Life Ins. Co., New York City.
PROGRAM: G. A. ORTH, Chairman
American Car & Foundry Co., New York City.
POSTER: H. D. HERRON, Chairman
International Harvester Co., Chicago, Ill.
ENGINEERING REPRESENTATIVE: G. A. ORTH
American Car & Foundry Co., New York City.
EXECUTIVE COMMITTEE (The Officers and)
G. E. SANFORD
General Electric Co., Schenectady, N. Y.
H. G. WIBERG
Lumber Mutual Casualty Insurance Co., New York City.
W. S. PAINE

HARRY GUILBERT
The Pullman Company, Pullman, Chicago, Ill.

October 26, 1926

HERBERT G. WIBERG, Chairman
Chief Engineer, Lumber Mutual Casualty Insurance Co.,
New York City

THE meeting of the Woodworking Section of the National Safety Council convened at 9:15 o'clock in the Sun Room of the Tuller Hotel, Detroit, Michigan, Mr. Herbert G. Wiberg, Chief Engineer, Lumber Mutual Casualty Insurance Company, presiding.

CHAIRMAN WIBERG: The first thing I want to announce is the Nominating Committee to select officers for the Section for next year. I will appoint Mr. G. E. Sanford and Mr. J. W. Smith.

G. E. SANFORD: There is a little uncertainty in the minds of some as to the appointing of Nominating Committees, and yet, the NATIONAL SAFETY NEWS, a month or so ago, published a list of all the Section Nominating Committees.

The reason for that dates back some five or six years. In the old days there was no Nominating Committee, and new officers were not considered until the time of the Congress. The Nominating Committee that was elected from the floor would pick out three or four names, men probably who had given addresses or those who were taking part in the discussions. In many cases, those men wouldn't know they had been elected officers of the Section. They may have been entirely unfit for the job; they might not have any time at all or only be slightly interested in the work of carrying on a Section, which is quite some job.

The present scheme is to tentatively appoint the Nominating Committee in the spring. That Nominating Committee sounds out the members, finds who are willing to do something and gets their consent to serve if selected. The nominations actually are not decided on until the time of the conference, but the Nominating Committee has a job to find out who in the Section is willing and able to carry on the necessary work.

We have a list of individuals who are willing to serve, if nominated. We don't want you to think that it is handled by a clique at all. If there is anybody present, he may be some total stranger to me, that is interested in the Section and wants a chance to do something, tell him to get in touch with me, give me his name and address, and we will try to find something for him. We may be able to use him as the chairman of a committee. We want everybody to work that is willing, and we are always very glad to get volunteers, because it is an awful job to get some of these people picked out who have the time to give to the work of the Section.

CHAIRMAN WIBERG: Thank you, Mr. Sanford, for explaining that situation.

The first paper this morning will be by Mr. W. J. Hockett, Safety Supervisor of the General Electric Company, Fort Wayne, Indiana.

METHODS OF INTERDEPARTMENTAL SAFETY COMPETITION

**W. J. Hockett, Safety Supervisor, General Electric Company,
Fort Wayne, Ind.**

That "competition is the life of trade" is as true of safety as it is of trade. After all machinery has been guarded thoroughly and improved methods of production have been adopted, so far as they have been developed, there yet remains a big safety job, which is to stop the accidents caused by carelessness of workmen.

This part of the job will depend upon education and interest. The spirit of competition may be used to a great advantage in creating and stimulating interest.

Men dislike to admit that sentiment affects their actions and they are liable to refrain from discussing subjects that are closely related to sentimental things. By making safety a game or contest it is somewhat removed from sentiment and may be discussed as a game. Groups will quickly get into the spirit of a contest and they will see that their fellow workers do their part.

Workmen don't like to see their department record trailing and they will boost it by their talk and carefulness if they are given full information as to what is happening.

The crowd at a race, the radio audience that listens to results of a football game, the groups in front of the score boards when the world series is in progress and the enormous gate receipts at the prize fights all tend to show that people are imbued with the spirit of contest. They get a big thrill and a real "kick" out of the progress of the game.

Arrange to let a group of employees follow the safety or "Keeping Fit" contest daily and they soon become enthusiastic.

Contests Appeal to the Sporting Instinct

Then, there is another big human element in contests that we must not overlook. We hear a lot about "chance taking" in our safety work. "Chance taking" has behind it the gambling spirit. We must take advantage of this trait by turning it toward safety if we want the most good to result from our safety work. The contest has a lot of the chance taking elements and this really appeals to people. Preaching, cautioning, disciplining, and scolding do not get the best results. It is the team spirit and the natural interest that must be awakened to produce real results.

In a large organization the safety engineer can not see all the individuals, so he must have help. Safety committees of foremen and workmen increase the safety salesmen in the plant and provide the necessary help. The organization of such committees may be used to develop team work and thus influence the person who can't be reached otherwise.

Competition may be arranged between individuals, departments, plants or specially arranged groups. In a plant of a few hundred employees, departments are a good basis for competition. Where a company has a number of plants, contests between plants put the entire group in each plant from the manager down on the alert.

In the General Electric Company we have used many schemes to promote interest. Our experience shows that we never really got under way until contests between plants were arranged. Now every plant is trying hard to stand near the head of the list.

In order to keep in the procession each plant organizes its departments into local competing units running them against each other. Now the person who breaks a department's good record is almost in disgrace.

We recently had a six-year-old no-accident record in a testing department broken by an employee carelessly and thoughtlessly short circuiting an ordinary plug with a screw driver. He flashed his eyes and had to lose three days' time. This entire group of 20 men were very much out of patience with the offender. This group had done all sorts of testing of a large variety of electrical machinery for over six years without a lost-time accident. It meant a great deal to have such a record broken.

We have used for a number of years a scheme of rating sections based upon hazards and the average number of employees and I shall describe briefly this plan.

First, we find the number and classification of the employees of each department by the use of a sheet of "Employee Classification." A copy of this sheet is sent to each foreman and he enters the number of each class of employee he has working for him.

Second, a hazard factor is established for each class of employee. The factor taken is the class number that insurance companies use in classifying various occupations. The factor used in our works varies from 1 to 9 as follows:

Select or preferred.....	Class 1
Extra preferred	Class 2
Ordinary	Class 3
Medium	Class 4
Special	Class 5
Hazardous	Class 6
Extra hazardous	Class 7
Perilous	Class 8
Extra perilous.....	Class 9

Next, figure the hazard of each department by multiplying the number of each class of employee by the hazard factor for that class and add the results.

Example: Suppose a department is made up as follows: One foreman, Class 5; one assistant foreman, Class 5; one clerk, Class 2; 30 machinists, Class 5; one trucker, Class 6; and one sweeper, Class 4.

$$\begin{array}{rcl}
 1 \times 5 & = & 5 \\
 1 \times 5 & = & 5 \\
 1 \times 2 & = & 2 \\
 30 \times 5 & = & 150 \\
 1 \times 6 & = & 6 \\
 1 \times 4 & = & 4
 \end{array}$$

Hazards of Department = 172

Having obtained the total hazard of the department we then divide the total hazard by the number of employees to obtain the mean rate.

The departments are then grouped into sections which operate as one

unit, e. g., Transformer, Meter, Fractional Horse Power Motor, Induction Motor, etc., and the total hazard of all departments in this section is divided by the total number of employees to obtain the mean rate for the section.

The percentage of accidents allotted to a section is the hazard of that section divided by the hazard of the entire factory.

The standing of each section with respect to the other sections is published each month in our works paper in the following manner:

Keeping Fit Contest

Standing of Major Departments March 15, 1925

	Percent Accidents Allotted	Percent Accidents Occurring	Standing in Percent
Apparatus	5.44	3.13	42.50
Induction Motor	4.57	3.13	31.50
Meter Department	17.98	12.50	30.50

The standing is found by subtracting the per cent occurring from the per cent allotted and dividing by the per cent allotted.

Planning the Contest

The plant executives must be sold on the plans for contests and they should be enthusiastic about them in order to give the scheme the proper backing. The entire plan should then be fully explained to foremen and safety men. This can best be done in a meeting. Bulletins describing the plan will carry the message to everyone.

This entire scheme of calculation is quite complicated so explanations should dwell on the basic ideas. For instance, it should be pointed out: (1) that the hazard of departments has been taken from insurance companies' experience. (2) The number of people working has a definite bearing on the rating. (3) Accidents occurring in a department or unit as compared to all accidents that have happened in the plant determine

How Long Should Such a Contest Be Run?

There is no limit to the length of time such a contest may be run. The report of standing of departments may be given as frequently as desired to keep the interest up. At the end of a period, such as six months or a year or every month, the winner may be announced and prizes and due recognition given. The contest is then started all over again, with all departments having a clean slate.

The big advantage in this plan is that departments of very great difference in hazards and in number of employees are placed on an equal and fair basis. They can not say they are unfairly compared with departments having scarcely any hazards.

The basis may be recalculated as often as considered desirable to insure fairness.

So many fine schemes have been tried out with success and several

of these have been described in the NATIONAL SAFETY NEWS that I shall not attempt to dwell on many of them.

Our Schenectady Works has used the following plan for creating interest: The Mutual Benefit Association is divided into many small sections of not over 150 members. Two years ago it was announced that the sections in the manufacturing division having the best record for each month would participate in a cash prize to be distributed by the company. The amount would be \$15 per section. This has created much interest and every section has been keen to get this monthly prize. The results are widely advertised on the bulletin boards.

In the last two years the frequency rate for lost time accidents per million hours worked has been reduced in this plant as follows: Year 1925: 18.92; 8 months, 1926: 15.18.

These 20,000 people are really gambling each month for this prize money. They are betting with caution, carefulness and the spirit of help for their fellow employees. We are anxious that they keep up this sort of "chance taking."

Advertising and Rewards

A constant shower of advertising is necessary to keep the interest up and here is where some hard work must be done. Facts of the same old kind have to be dressed up in new clothes to make them attract attention. To launch into this subject would require another paper but let it suffice to say that homemade bulletins, the works paper and the local papers are the best advertising mediums.

Trinkets and personal gifts have no place in the awards for accident prevention contests. The award must be of such a nature that it will create pride in the group. Trophies, banners, cups, cash for M. B. A. or dinners are best.

In conclusion we must do our part as employers in properly safeguarding all equipment but this is only a small step in the big program. Interest that carries through the entire organization must be created. The department as a unit competing with others for standing, with lots of advertising to bring the standings to the attention of everyone, will accomplish the desired result.

This plan has been used successfully by a large number of companies. That accident prevention can be accomplished by means of educational campaigns and contests has been proved. When we will to do the job it can be done.

(Following the reading of his paper, Mr. Hockett exhibited a number of lantern slides, illustrating the points he had made.)

CHAIRMAN WIBERG: We are grateful to Mr. Hockett for the interesting paper that he has given us. His paper brings out what apparently a great many people don't remember, and that is, if you want to get effective results in preventing accidents, you have got to keep the proposition before them almost continuously.

Another paper on somewhat the same subject will be given by Mr. Grier of the American Car & Foundry Company, Wilmington, Delaware. His comments on the problem of keeping the interest going every day brings up a couple of thoughts that ought to provoke some discussion.

I think we will defer the discussion on these papers until all the papers have been given. If you have any questions that come up as the papers are given, let me suggest that you make a note of them so that after the last one has been rendered we can bring up these various points and thrash them out.

STIMULATING AND MAINTAINING INTEREST IN SAFETY WORK

John B. Grier, Safety Inspector, American Car and Foundry Company, Wilmington, Del.

I can not very well begin this paper just as the title would indicate—it seems that the basic foundation of safety work must be spoken of first in order to bring out the larger part of the safety program. What I am trying to say is, that if safety is not first introduced in the proper manner, it is almost impossible to keep up the interest.

Let us begin in a shop where we are introducing safety. The number of men on the payroll may be large or small, some may have spent practically all of their lives working in this particular shop, others perhaps only one day's service. You can not step into this shop, cover up all of the machines as fast as possible, and expect to get the full cooperation of the employees. The ground work must first be laid.

The safety inspector should interview personally the men and groups of men in the particular shops in which he intends to place guards, and should be very active in and around this department previous to the beginning of the installation. He should get the ideas of the men working the different machines, also of the foremen through personal contact. He will find that some of the men have very good ideas, which can be carried out sometimes at a saving over the cost of the guard which had been planned.

The men then feel that their safety has been brought about by their own ideas and guards, and it will be a pleasure to them to keep the guards in place instead of tearing them off or leaving them off of their machines when they repair them. This not only interests the machine men, but the safety inspector's presence in and around the shop, talking with the different men, will get his message to both bench hands, machine men and other workmen in the mill, and he will find that they will work with him in preventing accidents in their department.

This procedure applies to every department and building in the plant, regardless of how large they may be. After the entire plant has been guarded in this manner, the new man coming into the shop must be taught that carelessness will not be tolerated, and that anyone working

in an unsafe manner will be immediately discharged. This is the ground work which really helps us keep the safety interest at full tension.

Accidents will occur, and careful records should be kept of the manner in which they occurred and the probable cause. The safety committee should be called to investigate each accident as soon after it happens as is practicable, and the safety inspector should talk to the men in and around the department and let them know that he is aware of the facts. He should promptly take whatever action the committee finds necessary. All of these things show the men in the plant that the safety inspector is on the job and that they must be on the lookout lest they become the object of his investigations.

Regular inspections of guards already installed on the machines should be made by the safety inspector in company with the different members of the safety committee. The safety inspector should be a man who can talk with the men in the shop and one whom the men will not hesitate to approach with voluntary suggestions. The guards should also be kept well painted—this not only attracts attention, but preserves the guards as well.

Cover the Plant Well With Bulletin Boards

The foreman of each department should be interviewed frequently, and minutes of the plant safety committee meetings should be sent to them, as well as other literature furnished by the National Safety Council, Insurance Companies etc. The plant should be well covered with bulletin boards; there should be at least one bulletin board in each room or department, and large bulletin boards should be placed in the most conspicuous places, including each entrance to the plant. The bulletins used should be short, snappy messages or pictures. Printed records of the right kind may be displayed, but these must be easy to read and understand. The bulletins should be changed often, at least once each week, and should be made as attractive as possible.

The safety inspector is personally responsible for at least 50 per cent of the safety of the workmen; and his job is in the plant, out among the men, finding and correcting unsafe practices as he goes through, warning workmen who seem to be a little lax and in general showing the men that it is his one idea to help prevent their injury.

The safety committee at its regular meetings should inaugurate safety drives and campaigns, including competitions between the different departments of the plant, to see whether or not one department can run longer than another without having a serious accident. I do not mean by this, "The Flash In The Pan" type of safety, the big drive once a year to run for one month without having a serious accident. After accomplishing this, when the tension is taken off, plants frequently have more accidents than before.

Safety rallies are fine and should be encouraged, but the interest should not lag after the first month. Safety effort should be carried on even more strenuously during the following months. I have no doubt that any

plant in the United States, regardless of how large it is, could work a single month under such favorable conditions, without having a lost time accident, but they are bound to show an increase in accidents after this rigid drive is over. I like the steady persistent safety method of giving the workmen all of the literature and talks possible at regular intervals.

Our method in the Wilmington plant of the American Car and Foundry Company is to take things as I have explained them. We do not have any big safety drive or spurge for a month or so, and then forget safety altogether; but we are continually driving home to the workmen our desire and intention that working conditions be made safe—that we are interested in our employees' welfare—that their welfare means increased production and is therefore an essential part of plant operation.

Use the Injured Employee to Stimulate Safety Interest

Inter-departmental competitions, if carried on monthly, are very fine. It is not necessary to have a banquet for the winner each month, but some kind of a prize can be given. Although we do not give prizes for this work, we do give some token of appreciation to our men who have shown out-standing interest in the safety movement.

The injured employee can be used to stimulate interest in safety among your workmen. If he is taken care of properly and gotten back on the job as soon as his injury permits, he will have a much better opinion of the company; and if, during his disability, he is told how this injury could have been prevented by the proper safety methods, he will be sure to put them into effect when he returns and his influence with his fellow-workmen will go much farther than you can imagine.

It is not our idea to criticise the injured employee, because I do not believe that anyone injures himself purposely. He is injured either because he has not been properly instructed in the safe manner of doing his job, or he is a careless and thoughtless man. If the former is the case, then the trouble is with the foreman or sub-foreman, and they must be gotten after and told to get on the job. If it is because of his own carelessness, he should be told that the company will not stand for this kind of work and that a second occurrence will cause his dismissal from the plant. I have found that a second accident very rarely comes.

An outline of the plan in force in our company is, I believe, worth while. The accident records are made up in each of the different plants and forwarded to our chief in the home office. He, in turn, compiles a monthly report giving the standing of the plants in reference to percentage of lost time accidents. Along with this report is sent a personal letter which is full of food for thought to the safety man. These records are also sent to the vice-president of the company, as well as to each of the district managers. In case of a major accident, it must be thoroughly investigated and a copy of this investigation forwarded to our home office. If the explanation of the accident is not satisfactory, it shows that the safety man is not on his job; and I believe this method does as much as

any other one thing to keep the safety man's interest at high pitch. This being the case, he cannot help but carry his enthusiasm to the foremen and workmen in the plant.

CHAIRMAN WIERG: There is one thing about Mr. Grier's paper that struck me as of particular value and that is the idea of having the safety man get personally acquainted with everybody in the plant. I have noticed that in a great many plants where they have organized safety propaganda work that a great many of the workmen at the bench know nothing about it. How can they expect to have real effect unless everybody from the office boy up knows it is going on?

The next paper, by Mr. Northrup, of the Labor Department of the state of New York, is a very interesting paper in which he demonstrates pretty convincingly the use of moving pictures as an aid to accident prevention. I think it is interesting, because it points to the increasing interest of the state authorities in the work of reducing accidents. Here is a state organization that is getting up moving pictures and going out and showing those moving pictures to those employers that show enough interest to ask for the picture.

MOTION PICTURES AS AN AID IN ACCIDENT PREVENTION WORK

Robert B. Northrup, Safety Inspector, Department of Labor, New York

During the year 1925, from the lowly point of no equipment and practically no knowledge of the intricacies and art of taking motion pictures, a fair start has been made, under auspices of the New York State Department of Labor, on accident prevention work through the use of the cinema. The equipment was provided and through the effort and study of two of the personnel, three pictures, totaling five 1,000 foot reels, have been produced.

Statistics in New York state show that only 27 per cent of all compensated industrial accidents are due to machine hazards. This is largely the result of years of work on machine protection. The balance, or 73 per cent, of such accidents result from unsafe physical conditions, lack of trade ability, improper handling of tools and objects, unsafe methods in operating machines, falls, careless practices and kindred conditions.

It follows that the human factor must be considered, that educational measures must be used to stimulate mental alertness until people are trained instinctively to work safely and avoid danger. The Labor Department is now working on this problem through four avenues, verbally in lectures given at industrial plants, through bulletins and publications, by photographs, and finally, by means of moving pictures.

Many of the industries in this country in the past protected their machinery, walkways, etc., and considered this sufficient. Accidents decreased, but only to small extent. This experience showed the necessity for education in accident prevention principles and cooperation between all forces that are working on the problem.

Let me define the word education as it is used in this connection. It is not in the sense of mental instruction in mathematics or history; rather an instructive propaganda, a constant agitation in the principles of safety first, hygiene and sanitation. Cooperative accident prevention committees of executives and workers are formed in industrial plants. Shop talks are given, social activities constituting safety rallies are held, safety poster service instituted, in fact well organized service has functioned until some concerns have reduced their accidents as much as 85 per cent. Many industries do this valuable work, but the mass do not; it is the duty of the state to reach the latter and instruct them in the principles of organized safety work and the specific causes of accidents and the remedy therefor.

Motion Pictures Are an Important Adjunct

Motion pictures are valuable for this work since an operation done in an unsafe manner can be seen in moving detail from start to finish, and conversely, the safe way can be shown. The worker hears that a safety lecture is to be given and stays away. He learns that a motion picture is to be shown and subconsciously feels the call of the amusement or interest feature of it and attends. The operator who sees in a moving picture a man theoretically killed when operating a circular saw in an unsafe manner will in 99 out of 100 times think of the safe way to operate that saw when he again begins his work. It would seem that this is only human nature.

The subjects whereon film pictures will give graphic aid in preventing accidents are endless. But a few examples are quoted as follows: a story picture which includes industrial settings, with an accident and its moral; reels of technical pictures showing artisans working the right and wrong way which really means the safe and unsafe way (one of the great sources of accidents today lies in the fact that many so called mechanics do not know how to handle their tools or operate their machines); the right and the wrong of situations and conditions, i. e., work clothes, shoes, chairs, floors, housekeeping, falls, falling objects, handling heavy objects, horseplay, poisonous substances, etc., etc.

Already sufficient work with the cinema has been done in this line to develop some of its reactions on an audience of workers. The picture must not be over one-half hour in duration (two reels) and at least one-third of the picture should be of human interest—domestic scenes or a bit of comedy.

One official of a large industrial concern gave us constructive criticism when he said: "You know many of our men can not read the titles which are in English and therefore they lose much of the worth of the picture." We now briefly explain the subjects as the film runs through and where the audience requires it even familiarize an interpreter with the picture sufficiently to enable him to explain it.

The art of producing safety moving pictures is entirely different from taking purely amusement pictures. In the latter the subject or story,

the ability to act well, settings, scenery, etc., are of paramount importance. In accident prevention work, acting must be subordinate to trade knowledge. There will be those in an audience who know the trade depicted and consequently are competent critics. If a person demonstrating an operation on a machine, either the safe or unsafe way, shows a lack of knowledge of the trade and makes mistakes, the lesson that is being conveyed loses practically all of its value.

Users of films should know how certain limitations can be overcome. Let us take the matter of eye strain: do not use faulty projection or old badly scratched film. With well maintained modern projectors, fresh prints from the master negative and a suitable distance from the screen no appreciable eye strain results. The fire hazard may be eliminated by the use of non-flammable film stock now on the market and by the use of projection booths constructed of fire proof material. These booths can be constructed permanently or may be obtained in the portable type so that they can be transported from place to place. Again, the standard width film may be reduced to miniature film which can be projected anywhere without the use of a fireproof booth.

The use of motion pictures in the world of pedagogics is well established and it seems that what is true in educational lives must also be true in the message of "Safety First." A bit of experience in school work is here quoted:

Men Are Quickly Influenced With Motion Pictures

"Through the use of motion pictures in school and college, students are taught more quickly with less fatigue or strain and retain the information better. Pictures are able to standardize impressions, and make them clear and complete, uniform, lasting and specific. By them the abstract can be made concrete, the absent present. They overcome time and space. Rapid processes can be slowed down and analyzed; slow processes can be accelerated; inanimate objects animated, dead facts made to live and pulsate. Attention can be held and concentrated and the memory more deeply impressed by moving images. Scientific experiments and demonstrations performed with ideal equipment under the best possible conditions as well as operations performed in the clinic, can, by means of motion pictures, be repeated indefinitely anywhere. Microscopic life can be enlarged many times on the screen, so that what can ordinarily be seen with difficulty through the microscope and by only one at a time, can easily be viewed on the screen by an entire class. By animated drawings and models the electric current passing through a series of wirings of an electric motor, the nervous impulses passing between various parts of the body and brain or the circulation of the blood through the body can be visualized. These are but examples of the vast field that can be utilized.

"The cinema expands the experiences of the pupils by bringing to them the whole wide world—things as they are. Rushing rivers, the bubbling lava, caldrons of great volcanoes, waving fields of grain, vast forest fires, storm clouds and the mighty ocean with its pounding surf.

When geography is studied they are transported as if by magic to the scenes of their studies where they live among the native people. They study biology, and the films bring the living animal life of the world and its native environment to the classroom. In geology, the formation of the mountains and canyons through the slow process of the ages can by films of animated drawings be vividly presented to students so that they will never forget.

"Slow motion pictures define detail; the flower's bud slowly opens to a full blown flower or the dragon fly emerges from its chrysalis. Every movement may be analyzed and the memory of the animations will last far longer than merely to read about such processes abstractly, coldly and distantly in a text book.

Tests Show the Efficiency of the Motion Pictures

"Tests to show the teaching efficiency of motion picture films as measured by results obtained by the teacher in the classroom have been made. One of the most significant was conducted to determine the effectiveness of four different methods of presentation: (1) the study of the printed lesson; (2) the same lesson presented orally by the teacher; (3) the lesson depicted by a film; and (4) the film presentation accompanied by explanatory comments. A summary of the results gave evidence that "Teacher" scored lowest; "Study" came next, "Film alone" scored a little higher, and "Film-Lecture" made the highest score of all. Another test showed:

Films alone scored an average of.....	75.5
The superior teacher scored.....	66.9
The average teacher scored.....	61.36

"The significant feature of this test is that the film alone beat the best teacher 8.6 percent and the average teacher 14.14 percent; yet, experience has proven that the best results of all are obtained by a combination of the three—accurate text, efficient teacher, and a truly educational film" (A).

The possibilities touched on through laboratory work or trick photography in the preceding paragraphs as well as the results of tests in efficiency surely justify the extensive development and use of film in accident prevention work.

We are showing our pictures in industry throughout the state and find the employees attentive and very much interested. It is fine after you have put your all into the making of a picture to see one man nudge another when a point is made in a setting, and say "Wonder if Bill is getting that? He needs it." It proves the subject matter is being assimilated, will be remembered and, let us hope, practiced.

Usually a portion of the noon hour is used. Where the lunch hour is short we have yet to find the executive who does not willingly give the employees a few minutes of company time to finish the picture.

A.—Quoted from "Motion Pictures in Education", by Don Carlos Ellis and Laura Thornbrough.

Our inspector endeavors to have some official of the company see the picture and we have received many gratifying written commendations relative to the reaction of the employees to this work.

These pictures will be gladly shown to anyone desiring it. Whereas there are no facilities for renting service, it is found that the cost of our pictures is not much more than commercial renting service. In the interests of the work, the Department is always glad to furnish the negative gratis, which makes the cost to the purchaser about four cents a foot for standard 35 m/m non-flammable film or three and one-half cents for miniature 16 m/m non-flam stock. In this case the film is the purchaser's property. An insurance company has availed itself of a picture in this manner.

The picture "Woodworking Hazards" shown during this session of the Congress is in conjunction with a field study and analysis, by the New York State Bureau of Industrial Hygiene, of three hundred accidents in woodworking factories (Bulletin 139).

All of the accidents that are shown have occurred, many repeatedly. We have endeavored to make the action sufficiently slow that all movements will be clear and defined. The film is being shown primarily to groups of woodworkers throughout the state by our lecturers.

Example of an Introductory Talk

Just before the picture is shown in a factory workroom a brief statement is made: it follows this general thought:

"I am from the State Department of Labor, a public department which is as much yours as mine or the other fellow's. Through it compensation is paid the injured workmen and through it great effort is being made to reduce the appalling frequency and severity of accidents.

"In the woodworking industry in this State there are approximately 72,000 workers. In this trade 2,573 compensable accidents occurred in 1924, costing \$943,935 to compensate. Nineteen were fatal accidents. These are only the accidents that caused over one week's loss of time. No one knows how many trivial injuries occurred or how many kept a man away from work three or four days.

"These 2,573 accidents in one year represent 1,000 years of lost time which, at the most conservative estimate, is \$2,000,000 (\$40 a week x 50 weeks x 1000) loss in wages in the woodworking industry in one year in New York state alone. Add to the wage loss the compensation cost of \$943,935, and you have nearly \$3,000,000 total loss in one year in your trade caused by accidents.

"What about the cost of the other 70,000 accidents that are compensated in all the other industries in the state? Well, they cost you and me \$70,000,000 a year in compensation, lost time and doctors' bills. Men, we pay this bill in increased living expenses and taxes. Consider also the suffering of the injured, the anxiety to themselves and their families, the straightened circumstances suffered in the home due to

no money coming in or at least only a little money from the compensation Bureau.

"Think over this matter in terms of suffering, anxiety and money and you will find that you must exercise more care in your daily lives and work at machines with your wits alive every minute."

CHAIRMAN WIBERG: After all is said and done, moving pictures show in one minute what it would take an hour to talk about. The first two papers were given by men not concerned entirely with woodworking machinery, while this latter one deals entirely with that subject.

Although the first two papers were not 100 per cent woodworking, I think both brought out the fact that the proposition of maintaining interest is the same in all plants. It seems to me to boil down to the proposition of getting right on the job with the workers in those plants, and devising literature and posters and bringing to the attention of every worker in the plant the peculiar hazards in that industry, whatever they may be.

Are there any questions or comments anybody has on any of the three papers?

The State Department Offers Reasonable Cooperation

W. G. DORSETT (Crystal-Lite Company, Indianapolis, Ind.): I would like to ask Mr. Northrup if he sends those pictures and reels outside of the state of New York?

MR. NORTHRUP: We have no way as a State Department to furnish them to you. As a public department, we are, of course, only too happy to furnish the negatives, if you will pay for the print. The cost of the print is practically the same as the renting service where the negative is provided. Of course, the State Department of Labor of New York is only too happy to be able to provide the negative, if you will pay for the cost of the print.

CHAIRMAN WIBERG: What would the cost be?

MR. NORTHRUP: The standard print of this whole picture would cost \$87.32. You could, if you desired, have that picture cut up and a number of portions taken out, which would considerably reduce the price.

There is one more angle to that. We had a little problem when we started this work on how to show it in plants, in New York City particularly. The restrictions on how you can show films are a bit stringent, as they must be, of course. There were several angles to it that were involved. This print in miniature, which is the 35 millimeter, I believe, would only cost \$55. Before you used the film, you would have to determine how the laws and rules of your city and state stood along those lines.

W. L. WALLACE (Edward Hines Yellow Pine Company, Lumberton, Miss.): The thing that interests me right now is the fire hazard as to these pictures being used in open plants. Would not the showing of them effect your fire hazards?

MR. NORTHRUP: Insurance companies do take that up when they find out a film is to be shown.

In New York City, you can not show the standard film. I use both the standard and the miniature. With the miniature film, which is five-eighths of an inch wide, there is no possible fire hazard.

MR. WALLACE: That is my point.

MR. NORTHRUP: There is no rule or regulation. In fact, the New York City fire laws make a special provision allowing its use, anywhere, at any time.

VOICE: Don't you have to use a booth?

MR. NORTHRUP: No sir. We use the Bell and Howell projector, which is made for that purpose. I operate it myself. It is operated in just the way that this so-called magic lantern was used this morning. You can take the small projector and show the picture anywhere.

It might be a bit interesting to know that we use what is called the daylight screen. It is made by the Du Pont people, and is like a piece of gelatin. It is made up of prisms, perpendicular, which gives the quality of showing through the screen. The projector stands here and the screen is about 10 to 15 feet away. The audience is on that side of the screen. We show it practically in daylight. You can not, however, show it in the sunlight.

Motion Pictures Growing in Popularity

F. G. LOVETT (Industrial Accident Prevention Association, Toronto): Our association is a manufacturers' association under the workmen's compensation act. We have during the past two years used very extensively the motion picture in our safety work. We found it very effective. I was very much impressed with the film shown here this morning. We have not got that far that we have something exclusively for one industry. Our film applies to every industry; it deals with the general hazards, and we find it very successful.

Just last week, I put on four shows in two towns, two in each town. One town had a population of over 5,000 and the other 7,000. We didn't take the film into the factory, we engaged a little theater, and had the performance in the evening, and the workmen brought their wives along. I want to tell you that when you get the story home to the wives, you are getting it to the right spot. In one place we had 900 people and in the other about 1,100 people. Favorable comments were expressed in the factories the next day to the foremen and the superintendents. I think the show was well worth while.

You have got to recognize in this work that the average man doesn't think for himself. What you show him on the screen goes right home to him and he remembers that, because he has seen it. We have found this very effective.

We started this work two years ago, and the demand for this film is almost more than we can keep up with. When we put on a program in

a factory or in a theater, we not only use our safety film, but we use the film of resuscitation, the eye and eye hazards. We also put on two educational films which we rent from our motion picture department in Ontario. The government has the safety films which can be leased at a reasonable rate.

Last year, after school hours, we had the children in the theater, and we got the story across to the children in that way. I would like to state that any gentleman who is a safety engineer or an inspector can not use anything better for his work, in my estimation, than the motion picture film. We have received wonderful results from it.

Mr. BURBON (Mengel Company): Every foreman gets a one-half day vacation for each no-accident month in his department. If he goes three months without an accident, he gets an additional day added to that. Our foremen are working harder for that than for most any kind of a badge or medal we can offer. We are getting wonderful results from this little system. I wonder if anybody else here does that?

A "Safety Derby Contest" in Indianapolis

CHAIRMAN WIBERG: Where does the workman come in?

Mr. BURBON: We are giving the workmen a badge for going one year without an accident. Of course, we can't give them a half day.

CHAIRMAN WIBERG: He is not left out in the cold. That is one of the numerous ways you can keep the safety movement right before the men every day of the year. I don't know whether anybody else is using that or not.

W. G. DORSETT (Crystal-Lite Company, Indianapolis, Ind.): I would just like to mention the contest that we put on in Indianapolis for our departments. We employ about 1,800 men. We have about 42 departments. We call our safety contest there the "Safety Derby Contest." We have it divided into 25 entries. Each department has a pony. The contest is run on a handicap basis. We try to estimate as near as possible a percentage of risk and give each department a handicap.

This contest runs for three months, and the department that wins out is given a banquet by the company. Last Thursday we gave a banquet to one of our departments that won. We seem to get very good results from this. It causes quite a bit of rivalry throughout the plant. It has been in operation for the past nine months. We have had three races and no department has won it twice. It is proving to us that the handicap basis on figuring the contest is proving very effective.

H. R. ORCHARD (Marathon Lumber Company, Laurel, Miss.): I would like to know if any of the gentlemen present have had experience with colored labor, and whether they find their negro labor react to the same things that the white labor do and the trouble they may have in interesting their colored labor?

CHAIRMAN WIBERG: I think Judge Wallace can give us some information on that.

I recall that we discussed that very thing last year in Cleveland. It

seems to me that it was brought out that the colored men took much more heartily to this contest idea.

E. R. FARRA (United States Gypsum Company, New Brighton, New York): I run about 20 per cent black in the common labor organization of our plant. We have about 90 right now. I want to say that we have 17 nationalities in our common labor organization. I would much rather work with the boogies than any of the others, because if you can sell your safety idea to one or two of your black men, they will sell the rest for you. The negro can always see the funny side of everything. If you appeal to that humorous side, you will get the colored man every time. When I was with the American Car & Foundry Company in Wilmington, we had quite a number of them there. We very seldom had an accident through a black man. Wasn't that right, Grier?

MR. GRIER: We haven't had any in the last two years.

Two Months Set Apart for a Special Safety Drive

MR. FARRA: I want to give you a stunt that we are running this month. We have a continuous safety movement in the plant, but two months in the year, May and October, we sort of try to make it better than the other 10 months of the year.

During the second week in October, I was tied up in my office with an insurance proposition and last week I was getting ready to come here. We realized early in the campaign that I would have these other duties and couldn't have that personal touch in the shop that I would like to. I talked the matter over with my manager one day and we arrived at this conclusion: that we would appoint four men, one to take charge each week. The first fellow we picked was a noisy fellow. He had served on the safety committee, but had retired. Then he got to work and dug up more things in that first week than I will be able to correct in the next two months. Many of the things we corrected right away. He went into places I never dreamed of going. I didn't know there were such places in the plant.

Here is what happened. That fellow was one of the bunch. I picked my men carefully. He moved around the men in the shop all day long. I told him to start on roof one and go clear down to the top of eight, which covers about 25 acres of floor space. The man that keeps walking all day long is earning his money.

Last week we had a Polish fellow in charge. We have a large congregation of Polish in our plant. They are the hardest nuts I have to crack. Last week this Polish fellow inspected the plant day by day. I particularly stressed to these fellows that their job was not so much to find mechanical safeguards that were needed, but to watch out for unsafe practices. I was one hour and a half explaining to him what unsafe practices he might look for. I got a report twice a day from that fellow, and all the unsafe practices that he found he called the foreman's attention to.

If there is a lost-time accident, they are going to send me a wire.

I am glad to tell you that up to the present minute I have not received such a telegram.

In one of our departments, there is not a month goes by but what they have a lost-time accident. They don't amount to much, but we have a lost-time accident charged up against that department every month. We appointed a new general foreman who has charge of the night turn. We operate from midnight on Sunday to 7:00 o'clock the following Sunday morning without a stop. Since we appointed this new general foreman they operated during June, July and August without a lost-time accident, and then a man turned on his ankle (I don't just recall how it happened) and he lost 40 days. That is the only accident they have had since the first of June.

The thought I want to bring out is that if you appoint a man in charge of the plant for one week, the men all know that he is one of the bunch. I do my work in the shop professionally. Every one of you men here who are safety engineers in the plant are looked upon by the workmen as professional workmen. This is a workman, one of their own kind, one of their own bunch, and if he does it in the right spirit, and you use the right kind of judgment in selecting your man, you will get wonderful results. It is well worth all its costs.

Getting the Colored Employee Interested

G. A. ORTH (American Car & Foundry Company): In connection with keeping the colored man interested in safety in our plants, we have 18 plants employing about 4,000 to 5,000 colored people. In the beginning, they were hard people to get interested in the subject of safety. We finally appealed to their spiritual side. Among the colored gentry, as you know, they have preachers who are called lay preachers. We set out to find a scripture lesson from the Bible and we finally located one. This lay preacher would get groups of colored men together. When you talk about the Bible to your colored man, you will get a hearing. In that way we have interested these men, and as Mr. Grier, who represents us in the Wilmington district, told you a few moments ago, in the past two years we have not had an accident involving a colored man. That I will also say applies in our larger plants.

In the Brunswick plant, employing some 2,500 men, about 30 per cent are colored, and we go around from year to year without any lost time accidents. In the St. Louis and Madison districts, employing about 2,000 in each, very few of them sustain injuries, because we have them thoroughly saturated with the idea that it is almost sinful to become injured. You know that the colored man when he is spiritually inclined knows that it is wrong to commit a sin. We believe in that way we have interested our colored people.

L. C. MAGIN (Union Indemnity Company): In further reference to this gentleman's remarks about the negro help, in the south, rough labor is all largely negro. I know the Celotex Company employ about 75 or 80 per cent negro. Accidents were piling up with their help. They

thought out this scheme, the race track scheme. They had a safety-first horse up on the board. They offered rewards of \$2, \$3 and \$5 for the best safety suggestions they could get from any of their employees. Each department had its own race board. It interested the negro very much. They had a safety-first horse and an accident horse. Each time that a man was careless or in any way affected their department winning the prizes, they would go in and report him. The result was that they cut down on their accidents.

W. L. WALLACE (Edward Hines Yellow Pine Company, Lumberton, Miss.): I think you will find that your negroes are more largely imitators than anything else. I am speaking from a life-time experience in association with the negroes in the south. I didn't know that anybody else had had quite the experience with them that we had. The reports of my experiences rather confirm yours, a negro is hard to get interested. You have got to appeal, it is true, to his religious side, but his religious side won't stay put. The negro's religious side is hardly a side, it is rather a vascillating quality. As long as you can get him interested from the religious standpoint, that is all right. His sporting proclivities I was rather impressed with. If you once get him interested, you are going to find that he is the best safety worker you have got.

As I say, he is largely an imitator. If you can get his confidence, make him feel that you are relying on him, I believe then you are going to get better results from him, more continued results than from the average white man of the same class.

The Safety Engineer Is New on the Job

We have had a spasmodic organization problem. Until about three months ago we never had a safety engineer. We are groping and feeling to see just exactly the best way to do this work. While we have practiced safety for some years, our safety engineer was a perfect stranger to the negro. I am gratified to say that he seems to be appealing to the negro and doing it in a way through the religious side. He is not altogether letting it be safety, he is trying to touch the negro's personality, his personal life. He has organized with considerable success.

I am very hopeful that we are going to get something out of that. I went down there not long ago, about two or three weeks ago, and made a talk to them. It was the first time that a layman ever talked in the church, I believe. I felt a little bit strange. Mr. Buchannon is working on the outside, organizing the negroes and sort of getting them bunched together. I think he is going to accomplish something along that line. Mr. Hartley has a paper (I don't know whether Hartley is here this morning) that he will read tomorrow. They have made quite a success in reaching their negro laborers.

I think Mr. Hartley will bear out what I say, that they have had as much or more success in their negro organization than in the white.

I think it would be well to discuss it tomorrow at the end of his paper, rather than today.

CHAIRMAN WIBERG: I think it would be a good thing.

MR. WALLACE: I know they have been successful in reaching their negro employees. Mr. Buchannon, have you gone far enough into your organization to tell the boys anything about it?

MR. BUCHANNON (Edward Hines Yellow Pine Company, Lumberton, Miss.): We have three classes of labor to deal with, the negro, the Frenchman, and the white man. Before I went down to Mississippi I studied the negro in Detroit a great deal. The negro in Detroit and in the north and the east, is a little different from the negro down south.

Free Eats Always Appeal to the Colored Boys

I was talking to a bunch of the saw-gang men down there and I asked them if any had ever been up north. One of them replied, "Yes, I have been up north."

"Where did you go?"

"I was in Detroit."

"Well, where did you work in Detroit?"

"Don't you remember me?"

"No, I don't think so. I see so many of you fellows up there that I don't know you all."

"Don't you remember me in the Hupmobile plant?"

"What is the difference between working up there and down here," I asked him.

He said, "There is one big thing. When I am down here, I can go in to Mrs. Caldwell's for something to eat when I am hungry, but I couldn't do that in Detroit."

That is a fact. While I live here, my wife is a southerner. I lived out in North Detroit. My wife's father was a great turpentine man in the south. He had worked with negroes from all over the south and some of them are still with him. They come out to my house and they say, "We want something to eat." Some of them she didn't know.

I found the negro preacher about a month ago. That is one of the most unusual types of negroes I ever had to deal with. This negro is an ex-slave, about 65 or 70 years of age, and he is a talker if there ever was one. He said to me, "The thing that you want to start down here among the negroes is to get them classified." Those are his words. He used to classify the negroes.

We have got in our logging camps and in our quarters where the negroes live, houses owned by the mill companies. That is where the negroes live. Pay day is every Saturday night. Every pay night, we find the roads flooded with women and bootleggers and everything else.

We started this organization. We got all the negroes down there in our main logging camp. We had this negro preacher go and give them a talk. Judge Wallace and I went along also. We took them over to the church and we told them what they were there for and what we

wanted to do. This negro preacher explained to them in his own words that he wanted to classify them.

In addition to my safety work, I do a lot of sanitary work. That is a thing that had to be started down there. I saw the condition of things, and I started it right away. I was through the quarters the other day. A negro said to me, "I want to move out of this house."

I said, "Why do you want to move; isn't this just as good as any other?"

He said, "Yes, but next door to me they have a crap game every other night, and I belong to that League down there and I want to move out."

We would like to get the better negroes, and let the others go. We don't care about them. We have now a better element quarter and a bad element quarter.

The whole thing with the negro, I find, is this: I haven't been down there long enough to be an authority on it, but the more personal conversation you get into with the negro and the better you get acquainted with him, the more you are going to get out of him.

I have negroes who are absolutely safety men. They work among themselves. I started on the thing with the idea that "I am my brother's keeper," and the religious negroes took it up. This year's record shows where we have had bad accidents before. The record came down with a drop this month and we have been working night and day; we haven't stopped this month.

Most of These Employees Are Southern Negroes

I would like to ask Mr. Orth a question. You say you have 4,000 negroes in your plant; are the majority of them born in the south?

MR. ORTH: Southern negroes.

We have a large plant in Memphis. It is more or less of a training school. We brought them up north during the War period. As you know, it was pretty hard to get labor anywhere. We sent the people down to Tennessee. It is against the law of Tennessee to take the negroes from one state and bring them into another, but that was waived during the War period. We can not do it, however, at this time. We named a town in Pennsylvania after our safety man down there, Mr. Gerard. It is now legally known on the books of the Common Council of Burwick as Gerardville, Pennsylvania. That is how much we think of the negroes.

MR. BECHANNON: That is the only way we are going to get at them. We have done everything in our mills and logging departments in the way of mechanical safeguards. I don't think a thing is lacking. We have got to educate them. Ninety-five per cent of our labor is negroes. They go to work at 5:30 in the morning and get back at 6:00 o'clock at night. They are out all day and naturally are all tired out at night. As soon as the cool weather started, I asked them to come over. I told some of them the other day that if they had a good record soon, I would

give them an oyster supper. A few days later I happened to be going to one of the quarters and one of the negroes said to me, "How about the oysters, bo?"

I think that we are going to have a good deal better success than we have by starting an educational problem. That is the only way you can do it among the negro employees.

ADJOURNMENT

WEDNESDAY MORNING SESSION

October 27, 1926.

The meeting convened at 9:40 o'clock. Mr. Herbert G. Wiberg, presiding.

CHAIRMAN WIBERG: The first paper will be given by Mr. G. V. Fuller, Assistant Secretary of the National Council on Workmen's Compensation Insurance. That organization is an insurance concern, a sort of a neutral body that collects figures and statistics on accidents and compensation costs all over the country. From those figures, they formulate plans of rating plants on the basis of the physical conditions, that is, the guards that have been put in and the conditions which are not guarded, and also determine rates for the various types of industry.

Mr. Fuller has analyzed woodworking conditions and accidents in nine different classifications over a period of six years. I think you will find that the data he has distributed will be of great value to you in indicating where to concentrate your efforts in preventing accidents.

WHERE ACCIDENTS OCCUR IN THE WOODWORKING INDUSTRY

G. V. Fuller, Assistant Secretary, National Council on Compensation Insurance, New York City

An analysis showing where accidents have happened in the past is of little value if it is regarded merely as a post mortem or a chapter of history. Its chief value lies in its use as a preventive of future accidents.

In order to prevent accidents, it is first necessary to know something about the physical and psychological causes. This makes it easier to determine which conditions must be removed or corrected in order to prevent their recurrence.

An employer of many men has some opportunity to learn from past results in his own plant alone, but the employer of only a few men does not have this same opportunity. His accident hazard per man may be as great or greater than in the larger plant but he does not have as many men and consequently not as many accidents even from the most common causes in this particular industry. A tabulation of accidents in a large number of factories in his industry and covering a long period of time will provide such an employer with information which will be invaluable to him, for he may then see at a glance where and how his accidents may occur in the future and he can take steps to prevent them. Nevertheless, his own analysis is of much importance for it will permit him to discover certain peculiarities of his own plant or process of manufacture.

There are many State Industrial Boards and Commissions throughout the country that publish a summary report annually of accidents which

have occurred within their states. These state reports, which generally quote accident figures in hours of lost time, are very comprehensive and employers would do well to study carefully the information contained therein.

The National Council on Compensation Insurance, an association of about eighty Insurance Carriers engaged in the writing of Workmen's Compensation Insurance throughout the country, receives from its members, for rate-making purposes, detailed reports of all accidents for which compensation or medical expenses have been paid. Extensively detailed reports are filed for all accidents resulting in death; permanent total disability, such as loss of both hands, both arms, both feet, both legs, both eyes, or any two thereof; major permanent partial disability which is defined to include the loss of sight of one eye; the complete loss or impairment to the extent of 50 per cent or more of a hand, foot, arm or leg; and any other permanent injury which is compensated on the basis of 25 per cent or more of a permanent total disability; and every minor permanent partial or temporary disability, the cost of which has equalled or exceeded 50 weeks indemnity at the maximum statutory rate for the state under whose law the accident was compensated.

An Analysis of More Than Three Thousand Reports

I have just completed an analysis of 3,038 of these extensively detailed reports of accidents which have occurred throughout the country in the nine principal manufacturing classifications of the Woodworking industry. A classification from the standpoint of Compensation Insurance, as you no doubt know, is a device whereby all risks of the same general characteristics as respects raw materials, processes, hazards of operation, products, etc., are given equal rating treatment.

Briefly, my analysis covers sawmills; plants engaged in planing lumber and the manufacture of window sash, doors, blinds and other assembled millwork; cooperage; the manufacture of wood-turned products such as pulley blocks, spools, wooden heels, hat blocks, etc.; the manufacture of wooden furniture; veneer products such as fruit baskets and barrels and veneer panels; miscellaneous woodenware, which contemplates a large variety of wooden products such as ladders, household utensils, etc., which can not be assigned to any of the more specific woodworking classifications. The manufacture of carriage and wagons has been included for although it is a declining industry, it represents a process in woodworking that can not be allocated to any other classification. There are, of course, numerous minor woodworking classifications used in the application of Workmen's Compensation Insurance, but these minor classifications from the accident cause standpoint are comparable to the important classifications which I have just enumerated. This analysis covers a period of six years (1918 to 1923 inclusive) and for the accidents involved, the national compensation cost to the Insurance Carriers has amounted to over \$5,200,000, paid or incurred. During this same period and in these same nine classifications our

Member Carriers have paid or incurred losses on a grand total of 71,024 accidents, which in monetary cost has amounted to nearly \$15,921,000. This spread of data corresponds to a concurrent payroll exposure of approximately \$1,047,144,000, and assuming that the national average wage in this industry is \$1,000 per man per year, it represents roughly an employment of well over a million man-years.

My analysis, therefore, represents a little over four per cent of the grand total number of accidents in these classifications but roughly one-third of the grand total cost. It is important to point out, however, that these 3,038 cases represent all those of the most serious character both from the standpoint of suffering by the employee and that of cost to the Insurance Carriers who have had to provide compensation; for these 3,038 accidents in the average amount of \$1,715 per case, including a total of 570 deaths at an average compensation cost of \$2,545 per case; and 30 permanent total disability cases at an average of \$5,100 per case.

General Facts Are First Classified

Yesterday your chairman kindly distributed copies of my analysis in order that you might have a little time to scan it in advance of my address. (See accompanying Tables, Part I and Part II.) You will observe that I have tabulated in the first nine columns, the accident data for each of the classifications involved. The grand total data are contained in the last column. While each classification has its individual story to relate, I will confine my references in general to the grand total for the industry.

The first part of the analysis represents general facts relative to the total number of cases involved, their character in terms of type or disability and their total average costs. May I again point out that the fatal, permanent total, and major permanent partial disability cases listed represent all that have occurred within these classes in the six year period. The few minor permanent partial and temporary cases included are those only whose compensation cost has amounted to more than the amount previously described. In addition there are some 68,000 minor permanent partial and temporary disability and medical cases from accidents which have occurred in these classes and which are not included in this analysis, but the compensation cost per case averages only about \$160.

The second part of the analysis represents a segregation of cases on the basis of specific cause and for each such cause is given the number of cases, both fatal and total, with the corresponding cost of compensation including medical expense. Percentages of total cost have been indicated for the general groups of causes and where any specific cause has produced a substantial volume of losses, individual percentages have likewise been shown.

Time does not permit me to discuss many of the interesting details of this analysis. I can only leave it with you in the hope that you will give

TABLE—PART I
Summary of Compensation Insurance Cost for Analysed Accidents

	Classification Divisions of the Woodworking Industry										Average Cost
	Code 2730-2731 Planing & Assembling Millwork Mfg.	Code 2710 Saw Mills	Code 2742 Cooperage	Code 2759 Box or Box Shooks Mfg.	Code 2794 Wood Turned Prod. Mfg. (N.O.C.)	Code 2841 Woodenware Mfg. (N.O.C.)	Code 2883 Furniture Mfg. (not metal)	Code 2915 Veneer Products Mfg.	Code 3864 Carriage or Wagon Mfg.	Grand Total	
Grand Total No. Cases (t)	729	1145	64	243	189	39	489	50	80	3,038	\$1,715
Grand Total Cost	\$1,233,098	\$1,931,354	\$99,355	\$446,255	\$292,965	\$76,599	\$874,231	\$105,202	\$142,393	\$5,201,442	\$1,558
Grand Total Compensation Cost	\$1,114,405	\$1,740,891	\$90,769	\$409,954	\$287,138	\$66,511	\$807,612	\$98,864	\$129,423	\$4,725,477	\$1,57
Grand Total Medical Cost	\$118,693	\$190,553	\$8,586	\$36,301	\$25,827	\$10,088	\$66,609	\$6,338	\$12,070	\$476,005	
No. Fatal Cases (f)	111	276	6	41	19	7	83	17	10	570	\$2,545
Total Cost of Fatal Cases	\$286,033	\$601,948	\$14,706	\$114,064	\$41,634	\$9,885	\$256,215	\$40,175	\$28,942	\$1,451,602	
No. Permanent Total Disability Cases	5	13	2	3	1	—	5	1	—	30	\$5,100
Total Cost of Permanent Total Disability Cases	\$32,367	\$49,121	\$8,018	\$28,712	\$5,500	—	\$26,096	\$3,233	—	\$153,037	
No. Major Permanent Partial Disability Cases	392	588	43	157	129	30	260	33	50	1,682	\$1,730
Total Cost of Major Perm. Part. Disability Cases	\$706,295	\$998,540	\$84,101	\$255,559	\$212,749	\$64,906	\$401,455	\$54,057	\$91,657	\$2,913,190	
No. Minor Permanent Partial Disability Cases	206	253	12	35	39	2	133	8	19	707	\$370
Total Cost of Minor Perm. Part. Disability Cases	\$186,467	\$202,422	\$11,598	\$34,915	\$31,684	\$1,806	\$115,559	\$7,737	\$22,848	\$615,006	
No. Temporary Disability Cases	15	15	2	7	1	—	9	—	1	50	\$1,370
Total Cost of Temporary Disability Cases	\$21,956	\$19,423	\$942	\$6,006	\$1,398	—	\$14,936	—	\$946	\$68,007	

it your careful study at some later date. There are a few specific causes, however, that I wish to call to your attention.

You will readily see that machine accidents have accounted for a great proportion of the compensation cost in the Woodworking industry. The 1,777 accidents at the "Point of Operation" alone are responsible for about 52 per cent of the total cost. The 256 cases due to "Driving of Mechanism and other Moving Parts" of the mechanical equipment have cost another eight per cent and "Prime Movers" and "Power Transmission" with their 61 cases have added about three per cent more. In other words, 2,094 accidents (238 deaths included), or about 63 per cent of the total cost of compensation, resulted from mechanical equipment. It is essential, therefore, in the Woodworking industry to first concentrate efforts on preventing some of these machine accidents.

The question then arises as to what specific machines have caused the most accidents. Without referring to the analysis you no doubt will say that circular saws in their various forms are the greatest accident producers. My analysis verifies this statement for rip-saws alone have produced 422 accidents or about 14 per cent of the total cost. In the manufacture of sash, doors and blinds, assembled millwork and furniture, rip-saws have been responsible for almost one-fifth of the total cost. All other types of circular saws have produced 976 accidents or an average of 22 per cent of the total cost. Here again the proportion of cost varies in accordance with the process, for in sawmills and in the manufacturing of boxes and miscellaneous woodenware these saws are responsible for about 28 per cent of the cost within these classes. These two machines, as might be expected, stand out clearly as the principal accident producers of the industry.

Many Different Causes for Ripsaw Accidents

There are many different causes for rip-saw accidents but the one which is most impressive is the "kickback of material." There are recorded in this analysis 120 cases of "kickbacks" with 73 of them fatal. In short 61 per cent of the "kickbacks" in this analysis have killed the man, and he may not have been the operator of the saw either. The cost of compensation for this one cause alone was over six per cent of the total cost. This cause with its large proportion of deaths does not stand out as a characteristic of any particular type of manufacture in the Woodworking industry, although in furniture manufacturing it is considerably higher than in the average, undoubtedly due to the large amount of hand feeding.

Does this not indicate to you that something must be done to stop this type of accident? "Kickbacks" may be absolutely prevented by guards that are on the market and I personally believe that employers should start here in the process of accident prevention.

So far as the other types of circular saws are concerned, the type of accident that stands out particularly is that due to flying chips, splinters, small cuttings, sawdust, etc. This cause has accounted for over three per cent of the total accident cost.

Planers come next in importance, for although the total average percentage of loss is only about three per cent, certain processes such as sash, door and blind manufacturing, planing of rough lumber and box manufacturing run from five per cent to 11 per cent of the total cost in their respective classifications. Kickbacks, flying chips, slivers, etc. and brushing off of shavings from machinery seem to be the principal accident causes although their respective percentages are relatively small.

Jointers, although being responsible for only around three per cent of the grand total cost, are frequent and serious accident producers in certain classifications of manufacture, such as sash, door and blind and furniture manufacturing where the proportionate cost is around five per cent.

Shapers are particularly bad in furniture plants where about six per cent of all cost in the classification is due to these machines, slipping of the operator's hand or his work in feeding, being particularly important.

The Operator's Hand Often Slips Near the Saw

A review of all mechanical accidents discloses that the slipping of the operator's hand in feeding the stock or the slipping of the stock itself while being fed is responsible for six per cent of the total cost. This cause appears in connection with practically all machines in the industry and in view of its common occurrence, it seems that steps should be taken either through mechanical devices or through education of the workmen to prevent such accidents.

Accidents caused by the catching of loose clothing and gloves in mechanical equipment are responsible for over four per cent of the total cost. It is apparent that supervision by employers over the clothing and gloves worn by their employees while in the plant, combined with general "safety-first" education, are the remedies for this type of accident.

Among the non-mechanical causes of accidents, the general group "Falling of Persons" appears to be the worst producer. The 188 cases, of which 39 per cent were fatal, were responsible for over eight per cent of the total cost. "Falls from ladders," one-third of which were fatal, produced about one per cent, while 37 cases of "Falls into hot water soaking vats" accounted for about two per cent. In the sawmill classification this type of accident has produced 26 cases, 23 of which have been fatal, and the cost has been about four per cent of the total for the classification. In Veneer Products Manufacturing, seven cases, all deaths, have been responsible for 14 per cent of the cost.

The "Handling of Objects" in general has been responsible for about five per cent of the cost and "Hand Tools" have cost the carriers a little under four per cent of the total. "Falling Objects" have resulted in over four per cent of the cost while "Elevators and Hoisting Apparatus" have produced accidents costing about three per cent of the grand total.

I have touched only the "high spots" in the analysis but I assure you that a careful study of it in detail will be worth the time so spent.

I have spoken up to this point purely with respect to compensation cost paid by the Insurance Carriers. However, this may be only a minor part of the total loss cost to the industry. When you stop to consider the aftermath of an accident, I am sure that you will agree with me that, after all, the employer loses more than appears at the casual glance. The direct losses to the employer appear in the forms of damaged equipment and imperfect work but principally in reduced production, due to the loss of producing time of the injured, the temporary shutting down of the department where the accident occurred, the mental effect upon the other workmen who may have witnessed it and so on. The effect upon the employee morale may go even farther, leading to internal labor troubles that are disconcerting and costly.

The Workman Is the Greatest Loser from Accidents

The greatest loser of all is the injured workman for the cost of the accident to him is bodily mutilation or loss of life. This cost can never be repaid and the outlay of a few dollars by the employer for safeguarding is of small consequence when compared with the suffering of the victim and his family.

I do not wish to give the impression that the only prerequisite to an effective accident prevention campaign is the determination of where and how the past accidents in the plant have occurred. As a primary step, there must be born in the employer a sincere desire to stop the suffering and death of his employees resulting from accidents within his plant. He must come to the realization that their safety is his responsibility and he must be prepared to assume it under all circumstances. If an accident is actually attributable to an employee's carelessness or stubbornness, he must still accept the responsibility, for the selection of his workmen and their retention on the payroll should take into consideration their general adaptability to "safety-first" ideas.

There may be present also the desire to stop the monetary loss to his organization resulting from accidents. This desire, however, should be secondary, for after all, the "almighty dollar" can not be placed above nor upon the same level with human flesh. Nevertheless, it does cost money when accidents occur in any plant and this cost can not be entirely ignored. It is reflected in increased insurance premiums but it also appears in reduced production which, in most instances, is of much graver consequence to the business.

There must be either existent or instilled in the workmen the genuine receptiveness to "safety-first ideas. They must feel or be induced to feel that safety bulletins, accident prevention talks, inspection committees, and other safety organization activities are not just poppy-cock or the work of some technical visionary but have been installed in the organization primarily for their own good. Confidence of all employees is the first goal and, after that is gained, loyalty and cooperation will

follow, resulting in real progress toward making the plant a safer place in which to work.

The converting of an employer and his employees into fertile ground for the planting of "safety seeds" is a problem in psychology and education, and perhaps is the most difficult step in the process of accident prevention work.

In concluding, however, I can not stress too strongly the importance of a careful accident analysis in any plant and the very material assistance which it may render in the prevention of future accidents. A general analysis of accidents within a general industry, such as the one I have presented, may be used as a basis of an accident prevention campaign but it can not take the place of one made by the employer from his own experience.

There is one feature that I wish to impress upon you most strongly; namely, the absolute necessity for greater cooperation and effort on the part of employers and investigators of the various Governmental Agencies and Insurance Carriers toward the production of more accurate accident reports. An accident report, regardless of who makes it, should not be considered as a "piece of red tape" that can be submitted in a half-hearted and semi-correct form. Every accident requires a careful investigation of the circumstances surrounding it to determine its exact cause.

Reports Should State the Real Cause of an Accident

Suppose an accident occurs where the operator's hand is caught in the saw. That accident should not be recorded simply as "hand caught in saw," for the catching of the man's hand may be only a resultant of the true cause. The accident actually may be due to the structural or other physical conditions around the machine; it may be due to some permanent or temporary abnormality of the employee, either mental or physical; it may be due to poor light, poor ventilation or any number of such preliminary causes. To prevent the recurrence of the "hand caught in saw" accident, the employer must first correct these preliminary conditions and in all probability, he will then have removed the true cause. All employers today who are truly interested in accident prevention are beginning to realize that poor lighting in a plant is causing more accidents than is generally supposed and you will find many who are providing more efficient lighting around dangerous machinery principally with a view to accident prevention.

When reporting an accident, therefore, do not write the fewest words possible, but go into the details of the actual circumstances surrounding the unfortunate event. You can not give too much information, for at the time of making your report, you do not know what it may be used for. Be careful to state the cause and do not mistake an effect for that cause. The accurate report of an accident and its correct analysis is an educational function of every plant safety organization that should not be overlooked. I am sure that the sooner we all realize that complete accident reports and careful accident analysis are important as

the only means of determining the cause, the quicker will it be possible to reduce the number of accidents by proper prevention methods and their cost in terms of reduced production, monetary compensation and most important of all the reduction of human suffering.

CHAIRMAN WIBERG: I want to thank Mr. Fuller personally and on behalf of the Section for the amount of work that he has put in in giving us this contribution. The data that you have been given should be something that you can refer to in the future and which should be of great value to you in preventing accidents.

I am now going to ask for the report of the Nominating Committee. Mr. Sanford!

REPORT OF THE NOMINATING COMMITTEE

MR. SANFORD: The Nominating Committee of the Woodworking Section presents the following names for your consideration:

Chairman, E. Ross Farra, U. S. Gypsum Company, New Brighton, Staten Island, N. Y.

Vice-Chairman (Manufacturing Group), J. B. Grier, American Car & Foundry Company, Wilmington, Del.

Vice-Chairman (Logging Group), W. L. Wallace, Edward Hines Yellow Pine Company, Lumberton, Miss.

Vice-Chairman (Sawmill Group), J. I. Thompson, J. J. Newman Lumber Co., Hattiesburg, Miss.

Secretary, A. O. Jackson, Aetna Life Insurance Co., 100 William Street, New York.

Executive Committee, the officers and the following past-chairmen: G. A. Orth, New York City; W. S. Paine, Aetna Life Insurance Co., Hartford, Conn.; G. E. Sanford, General Electric Co., Schenectady, N. Y.; H. G. Wiberg, Lumber Mutual Casualty Insurance Co., New York City; Harry Guilbert, the Pullman Co., Chicago, Ill.

CHAIRMAN WIBERG: What is the pleasure of the meeting? If there are no other nominations, I will hear a motion to accept the report of the Nominating Committee.

H. R. ORCHARD (Marathon Lumber Company, Laurel, Miss.): I make such a motion.

MR. ORMOND (Imperial Furniture Company, Grand Rapids, Mich.): In hearing the names mentioned, I did not hear any names familiar to me from any of the furniture industries. I think it would be a good thing to have one representative on that committee from the furniture industry.

CHAIRMAN WIBERG: Have you anybody in mind that would serve?

MR. ORMOND: We have some men here if they would only make themselves known.

CHAIRMAN WIBERG: Can you suggest the name of one man that you think would do some good?

MR. ORMOND: Is the representative of the American Seating Company here? I don't know what his name is.

CHAIRMAN WIBERG: I am very glad you spoke up. We would like to get the name of somebody that would be an active member.

MR. ORMOND: In Mr. Fuller's paper, he has covered a lot of the facts of accidents that happened in the furniture industry.

CHAIRMAN WIBERG: Have you in mind anybody that would take the place of Mr. Lund?

W. H. YEOMANS (Imperial Furniture Company, Grand Rapids, Mich.): Mr. Griffin or J. J. Frye. Mr. Frye is located in Grand Rapids and he is connected with the furniture industry.

MR. FARRA: I would suggest to you that Mr. Frye be nominated another vice-chairman.

J. J. FRYE: I would like to have you nominate somebody else. I have only been a few months in the work, and my knowledge therefore is not sufficient, I think, to give satisfaction. I think Mr. Griffin, of the American Seating Company, would do better work and give better satisfaction.

CHAIRMAN WIBERG: I think probably the best way to take care of that situation would be to leave the matter with Mr. Sanford and Mr. Farra. They will get in touch with Mr. Griffin, and if he is willing to serve, he will be elected as a vice-chairman in charge of the furniture industry.

Nominating Committee's Report Is Accepted

MR. SANFORD: If you want to leave the matter in abeyance for a day or a week and then send in to Mr. Farra the name of the man that you would like to have, we will be glad to have him. The Executive Committee of the Section is empowered to add vice-chairmen. If someone shows up that they haven't known about heretofore that represents some one certain line, it is the privilege of the Executive Committee of the Section to add that man's name for the year without going through a Section vote.

CHAIRMAN WIBERG: Is there anybody from the box manufacturing industry that knows of anyone that might take some interest in the proposition? We would be very glad to have the furniture people suggest someone.

I am waiting for a second to the motion that we accept the report of the Nominating Committee.

W. H. YEOMANS: I second that.

(The question was put to a vote and was carried.)

CHAIRMAN WIBERG: The next item is the discussion of Mr. Fuller's paper by Mr. McA. Keown, engineer of the Industrial Commission of Wisconsin. Mr. Keown has been working with this woodworking question for a long time. He is very thoroughly conversant with the proposition. He has investigated a great many accidents and examined a great many plant machines and guards. I don't know of any one better qualified to discuss such a paper.

I don't believe he has had a chance to go through it thoroughly because of the large amount of figures and information that the paper contains. However, I am pretty sure that Mr. Keown will give you an interesting talk.

DISCUSSION OF MR. FULLER'S PAPER

**R. McA. Keown, Engineer, Industrial Commission of Wisconsin,
Madison, Wis.**

I can not competently discuss this paper which was so well given by Mr. Fuller without further study. I want to emphasize, however, some of the points that he brought out. The first one is the value of accident prevention. These tabulations that he has presented here are actual facts, and anyone will do well to give those figures careful study so that the experiences of the past can be used in preventing any accident in the future.

Mr. Fuller spoke particularly of the 3,000 major injuries of which 1,777 were at point of machine operation. Of those accidents, a very large number, as he pointed out, were caused by circular saws. The figures that he has given there check out very closely with the accident experiences in my own state, Wisconsin.

Mr. Fuller also mentioned the hazard of the operator's hand slipping into the machine while the machine was operating. That is, I think, a very important cause of accidents, and one which can be pretty largely prevented by the use of slip mats and the proper kind of guards. We so often find guards on saws that are simply a hood over the top, fixed or adjustable, and if adjustable, it is adjusted for the material put through and then becomes no guard at all. The only right type of saw guard, in my opinion, is one that rests on the material while it is being processed and on the table when there is no material in the saw.

The responsibility of employers for accident prevention is very explicit. I think it is almost impossible to have the workmen safe unless the employer does his part, makes the plant safe by furnishing guards, a good type of guard, wherever they may be necessary. That is an incentive to the workman. It is just like good housekeeping. It gives the workman more of an incentive to take some pride in his work and the place in which he works.

Before I came down here, I did not know from the title of Mr. Fuller's paper just what line of discussion he would use. I brought along a few pictures of saw guards. These are not commercial guards, they are guards that have been made in various plants. There were several others that I expected to have to show to you, but they had not arrived.

We have been doing considerable in Wisconsin during the last few years on saw guards. We found that 50 per cent of our woodworking accidents occurred on saws of various kinds, not all circular saws, but saws under the broad classification. In 1923 we had 677 saw accidents. In 1924 we had 637. In 1925, 545. I don't think there were any less saws used, but I do know they are being better taken care of. You can buy on the market now some very good commercial guards. There are still some operations on which there seems to be no satisfactory commercial guards, and it is up to the individual employer to develop the guards for that particular kind of a job.

The jointer accidents that Mr. Fuller spoke of, we have the same trouble with in Wisconsin, 10 per cent of our woodworking accidents being from jointers.

If we can have the slides, I will be glad to explain them to you.

(*Slide.*) This is in the box department of a lumber company. It is just a little side light on that particular guard. The Milwaukee Association of Commerce runs each winter a foreman's safety school. One night I was talking to the woodworking section on saw guards. A number of the individuals showed commercial guards and home-made guards. This was three years ago. One of them showed me a hood over the top, that I mentioned before, which I considered almost useless in the way of a guard. When it came time for the discussion, a foreman from this particular plant said it was the best guard I showed, in his opinion, and that he wanted to see the saw. There was no doubt about that. That brought on quite a lot of discussion and others didn't agree with him.

He went back to the plant and the next winter he brought up a saw table with that guard on it. It is cutting box material, half the table splined. You will notice there is a spring here. This guard rests on the splitter here and is also forward. As you push this part of the table, the guide comes against it and the guard recedes until the piece has been cut. It has no movable side wing.

Another Guard With Splitter and Slide

(*Slide.*) Here is one developed in the Kiwechefer Container Company. Here is the splitter and the slide. This piece has a slot in it going over the pin and a spring inside that barrel which keeps the pull forward. That is somewhat similar to the other, except that it has the adjustable side wings. That was developed in that particular plant about three years ago.

(*Slide.*) Here is one that is used in a box factory for a sliding table. The particular thing they do on this saw is make Kraft cheese boxes. They take 12 thicknesses of material. It is just a wooden veneer hood, made of veneer stock. This part up here is adjustable. Whatever the width of the material is, it is adjusted so that that projecting part comes out in front just as with the material, so that as you push your table forward, you don't see the saw at all. The whole hood is pushed back against the spring. As you withdraw the table, the hood follows back to the forward. That was developed in the Keel Woodenware Company.

(*Slide.*) Here is one that is rather crude. All they had at first, however, was the cast iron guard that covered the upper half of the saw. They then took veneer stock and put side wings on it. I think they had several accidents before they put them on. They haven't had any, as far as I know, since then.

This comes out pretty well to the front and does not give you a whole lot of protection. It could be changed somewhat to take care of that.

(*Slide.*) Here is another home-made one. It is rather crude look-

ing, as you can see, but it is pretty good protection. This slides up and down on the back. It is an overhead swing saw.

(Slide.) I have one more of this. This is for an under saw. These are loose pins that move up and down as you pull the lever forward to bring the saw out in the open. The whole thing drops and the pins come down until they strike the material or the table, if there is no material. I think the next slide will, perhaps, show that a little better.

(Slide.) This one shows it down, the saw forward and these pins which are loose upset at the upper end and striking the table and the saw. I don't think that would be very satisfactory in a plant that is a production plant, because they do bend these pins. They are perhaps five-sixteenths of an inch in diameter. It, however, shows what somebody was trying to accomplish.

A Guard for the Under Swing Cut Saw

(Slide.) Here is another one for the under swing cut-off saw. It is a home-made guard. This is all wood. This is made of wood bound with strap iron. It has been guarded in that way for perhaps five years, and they haven't had any accidents since it has been so guarded.

(Slide.) Here is another one for the under swing cut-off saw. The hood is fastened to the extension on the arm.

(Slide.) Here is another one where there is an arm fastened. These slots are made to fit the particular work that is being done.

(Slide.) Here is another one where the back rest is cut out.

I have not shown these with the idea that they are 100 per cent guards. What I want to convey is that people are interested in the guarding of these dangerous machines, and they have some man in the shop, some foreman, design a guard. That is his guard, and he takes more pride in it than if some party from the outside came in and told them to put on a certain kind of guard.

The Ward Hemlock Company has a quick action under-swing saw with a guard that I haven't the picture of, which is very interesting. The saw is guarded entirely when the saw is in position, with a cast iron guard. They had a number of accidents on this saw. The men always had to use gloves, because it cut their hands up. Fortunately, they had no serious accidents. One of the men in the plant decided that he could guard that. They cut off this cast iron hood, and put on a separate one that is operated not from the saw itself, but from the floor, connected to the floor, and from there to the swinging saw and it works fine. They haven't had any accidents. It has only been put on since this summer. There is no objection on the part of the operators to using it, and that is a great thing in saw guards.

CHAIRMAN WIBERG: I think in accordance with our regular procedure, we will have the other papers and then come back and discuss them if any one has any points.

Our next paper will be given by Dr. David Shapiro, who happens to

be connected with the same company that I am. He will give us a talk on first-aid out of the experience of at least 14 years of industrial surgery work. During that period he has come in contact with thousands and thousands of different types of injuries and different requirements for their treatment.

PRACTICAL SUGGESTIONS FOR EFFECTIVE FIRST AID.

Dr. David Shapiro, Medical Director, Lumber Mutual Casualty Insurance Company of New York, New York City.

From both humane and economical view-points, the subject of first aid is of vast importance. Its economical value consists in preventing the loss of service of employees and decreasing the cost of insurance by keeping down the loss experience on the risk. I shall therefore endeavor to impress upon you several of the practical principles in the application of first aid. First aid treatment is not intended to replace the services of a physician, but to prepare the patient for the treatment that is to be instituted by the doctor upon his arrival, which frequently may be delayed by various circumstances.

In all instances where the injury is not a very minor one, a physician should be summoned, because there are injuries not alone to the various internal organs, but even superficial wounds which may appear trifling at the onset but become of serious consequence if surgery is not resorted to as soon as possible. The results obtained very frequently depend upon the intelligent handling of the injured individual immediately after injury is sustained; therefore, I would suggest that every employer assign at least one, and if possible two, persons in his employ who will be prepared to handle emergency cases by having made a thorough study of the principles of first aid. The all-important factor in the application of efficient first aid, is calmness and collected thought on the part of the individual administering it. Several of the conditions with which you are confronted quite frequently, will be taken up briefly in the order of their importance.

The first is the condition commonly known as shock, also termed collapse or prostration. This varies in degree according to the severity of the injury and is recognized by faintness, at times complete unconsciousness, extreme pallor, profuse and cold perspiration, shallow breathing with very rapid pulse. Collapse is thought to be produced by a dilatation of the internal blood vessels, thereby causing a stagnation of blood internally; treatment must therefore be directed toward accomplishing an adequate circulation.

Where patient is suffering from shock, medical aid should be summoned immediately, but before the Doctor arrives, lay patient flat on the back, and if possible, with head lowered in order to have blood rush back to head; loosen clothing and apply external heat to the extremities by means of hot water bags, heated blankets, etc., after hav-

ing first made certain that applications are not hot enough to cause burns of the skin. If patient is unconscious and, therefore, unable to swallow, do not force stimulants into the mouth as it may cause death by strangulation. If unable to swallow, use inhalation of smelling salts or ammonia water that has been well diluted. If capable of swallowing, give one teaspoonful of the aromatic spirits of ammonia in water, or whiskey well diluted. In the absence of any stimulant, a small quantity of hot water may be given.

The second condition to which our attention must be directed is hemorrhage. The symptoms of excessive bleeding are exactly similar to those occurring in shock. Hemorrhage must be controlled immediately, as it greatly lowers vitality and may cause death. Slight bleeding from a superficial abrasion, or more particularly from a punctured wound of a limb, should not be interfered with; in fact a little gentle squeezing of area so as to increase the amount of bleeding will frequently prevent infection, by blood actually washing out the wound. This should always be carried out after perforation of the skin by nails, rusty metal, splinters, insect bites, etc.

Procedure for Profuse Bleeding

If bleeding is profuse, first expose the wound by cutting away clothing, then determine its exact site of origin. There are various sources from which bleeding occurs: 1st, from arteries; 2nd, from veins; 3rd from the very small vein vessels known as capillaries. In arterial bleeding, the blood is bright red and is expelled in jerks. In bleeding from veins, the blood is a dark blue color and escapes in a steady flow. In capillary bleeding the blood is dark red and oozes out gradually.

The temporary treatment for bleeding from arteries, the blood flowing from the heart into arteries and outward toward ends of extremities, should consist of forcibly applying direct pressure with the thumb along the course of the blood vessel, between the bleeding point and the heart and a short distance above the site of bleeding; pressing this area very firmly against the underlying bone. While it is thus held have some one else apply a tourniquet.

A tourniquet must be applied very tightly, otherwise it is of absolutely no value. The most effective type of tourniquet is made of rubber tubing on elastic, and in their absence use anything available such as a handkerchief, necktie, bandage, or cord. A small pad, preferably of folded gauze, (a pencil or other solid object may also be used), is placed directly over the artery a short distance above the bleeding point and the tourniquet is wrapped tightly about the object, making certain that pressure is sufficient to compress the artery and thereby stop the flow of blood.

Where bleeding is from a vein remove all bands such as collars, belts, garters, etc., as slight pressure only increases bleeding by preventing circulation. The limb should be elevated and direct pressure applied

over the wound by means of a finger covered by a small pad of gauze. Bandage should then be firmly applied.

If bleeding is capillary, and the blood simply oozes from the wound, pressure applied directly over site of incision by means of a gauze pad, will generally cause it to cease within several minutes.

Injuries to Bones and Soft Tissues

The third condition to be considered is injury to bones or soft tissues in which skin remains unbroken. There are several essential points to be remembered in differentiating the various types of injuries that may be sustained. These may be classified into four divisions: 1st, bruises; 2nd, strains; 3rd, dislocations; and 4th, fractures.

A bruise only involves the skin and tissues immediately beneath it, and is characterized by localized pain, discoloration of skin and swelling; but it does not produce any interference with the normal function of the limb.

Strains affect the muscles and are recognized by the pain complained of upon attempted motion, but the extent of motion remains normal. The skin is not discolored or swollen.

Dislocations affect the joints and are diagnosed by the presence of deformity, the entire contour of the joint being changed; there is severe pain complained of at the site of the deformity, with a total loss of voluntary motion at the joint. All attempts at manipulating joint are strenuously resisted by the contraction of the muscles in the area affected. Examination reveals an increase in motion at the joint in abnormal directions, and a marked decrease in motion in normal directions.

With fractures, usually very severe pain is manifested upon attempting to use the limb: there is marked discoloration of the skin and swelling appears very rapidly. Upon the application of direct pressure, a distinct point of severe tenderness can be located. If fracture is incomplete, that is, if it simply consists of a crack through the bone structure, the chief symptoms consist of pain complained of upon attempted motion, with swelling and discoloration of the skin. If the fracture is complete and the fragments are in perfect apposition, the above signs are noted, but with them a sign called "crepitus" is found; this consists of a grating sound that is produced when the fragments are manipulated against each other. Motion is also found to exist at an abnormal site. If the fragments are displaced all the above signs are found, but to a very exaggerated degree; especially, the fact that free motion occurs at an abnormal site. The limb becomes soft and bends like a hinge at site of fracture.

The first aid treatment as applied to the foregoing should consist of the following:

For simple bruises or contusions, expose the part affected and devote attention to the relief of pain. This is best brought about by the appli-

cation of extremes of temperature, either cold or hot, preferably cold, such as ice applications.

For muscle strain, keep the part at total rest. Heat applied locally followed by a thorough massage is of distinct value. Alcohol, witch-hazel, chloroform, liniment or the like may be used as they frequently relieve pain. The part should be kept at rest for several days and active motion then resumed.

Treatment for Dislocations and Fractures

For dislocations, the head of a bone having slipped out of its socket, it must, therefore, be replaced. Dislocated fingers can usually be replaced by firmly grasping the finger and pulling directly forward. For the larger joints, have the patient lie down at complete rest and send for a physician. If patient must be moved, apply splint to the limb as in case of fractures, so as to keep the limb at rest, until medical aid can be provided.

For fractures to long bones, as in the arm or leg, apply a splint made of wood, cardboard in several layers, wire gauze, tin, etc.; these splints should be very well padded with cotton or anything soft available and the injured part bandaged firmly to improvised splint so as to prevent motion at the site of fracture; then obtain medical aid. There are a few sites of fractures that require special consideration.

The treatment for fractures to the clavicle, commonly known as collar bone, is as follows: a pad made of cotton or folded handkerchiefs should be placed in the arm pit on affected side, then bring the elbow firmly against the side of the body, bringing it backward as far as possible; bandage securely to side of body. The hand should be elevated on the front of the chest, palm lying flat on chest, and kept in this position by applying a bandage over the uninjured shoulder thereby supporting the elbow on the affected side at the same time, and preventing the injured shoulder from drooping. This will overcome any overriding of the fragments.

For fracture of skull, the patient should be kept at absolute rest, lying flat on back with head elevated. Treat as for shock. Apply ice bag or cold application to the head and obtain the services of a physician as soon as possible.

For fracture of spine, patient must be kept lying flat on back. It is very essential to remember that when any attempt at moving the injured individual is made, the body should not be raised from the level surface in order to be placed on stretcher or bed, but improvise a stretcher and slip under the body; then move very gently, being extremely careful not to bend the spine.

For fractured ribs, a long towel about eight or ten inches wide should be bound very tightly and securely around the chest.

The fourth type of injuries to be considered are those in which the skin is actually broken. These may be divided into three groups: 1st, incised; 2nd, lacerated; and 3rd, punctured wounds.

Incised wounds are those produced by sharp instruments, such as knives, glass, ax, chisel, etc.

Lacerated wounds are those in which the tissues are torn or crushed; as in fingers caught in machinery, cuts by various types of saws, grooving machines, etc.

Punctured wounds are usually deep, the entrance into the skin being of small size, and are produced by splinters, bullets, stab wounds, nails, etc.

To Control Excessive Bleeding and Infection

In injuries of this type there are two things to be considered: 1st, the control of excessive bleeding, and 2nd, the prevention of infection.

The wound should be thoroughly exposed immediately after being sustained. If bleeding is severe, control the flow of blood by methods previously mentioned. If merely oozing, disregard bleeding entirely and cleanse the injured part very thoroughly. I prefer doing this by first immersing a piece of sterile cotton or gauze in benzine or gasoline and rubbing this sufficiently over the wound and the entire surrounding area to remove all accumulated dirt; this is then followed by washing thoroughly with soap and hot water. Do not hesitate to allow soap, benzine or gasoline into an open wound. The majority of infections can be prevented if wounds and surrounding skin are thoroughly cleansed as soon as injuries are sustained.

For incised wounds, after thorough cleansing of the external surface apply a solution of the tincture of iodine that has been diluted with an equal amount of alcohol into the wound, and pull edges together by means of a very narrow but long strip of adhesive plaster placed across the wound; apply a sterile gauze dressing and bandage. Refer to a physician for subsequent care. If medical services are not obtainable and the injured part becomes very painful, red and swollen, it is indicative of an early infection.

The ideal treatment for this condition is to immerse limb in a basin of hot water for a period of at least a half hour, hot water being added from time to time so as to keep the temperature of water constant; repeat this procedure at frequent intervals. In my opinion bathing the limb in hot water as described has accomplished more toward localizing infection, that is, preventing its spread, than any other method tried by me in the care of thousands of wounds. When there is evidence of infection, by all means obtain the services of a physician.

For lacerated wounds in which there is an actual destruction of tissue, first cleanse very thoroughly as previously described, and then apply a sterile dressing saturated with a mild antiseptic solution such as boric acid, and keep dressing constantly saturated with this solution for at least 48 hours. Strong solutions such as peroxide, bichloride of mercury, pure tincture of iodine are not only of no value but are detrimental toward healing, as they actually destroy the cells exposed to their con-

tinued action. After experimenting in the care of a great many wounds over a period of several years, I am firmly of the opinion that my best results were obtained through the use of wet dressings. These wounds appeared to heal more rapidly and produced the least amount of permanent defects, such as contracted scars, etc.

There is one other extremely important feature that I want to impress upon you and that is, to make certain that a fresh preparation of Tetanus antitoxin is obtainable at all times, and that its administration is called to the attention of the attending physician within a very short time after deep perforated wounds are sustained. I can recall several occasions where failure to administer the antitoxin has been the direct cause of a fatal result.

Splinters, and Foreign Bodies in the Eye

For removal of splinters, use pincers provided in first aid kits, or in their absence use a needle, after having first passed it through a flame. After removing splinter, soak limb very thoroughly in hot water, cleanse, and apply bandage. If splinter is deeply embedded in tissue, apply a wet dressing and refer to a physician, as meddling at site of splinter will frequently cause it to become deeply embedded in the tissues, making it very much more difficult to be removed. Do not under any circumstances seal a perforated wound with collodium, new skin, etc., because if infection appears it will spread rapidly, if there is no proper drainage.

For foreign bodies in eye use an eye cup, filled with warm boric acid solution; wash the eye, do not rub, as it only serves to embed the foreign matter more deeply into the eye ball. If this fails, grasp the eye lash of the upper eye lid by means of two fingers, using the thumb and index finger, pull the upper lid over the lower one, repeat several times. If foreign matter is still present after these attempts to remove same have failed, apply a wet pad over eye, tie with a bandage or handkerchief and obtain medical aid. Do not under any circumstances allow anyone but a physician to introduce an instrument of any kind into the eye, as it will undoubtedly produce disastrous effects.

For poison ivy: wash the limb thoroughly with soap and water and apply a large strip of gauze soaked in a saturated solution of epsom salts. Keep the dressing constantly wet with the solution.

This discourse could be continued to cover many other varieties of injuries, but in a limited paper it is impossible to discuss them all. I shall feel particularly grateful if I have been able to impress upon you the importance of the following:

First: Having at least one intelligent individual in each office who is qualified to administer first aid, by having carefully studied the subject.

Second: Supplying yourselves with a completely equipped first aid outfit.

Third: The treatment of shock and the controlling of excessive bleeding.

Fourth: The cleansing of the wound and the entire limb by use of soap and hot water, also benzine or gasoline, immediately after injury is sustained.

Fifth: Soaking an infected wound, for prolonged periods, in hot water, repeating this procedure very frequently.

Sixth: The extreme importance of using Tetanus antitoxin for all perforated wounds.

In conclusion, gentlemen, remember that first aid applied at the time the injury is sustained, is, as its name implies, purely in preparation for all treatment that must be subsequently instituted by a regularly licensed physician. Do not take the responsibility upon yourselves to treat the injured individual after your initial services have been rendered.

CHAIRMAN WIBERG: I think that Dr. Shapiro has brought out several valuable points. I know on the question of hot water treatment, I have had a couple of cases of minor infections in my own family, and the doctor that we had did just what was recommended by Dr. Shapiro.

Yesterday, we had the moving picture given by Mr. Northrup of the State Labor Department of New York. That moving picture was based on some 300 accidents that were reported to Mr. Reid of the Labor Department. This morning we will have a paper by Mr. Reid.

ACCIDENTS IN WOODWORKING

Herbert L. Reid, Safety Inspector, New York State Department of Labor

The safety inspectors of the New York State Department of Labor are engaged in investigating recent accidents in the different industries, after which an analysis of the accidents with suggestions as to their prevention is issued and sent to the manufacturers in these industries.

Last year I made an analysis of 300 accidents in woodworking factories, each one of which occurred in a different factory. These accidents were personally investigated by myself and another safety inspector.

The compensation statistics in our state show that the ratio of accidents to the number of employees in the woodworking industry is not as high as in some of the other industries yet the percentage of permanent injuries is higher in woodworking than in any other industry. The circular saw still maintains its place as the great accident producer. Over \$700,000 was paid in compensation during one year in New York for accidents occurring on circular saws (about 1,000 accidents): the total compensation for that year for accidents on all woodworking machinery was about \$1,100,000. There is only one machine in industry on which more accidents occur than the circular saw and that is the power press.

The operation of woodworking machinery is very dangerous owing to the degree of sharpness at which the tools must be kept, and the high speed at which the machines are required to be run, if a well finished article is to be produced.

Among circular saw accidents the one due to pieces of stock "kicking back" is very prevalent. Of 113 accidents which occurred on circular saws, 32 were caused in this manner. Many persons are of the opinion that all "kickback" accidents injure the operator's body, but this is not a fact, for of the above number, 12 injured the body and 20 caused injuries to the fingers or hands. Twenty-two of these accidents occurred during the operation of ripping or cross-cutting. Twelve occurred while ripping and two while cross-cutting pieces of wood, caused by the wood binding between the saw and gauge, or by the wood pinching and riding up on the back portion of the saw. Three occurred when the waste piece which had been cut off the end of the board caught on the back of the saw and was thrown back striking the operator's body. Three occurred when the operator was pushing the stock past the back of the saw after the cut was finished, in one case striking the operator over the heart and causing his death; in another the saw struck a knot in the board causing it to break and kick back; and in the third the operator picked up a piece of stock and while passing it over the saw dropped it on top of the latter.

Many Contributing Factors to Accidents

Contributing factors to this type of accident may be as follows: improperly seasoned or damp wood which tends to pinch the saw; cracks or knots in the wood which cause the boards to break when the saw strikes them; a dull saw or one that has been improperly filed or set.

The hazard of a dull saw or one not properly filed or set can not be too strongly emphasized, for during the investigation of these accidents I noted that many of the saws were in this condition; so it is safe to say that the primary cause of many accidents on saws is due to lack of knowledge how properly to file and set a saw. Other causes of accidents on circular saws include placing the stock down on top of the saw to cut a blind "kerf" or slot, when the board catches on the saw and kicks back. This type of accident could be prevented if a stop were provided on the gauge or table against which to hold the stock. Another unsafe practice is using the hand to remove waste pieces of stock lying on the saw table when the saw is not protected by a guard.

Then there is the unsafe practice of the operator keeping his left hand on a narrow waste piece of stock as the cut is about finished. Accidents of this type occur even when the saw is guarded and to workers who have had many years experience around woodworking machines.

Accidents are also due to using a removable plate or throat piece which has a slot much wider than the thickness of the saw blade; thin pieces of stock are liable to become caught between the edge of the slot and the saw.

The question of safety in the operation of the circular saw has prob-

ably caused more discussion than in the case of any other machine, and often the question is asked, what has it accomplished?

The reason more accidents have not been prevented by guarding circular saws, is that practical saw guards have only recently been manufactured. Numerous types of saw guards have been made, both commercial and by individual employers, but hardly 10 per cent of them were used after they were installed. For in the past not enough thought has been given to seeing whether the guard afforded adequate protection to the operator, or if it was the proper type for the kind of work to be performed.

A practical saw guard must be substantial and rigid enough to protect it from a rubbing contact with the saw, but still preserve sufficient lightness to permit of easy handling.

Guards which give a good view of the saw are to be preferred to the solid type, and those made of the softer metals are recommended as savers of good saw steel, eliminating much of the breakage experienced when harder metals meet the blade through accident.

Make the Guard as Fool Proof as Possible

Some steps should be taken to make the guard as fool-proof and as automatic as possible. It should adjust itself to the varying thickness of stock and the supports should be made so as not to interfere with the work.

When circular saw blades are not in use they should be placed in such a position that the teeth are protected against accidental contact. Serious accidents have been caused by workmen striking saws hung on a post where the teeth projected beyond the post edge.

It is important that the person in charge instruct new employees in the proper operation of circular saws, especially the necessity of close attention to their work and the proper manner in which to hold the stock being sawed.

It is dangerous to allow pieces of stock to remain on the saw table where they may be brought in contact with the saw and thrown back. Also it is important to keep the space about the machine free from loose material which might cause tripping and falling.

The spreader or splitter is a very essential part of circular saw guarding, and if proper spreaders were provided and used whenever practicable many accidents would be prevented. The spreader must be rigid, set in true alignment with the saw, and slightly thicker than the saw blade. It should be set not over one-half inch back from the saw.

Where different diameter saws, or those of varying thicknesses, are used on the same machine, an equal number of spreaders can readily be set up in different throat pieces which may be inserted in the saw table for each size saw. A "kick back" pawl should be provided on all guards. Many of the standard makes of guards have pawls attached to them, but they are not very effective except on automatic guards, for the operator does not adjust the other guards close enough to the stock to bring the pawl in contact with the stock.

Saw guards that are not automatic should always be so adjusted that there is only working clearance between stock and bottom of guard.

Accidents on handsaws as a rule are either caused by dull saws or are due to an unsafe practice, such as cutting the end off a round piece of stock without first attaching a strip of wood to prevent it from turning, adjusting the guide with a saw in motion, or removing waste pieces of stock while the saw is in motion.

The swing saw is probably the safest type there is to operate, yet accidents occur on it, due in the majority of cases to the unsafe practice of straddling the saw while making the cut, i. e. holding the stock on one side of the saw and pulling the saw across with the other hand on the opposite side of the saw from which the hand holding the stock is located.

The machine causing the second largest number of accidents however is the jointer. There should not be such a large number of accidents on jointers and they could be reduced if proper guards were provided and kept in working condition, and if safe practices were observed.

The "kicking back" of stock occurs on the jointer almost as frequently as it does on the circular saw and in the main is due either to attempting to joint or face short pieces of stock or having the table set for too deep a cut.

Guards will not prevent accidents if the workman persists in doing his work in an unsafe manner.

A Push Block to Make the Jointer Safer

The planing of short pieces of wood on a jointer is dangerous and should be avoided as much as possible. Where it is necessary to do such work a push block or some other suitable device should be provided and used. Such a device would eliminate the danger of the stock being thrown from the operator's grasp and his hands caught by the cutter head.

Another unsafe practice of workmen is putting a pin through the guard. This pin passes down along the edge of the jointer table and in this manner the guard is held away from the stock, thus creating a condition the same as if the guard was not attached to the machine. Other unsafe practices are keeping the hand on the end of the stock when it is passed over the cutter head, or holding the fingers over the edge of the stock while doing a facing operation.

Many persons are of the opinion that since the cylindrical cutter head has been installed that an accident on the jointer will result in only a laceration and will not cause the amputation of the fingers, but this is not a fact. Accidents have been investigated where the back of the operator's fingers have come in contact with the cutter head and the knuckle or bone of the finger was gouged out, resulting in amputation at the first or second joint. In one case the operator had a small

portion of the knuckle of the first joint of four fingers gouged out and they had to amputate the first joint of each of these fingers.

When jointing short pieces of wood it is a safe practice to note the direction of the grain of the wood (this is called graining the stock) and always push it over the cutters with the grain. This would prevent many accidents that are caused by wood "kicking back" when it is pushed over the cutters against the grain.

It is an unsafe practice to hold the hands on front end of stock when starting cut; also, when finishing cut, the hands should not be on end of stock while it is being pushed over cutter head.

In some shops it is a practice to put cutters on the jointer head to make mouldings. Often this is done by removing the arc pieces from two sides of the jointer head and then attaching cutters. To provide clearance for the cutters they move back both the front and back tables of jointer which causes a very great hazard.

Then they leave the jointer set up this way after the special operation has been finished. This is a very unsafe practice for another employee is apt to start the jointer and, thinking it is in regular operating condition, injure himself severely.

Jointer guards should be so constructed and set that the point of contact of the guard and gauge will be directly over the cutter head at all times, no matter in what position the gauge is on the table.

The front and back tables of the jointer should be set as close to the cutter head as possible, leaving only proper clearance for cutters and shavings.

The Shaper Always Considered Very Dangerous

The shaper, or what is commonly called the variety machine, has always been considered very dangerous but the percentage of accidents on this machine is not as large as is generally supposed. Here again many of the accidents are due to the stock "kicking back."

There are several ways in which this type of accident occurs, such as pushing the piece of stock against the cutters too suddenly; not holding the stock securely when the cut is nearly finished; making too deep a cut at one time, especially when cutting a groove or sinking a panel. Also starting the cut against the grain of the wood. Other causes of accidents on shapers are backing pieces of stock against cutter head, not using a form or jig to hold small pieces, also having fingers over edge of stock on the side where the cut is being made.

Before starting to shape a piece it is a safe practice to note the direction in which the grain of the wood runs and to start the cut with the grain and not against it. Of course this is not always practicable.

When a circular saw is used on the spindle of a shaper, even if a fence or gauge is used to hold the stock against while doing the operation, there should be a cover over that part of the saw which is exposed at the back of the fence or gauge.

Guards for shapers should not only cover the cutter head, but also provide a certain amount of tension on the stock.

Accidents on sandpaper machines are either due to unsafe practice or not keeping the equipment in proper working condition.

Self-feed circular saws have caused accidents due to pieces of the stock breaking off and being thrown back when caught on the back of the saw blade; this could be prevented by equipping the saw table with a spreader.

Accidents on speed lathes are caused by the operator not having the spur center properly inserted in the end of the stock or holding the stock in such a manner as to catch the operator's finger between the stock and tool rest.

Some of the causes of accidents with hand tools, are, not using the proper tool for the operation to be performed, a dull tool, one not in proper condition, or not held in the proper manner.

In one case a workman was injured while using a chisel to remove glue instead of a glue scraper. In another instance a workman was holding a piece of wood in his hands while cutting it with a chisel which slipped; a dull chisel will slip easier than a sharp one.

We have all heard of persons injured by flying nails. I recall an accident in a factory manufacturing packing boxes. A workman was struck in the eye by a nail he was driving into a box, and lost the sight of the eye. I inspected the hammers and hatchets used by the workmen in this factory and found that every one had the head either chipped off or badly mushroomed.

CHAIRMAN WIBERG: On behalf of the Section, I want to thank Messrs. Reid and Northrup for coming and giving their papers and the pictures. I also wish them to convey to the State Labor Department our thanks.

Mr. Fuller mentioned in the paper that he read that the operator isn't always the one that is hurt, and Mr. Reid brought out the same thought.

We are going to have the pleasure of seeing a film made by the American Car & Foundry Company. This film was made for the benefit of the personnel of the Berwick plant at Pennsylvania. You are going to receive the usual holiday wishes for the first time this winter season in connection with this picture. We will now have the picture.

(Pictures were then shown of the American Car & Foundry plant at Berwick.)

ADJOURNMENT

Joint Meeting Woodworking and Paper and Pulp Sections

October 28, 1926

HERBERT G. WIBERG, Chairman, Woodworking Section
Chief Engineer, Lumber Mutual Casualty Insurance Co.,
New York City

W. J. PEACOCK, Chairman, Paper and Pulp Section
Head, Department of Personnel, Northern Paper Mills Co.,
Green Bay, Wis.

THE Joint Meeting of the Woodworking and Paper & Pulp Sections convened at 9:30 o'clock at the Tuller Hotel, Detroit, Michigan, Mr. Herbert G. Wiberg, presiding.

CHAIRMAN WIBERG: The session this morning is a combination of the Woodworking and the Paper and Pulp Sections. The first paper will be by Mr. Hartley of the J. J. Newman Lumber Company, which company conducts lumbering and logging operations very extensively.

SAFETY IN THE WOODS

L. H. Hartley, Safety and Welfare Department, J. J. Newman Lumber Company, Homochitto Lumber Company, Hattiesburg, Sumrall and Bude, Mississippi

"Safety in the Woods" presupposes the idea that there is a need for an organized safety effort in the logging industry. The fact that you gentlemen are present proves that you are believers in the results that safety can obtain.

Before going into a discussion of the actual methods of placing safety in the woods, it will be necessary for us to discuss first the different hazards and conditions peculiar to the logging industry.

Down in the sunny south, where unskilled labor is about 60 per cent colored and 40 per cent white, this produces a little different condition from that in other parts of the country where the matter of "Race" has little or nothing to do with the work in industrial organizations. The colored race in the south is largely an ignorant class of people. The majority of them can neither read nor write their own names.

The white people living in logging camps are usually a class of people whose education is mostly confined to the meager opportunities of the camp school, which is in session approximately six months of each year. When the boys reach the age of 14 to 16 they are taken out of school and are put to work driving an ox team, sawing logs or other unskilled labor found in the logging business.

The logging operations, as a general rule, (and such is the case with the J. J. Newman and Homochitto Lumber Companies) are from 15 to 50 miles from the plant where the raw material is manufactured into its finished product. The logs are hauled from the woods over a railroad known as a "dummy line." The workmen are transported from the camps to their place of employment by an engine coupled to one or more cabooses and over tracks on which the ordinary common carrier would not even run a work train. The same precautions in building logging railroads can not be taken as in building railroads such as you and I are accustomed to riding on, because the dummy lines are thrown on top of the ground in a hurry and seldom remain over a period of 60 or 90 days until they are torn up and placed in another location. As soon as one tract of timber is cut out, teams, skidders, loaders and employees are quickly transferred to another location. Therefore the railroads in the logging industry are merely temporary propositions. Wrecks are not at all infrequent, but the shay engines, which are gear locomotives, unlike the rod engines, and sound like they are traveling from 60 to 80 miles an hour, run so slowly that when a wreck does occur there is seldom anyone injured.

The Rail Laying Machine Described

In building our road-bed a machine known as a "rail-laying machine" is employed. It is a form of flat car with an arm at either side running to about eight inches above the surface of the ground. On either side of this flat car runs a set of chains and they continue down the two arms and underneath the car. These chains are operated by an engine at the rear of the flat car. Ties are loaded onto this flat car and are carried by the movement of the chains and dropped to the ground, getting their proper distance by the use of a shay engine which pulls the rail laying machine. Workmen then follow the machine and lay the steel, and in this way the building of track is greatly expedited, but additional hazards are created against which few protective devices are available. Brain work is the greatest factor in preventing accidents in this kind of labor.

The log sawyers are placed in a position where the human brain is practically their only safeguard. The trees have to be felled where they grow, whether it be in a swamp, on a hillside or on the level. Constant care alone prevents the men from being injured. We were at one time confronted with a number of injuries caused by what is known as "kick-backs." After the sawyers had felled their tree, the butt end of the tree would frequently kick-back over the stump and cause an injury. This has been practically overcome by first "gapping the tree." This is nothing

more than cutting a notch in the tree, on the side towards which it is intended to fall, and below where they intend to saw; then when the tree falls it will break off where it has been gapped, leaving an offset, and the butt end of the tree will lodge against the stump, thus avoiding the kick-back. Our log sawyers work on a contract basis. They furnish their own saws, axes, etc., and are paid by the thousand feet of lumber cut. They oftentimes let their tools get in a bad state of repair; however, we endeavor to impress upon them the necessity of keeping their tools in good condition; and through this means the sawyers hazards are materially reduced.

After the trees have been felled, the next in line is the skidder operation. This is where the greatest danger in logging lies. Oftentimes the skidder is located a quarter or half-mile from the log it skids to the track.

The Skidder Takes Everything In Its Way

The skidder is merely a high powered machine, operating from two to four lines, with a drum man in control of each line. The lines are carried to the woods, generally by a mule, but in thick timber or exceptionally hilly country, (as is the case in the Homochitto woods), a mechanical rehaul line is used. We have four skidders in operation. After the skidder line is carried to the woods an employee, known as the "tonger," hooks the line to the log, and a whistle signal is then given to a drum man to pull in his log.

Everything in the way of the line and log goes with it, whether it be human being, beast or reptile. Its power is so great that it has been known to tear out embankments and break down other trees; and with the tonger oftentimes out of sight of the drum man, the workmen have to depend entirely upon the accuracy of their signals in order to prevent injury.

Accidents, however, have been very materially reduced on the skidders. We have not had a skidder accident in over nine months. This has been accomplished by constant drilling of the proper signals and by extreme care upon the part of every one of the score or more men employed. One foreman, who felt his inability to cope with the accident evil, adopted what is known as his "Morning Prayer and Safety Service" which usually takes about 15 to 20 minutes; and his skidder has had but one slight injury in the last two and one-half years.

After the logs have been skidded to the track and roughly piled into what are known as "log decks," the skidder then moves on to another location and is followed by the loader. We have from two to three loaders to each logging operation. The loader is somewhat similar to the steam shovel used by railroads, only in place of the shovel there is a set of tongs which are hooked onto the log, and the loaderman then lifts the log onto the log car. The log car is merely an unbedded flat car, and on this car is an employee known as the "top loader," who places the logs in the proper place and unhooks the tongs. The loaders employ approximately 25 men. Tongs frequently slip from the log when

the bark slips off, or when the tongs are allowed to become dull they sometimes fail to hold. If the tonger becomes careless and fails to fasten the tongs securely to the log, the log will invariably slip. Here extreme care must be taken, because if a log ever slips from the tongs it places the top loader in grave danger. We had had one or two deaths and several serious injuries because of a log falling from the loader boom. The loader employees are carefully instructed, and instructions repeated at proper intervals, how to stand on and about the cars and decks in order to avoid all possible danger in the event of such a mishap. Loader accidents have been reduced during the past two years approximately 75 per cent, and we have put on numerous "No Accident Month" campaigns with good results.

After the logs are loaded they are then hauled from the spur tracks onto the main line, where they are carried to the plant and unloaded into the log pond, ready for the mill to cut the next day.

Cooperation Between Men to Avoid Accidents

We have a number of section and bridge crews at work in each woods operation building and keeping up tracks, bridges and clearing away wrecks; and as generally is the case, we have been confronted with the usual type of section accidents, such as strains and "the other fellow letting his end of the rail or tie down too soon," thus bringing about a mashed toe or foot, and other similar needless accidents. We worked with these men, endeavoring to teach them to work together, especially in lifting heavy steel and bridge stringers; also how to lift in order to run less risk of straining themselves; and section accidents have practically been eliminated.

Besides the crews I have just mentioned, we have the teams, grade crews, right-of-way crews and numerous other departments in the woods, in which accidents frequently occur.

Now that we have described our logging operations, in that we have built our railroads, cut the trees, skidded the logs to the track, loaded them onto the flat cars, carried them into the plant and dumped them into the pond, I shall endeavor to tell something of the safety campaign we have waged and of the department known as the "Safety and Welfare Department."

It is needless to say that the management of our companies are thoroughly sold on the work of the safety and welfare department, otherwise our efforts would all be in vain; our management is strictly in accord with our movements, and next to be considered is our foreman.

The foreman is the key-man in the logging industry, just as he is the key-man in any industry. He is the point of contact between the management and the men. By his attitude he can materially affect the morale of the men under him. The foreman, in the eyes of the workmen, is the company. If the foreman believes in safety and practices his belief and talks it among his employees, his men will soon catch the spirit. Our experience has been that it is the foreman one must first interest and sell the safety idea to.

There are many different ways of engaging the foreman's attention and enlisting his support in the safety work. No foreman would wilfully injure one of his workers. All good foremen are vitally interested in keeping production figures high and cost figures low. Through safety measures all of these highly desirable ends may be accomplished. By frankly letting our foremen in on our plans we have gained their wholehearted support.

The biggest task of all is that of selling the safety idea to the men themselves. We have gone about this in two ways: first, by correcting all the hazards we could find; and second, by trying to educate and encourage our men into the *habit* of being careful. We first made a careful survey to determine what injury hazards might be corrected through mechanical measures and then proceeded accordingly. We covered up all exposed gears on shay locomotives, skidders, loaders, rail-laying machines and motor cars. We built cabooses, or "dog houses," for the men to ride in, instead of allowing them to ride on the open flat cars, and we insisted upon them riding in them. We devised a special link knife, and make our switchmen use it or a stick in making couplings. We provided our motor cars with safety railings and see to the proper piling of tools thereon, so they will not fall off; we devised a special crank for our motor cars, one that does not place the employee, while cranking the car, in danger of being injured by the crank kicking him.

Posters Help in Preventing Unsafe Practices

We belong to the National Safety Council and get from it many posters which are placed at different points on the works. We also put up posters, signs and warnings of our own designing.

We bought a lot of cloth caps and had the words "New (Safety) Man" or "Homo (Safety) Chitto" printed on them, and every member of the crew going through a given month without a lost-time accident was given one of those caps. Putting it on a crew basis made each member of that crew watch out for his fellow-worker's safety as well as his own. Our entire campaign has been from the standpoint of educating our men to look out for others as well as for themselves.

We issue a little plant publication known as the "*Safetygram*" and in it the employees find comparative accident records, safety suggestions, safety editorials, local items of interest and other news items that are of interest to them, at all time stressing the spirit of "Safety." We find that our little plant publication is one of the best safety advertising mediums we have yet employed.

Quite a bit of enthusiasm and interest were aroused by putting on safety contests between different departments of our logging operations, the losing side giving the winners a banquet. You can easily imagine the "*ragging*" the losers receive at these banquets. In case of a tie, if both departments went through a given period without an injury, then the safety and welfare department entertained both departments with a banquet.

We hold safety meetings, provide "movie" entertainments in our log camps, and in various ways do our best to keep the subject of safety always before our men.

We are trying to do one of the hardest things in the world to do. We are trying to re-educate our people. We are trying to help them form entirely new habits. We are trying to help them eradicate the chance-taking habit, and in its stead cultivate the habit of being careful. This takes lots of thought, planning, talk, signs, pictures, movies, everything.

It may be interesting to you to know that in our three woods operations, where we employ from 600 to 750 workmen in the most hazardous of occupations, we had only 111 lost-time injuries during 1925, as against 263 in 1923 when we first started our safety work. This decrease of 152 accidents is 56 per cent. A wonderful reduction has so far been made during the year 1926.

We feel we have made a record of which to be proud, one that has benefitted our employees, their families, our company, and that we have placed the literal fulfillment of the Golden Rule into effect with our workmen.

The Skidder Not So Bad As It Is Painted

MR. HARTLEY: At practically every meeting something is said about the skidder operations and wanting to do away with skidders on account of the devastation wrought upon young timber. I have touched on that briefly, as to the power of the skidder to tear down young timber.

I was disappointed in that I didn't get to bring one or two sketches of the skidder trails which I had prepared, showing the condition of the woods within a period of six months after the skidder had been moved down.

When the skidder is in operation it cuts a particular swath and it does take practically everything in its way. There is less opportunity for fire through the use of skidders than through any other method of getting your logs to the track. The skidders are not by any means as bad as the average body of people think, when you consider the force and power with which the logs are carried through the woods.

I would like to hear from the other members here who have had experience in this branch of the business.

OLIVER F. W. CROMWELL (Central Pennsylvania Lumber Company, Ridgway, Pennsylvania): I want to ask how many employees you have in the woods and in the mill together?

MR. HARTLEY: We have around 225 at one time in one place.

MR. CROMWELL: Do you take the soft pine?

MR. HARTLEY: No, we use the industrial pine.

MR. WALLACE: Mr. Wiberg, on Monday there was some discussion here, or rather some inquiry made, as to the susceptibility of the colored help in the logging operations and I suggested then that when Mr. Hartley made his talk here that he could tell us how they reached their negro

help and how they responded to the safety effort. I am sure Mr. Hartley can tell us about that.

CHAIRMAN WISBERG: The question came up at one of our other meetings as to whether the colored man took hold of the safety proposition as well as the white man and the opinions given by several representatives of employers that used large quantities of negro labor was that the negro responded more readily. How do you interest them, Mr. Hartley?

MR. HARTLEY: You remember I stated that our labor is approximately 60 per cent colored and 40 per cent white. You gentlemen from the south know the colored man.

The southern negro is the most religious man on the face of the earth. He will get down on his knees and shout all night long in one of his religious meetings and on his way home will rob your chicken roost, but nevertheless, he is extremely religious. Any time you can succeed in showing the negro that safety work is in line with his religion you have solved the problem and sold him on that idea.

First the Negro Preacher Was Interested

That was the angle through which we started our safety campaign with the negroes. It took us some little time to get them together to talk to them. First we got the negro preacher lined up. Their negro preacher is just as big a man as the President of the United States. We got him to preach a sermon or two on the subject of being my brother's keeper and other passages in the Bible that to them refer specifically to life. They like to refer to that verse in Romans where Paul says, "I beseech thee, brethren, to present your bodies a living sacrifice," etc. They stress on that *living* through their church. The negroes are really the biggest safety boosters we have in the south.

Another thing, if you pin a badge on a negro he is on top of the world. He doesn't care for the money. He wants something with which to decorate himself, something that makes him an outstanding figure before other people. We have used that a great deal. The cloth caps went over big with them. One crew had a slight injury and we had worse than a lost time injury because every member of that crew insisted on going to the doctor's office with him to see if the injured man was going to get well. It paralyzed that particular crew for that morning's work. But they do respond to our safety campaigns.

W. J. PEACOCK (Green Bay, Wisconsin): I would like to ask the speaker what rate of compensation they carry, what insurance rate do they carry?

MR. HARTLEY: We do not have a compensation law in Mississippi from the outside standpoint, that is from the standpoint of outside insurance. Two years ago we assumed our own liability. I am not able to speak from the insurance companies' standpoint because I do not know. We carry our own insurance but we operated during 1924 on approximately three per cent of the pay roll. In 1925 it was 2.60 per cent, and so far in 1926 the combined operations have been around 2.65 for the first nine months.

MR. CROMWELL: May I ask the speaker what kind of country they have in Mississippi? Do you have a rolling country down there or is it more of a flat territory?

MR. HARTLEY: The country down there is extremely rough. It is hard to tell just how rough it is. I can give you a pretty good idea of our hills when I tell you that from our pine mill to our hardwood mill it is approximately 36 miles by rail, but by road where they dodge a few bridges and cut in and out it is 46 miles. It is a regular mountainous country filled with underbrush. That is the point I brought out about the skidders, where the mules are used to carry the line back to the woods after the logs have been skidded to the track.

MR. CROMWELL: How about your underbrush and shrubs? Do you have any accidents with axes catching in the brush?

MR. HARTLEY: Yes, once in awhile.

MR. CROMWELL: Don't you have accidents from rolling logs suddenly released when they roll down and roll over one of your men?

MR. HARTLEY: We haven't had that trouble for quite awhile with rolling logs. They jack their logs up as soon as they are cut. They used to have a number of them before they started jacking and blocking the logs. We do have lots of injuries as a result of the right of way crew cutting themselves through an ax catching in the underbrush. You can't overcome this feature in the underbrush. You have just got to try to use means of constant watching all the time. Brain work prevents that kind of accident to a large degree.

Dropping Limbs and Splinters Accident Causes

MR. CROMWELL: Do you have accidents from dropping limbs?

MR. HARTLEY: No, I do not recall any.

MR. CROMWELL: Do you peel your hemlock bark?

MR. HARTLEY: Yes, we peel it.

CHAIRMAN WIERG: Do you cut both hard and soft wood?

MR. HARTLEY: Yes.

CHAIRMAN WIERG: There is a pronounced difference in the hazards of hard and soft wood.

MR. HARTLEY: We haven't noticed any difference.

MR. CROMWELL: We have about 2,500 employees, but we have more of the hemlock timber. In spotting, peeling and turning timber over to get the bark off, it gets slippery and pretty hard to handle. The saw will fall on their fingers or something of that kind.

MR. HARTLEY: In our hardwood ours is mostly the oak, gum, ash and poplar. I do not recall having seen very much hemlock in the woods. Most of our operation is in southern pine. We have one hardwood mill that takes care of the others mentioned.

CHAIRMAN WIERG: We have rather large lumber operations. One crew cuts over the tract of timber, taking out the soft wood and the other crew comes through later and takes out the hard wood. There is a dif-

ference of about 75 per cent in accident cost on those operations. The soft wood cutters always had very good experiences, whereas the fellows cutting hard wood had very bad experiences and the secretary of the company always claimed that there should be a differential for the cutting of soft wood. He said that was very much less hazardous because the limbs were much shorter and not nearly so large and stiff, so that when a tree came down there was much less liability of anybody being struck. And his contention seemed to be borne out by his accident record. Of course he got credit for it through a rating on the basis of his accident record.

MONT HENEGHAN (Standard Accident Insurance Company, Detroit, Michigan): What was the relative sizes of the two characters of timber?

CHAIRMAN WIBERG: The soft wood was a little smaller but not very much. They had hemlock as large as two and two and one-half feet in diameter, and the ash and maple ran about the same.

Wouldn't it make it somewhat easier for the hardwood people if the soft wood had been cut out?

Conditions in Felling Timber Are Discussed

MR. HOYMAN: It would all depend on how thick the soft wood was. It would make it hard in felling the trees. You would have more stumps for your rolling logs.

MR. CROMWELL: We had some 28 by 28 50-foot logs. We had some trees 54 feet long and while they were cutting I happened to be in the woods and I noticed particularly in that big timber that the brush was heavier than it was in the other sections, just in that particular spot where they cut that big timber.

MR. HOYMAN: Naturally it would be for those big trees were up in the air and had more room.

MR. CROMWELL: That brush is what increases the hazards in mechanical skidding. You frequently have somebody get hurt who may be 100 yards away, by the skidder line picking up a man outside of the area.

CHAIRMAN WIBERG: There is one phase of the proposition in the woods that Mr. Hartley doesn't touch on in his paper. Mr. Hartley, perhaps you could give us some information as to how you take care of the man who is hurt in the woods?

MR. HARTLEY: In our woods we have regular camp surgeons and we pay them a salary and the employees pay them so much to do their private practice. We have operations that are quite a distance from the camp, as much as five or 10 miles from the camp and there we have first aid kits. We have tried as much as possible to keep away from first aid kits because everybody tries to mess with them and very few know how to handle them.

Our camp doctor has a motor car, a one man car and we have a little telephone system through our woods and different ways of getting messages through. In an urgent case the doctor will go to the patient if he is not able to be brought in. At the plant which is about 25 miles from

the woods we have a regular X-ray and clinical laboratory, where a doctor is employed to take care of the men who are brought in from the woods as well as the camp. Our camp surgeon is pretty actively engaged in going from place to place.

CHAIRMAN WIBERG: You have someone in each camp, I suppose, who is sufficiently intelligent to be a first aid man?

MR. HARTLEY: We have gotten our foremen together and had our surgeon drill them on first aid. In an ordinary case of a cut or a bruise he has a pretty well-equipped kit for that purpose. In case of bleeding arteries, they are pretty well lined up on how to handle a situation of that kind but broken bones or sprains have to be treated more carefully. They do not try to do anything in cases of that kind, they leave that entirely to the camp surgeon.

AL KROES (Director Safety Education, Employers' Mutual Liability Insurance Company of Wausau, Wisconsin, Milwaukee, Wisconsin): What is your experience in the men getting infection from minor injuries?

Some Points About Infection from Splinters

MR. HARTLEY: We haven't found many cases of infection in our woods operations. We were just discussing the difference in infection cases in the woods and the plant. There seems to be something in the woods that isn't in the camp. I don't know what it is, but I don't recall having an infection case in the woods since I have been there and that has been two and one-half years. Sometimes we have an employee get a splinter in his finger and keep on working and not let anyone know anything about it and then sometimes we have a case of infection but that does not happen often.

MR. CROMWELL: Speaking of first aid, do you find any difficulty in getting the men to go to the doctor after they have been given first aid? You said you were trying to get away from first aid as much as possible. I apprehend that if the man gets the first aid treatment he has a disinclination to go to the doctor.

MR. HARTLEY: Especially is that true among the negroes, and all our woods laborers are negroes. They think the first aid is all they need.

MR. CROMWELL: Don't you think perhaps the reason that you have more infection cases around the mill is the difference in the cleanliness of the two locations? In the woods, if there is a cut it is with a keen ax that is perfectly clean or a keen saw that is perfectly clean or even a splinter, whereas in the mill operation you have got more or less grease and dirt and trash in that kind of place and it is more likely to get into the wound and thereby become hazardous. That has been my observation.

B. M. ALMON (Memphis, Tennessee): On the splinter proposition, don't you find this difference in the woods and in the plant? The lumber is kiln dried and that process creates a kind of acid that forms in the wood; when a splinter gets into the flesh from that wood there is a big difference to the splinter in the woods. Don't you think it creates a

tannic acid and the infection therefore is more dangerous than if it were straight out of the woods? We have found it to be so.

A. W. HOFFMAN (Superintendent Groundwood Pulp Mill, Kimberly-Clark Company, Niagara, Wisconsin): How about your dressed lumber, do you have more splinters from the dressed lumber?

MR. HARTLEY: We have more from the finished lumber than from the rough lumber. We take the splinters out of the men from the yards where they stack the lumber on the trucks. Their wounds are very seldom as bad as those in the mill when the lumber has gone through the kiln process.

MR. KROES: Do you have any accidents to the men carrying saws?

MR. HARTLEY: Yes, we have had several accidents in the woods. The log sawyers are practically the only ones who carry saws in the woods. They also carry their axes and measuring poles, their dinner pails and Lord knows what else they carry; but going through the heavy brush we find they are eternally letting their saws drop and cutting themselves in that way. We have a wood guard that we are using now that we hope will eliminate most of those accidents.

Sawdust Blowing in the Eyes is Troublesome

MR. HOFFMAN: Is that wood guard just a little clamp that clamps over the saw teeth?

MR. HARTLEY: Yes.

MR. HOFFMAN: Have you had the experience of having sawdust blow into the eyes of your mill men and cause abscess? We have had that experience.

MR. HARTLEY: We have had a lot of men get sawdust in their eyes but nothing serious has resulted from it.

MR. CROMWELL: Do you have any trouble getting the men to wear goggles?

MR. HARTLEY: Yes.

MR. CROMWELL: What is their objection to wearing them?

MR. HARTLEY: Steam and perspiration and dust will collect and form a regular little mop of sawdust.

MR. CROMWELL: The other day while I was attending the safety exhibit I ran across the goggles department and in talking to them about the different forms of goggles I asked them if there was any way to control the sweat or mist forming on the goggles and they stated only by using a little glycerine on a cloth.

CHAIRMAN WIBERG: What does the man do who wears ordinary glasses?

MR. HARTLEY: He is continually wiping them off.

CHAIRMAN WIBERG: The thing I want to bring out is that there isn't any more trouble to wearing them than there is in wearing ordinary glasses. The fellow who has to wear glasses in order to see has the same trouble.

MR. HARTLEY: As I have observed around the saw mill, I don't believe I have seen more than three or four men wearing glasses. But in the

summer time in the south you can't wear a pair of goggles, it is too hot. Of course, the less weight they carry the better they are.

MR. HOFFMAN: I believe the fiber goggle is better than the celluloid because it is not inflammable and it is about half as heavy as the metal goggle.

MR. HARTLEY: Bringing up the question of eyes, reminds me of the first aid and particularly why we objected to it in some operations. We had a negro that got a foreign body in his eye and it became imbedded in his eyeball. The doctor administered cocain in order to relieve all possible pain and placed a little iodine over the wound. Of course the cocain took away the feeling and the iodine didn't burn at all. The doctor was busy with other cases and the negro asked him, "Doctor, what was that you done put in my eye?" And the doctor told him it was iodine. The negro went back to the plant.

That afternoon another negro got something in his eye and he wanted to go to the doctor and this first negro said, "Shucks, nigger, I can fix that eye for you," and he persuaded the second negro to let him pour iodine in his eye, and we haven't seen that negro since. That proves that very few know how to mess with a first aid kit and every person who comes along is trying to.

CHAIRMAN WIBERG: It is better to appoint someone to take care of the first aid kit.

MR. CROMWELL: Do you give the men water while they are working?

The Water Boy Carried a First Aid Kit

MR. HARTLEY: Yes, we have water boys who go the rounds continually from the water wagon with water for the men. We have work trains who take it out to them every morning and from there it is distributed by barrels to the men.

MR. KROES: I saw a water boy carrying a first aid kit strapped to his back and he knew how to use it.

MR. HARTLEY: That would be a good combination.

CHAIRMAN WIBERG: That would be an excellent idea, if they were given proper instructions as to how to handle the kit.

We have another very interesting paper. We can resume this discussion after Mr. White has given his paper. We had better get that going and come back to this later.

As I said before, this is a combination of the Pulp and Paper and Wood-working sections. The next speaker comes from the Pulp and Paper Section and I am going to turn this meeting over to Mr. Peacock, who is chairman of the Pulp and Paper Section.

(Chairman Wiberg retired and Mr. W. J. Peacock took the chair.)

CHAIRMAN PEACOCK: It is a very great pleasure for us, gentlemen, to enjoy this joint meeting with you. I believe the proposal for the joint meeting came from our Section. Last year we had a presentation of the problem of the work at our Section by Mr. White who will speak to us again this morning and we were impressed by the discovery of a rather neglected phase of our own pulp wood hazards.

Because we wanted more light on the matter of the woods and also because we desired, with you, to emphasize these hazards, we proposed a joint meeting for this morning.

It is my pleasure and privilege to introduce to you at this time Mr. Alexander R. White, Chief Sanitary Inspector, Province of Ontario, Toronto, Canada.

THE WOODS AS A PROBLEM IN OVERHEAD

Alexander R. White, Chief Sanitary Inspector, Province of Ontario,
Canada

I must confess the title given me by your Program Committee rather startled me at first, and while I have at times attempted to deal with an occasional factor in overhead cost, I am still doubtful whether I am able to do justice to this extremely important question.

In treating with this subject I do not expect to be able to offer a positive solution for the many ills that contribute to abnormal overhead costs. I am rather actuated by the desire to place before you such facts as have come to my attention, which appear to bear upon this question, and which I have studied at some length while carrying on my regular work of improving the sanitary conditions under which workmen labor and the control of disability from preventable diseases.

Accident prevention and the multitude of contributory factors that make for high accident cost is, of course, the general theme which we shall discuss; it may be that the points raised may not appear to be sufficiently applicable to the whole of North America to be practicable; and in this event I would ask that the doubtful points be thoroughly debated in order that as much good as possible be derived from our discussion.

Previous to the enactment of the Workmen's Compensation Act in the Province of Ontario, and indeed until the present year 1926, the bulk of woods operations, including the 900 logging camps which operate annually, were classed for insurance purposes as general lumbering. This term included the cutting of saw logs, the cutting of cordwood, the manufacture of railway ties and the cutting of pulpwood for consumption in our pulp and paper mills.

Apparently there was no noticeable difference in accident cost in the minds of those who framed this act as between these various operations. This situation may have been influenced by the absence of dependable statistics, as no regular methods for a complete study were available and accident prevention associations had not yet come into being. We have, however, within the last two years, made a rather remarkable discovery in that we are now sure that accident cost in heavy pine timber is almost twice as high as compared with operations in small spruce pulpwood; and this knowledge has led to the establishment of a new rating for pulpwood camps situated upon pulp and paper timber limits, which is to apply to contractors and jobbers as well as company camps, the new

rate being \$1.75 per \$100 of pay-roll as against the \$3.25 and five per cent previously paid by these industries before the reclassification.

You will see at a glance that this revision is of first importance to the pulp and paper industry and means the saving of thousands of dollars annually without further expenditure in capital cost. The position in Ontario is now therefore this: industries in Class Number One (General Lumbering) pay from \$3.25 to \$5 per hundred dollars of pay-roll dependent upon the size of the camp, while the industries in Class Number Two (Pulp and Paper Making) pay a flat rate of \$1.75 for all camps big and little.

In going into the various details that brought about this change in rating the question of accident prevention is, of course, very much involved, and the following are some of the points which I think bear very closely upon the situation:

Points in the Accident Prevention Problem

1. There are few fatalities, but those that do occur are the occasional man lost by drowning while driving timber to the mills.
2. As compared with general lumbering in heavy timber, there are fewer cases of fractures or broken bones, the type of case which is, of course, the most expensive and usually contributes some form of permanent disability.
3. Infection of wounds is much less than in general lumbering.
4. Labor turnover is much less in Class Two, largely because of piece work and a higher rate of wages paid.
5. Because of the excellent medical and hospital service provided by the pulp and paper companies, great headway is being made in reducing accident severity and in keeping the men healthy.
6. A very much alive accident prevention association, composed for the most part of responsible officials, among whom may be numbered presidents, vice-presidents and general managers who are interesting themselves in the movement.

After this explanation let us return and deal, in detail, with some of the main causes which contribute to excessive overhead cost. Let us, therefore, study the first great question which affects all pioneer industries alike but which is perhaps more seriously affecting the two industries which we are discussing than any other at the present moment. This is the question of labor turnover, said by many students of industrial economy to be a form of waste that has assisted many companies into the bankruptcy courts that otherwise might be prosperous and happy.

Labor turnover may be caused by distasteful working conditions, such as long hours, low wages and undesirable physical surroundings, and may easily be lowered by systematic effort to improve the conditions under which men live and labor, and also if some wholehearted effort is made to teach the new employee to carry on his work more skillfully and thus more intelligently.

It does not appear possible to estimate correctly just exactly what percentage of turnover actually exists among lumberjacks in Ontario today.

Camps drawing their quota of men from a farming community nearby seem to have succeeded in stabilizing their labor to a remarkable degree, while others far removed from the railway and from settled territory have a turnover of easily 200 per cent or even higher.

There are many reasons for this enormous turnover or waste. A sufficient supply of skilled woodsmen is no longer available and it would appear needless to recite what most of you who have studied this question must already know, that there is not now a sufficient supply of good woodsmen to meet the needs of present day employers.

This same state of affairs obtains in most of our building trades. There are practically no more apprenticed carpenters, stonemasons or bricklayers, and as I see it, little is being done to induce the young man starting out in life to apprentice himself to any of these trades. Thus we find such occupations filled with what is known as the "handy-man" who is able to carry on well enough at rough work, but who falls down badly when something out of the ordinary is to be accomplished.

A Low Class of Labor Goes to the Woods

There is this advantage with the building trades, however, that once the handy-man becomes proficient with the tools of his craft, you find him back on the work year after year. This is not the case with the men employed in the lumber woods. The men hired by agents in our large cities come to the camp from necessity, not from choice, and apparently leave for good at the first available opportunity. Thus we find that in Ontario we are depending much more than is now being appreciated upon a remnant of the old guard of experienced woodsmen which can not be more than one-quarter of the men required to act as a leaven among the 30,000 men required each winter.

Your new employee comes to his job with insufficient training and in many instances has no knowledge of the use of edged tools, viz., the axe, saw, etc. He therefore makes mistakes which eventuate in accidents so that he is himself injured or is the cause of some one else being injured, perhaps fatally.

Herbert Hoover, in his book on "Sources and Causes of Waste in Industry," states that one of the four great causes of waste is lost production caused by ill health, physical defects and industrial accidents.

Here are some remarkable facts to show how green unskilled men boost your accident record and of course add to your overhead. Here is an industrial physician who specializes in treating men employed by lumber companies whether from accident or sickness. He has under his control some 16 small companies who employ roughly 1,608 men. He states that the great proportion of new men cut themselves or are injured in some manner during the first two weeks of their employment. He further states that there can be no doubt of this, since most of these men are either foreigners from central Europe or are illiterate, and this particular physician has to assist in making out the men's compensation report. This fact presented by a recognized authority, while disturbing, is by

no means new. Professor Collis in his book, "Labor Turnover and Lost Time," says "Employers suffer because newly engaged workers experience more accidents and suffer more sickness than the more permanent staff and that they are also less productive units."

Such items as have been mentioned in the foregoing should be studied by the business executive, and particularly by company foremen who seem to have forgotten that the standard of perfection set by them as to the qualities to be possessed by a lumberjack, is almost unattainable today, and in his zeal to keep only the best sent to him by the employment agent he discharges regularly half of the quota, forgetting altogether, seemingly, that there may be a \$15 fare plus a \$5 van account against this man who has not yet earned a fraction of this amount in wages.

Here is a little incident that may help to illustrate my point. I remember one camp in particular which had been built to house 125 men, as complete and comfortable and good as a camp should be but which had a crew of eight men only. In addition to the cook, cookee, chore boy, burn boss, clerk, etc., so that sufficient overhead was being carried to have taken care of a full crew. I had of course often visited camps where only half a crew were at work, oftentimes due to labor shortage, but never a case as bad as this. I therefore made inquiry of the doctor who was with me the cause of this obvious bad management; who replied that the foreman had belonged to the old school of efficient lumbermen and had set such a high standard for his men that few of the lumberjacks available could please him, so that they either quit from being bullied or he fired them. I wonder if this man, although an efficient lumberman, was a really good foreman? And might it not be well to look into an item such as this when studying production costs?

The Injured Workman Commonly Paid Off at Once

Now before leaving the question of turnover there is another point which I think is worthy of mention and this is the common practice of discharging or paying off the injured workman when he goes to the hospital or to see the doctor. This practice, to my mind, is poor business economy and must stop, and even if the injured man requests a settlement, some effort should be made to have him return to work when cured. Surely in these days of a tremendous shortage in skilled men, a full appreciation should be placed upon the fact that it has cost the company good money to train this man who is now injured, and that if he does not return, a green unskilled man is to take his place; the fact that he has been injured, if he is not habitually careless, should, in my judgment, actually make him a better risk than before.

Some one has said that if you really want to reduce your accident frequency then reduce your labor turnover, and if your number of new employees could possibly be reduced to zero, then your accidents would probably be reduced by 75 per cent.

Now if this is correct or even reasonably so, our forest product industry in Ontario, by stabilizing its labor, would save annually upwards of

half a million dollars from accidents alone. Here, then, is perhaps the most outstanding question before your accident prevention associations and the employers of labor at the present time.

Now if, as I have already stated, a sufficient supply of skilled labor is not available, where then do we get the hosts of men who now fill our camps? The great percentage, I believe, is being recruited by agents in our large cities, who know very little about the character of work to be undertaken or the qualities the applicant should possess to be suitable for the work; and as there is no standard of perfection set up by the industries almost any one who presents himself is sent to the woods; with the result that many possess diseases which, while not always communicable, are very often of such chronic character as absolutely to prevent these men from engaging in strenuous labor, with the result that they soon break down and are discovered by the company doctor who sends them to the hospital where they become a charge upon the industry.

My contention is that your forest product industries, by reason of the extremely low rate of wages paid to workers in the woods, the seasonal nature of the occupation and the absence of any prospects of better life after working hours, are being forced to accept the kind of labor that has already been rejected by the other more favorably situated industries of the country.

The Mitigation of Accident Severity

We now come to one of the most important points of our discussion, namely, the prevention of accidents with the mitigation of accident severity and rehabilitation. At your Christmas dinner last year I dealt with this question from the standpoint of accident reduction by a comprehensive first aid plan and by the early return of the workman to some light job until strong enough to assume his old duties. As I told you last year, I am as great an enthusiast for preventing injuries as anyone can be, but how I am going to make a success of this idealistic job in view of what I have said in the preceding paragraphs rather stamps me. It seems to me that as long as labor turnover remains as great as it is, and you are given no opportunity to select your labor, and the bulk of your men are unskilled, how can you possibly expect to cut down your frequency rate? You will have to try, of course, and resort to every trick in your repertoire to do so, but until a radical change in labor policy is inaugurated by the employer himself your success will be small in comparison to the effort put forward.

In dealing with the cost of the accidents or severity, which is of course overhead cost, we have every reason to feel optimistic, but we must approach this angle of the situation from an entirely different direction for we can not deal effectively with severity without effecting a partnership. We must join forces with the doctor who can make all the difference in the world between success and failure from the standpoint of accident cost. Almost any good physician who has a liking for economics, and in whom the pioneering instinct is strong, can easily reduce your accident cost, and of this we have conclusive proof.

We have in the Province of Ontario, of course, a physician connected with each camp whose duty it is to supervise the sanitary conditions in and around the operations, and also to treat and to hospitalize any men who may become sick. The doctor in such cases has a sworn responsibility which is set out under the law as well as specified in an agreement of which the government forms a part. This plan works admirably, as our disability statistics from preventive disease will bear witness.

Disability arising out of accident cases is quite another matter, however, because in such cases the doctor has no responsibility save such as commonly exists between doctor and patient. Under the arrangements existing today the employer is held responsible for such first aid as may be practiced and which is a half-hearted effort, for lack of direction, if it exists at all, and the physician does not seem to come into the case until the injured man arrives at his office or at the hospital when treatment commences, and in due time the patient is discharged and either returns to his former job or goes in search of another.

The Problem of Further Cost Reduction

Now as I see it this is all that is being expected from the industrial physician today with respect to accident cases, and if we leave matters just as they are then there will be little or no reduction even in accident cost. Now what can we do further? We can not expect the doctor to assume our responsibilities or the responsibilities of the employer, or even to assist us in this matter if he has not been invited or arranged with to do so. I have spoken with a great many industrial physicians upon this point and I am sure they are ready to help. Few doctors desire to see small trifling minor cuts come to them infected, when the simple but effective treatment of the wound with iodine when the accident happened would have prevented perhaps the amputation of a hand or saved a leg; and many doctors of my acquaintance would be glad to have the manager call at the office to know why John Jones was being kept so long in the hospital.

To be brief a new arrangement must be made with your doctor. He is the proper official to train your first aid crews, since he is to take the responsibility for the cases after the first aid man has done his part. He is the right person to show you how to deal with infection which runs as high as 70 per cent among open wounds in some camps; and he should also show you how to put up a simple fracture to prevent it from becoming a permanent disability case. If it could be possible to pay your industrial physician a premium for low accident cost instead of for extended disability, as we now pay, what a difference it would make!

The question of rehabilitating your injured workman is another matter with which the industry must soon begin to grapple, and it is just possible that after mature consideration is given this question, some way may be found to reabsorb these permanent disability cases, who can still perform certain kinds of work, that will be much more economical as

well as more satisfactory than the mere payment of pensions; but in this instance as above, the services of your industrial physician are of paramount importance if you are to do justice to yourself as well as your handicapped employees.

MR. WHITE: You will see at the outset that I am not what you might call a real dyed in the wool accident prevention man. I am for the general improvement of the condition. I am speaking about the accident end from the point of an observer in part at least.

If it could be possible (I don't say it is) to pay your industrial physician a premium for low accident cost instead of for an extended disability as we now pay him, what a difference it would make!

Of course, I have given you the conditions in my paper as they exist in Ontario.

Discussion Following Mr. White's Paper

CHAIRMAN PEACOCK: Inasmuch as Mr. White is dealing directly with matters more generally under the experience of Mr. Wiberg, I am going to ask Mr. Wiberg to resume the chair and conduct the discussion.

(Mr. Wiberg took the chair.)

CHAIRMAN WIBERG: I thought I was going to have the pleasure of listening. I want to ask Mr. White a question regarding the state of rehabilitated workmen being a different matter. In the case where you repeated that statement did you mean that we should induce the industrial surgeon to follow up his cases much better and much more closely so as to prevent permanent injuries or permanent impairment of functions, and that the rehabilitation proposition goes on after the injury has become a settled fact?

MR. WHITE: Yes. Perhaps I might clear up the atmosphere and give you a better chance to discuss it if I went a little further back on some of my last year's proposition. Looking at this question of cost without going into the question of the injuries themselves, perhaps is not quite fair to you but I felt that my partner was dealing with injuries and that I might keep off that question.

I will tell you about another side of the question. I will tell you why I am so strong on this question of severity, why I am so strong on rehabilitation, though I haven't a plan at all for rehabilitating. This is just a question forming within my own mind.

As I said today, we have a physician in connection with every camp that we have in the Province of Ontario. It makes no difference as to distance, we try to have the same service that we would have if the camp were a mile away. We have a hospital in connection with the camp that will give the same service as it gives the man who is injured in the mill. In other words, the thing has got down to such a scientific arrangement that (this is for health purposes, not for accidents) between the employees and the physician, we have succeeded in changing some of the evils that we have had to contend with from sickness and so forth. I

mean by that, typhoid fever and such diseases are no longer a problem with us. Smallpox is a thing that bothers us very little, and these two things used to be the major killers but are fast becoming last on the list.

These things have been growing less and less frequent and we have gradually gotten rid of them. If you maintain a large group of men who have to be examined, you have not only aggravated the employer but you have created a lot of expense so we do not regard the physician as a man who merely helps the sick. That idea isn't worth anything to the industry. A healer is a valuable man but it is the fellow who prevents the accident who is really most valuable.

We have tried to make of our physician a man who is not only fair in the healing line but a man who is interested in the preventive line. He has had to study prevention, has had to study transmission of smallpox, pneumonia, and work at these things and be found fault with if he wasn't making good on the job. In addition to that pressure and the desire to do better he is also paid on time the man is well. He gets nothing when the man is ill so it is not a very profitable thing for him to have sick men. Just so long as you put a premium on disability you will never reach your objective, but if you offer a premium or a price of some kind for good work I think it would make all the difference in the world for a low accident record, and then make it so that if there is a high accident record the man loses his job.

Hold the First Aid Man Responsible

The percentage of accidents in Ontario would run about 60 or 65 per cent, I believe. That, of course, is an appalling cost to pay for carelessness. That includes a great many of these permanent disability cases that your industry has to pay for if you don't pay them off in a lump sum. These are the things that are contributing to your high rate.

My idea in dealing with that phase of the thing is not to let Tom, Dick and Harry deal with the first aid kit, nor is it my idea to nominate some particular person and let him get his education where he may and carry on his opinions and dictate just as he pleases.

Physicians are rather peculiar men to work with and I am not sure that they would be wholeheartedly in favor of your first aid methods if you used something they didn't like for sterilizing. We are going to hold these first aid agents responsible for their work. I don't care what ideas he uses just so they are effective. I don't care whether he puts splints on or not just so long as he hasn't any compound fracture and he is going to be treated very generously if he can deliver the goods; if he can not deliver the goods he is not going to be treated well at all. That is justice to the company and justice to the physician himself.

MR. KROES: I would like to ask Mr. White if that question of putting a premium on the well man does not include getting the man back to work after he is well?

MR. WHITE: Yes.

MR. KROES: Don't you think there is a little bit of danger in that method for the reason that he perhaps may try to get the man back to work too soon?

MR. WHITE: Not a danger in the world.

CHAIRMAN WIBERG: It is not probable if you have the right kind of doctor. I don't know whether any of you were at the Health Service session yesterday or not. The president of the American Medical Association talked on health and he propounded the proposition that the doctor should exert all his efforts in taking care of the families so that they would not become ill rather than to taking care of them after they came down sick, and he said if we could get 50 per cent of the country working on that basis that we would add at least seven years to the average life. He said that we had added 15 years to the average length of life in the last 50 years and that in 10 years more we could add another seven years by this method. I am wondering what Mr. Keown has to say on this proposition?

Cooperation from Employers is Enjoyed

MR. KEOWN: This is along another line of our work. I don't have anything to do with that branch of it, that is the accident end. We have not been able to do very much with the woods accident problem. Our staff is very small. We have only two men in it, two men in the logging part of the state and they have to take care of all the factory inspections as well as investigation of accidents that occur. I feel that we are very lame on that part of the work.

We have, however, very good cooperation from employers but I feel that there is a very great deal to be done along the line of accident prevention in the woods. The sawmill end of it is very well taken care of.

MR. KROES: Mr. White, I don't want you to think I am against the idea brought out in your paper; I think it is a very splendid idea, and while I am up I want to compliment you on your very able paper. When the transactions get out in book form, it is the first one I am going to read.

MR. BLACK: I presume that Mr. White handles the pulp proposition. With your permission, Mr. White, and with the permission of the meeting, I would like to read a few lines.

(Mr. Black read from booklet, "Industrial Medicine, being addresses and reports of the annual symposium Committee of Industrial Medicine of the Ontario Medical Association, Toronto, Canada.)

CHAIRMAN WIBERG: There is one thing in both of these papers by Mr. White and Mr. Black that interest me very much. They both brought up the question of labor turnover; Mr. White mentioned the fact that when a man is injured he asks for a settlement, and Mr. Black touched on that point, too.

Our experience has been that when the man is injured he wants his money with the usual intention of going home. In New York the logging

is done adjacent to Canada and a lot of lumber jacks come from Canada. If they get hurt, the first thought is to get back home as soon as possible. We give them the first two or three treatments and they disappear and maybe a month later they come back in far worse condition than when they left. We would like to get hold of some method of keeping in touch with them until the injury has been cleaned up.

We have another difficulty in New York with these jobbers. That difficulty with the jobbers is making the rate situation on the logging operations somewhat the situation of the old dog chasing his own tail. The jobber gets a contract and he gets an insurance policy. He cleans up that job in a month and he gets another contract. He has had no accidents, we get the premium on that and we keep in close touch with him and he gets another job. He may run there two or three weeks and he don't have any accidents and we don't know a darn thing about the premium on that but if he has an accident there is \$4,000 or \$5,000 and we hear of it immediately and we have to pay it.

Employers Are Responsible for the Jobber

MR. BLACK: In Ontario under the compensation law all employers are responsible for the jobber. When we make a contract with the jobber the first thing is to give the estimated amount of what he is to be paid and the board makes that assessment and we make a charge against his operations. It is obligatory upon us to be responsible to our jobbers under the act. The law is there and we can't get beyond it.

CHAIRMAN WIBERG: Another very interesting point brought out by both you gentlemen is the fact that the small operation pays a much higher rate than the larger operation.

MR. BLACK: That is based on the accident record. The smaller plant has not the safeguards that the larger one has. We have very strict rules and regulations laid down. First aid of course is given and then they are immediately brought to where they get proper medical care.

MR. HOFFMAN: Where do you draw the line between the small and large jobber?

MR. BLACK: The board sets that. The small operator is one whose income is \$10,000 or less and the large operator's income goes over \$10,000.

CHAIRMAN WIBERG: Do you employ all your men from your neighboring provinces?

MR. BLACK: They come from other provinces as well as our own. I may say 70 per cent of our woods employees (we are right on the border) come from Quebec and up until last year we were liable for compensation under the two provinces; but the situation in that respect was so ridiculous that we applied for an amendment to the act, and the act has been further amended in Quebec. There was a new act to be passed the first of April and I am afraid it is going to work a hardship until we can devise some means of offsetting it. It is going to be hard on the employers.

I am talking about logging camps. The small jobber doesn't take the same interest as the larger companies do.

CHAIRMAN WIBERG: He hasn't the machinery for operation either, you see. When he gets through with one job he may be through with it for the year. Next year he is with some other man, anybody who may hire him and he may never be back.

There is one other idea that I am wondering if we should take up. I would like information on it myself. I don't know just what the wage scale is in Canada but I know, since the war, the lumber jacks in New York state are fairly well paid. They are pretty well paid when you take into consideration that their monthly wages of \$80 or \$100 is clear money, that is, they are given that plus their board and lodging so that they haven't any expenses. I think their pay compares very well to the sawmill operator in the same locality. He is getting \$4 a day but out of that he has to pay quite a bit, whereas the man in the woods gets his \$80 or \$100 and it is clear money.

MR. WHITE: Our lumber jacks get from \$30 to \$35 and their board, which would be \$70 including his board, and compensation and disability awards are based on \$70 a month board and pay.

That is why I argued so strongly that one of the cardinal sins of the industry is paying too much for this lost time. Perhaps I shouldn't say this, but I have a faculty for saying what I think and it is usually reached by fair argument. I think as long as we are only paying \$30 or \$35 a month you will not get men except those who can not do any better. That will finally be exploded or agreed with, that is my opinion. You will not get a man for that money, in the absence of city comforts or home life or social hours after work.

The Problem of Labor Turnover a Serious One

MR. WALLACE: Do you have the same condition with respect to constantly changing labor in your logging camps? We have a very large turnover. I understand this condition exists in Canada only during certain seasons of the year while ours continues for 12 months in the year. The climatic conditions are vastly different, of course. We work in the sawmill and the logging operations for one continuous year. We have a good deal of trouble from labor turnover. Our camps are permanent. It is 52 miles between mills at the two extremities. Our main logging camp is located just about half way between the two points. That is a permanent camp. We have a hospital at one of the operations but it is easily accessible from any one of the others so that the labor situation is quite different from our standpoint than it is with you, though Lord knows we have enough trouble and it is a very fruitful cause of accident, particularly in the woods.

MR. WHITE: We have practically 75 per cent new or different men in the woods all the time and that increases your accident hazards, of course. I should think with your permanent conditions there would be more chance for you to secure stable workmen.

MR. WALLACE: The man in the woods is a fleeting, transient sort of chap. He is here today and gone tomorrow. I find that is true in all the logging camps throughout the south. They are just going about from place to place where the pickings are the best. If a fellow finds he can get a little better supply of liquor at another place he will go there. Of course we have one class of them who are rather permanent, and who stick but a large percentage is transient.

MR. KROES: I had the opportunity of spending some time in the coal docks of Wisconsin. At that particular time the class of labor there was very low. The conditions were scandalous. It was a bad risk, nobody wanted them and when I was going from one dock to another I found the same condition. The scum of labor came to the coal docks and when you asked a coal dock man in the office why this was so, he said that was all he could get.

When you looked at the condition of those coal docks it was terrible (that was in 1918 and 1920), but since that time there have been some changes and conditions have become better. They used to say that fellows that never made good at anything else went to the coal docks, but now by better wages and better conditions the coal dock crew of today is a better class of men than it ever was before and the conditions are so much better the men often say that they had just as soon work in the coal docks as at the mills, that they get their hands dirty in either place. Mr. Black and Mr. White, won't that alleviate the condition, when you make the working conditions better it attracts good men, is that not true?

A Labor Shortage in the Woods Always Imminent

MR. WHITE: I believe that can be done but we are unfortunately not in a very favorable position as regards labor. The industry is expanding, of course, and we have a rather small population. Today we are getting, as I said before, so many men from other sections. I am sure of this, because I have taken the time to go through the employment office records and find out all they had to tell about it, and I reached my own conclusions. I haven't left anything unturned to find out what ails us because I feel the situation affects me to an alarming extent.

I know very well by the men who apply for work something of the conditions. I know by reason of the doctor, the little hub-bub and kickup between the company and doctor after the man falls sick that he had this disability before he went there. I have some knowledge of the time these chronic ailments take to develop before they come to the surface. They are developed sufficiently clinically for the doctor to be able to make a diagnosis. If we could get away from that completely what would we do? We would still have a labor shortage on our hands, perhaps next year or the year after that, when some of those big new mills start operations and naturally when the woods operations follow to supply the raw material we will need 15,000 men that are not in the country today. That is something of a problem. Cut out this seasonable

business as you can until you have a sufficient crowd that will remain with you to easily absorb the green men when they come in.

CHAIRMAN WIBERG: We have the same proposition in New York. After the logs are cut, the drive is made and the logging crew goes out of existence.

MR. KROES: The first five years of my experience were spent in the states where they conducted these employment offices. The small ones don't cause any trouble, it is the larger ones like Chicago and the other large cities that cause all the trouble. They don't care who they send out. If they could pick up 25 fellows with syphilis they would send them, they don't care what they send to a camp.

CHAIRMAN WIBERG: It has been a question of getting men to take hold of a pick and shovel or canthook and be able to do some work.

MR. WALLACE: In the south we are going through the same thing that Florida went through, with so many big buildings going up all over the states, big hotels, big golf links and so forth and no sooner do we get men than along comes someone willing to pay bigger wages and our men are gone. We have them one day and they have them the next day.

Saw Mills Are Frequently Short of Men

CHAIRMAN WIBERG: We have those conditions in New York as the summer comes on and the road work begins. These fellows who get \$8 and \$10 a day leave the mills and go to the roads, then it is a very hard thing to get sufficient men to run the sawmills.

With your logging proposition you will always have, it seems to me, a very difficult situation because you have got to take these men and throw them out in the wilderness. They work hard all day and in about a week or 10 days, very naturally, they are full of health and energy and they want to get out and have a good time. It is only natural. It always has been natural for these lumber jacks to grab the most pay they could get and beat it for the bright lights and never think about anything else until the last cent is gone.

MR. WALLACE: At one time we couldn't get the logs out of the woods and we went down to New Orleans and got a bunch of sailors as log cutters and you can imagine how much they liked it and how long they stayed on the job.

MR. BLACK: Evidently the small wages Mr. White referred to has a great deal to do with that condition. We were paying \$35 and \$40 a month and the production was lamentable. Naturally you would say we deserved it on account of low wages. We put the men on piece work and of course they made a lot of money but that didn't hold them. They would go to the timekeeper and ask how much they had made and he would tell them \$150 and then it was the bright lights for them. We had three gangs, one going, one working and one coming.

MR. WALLACE: We pay our men eight cents a log and they get a house for \$1 a month. They cut 600 or 800 a day. We pay them about 11 cents and they board themselves and we give them a team free of charge to do the skidding.

MR. HARTLEY: Here a few years ago we adopted one thing (I wish, Mr. Wallace, I could give you the figures), but still we have our labor troubles, too. We took out a form of group insurance, life insurance. As he stays with the company it increases in value. We have found that has been a great help to us in holding labor. Of course we have a labor turnover. But we have found that has held the men to a large extent.

DR. BARNHARDT: I don't think there is much that I can add to this meeting or to this discussion. It has been pretty well covered on general principles and I don't think there is any necessity of going into details of first aid.

I think we should realize that the first aim is prevention of accidents by the use of safeguards. By education, methods of different kinds, we do what we can to help the man, giving him immediate first aid, and it has been found that if the open wound is treated within one hour by proper first aid methods, as a rule there will be no infection.

The Workmen's Compensation Board in Ontario recognizes the efforts that any company makes in placing these men back at employment where they will earn a fairly good wage and instead of paying the man the full amount of his compensation there is an adjustment made so the company shares for its effort: that is, the man is perhaps placed in a position where he can earn 100 per cent of the wage he was getting before and the refund goes back to the credit of the industry. If the man leaves the industry, of course, he is provided for by the board.

All these major accidents are capitalized and in that way provision made for all cases.

CHAIRMAN WIBERG: One point brought out by Mr. White is of especial interest to me; I had an example of that kind in the paper mill. The doctor we had at that particular paper mill was seemingly more than an ordinary M. D. He had a number of cases and after he had been there two or three months he had me come up and he made a special point of going over some of these cases, pointing out the fact that they were repeaters and that there should be stress laid on some of them due to the fact that they did not recover because of some previous disease.

I am wondering if you have made a definite effort to link up on accident prevention the possible use of the doctor as he gets these cases before him with the safety man in the association? I think all industries could very profitably do that.

Public Safety and Education

(General Session)

October 26, 1926

HOWARD BROWN, Chairman
Attorney, Detroit Automobile Club, Detroit, Mich.

THE Public Safety Education session convened at 2:20 o'clock, Mr. Howard Brown of Detroit, presiding.

CHAIRMAN BROWN: Ladies and Gentlemen: This afternoon's session is devoted to public safety education. There is no more important subject before the American people today than this. In 1924 Mr. Herbert Hoover called a conference to consider ways and means for the reduction of accidents in this country. In the year 1925 there were 23,900 persons killed and over 600,000 injured in automobile and other traffic accidents. The situation had become so grave that conferences were called to consider the reduction of these accidents.

This afternoon the speakers on this program will talk on the various phases of public safety and education. It appears to me that each of us could carry back to our own communities a great deal of good that will be derived from these speeches. Personally I think that there is no better way to get at this accident situation than to have it carefully analyzed and have the problem isolated. We create laboratories to run down and isolate certain disease germs, and yet day after day we are killing hundreds of people over this country recklessly and through carelessness. In the state of Michigan, up to September 1, there were over 657 people killed through automobile, railway and street railway accidents. Think of that situation a moment and you can see how grave it is. There are various phases to this question and this afternoon we are going to have the pleasure of listening to various speakers who will present the different sides of the problem.

The first speaker is Mr. Frederick J. Haynes, Chairman of the Board of Dodge Brothers. It will be interesting to hear what Mr. Haynes has to say as coming from the manufacturing side.

SAFETY—A NECESSITY OF THE MOTOR AGE

Frederick J. Haynes, Chairman of the Board, Dodge Bros. Inc.,
Detroit, Mich.

It is most gratifying and impressive and indicative of a true and real advancement in society, when a large group of men and women are assembled, all vitally interested in and studying the problem of how to secure 100 per cent safety for all.

The cause for which we have come together is one incapable of criticism. We may never achieve the ultimate goal we are seeking, but any advancement, no matter how small, can only work for good and is most commendable.

Having in mind the improvement of conditions for others, also improves our own conditions because it is absolutely impossible for one to work for a worthy cause and not be improved and happier himself.

Were I asked for a "panacea" or "cure all" for the accidents happening every day throughout our land, I should say that courtesy and education would come nearest to accomplishing the result desired—and the keynote of this paper will be—"Courtesy and Education."

To some, courtesy and education may not seem to be sufficient, but I believe that in some form or other they practically cover the entire field.

The motor car industry is today the greatest single industry in the United States, and hence in the world. It has achieved that position because of deserved merit. The present splendid industrial position of the United States, the greatest country in the world, has been attained largely because of the motor vehicle. It marks an epoch in the world's advancement. Like all improvements, it has caused changes, and a readjustment of many things is necessary.

Among others it has caused an enormous increase in the use of all highways. This increased use has directly and indirectly caused many accidents. It is the thought of some to blame entirely the motor car, but this is decidedly unfair, as I think all will agree.

I have even seen printed articles which stated that the automobile manufacturer himself was to blame as the cause of all traffic accidents. Were that argument to prevail, then every manufacturer of every commodity made would be included in the same category; no one would be exempt, for knives made to cut bread with have been used to kill, croquet mallet heads have flown off and inflicted injuries, babies have choked on buttons and safety pins, books and papers have transmitted disease after being used by sick persons, water has caused colds and deaths.

All the things mentioned are necessities—knives, buttons, pins, books, papers, motor cars, water to drink—but they can all be provocative of accidents when improperly used.

Obviously this is either the result of ignorance or inexperience on the

part of the user. He must be educated—the article itself should not be blamed.

The automobile of today is a wonderfully perfect mechanical creation. It is extremely durable and reliable as regards materials and workmanship—it can be promptly started, easily controlled in action, and abruptly stopped. There, one might say, the manufacturer could consistently stop, but neither he nor I would agree to that. As a good member of the community he must go farther and join with others for still greater results.

According to records taken from "Facts and Figures" edited and published by the National Automobile Chamber of Commerce, it appears that in 1917 there were 9,097 automobile fatalities. This mounts steadily year by year until 1925 when the total reached is given as 19,828. These figures do not include cases of collision between an automobile and a railroad train or street car.

This is indeed startling, but after close study it is revealed as very much better than at first appears.

It seems to me that the only proper basis on which to compare progress or retrogression in accidents is to consider them in relation to population and number of motor cars in use.

In 1917 the population of the United States was 102,000,000. In 1925 it was approximately 110,000,000—an eight per cent increase.

In 1917 there were 5,104,000 motor vehicles registered, with a fatality list of 9,097, or—178 per 100,000 vehicles registered.

In 1925 there were 19,900,000 vehicles registered with 19,828 fatalities, or 100 per 100,000 registered vehicles.

Encouragement for Those Who Work for Safety

Had the rate in 1925 been the same as in 1917, then 35,422 fatalities would have resulted instead of 19,828; but instead there is a reduction of 15,594, or 44 per cent. Forty-four per cent reduction in the face of an eight per cent increase in population and a 300 per cent increase in the number of motor vehicles—that's a measure of the general result of the work done in the United States for more complete safety.

Therefore, I believe that every one who has worked in the interest of safety—organizations, cities, towns and villages—should be warmly commended and encouraged to give still further of their splendid thought and action. You are gaining and winning—there is no question about it; and you have great cause to congratulate yourselves on the results accomplished.

The fatalities which have resulted in different cities show an astonishing divergency. Take for instance the cities of Philadelphia, Baltimore, New York, Boston, Chicago, San Francisco, Buffalo, Cleveland, St. Louis, Detroit, Pittsburgh, Los Angeles—named in the order in which the per cent of fatalities per 100,000 population occurred. Philadelphia for the

year 1925 had the lowest rate, 15.6 persons per 100,000. Los Angeles, California, had the highest rate, 41.1 persons per 100,000.

My understanding is that Los Angeles has since these figures were compiled gone to great extremes in the matter of protecting the public, and that later figures which I do not have show a very splendid reduction, for which Los Angeles deserves commendation.

Quoting from the NATIONAL SAFETY NEWS of July, 1926: "One encouraging aspect of the situation however is that deaths of children less than 15 years of age increased only about three and one-half per cent in 1925 over 1924—whereas the fatalities among the grown-ups increased about 14 per cent. These facts seem to indicate that safety education in the schools is having an effect, a result abundantly corroborated by the individual experience of cities in which such work is being carried on."

Right here I would suggest that safety education and drill be made a very distinct and prominent part of the school curriculum. It should not be lightly touched upon—that is only now and then—but it should be drilled into the pupils for a certain time each day, until it becomes part and parcel of them, especially since children's minds are most receptive and retentive.

The Human Factor Responsible for Most Accidents

What is the cause of all these fatalities? From personal experience and observation extending over a period of more than 22 years, I am inclined to believe that approximately 95 per cent of them are due entirely to the human factor, and are caused by ignorance, selfishness and carelessness. In fact they could practically all have been averted had there been knowledge or use of courtesy and education.

Everywhere you hear the statement, "Protect the pedestrian." I agree with this fully, and yet do not know that it is entirely the correct principle, because, primarily you can not think for some one else, you can not act for some one else. If one is not interested enough to act for himself, it is a hard task to do it for him.

In 22 years I have driven somewhere between 250,000 and 300,000 miles. I have been fortunate in inflicting no human injuries. But time and time again, when using my best endeavor to protect, I have been extremely exasperated by the heedlessness and indifference of the pedestrian—likewise the discourtesy of many motorists.

I once saw a woman standing on the curb talking to another lady. She deliberately proceeded to back right out into the street. A friend of mine was coming along in his automobile—in those days there weren't so many—and he saw her and stopped his machine. Later he killed the engine. She never knew there was such a thing as an automobile until she backed into the radiator and then she proceeded to trim him for being such a poor driver.

The other day, probably two months ago, when coming from Syracuse to Buffalo our train had just stopped at Batavia. I turned to look out of the window and I noticed that a fast freight train was grinding its brakes and coming to a stop just as fast as it could. That freight train running on a parallel track was probably not more than a few seconds behind us and yet during that period an automobile driver had thought—mind you, the train was in plain sight and had a bright headlight—he could cross and get beyond that train. What was the result? The train hit the automobile. It rolled it up into a ball between the two trains and threw the man who was driving it under the wheels at the front end of the rear pullman and then they disconnected that while the coroner extricated what was left of him.

One Automobile Encounters a Street Car

Some time ago I was driving up Oakland Avenue in Detroit. I saw a big vacant lot on the corner and I saw a street car coming south and a Ford car going east. The street car was giving ample evidence of its approach—its gong was ringing. Having had some experience, I figured that the automobile wasn't going to stop and if I went on I would probably get to the corner just in time to have that automobile landed on me so I pulled up to the curb about 150 feet from the corner and waited. The automobile did pretty well. It got almost across and then the street car hit it, caught it right on the rear wheel, turned it around three or four times and landed it up in a drug store window. The man fell out as the car was going over the sidewalk.

If you picked up the paper here in Detroit a short time ago you would have read a sad story about a father who was taking his ten-year-old boy, his wife and little daughter out on the occasion of the son's going away to school. The father, in order to be particularly nice to the boy, said he could drive. They got down here in the western part of the town and the boy got confused at a railroad crossing and the car went into the ditch. The boy was killed, The mother was killed, as was the sister, and the man was badly hurt.

I do not believe the time will come when there are no accidents until human nature shall have changed, and people shall have acquired some education, some courtesy, and some discrimination of judgment.

I feel entirely different toward children and elderly people. Children are spontaneous and irresponsible; we would not have them otherwise; if they were not so, much of the beauty of child life would disappear. It is because of this that I would be very thorough in my plan to educate them to protect themselves. I would go to any length to protect them. As children we have all "hitched rides" and done the hundred and one things which mature judgment later in life tells us are dangerous.

But children are susceptible to education, and quoting again from your own record,—the fact that only three and one-half per cent of children were injured, as opposed to an increase of about 14 per cent in the fatali-

ties of the grown-ups, shows that you are making splendid progress along that line.

I want to congratulate the schools of this land, not alone the school officials, but the janitors in overalls and the school children themselves. I always get an intense thrill when I see the "janitor traffic officer" with a handmade semaphore aiding the children across the street, also the serious minded school boy who sometimes is delegated to the task. They are splendid and doing wonderful work.

As a help in educating children, the automobile manufacturers through their trade organization, the National Automobile Chamber of Commerce, for years have annually spent thousands of dollars in an endeavor to promote greater safety, or rather, to educate the public.

The National Automobile Chamber of Commerce is giving \$6,500 in prizes annually for the best essays and lessons on highway safety.

These awards are divided into more than 500 prizes to be competed for by grade school children all over the United States.

There are three national prizes for the children, of which the first is a trip to Washington and a gold watch..

There are three national prizes for teachers, the first of which is \$500 in cash and a trip to Washington.

These prizes are given every year, and approximately half a million children and 60,000 teachers enter the competition.

In the contests to date the President of the United States has received the winning pupil and presented the award.

Interstate Traffic Is the Minor Problem

Mr. Alvan Macauley, President of the Packard Motor Car Co., estimates that 94 per cent of accidents occur in the home state of the car; that 53 per cent are in the home town, while only six per cent occur because of foreign state cars involving interstate traffic.

That would seem to show that the great bulk of your problem is at home, fortunately where it can have the greatest thought and effort. It would also mean that the greater part of the work falls first upon cities, towns and villages, and then upon the state as a whole.

Complete protection of the motorist and pedestrian does not always fit in with their inclinations. Street crossings could be made 100 per cent safe if pedestrians would cross in tunnels which are possible of installation, but that many times would conflict with their personal inclination.

Most, or all, grade crossing accidents would be avoided if people would only be educated to "Stop, Look and Listen," as exhorted to do by the railroads themselves. That alone would have prevented the 2,206 automobile fatalities at grade crossings in 1925, as reported by the American Railway Association.

The legal department of the Grand Trunk Railway declares "that 20 per cent of all crossing accidents along this road in the state of Michigan

are caused by motorists striking trains, and not trains striking motorists."

It is not right or fair for any one person to be so selfish as to want exclusive protection for himself alone. We all have responsibilities—the motorist—the pedestrian. Neither has less than the other. The motorist is in duty bound to protect the pedestrian; likewise the pedestrian must protect the motorist. The pedestrian can not selfishly claim that he alone has all the rights and the motorist none, and vice versa.

As another cause, I would include most if not all city fire departments. Personally, I do not believe there is any perceptible gain in fire apparatus running at full speed with clamoring gong through crowded streets, and ignoring all street signals unless there is a traffic officer at the intersection to assure them that the way is clear. These engine companies are located in and cover limited districts, which in the main require only a short run.

Quick Thinking Often Prevents Auto Accidents

I once saw a near-accident which would have been terrific. From my home near the corner I could see a heavy hook-and-ladder truck drive at a high speed westward, and a heavily laden double-deck bus was traveling north. Neither could see the other, due to houses being near the corner, and there was no time for me to warn them. Suddenly both came into view. Quick right and left hand turns were made—the sides of the vehicles scraped—the accident was averted.

Afterwards both drivers were as white as sheets. Had the two vehicles come together, I have no doubt that between 40 and 50 people would have been injured, perhaps killed.

By observing street regulations this fire apparatus probably would not have been more than a minute or a minute and a half later in getting to the fire. As it was they lost over 10 minutes in getting straightened up and away again.

Now, what is the remedy? What can be done to overcome completely or partially this appalling loss of human effort?

As I stated in the beginning, the greatest remedying factors are education and courtesy. There is no discounting this statement.

Do you realize how important courtesy is, and how dangerous is discourtesy?

Were complete courtesy—which is the absence of selfishness—to prevail, practically all the accidents which you deplore would be eliminated. Courtesy, would—

Prevent right angle crossing accidents, saving life and property.

Keep motorists in line and prevent accidents caused by getting out and then trying to crowd in line.

Never pass another car near the top of a hill, or on a curve, where the possible oncoming car can not be seen.

Save pedestrians, on right and left hand turns.

Always operate their vehicles with a keen regard and consideration for the rights of others.

Work with the Traffic officer instead of against him, thus causing a smile to replace the serious face necessary when many are trying to outwit him.

These are but a few of the things which courtesy will do. Education promotes courtesy, since discourtesy is mainly due to ignorance and selfishness.

Very comprehensive plans should now be laid along the lines of promoting education and courtesy, and should be most completely and fully carried out. The result of this work will begin to show an increase in results as the years go by.

In the meantime also, I would suggest the following for your consideration:

Additional Safeguards and Uniform Traffic Laws

A uniform system of traffic laws for the entire United States.

Widening of streets wherever possible, and to the greatest extent.

Removing all bottle necks in all arteries.

Removal of shrubbery and hedges where they tend to obscure a crossing.

Abolishment of grade crossings wherever possible, within reason. (Railroads could do much to help if they would change the land contour at various crossings. Many such places have come to my notice where a day's work with a steam shovel would give an unobstructed view and be as good as an overhead crossing).

A drastic enforcement of traffic laws, including in cities the use of plain clothes men instead of uniformed officers to detect violators.

Prohibition of parking within 50 feet of street intersections.

Many playgrounds for children, located in all parts of the city or town.

Safeguarded street crossings and safety zones to the greatest extent possible.

Express routes around towns and villages, relieving traffic congestion in these places.

Through routes—well marked—through cities avoiding heavy traffic for touring motorists not desirous of stopping in cities.

Removal of all bill-boards or roadside signs where they obstruct in any way the view of the motorist.

Non-use of wood block paving material as being very slippery in wet weather.

Rapid sanding of streets in icy and slippery weather.

Better lighting of streets by municipalities.

Splendid lighting at street intersections.

Overhead or one side traffic signals as opposed to center street

installment. (Every time a signal is erected in the center of a thoroughfare a possible accident promoter has been put up).

The publications of the country can be of invaluable assistance if they will hammer continuously along safety lines.

The aid of all merchants and manufacturers operating one or a fleet of commercial cars. (All drivers should be most carefully selected, and before they have driven a foot the value of human life and limb and property should be impressed upon them. This should also be regularly continued at set times.)

Manufacturers can well afford to pay as a reward a regular bonus to their drivers, say every three or four months, based upon their freedom from accidents and the condition in which they keep the vehicles. This would not be a loss but rather a saving, because if the vehicle is carefully driven and the upkeep reduced, that saving should be shared with the employee because he is directly responsible for it.

The saving in freedom from accidents is tremendous, both in thought and worry, and the time consumed in settling the matter.

Along this line the following was taken from a recent issue of the Detroit News:

"Reward for Careful—An insurance and benefit association, which employs a number of salesmen, recently announced that \$50 will be given to each salesman who refrains from violating the traffic rules from September 1, this year, to January 22, 1927. 'It is a good idea, I wish other concerns would do the same,' said James Spratt, superintendent of police, when informed of the plan."

This line of action has been followed for some years by the Yellow Cab Company of Chicago, with very splendid results. Besides saving life it is good business, because it instills a feeling of confidence in patrons.

Three Safety Rules for the Careful Driver

It may interest you to know three rules which I have followed consistently and which have given me good results. They are:

1. Never drive at a speed in which you can not stop in a clear space ahead of you.
2. When passing parked vehicles watch the ground under the vehicles for feet. If there are no feet no one can step out on you unawares. If there are feet you must be ready for any emergency.
3. When passing trucks or commercial vehicles watch out for possible children catching a ride.

Now how can we get results?

First. Start with ourselves. Let each one vow that for the next year he will always be courteous to the other fellow—vow to keep your temper, no matter what the other fellow does, for he will do some exasperating things.

Second. Get a convert every day to the cause of courtesy, and pledge him to do the same, thus starting an endless chain working for Courtesy. By doing that you will at once have started Education.

As a closing suggestion, would it not be advisable to issue some national emblematic award for Safety? This might be splendidly and beautifully designed, and issued by the authority of some standard organization, perhaps the Red Cross Society.

It should be issued to those who have not inflicted human injury, and be given upon proper proof, to be bestowed only after the applicant has driven 25,000 miles, and revokable on the occasion of the first accident. Such an emblem would be given universal standing so that the persons carrying it on their cars would be recognized by traffic officers in every state.

It should be given much the same importance which the Red Cross life saving emblem carries when it is seen on the bathing suit of a swimmer. It is known that that emblem can never be obtained until a certain proficiency in swimming has been attained.

CHAIRMAN BROWN: I feel that we are all deeply indebted to Mr. Haynes' clear analysis of this situation.

The next address on the program will be by Dr. Zenos E. Scott of Springfield, Massachusetts. Springfield has become nationally known for its system of teaching safety in the schools. I know we will be delighted to hear from Mr. Scott, who will tell us about the plan in Springfield.

SAFETY EDUCATION AND CITIZENSHIP

Dr. Zenos E. Scott, Superintendent of Schools, Springfield, Massachusetts

Democracy demands that practice in the acts of good citizenship should keep approximately close to the theory of good citizenship.

It is never easy to make the theory underlying any movement or truth advance at such a pace that the practice may keep abreast. The general tendency is for theory to far outstrip practice. The thinker, for example, wants to advance far ahead of the doer; the idealist wants to keep a great distance ahead of the man who is supposed to put the ideals into practice.

Our democracy has reached such a stage that at present the average man possesses a suitable task at which to work, a house in which to live, means by which to pay for the education of his children, money with which to travel, opportunities for recreation. These conditions make it necessary and possible for the average man to develop new habits and new skills.

If there were but a few of the hundred and twenty millions subjected to dangerous situations each day, there would be little need for the remaining millions to be so concerned with the acts of the small group. However, when conditions are reached in which the lives of a great number of the hundred and twenty millions are in possible danger each

day, it is time for all to learn how to make adjustments to meet this new situation.

These new adjustments are as essential for the present and future good of our citizens as are interest in public affairs and participation in community endeavor.

"Citizenship and safety education," therefore, but represent the application of well known principles to new conditions and new needs.

The program of public education must be directed toward preparing children to take their place in the life of the world. It must develop knowledge and technique to meet immediate situations. It must also develop insight into the problems of life in general.

Safety education in the industries began with providing protection for the workman against the dangers of high powered machinery by caging the machines, or placing high power belts overhead, or creating safety zones, so to speak, in the machine areas.

Teaching Safety in Schools Involves New Problems

An advance step was the education of the workman, teaching him not only to adjust himself to the dangers of the situation in such a way as to prevent accident, but giving an insight into the problem and teaching him to assume individual and collective responsibility for the safety of all. Such assumption of responsibility is an obligation of the citizen within the industry. In this respect the various industries have served very definitely in citizenship training.

Within the school we face new problems. We know the need for safety education, for safe adjustment to immediate situations. There is just as great need for the solution of that larger question, that of developing insights into the whole problem in its relation to life in general, and of teaching children to assume greater responsibility for the safety of all.

There are in the field of safety education two types of outcomes: the successful adaptation to immediate situations, a definite and immediate result; and those ultimate and more remote outcomes manifesting themselves in social and moral life.

In education, present-day interpretation conceives citizenship to be qualities of behavior guided by an appreciation of all the factors that enter into a group situation.

No classroom or school unit is without innumerable opportunities for such training. For whenever a group of individuals gather together for a common purpose, such problems as those which involve the rights of others, recognition of another's contribution, harmonious agreement or disagreement where there is conflict of opinion, are bound to be present.

The quality of behavior desired in such situations must be developed by an insight into the problems presented and a clear understanding of the types of behavior which make for sympathetic cooperative living. The ultimate outcome reaching into adult life must be knowledge and attitudes acquired in and through such procedure.

We are not here raising the question of the cost of accident. We are concerned with bringing about conditions which may reduce losses to a minimum, with the thought that the by-product—*citizenship*—is the thing which in the long run will most probably reduce accident, losses of money and property; and which will eliminate suffering, prolong life, and increase happiness.

In terms of safety education, who is the good citizen? What is citizenship? What is it which shows growth in citizenship? Can this new aspect of community life be taught? Must we, the members of corporations, schools, and private individuals, teach this aspect of good citizenship? Must we make over many of our old habits in order that there shall develop higher types of activities which consider the interest and welfare of all?

The man who removes the danger when he sees a board with a rusty nail has a chance to be a good citizen. The clerk who double checks himself when labelling a can containing gasoline is a good citizen. The boy who never points a fire-cracker or a toy gun at another is a good young citizen. The boy who never "catches or hooks on" is a good citizen. The driver who signals and slows down at each turn in the road is a good citizen. The pedestrian who guides himself across the street as carefully as he would want the driver of a car to steer is a good citizen. The parent who keeps his child isolated because of contagious disease is a good citizen.

Characteristics of the Good Citizen

In all situations there is implied, first, intelligence upon the part of the individual; second, a training of intelligence in safety; third, willingness of the individual to see his own act and its possible result; fourth, a willingness to have a care both for his own safety and for the safety of others; fifth, a determination to make himself obey the higher motives in life and listen to what public opinion says as well as his own conscience.

Can such aspects of citizenship be taught? The question answers itself. Circumstances alone teach men and women, boys and girls to behave successfully under difficult conditions. Let me draw some illustrations from the schools of Springfield:

The pupils in one of our large elementary buildings were in the habit of skating to and from school. The walk leading to the street is on a sharp incline.

At a meeting of the children's council one afternoon, the statement was made that children who skated to the corner frequently found that they could not stop and were forced to skate into the street. The children decided that since this was dangerous it would be wise to forbid the putting on of roller skates within two blocks of the school. A motion to this effect was carried out. When the council adjourned, the dismissal of school was in progress. Members who assisted in the dismissal took their places in hallways and yard. One boy who had assumed the full responsibility of his office took his place at the busy corner.

Two older children skating toward the corner were stopped and informed in regard to the new ruling. The children objected to removing their skates at first, since they had not been officially notified. The younger lad explained the reasons for the ruling and after some little argument first the older lad and then the girl unstrapped their skates and walked down the street, law abiding citizens of their school community.

This illustration shows that individuals do learn how to act under varying circumstances of danger. They are taught by their own thinking, experiences, circumstances, the sayings and teachings of others, the examples of others, and also by that intangible public opinion which indicates somewhat indefinitely but persistently what things are demanded of a good citizen.

The first important contribution to ask is that a better understanding take place among all who are participants in any line of work.

"Fire Prevention Week" Began the Safety Program

When the matter of traffic hazards, fire, water, explosions, and similar dangers are understood and appreciated an important step will have been made. The following example shows how understanding takes place:

The observance of "Fire Prevention Week" was the beginning of a safety program in one of our schools. The children and firemen talked together about the best ways of working for the safety of the school and community. The children constructed an engine house, fire alarm box, and made equipment modeled after that which had been seen in a nearby fire station. When any question arose on which help was needed the children consulted the firemen as well as the teachers.

The entire building made a study of what to do in case of fire at home or at school. In each fire drill the children formed the habit of thinking and acting as if there were a real fire. Rules made by children and teachers were obeyed to the letter.

A few weeks ago a room in this school began to fill with smoke. Teachers and children discovered the smoke and flames and turned in the signal immediately. The custodian's bell and the fire bell rang simultaneously.

The children vacated the rooms and the building under strict drill orders. In less than two minutes the building was empty. For 20 minutes the children kept in their assigned places at some distance from the building, and when the "all-out" signal was given by the firemen, they returned to the building without disorder or undue excitement. The results of study and practice in adequate fire drill were all that could have been asked. The way in which this difficult and dangerous situation was met showed how necessary it was to prepare for such an emergency. The results were great enough to pay fully for all the precaution made by fire drills throughout the city.

We know that a program in safety education will really influence life to a great extent; that through persistent practice in school, at home,

in industry, and on the street the result of cooperative thinking and cooperative acting will reach such a point that all will learn better how to act wisely and safely. The results are citizenship products.

How did the Springfield public school system find its part, and what has been the spirit on which that part has been played? A page from the yearbook of the National Society for the Study of Education approximates the answer to this question:

"The first step in the Springfield program was a study of such activities as might be helpful in reducing accidents among the children of congested areas, and a consideration of a program of general safety for the entire city.

"It was soon evident that these activities should be organized in a city-wide program. To this end, a committee made up of teachers, principals, and supervisors was selected to formulate a course which could be used in the elementary schools.

A Special Committee Studied Local Conditions

"This committee studied local conditions and examined all available courses of study in use in other cities. Conferences were held with members of the Springfield Safety Council and the National Safety Council.

"The committee had several meetings at which the general ideas underlying safety education were developed. The committee was then so organized that special phases of the program could be prepared for each grade. Teachers and principals who had contributions to make were organized as sub-committees and were called upon to work for consecutive days upon the subject matter, method of presenting, etc. The materials presented covered physical education and health as well as so-called safety ideas. Almost one year was spent in perfecting the program and in trying out the materials.

"When the program was ready for use meetings of teachers were called for the distribution of the tentative course. Supervisors of special subjects discussed the relation of safety education to the work of their respective departments. Plans for the use of this material were presented by the general supervisors, under whose direction this work was to be carried on."

Those who were active in developing the program of safety education considered the course of study and methods from two points of view: first, the more immediate development of better and safer behavior in the pupils themselves in order that they might meet the hazards of life more effectively; second, the development of appreciation of the organizations at work in the community at large for the protection of life and property, with the hope of developing a consciousness of the duties and obligations which rest upon each citizen to be familiar with such organizations and to ally himself helpfully with them.

Consequently, in the kindergarten and primary grades, the selection of subject matter was made from family life and the home, and from the more immediate situations involving potential hazards of any kind.

In the upper grades the subject matter was selected from the organized agencies for public safety. Such selection was intended to provide for continuous growth in right habits of thinking and acting. The course of study illustrates definitely that objectives and materials of safety education may be so organized as to become an integral part of the curriculum, not a unit isolated from other subjects of that curriculum.

How significant is this program of safety education in the public schools? I am not detracting from other specific purposes or accomplishments when I say, that in my judgment what is being done in safety education is equal in importance to any other accomplishment. The work lies within the experiences of children. It is making them more thoughtful, more painstaking in their efforts to protect life and property. In every school visited at any time throughout the year, there is constant evidence in recitations, on posters, in attitudes and habits of pupils in class rooms about the buildings, and on playgrounds, that safety education pays big dividends.

May I again quote from the yearbook? "However well organized a public school system is, a full program in safety education can not be adequately carried on without cooperation with other important agencies.

"At all times the Springfield Safety Council has furnished constant inspiration to us. Springfield is fortunate in having many of the more able business men of the city interested enough to give careful attention to an industrial safety program in our city. In addition, the interest of these men goes much beyond that of industrial education. It is carried over into that type of safety education which goes on in the school. These men have spared neither time nor effort in their willingness to study and assist in the program.

Cooperation of Many City Agencies of Large Value

"The Safety Council has also furnished an abundance of valuable statistical and teaching materials. The Council has given much help by the way of wholesome and sane publicity in the general safety program.

"The Department of Streets and Engineering has aided materially in the enrichment of our program and in making it possible for this program to be carried out.

"The Police and Fire Departments have also been a source of great encouragement in the development and in the carrying out of safety education in Springfield. Equal in importance has been the spirit manifested by the men of these two departments in making it possible to secure the right attitude on the part of the school children. The slogan 'each fireman and policeman is the friend of the children' has become a meaningful slogan with us."

We are not asserting that Springfield has solved the problem of full citizenship training in regard to safety education. We believe that the problem has been fully realized by those in school and community life. The progress that has been made indicates that it is only by a carefully planned program of education for both children and adults that the solution will be reached.

The present conditions are encouraging throughout the entire country. The illustrations which I have used from my own city are but indicative. They show that thinking people in school, in industry, and in communities are earnestly making efforts to lessen these dangers of everyday life. We may look forward soon to a time when even with the increased difficulties, greater progress toward the solution of our problems will be made.

Years ago, plays and games, sports and general athletic life affected us but little. At that time there were few rules to the games and even these rules were not always lived up to. The present development shows a situation quite different. We now have elaborate rules and regulations. All of those participating are quite willing to obey the rules. The spectators numbered by the millions (football, baseball, basketball, golf, tennis, soccer, swimming, etc.) have learned enough of the rules and regulations to understand the games and to appreciate the skill, the technique, the sportsmanship of the players.

Sport May Often Be Enlisted in the Cause of Safety

The spectators are the supporting public who help definitely to set the standards of behavior for both the players and the spectators. The combined groups make one of the great socializing agencies in American life. Sport is a new factor in our democratic society. We may call this factor whatever we will, it contributes one of the sane and wholesome aspects of public life today.

The way in which the Boy Scouts of America conduct their games, plan their programs, and carry out their activities with the slogan "on my honor" uppermost in their hearts illustrates what citizenship attitude is being developed in this great organization.

When Bobby Jones lost the golf championship a few weeks ago there was universal regret that he was defeated. There was, however, nationwide admiration, for he played his best and in defeat showed the highest type of sportsmanship. The public appreciated his efforts.

The millions of people listening in and watching score boards wanted Alexander to win in the final game, when he stepped into the box in that hectic seventh inning. There was still the splendid fighting spirit in the team. Alexander has been a national figure in baseball for years. The public support was his. Through his pitching, and under Hornsby's leadership, the Cardinals won and the millions of people felt a bit prouder of American sportsmanship.

All will agree that these illustrations show growth in sportsmanship. They represent new aspects of life which we have learned within the last generation. All have learned sportsmanship ideals through the observance of games and recreational activities. The rules are observed by participants and millions of spectators. No richer field is offered for the development of proper citizenship ideals and attitudes.

There is a lesson here for us interested in safety education. It is now in its mere beginnings. There are but a few rules. These are not fully

understood, neither are they obeyed willingly, nor is compulsion yet used to any great extent. There are not yet millions of cooperative spectators eager to support the work and to aid in carrying out the rules. This situation is comparable to the beginnings of sport as we now use that term.

With constant effort and adequate enthusiasm we may make our program of such importance that the majority of our citizens will be willing to cooperate. Safety education will compel all of us to live up to the rules of the game of life.

When each one acts with reason and care in whatever he does, his action will look toward his own protection and happiness and in addition it will consider and include the protection, happiness and safety of friends and neighbors. In this sense, citizenship will have a new meaning, and it may even be placed on a higher plane.

CHAIRMAN BROWN: I am sure there is plenty of food for thought in Dr. Scott's address.

Many of us who have been unfortunate enough to have been involved in accidents have wondered how they did happen. This afternoon we are going to be told how accidents happen. Dr. Louis I. Dublin, chairman of the Statistics Committee of the National Safety Council and statistician of the Metropolitan Life Insurance Company, of New York City, will now address us on that subject.

HOW ACCIDENTS HAPPEN

**Dr. Louis I. Dublin, Chairman, Statistics Committee, National Safety Council, and Statistician, Metropolitan Life Insurance Co.,
New York City.**

This is the fifth report which this committee of the National Safety Council has rendered to the association. What I shall say to you will be less in the nature of a paper of my own than the report prepared as the result of work done by a group of loyal members of the association in and out of season, year in and year out.

As is usually the custom, I shall give you a few words with regard to the situation throughout the country on the score of public accidents and of accidents in general.

You should know, for example, that there were in 1925 a total of approximately 90,000 fatal accidents in continental United States and that those 90,000 fatal accidents represent a total of at least 5,000,000 to 6,000,000 accidents of all kinds. The total losses sustained by the country as the result of these millions of accidents and these 90,000 fatalities are simply enormous. I, who am in the habit of conjuring up large figures, hesitate to attempt to calculate the total loss involved. It would be almost impossible to do so, so great are these losses.

It is also most interesting to observe that the accident rate during the last few years has shown very little tendency toward improvement. I shall show you some figures in a moment indicating that from year to year during the last five years the figures have been vacillating up and down without any regular tendency. During that same time the improvement in general health conditions has been enormous and there has been a marked decline in the mortality from various preventable diseases. We must think in similar terms of a series of preventable accidents which can be controlled, just as diptheria and tuberculosis and typhoid fever can and are being controlled. But these accidents are not being controlled.

TABLE NO. 1

Estimated Fatal Accidents in Continental United States, 1925 and Prior Years—Principal Causes

Cause of Accidental Death.....	Estimated Deaths In:				
	1925*	1924	1923	1922	1911
All fatal accidents.....	89,880	86,579	85,351	76,255	79,255
Accidental burns	7,615	7,840	7,495	6,992	7,214
Accidental drowning	6,807	7,499	6,935	6,992	8,306
Accidental falls	15,922	14,884	14,318	13,219	14,052
Traumatism of machines	2,423	2,386	2,573	2,185	1,967
Railroad accidents	7,269	7,385	8,168	6,664	12,179
Street car accidents.....	1,385	1,813	2,014	1,748	2,998
Automobile accidents†	19,037**	17,725	16,555	13,656	2,061

*Provisional estimates from experience of Metropolitan Life Ins. Co. Figures for 1924 and prior years based upon U. S. Registration Area data, Bureau of the Census.

**Estimate of 19,800 automobile accident fatalities by E. E. Robinson for 1925 should be accepted in place of this one.

†Does not include deaths in collisions between automobiles and heavier vehicles.

If we look over the period of 15 years we find a slight rate of decline, a decline of less than 10 per cent. During that same period there has been a decline of 20 per cent in the mortality of the general population. So you see there is a field full of promise justifying the activity of the National Safety Council. In fact, the very situation which I now describe is the greatest justification of this association of ours and explains its great progress.

The valuable lives of men and women included in this total could hardly be evaluated and the promising children who are killed by one kind or another of these accidents which we have been discussing could not be evaluated. But it is most interesting to observe that these accidents of ours are occurring at a rate very much higher than seems to be necessary in any other part of the world. If we turn to the European countries, and especially such countries as great Britain, we find that

our fatal accidents are at a rate two and one-quarter times as high. If we take industrial Belgium, a bee hive of activity, a country in which almost everybody is actively engaged in industry, we find that our accident rate runs nearly three times as high as theirs. I am now thinking in terms of all accidents, not merely vehicular or mining or any other species of accidents.

TABLE NO. 2

Death Rate per 100,000 Population for Specified Accidents in Certain Countries

Country: year	Total accidents	Falls	Burns	Drownings	Steam railroads	Automobiles	Street cars
U. S. Reg. States—							
1924	76.2	13.1	6.9	6.6	6.5	15.6	1.6
1911	84.6	15.0	7.7	9.4	13.0	2.2	3.2
England & Wales—							
1924	34.1	7.1	4.0	4.0	1.5	6.5	0.2
1911	45.5	7.8	6.3	7.3	2.3	1.8	0.1
Scotland—							
1924	45.2	4.5	*6.8	6.3	1.7	4.9	0.4
1911	55.2	5.2	**8.5	10.6	3.1	0.8	0.3
Belgium—							
1922	28.3	3.6	3.1	3.8	2.6	2.4	+
1911	34.7	6.6	4.4	9.5	3.6	+	+
New Zealand—							
1923	46.1	2.8	**2.0	13.1	5.4	4.6	1.1

1911	+	+	+	+	+	+	+
Norway—							
1922	39.6	4.9	1.6	20.4	+	+	+
1911	47.1	3.8	1.8	30.2	+	+	+

*Includes conflagration.

**Includes scalds.

+Data not available.

Now, these 90,000 fatal accidents that we are talking about—how are they caused? You will be surprised to learn that half of them, 48 per cent, in fact, are of the variety which we call public accidents; a sixth are strictly industrial accidents; a fifth are domestic accidents; and the remainder comprise a series of odds and ends which are hard to classify. The outstanding group is the public accidents.

Please realize that with regard to industrial accidents, a concerted effort through 15 or more years has been accumulating momentum and doing big things. In fact, it was against the growth of the industrial accident that the National Safety Council was first organized and has found its largest opportunity for service.

The domestic accidents, numbering almost as many as the industrial accidents and perhaps even more, have scarcely been touched as a field for preventive work. But the field of public accidents is now beginning to receive attention. There are 43,000 or 44,000 fatalities a year and several million accidents involving injury and loss of property. These demand attention. And of these public accidents those which concern us especially, and which concern my committee especially, are the accidents on the highways.

In the last year 19,000 and some hundreds of fatalities occurred as the direct result of the automobile on our highways. These do not include the several thousand fatal accidents which resulted from the collision of an automobile and a heavier vehicle, such as a train or trolley. If we combine these two, and I think they should be combined, we get a total of 22,500 as the probable total number of automobile fatalities in the year 1925.

That represents a total of about 65 fatalities a day. This number has been increasing from year to year from almost nothing 15 years ago until today this group of accidents is of first importance leading all other groups.

The Fatality Rate is Apparently Dropping Back

You will be interested in knowing that the figure for 1925 is only slightly in excess of the year 1924 and that the figure for 1926 to date—that is, the first eight or nine months on which we have data available—indicates that there has been a staying of the rate of increase. In fact, the figures for the fatalities in my company show that there has been a slight decline among these 17,000,000 people whom we have insured. For the first time in the history of our record keeping we have gotten somewhere. We seem to see the light. These activities that have been described in Springfield and other places are beginning to bear fruit. Heretofore we were prepared from month to month to see a rising curve. We are now looking for a decline. We seem to reach the crest. Let us hope that is true and that from now on, as this splendid work is multiplied from city to city, we shall actually see a declining tendency from this, the largest, the most expensive, of our forms of fatality.

These figures which I am quoting, this decline to which I refer, is largely the result of the efforts of a few organizations and I think pre-eminently the result of the work of the National Safety Council. In recent years other organizations have taken up the cue. The Hoover Conference, the Automobile clubs and Automobile Chamber of Commerce, and the Chambers of Commerce affiliated with the United States Chamber of Commerce have a splendid program and I believe they will cooperate and coordinate their efforts with ours and so these results may grow and become more and more important.

But it is my function this afternoon to tell you about the work of the committee, the work that is carried on from day to day through the

Figure I. Distribution of Major Fatalities.

office of the National Safety Council in Chicago. A few years ago it occurred to us that perhaps the most important thing we could do was to develop a system of record keeping which could be made the basis of the program of those who were actively engaged in the prevention of vehicular accidents.

We realized perfectly well that we were just a spoke in the wheel, that we couldn't ourselves prevent accidents, but we also realized our primary position in making it possible for constituted authorities and for those others who are engaged in the prevention of accidents to do

TABLE NO. 3

Percentage Distribution of Fatal Accidents in 1925, According to Origin of Hazard. Metropolitan Life Insurance Company, Industrial Dept.

Origin or type of hazard	All ages		Under 15		Ages 15 to 64	
	Number	Percent of total	Number	Percent of total	Number	Percent of total
All accidents—total	10,656	100.0	3,299	100.0	6,355	100.0
Industrial	1,582	14.8	13	.4	1,478	23.3
Public	4,917	46.1	1,805	54.7	2,782	43.9
Transportation	1,069	9.5	173	5.2	808	12.8
Sports & recreation	494	4.6	214	6.5	276	4.4
Pedestrian use of streets	2,020	19.0	942	28.6	850	13.4
Use of public buildings	99	.9	16	.5	70	1.1
Others in this class	1,295	12.2	460	13.9	778	12.3
Domestic	2,328	21.8	1,018	30.9	959	15.1
Misc. and not specified	1,829	17.2	463	14.0	1,116	17.6

their work better. There are those, like the state and municipal officers, whose business it is to control accidents—the city planners, the traffic and safety engineers, the automobile manufacturers, the parents and teachers and that whole list of other people whose business it is to try to prevent accidents. It was our purpose to put into their hands that information without which they couldn't function. That was the goal we set for ourselves, that we should work out a system of obtaining basic information so that the work of these people would not be merely sentimental but effective.

The system that was worked out was essentially this: we realized that first of all there must be knowledge of every accident that occurs—every accident on the roads and on the highways. That meant a card on which a record could be made, which card should be so simple and so effective that it would be accepted by the constituted authorities as the official card on which records should be made. Let me tell you, my good friends, this was no easy matter. It took five years to work out this system of record keeping. I have this small card in my hand, a 4 by 6 card, which is now in operation. You will hardly believe it but this or some very similar form of card is being used in nearly 100 of the large cities of the country and in one entire state of the Union, largely due to the efforts of the National Safety Council in Chicago.

This card (most of you are familiar with it) calls for a statement

Figure II. How Motor Vehicle Accidents Occur.

of the outstanding facts with regard to the accident. It is intended to be made out by the officer in the location. In some communities it is supplemented by the participants in the accident; in fact, that is the

requirement of the state of New York. It calls for an investigation later, made when the smoke has blown away, when the facts can be gathered. It calls for a statement as to what the drivers were doing, what part the pedestrian played in the accident. It brings out the facts. It does not attempt to place the responsibility upon either driver or pedestrian. It attempts only to gather the facts together, from which a judgment can later be made and upon which conclusions can be drawn, not from one accident alone but from the thousands that occur, indicating what communities can do in order to prevent the recurrence of these accidents.

TABLE NO. 4**Albany Street Accidents in 1924**

- 76% occurred during clear weather.
 - 75% occurred on dry streets or roads.
 - 62% occurred during daylight.
 - 46% occurred on street levels or roads between intersections.
 - 43% of motorists involved in accidents were reported as being inattentive.
 - 22% of these motorists were reported as violating traffic rules.
 - 42% of pedestrians involved in accidents were reported as walking, running or playing in the streets.
 - 17% of these pedestrians were crossing streets between intersections.
-

It seems to us that after the development of these forms over a period of years we have a system that works, we have a system which has been rather enthusiastically received by those who know of it, who are recommending it from one community to another as a means which is helping to control the situation locally.

Let me call your attention especially to such communities as Albany, where this record system has played a most important part in controlling the situation there. I would call your attention to the situation in Grand Rapids where, under the direction of Col. Sinke, this record system has resulted in a splendid improvement in the situation. If only other police officials would follow his lead!

On the basis of the returns from this record system he prepared a report, the like of which I know not. It is a splendid document analyzing the accidents which occurred in his community. He knows where those accidents occurred. He has a spot map. He knows when they have occurred, in relation to school time, in relation to fatigue, in relation to the morning and afternoon and evening. He knows how those accidents have occurred, whether they are between pedestrians and automobiles or between cars by collision. He knows where these accidents oc-

curred, whether they are at intersections or between intersections. He knows the condition of the car and whether it was the fault of the driver or the fault of the car itself. He knows a thousand and one things with regard to those underlying conditions which resulted in the accident, with the result that in having this information he can and he has applied common sense in the removal of the causes.

What do you suppose is the result? Whereas, in Grand Rapids there were 41 fatalities due to automobile accidents in the first eight months of 1925, there were only 18 in the first eight months of 1926. The same situation occurred in Albany, and in Providence, Rhode Island, where this system was used; and it will occur in any city which seriously takes up the recording of every accident, the tabulation of the facts and the analysis of the facts and which is willing to do the right thing after the facts are at hand.

An Appeal for Cooperation in Statistical Work

My appeal to you this afternoon is a simple one. I ask you, ladies and gentlemen, to forward the work that Mr. Williams and Mr. Robb of the National Safety Council have so splendidly started in 100 cities of the country. What we want is not one-third of the population of the United States under the protection of this record system, but 100 per cent. This can be done if each one of you will go back to your own community and find out whether the police officials, and those others who are entrusted with the safety program, are using this system or a similar system and are reporting monthly to the central office in Chicago. The reports which you send in, which could be sent in by your police officials or your local safety council or your local chamber of commerce, would be tabulated in the Chicago office and the returns made available to you very shortly thereafter. If more of you will follow this clue and cooperate with the National Safety Council office in Chicago, I have no doubt at all that in the years to come, as we come to these meetings annually, we shall see the record for automobile fatalities and injuries go down as rapidly as we who have followed the industrial situation have seen it improve there.

All of these figures I have quoted and many more are available in tables and charts published in the report of our committee, which may be had upon request to the National Safety Council.

CHAIRMAN BROWN: I feel that none of us could do a better work than to cooperate with Dr. Duplin and see that each home city adopts this system of keeping accident statistics and forwarding them to the National Safety Council.

We are now going to hear from a gentleman who very early in life learned something about the decimal system and recently in Detroit has been attempting to teach others that system. He usually starts in somewhere with about 30 and then jumps to 60 and then usually to 90, and he adds days at the end of it.

I take great pleasure in introducing Judge Charles L. Bartlett, who will speak to you on "What are Laws for?"

WHAT ARE LAWS FOR?

Judge Charles L. Bartlett, Recorder's Court, Detroit, Mich.

I am of the firm belief, after years of experience on the bench and after the practice of law for nearly a quarter of a century before that, that these educational campaigns, this wonderful work carried on by these great safety organizations, the National Safety Council, the Detroit Automobile Club and other safety organizations, is of great value. I want to mention only a few of them: Capt. Galbraith and Mr. Brown here. From early morning till late night he is working on your problems. Then there is Mr. Van Schoick who goes throughout the state of Michigan and puts on these safety drives.

Recently in a small city of 40,000 inhabitants I witnessed a safety parade such as I have never seen in my life, which Mr. Van Schoick and the safety committee put on there. It was at that meeting that I spoke to over 16,000 people. Now if people in a city the size of Battle Creek will turn out 16,000 strong, you can see the interest that is being taken in this safety work throughout the United States.

Then there is Sergeant Brown, who has charge of the automobile school, and his instruction of green drivers on how to operate a motor car; our Commissioner of Police, Mr. Rutledge, who has taken a great interest in safety work; the newspapers that have kept down accidents by reporting the causes thereof and giving the public the true facts; the inspector of the Traffic Department, Inspector Sheehan and his splendid officers.

So, friends, if they tell you that these organizations are not cooperative and are not getting big results along safety lines, I want to say to you that it is untrue. Of course, they must have the assistance of the courts. They should have the assistance not only of the police department but of the court.

The situation has become a public calamity. I am informed that last year there were more than 676,000 people injured by automobiles. Of that number, 257,000 children were injured. I imagine that a line from Chicago to New York packed with those people would about cover the area. So we are confronted with this problem and confronted with this question, "Who are those who are causing these accidents?"

If any of you ladies and gentlemen have time tomorrow morning and will come over to court room No. 6 I will show you who are causing these accidents. I will show you that the men of this country are causing these accidents to a large extent. I will show you that the women are very seldom involved in serious accidents because they drive carefully, because they are more unselfish than men are.

To be sure, once in a while we have a woman driver before us, but very seldom, so I fully coincide with what Mr. Haynes says, that it is largely a matter of selfishness on the part of many drivers that causes accidents.

Those men are selfish in their own homes. They are men who care nothing for life or property. They care not for your rights or for mine.

And who are they? Many of them are morons. Many of them are epileptics. Many of them are confirmed drunkards. I have had many cases where men received operators' licenses, for instance, who had a criminal record, and that class of men is put upon the streets of every city in the Union to strike down innocent people.

Now, dealing with the subject of pedestrians, they are at fault in many cases. The carelessness of the pedestrian undoubtedly causes many accidents. Pedestrians must be educated to go with the traffic and not to cross in between streets and to remember that every eighth or tenth driver is either a reckless or a drunken driver.

Many people have asked me how I happened to start sentencing drunken and reckless drivers to jail? How is it that I take these men to hospitals and morgues? I will tell you just why. I think that those men should pay the penalty for their crime. I think they should be obliged to witness the havoc they have wrought and the lives they have taken, especially of little children. As long as I sit upon the bench in the city of Detroit I shall deal out the same punishment to them because I believe no man should escape who has struck down a beautiful child or torn to pieces an aged man or woman, who are incapable of protecting themselves.

Tracing the History of the Law of the Land

What laws are for, the subject assigned to me by your own body, is a most comprehensive and technical one and volumes could be written regarding it. In order to fully understand what law is, I will give you an approved definition from Holland's Jurisprudence, which is as follows: "Law is a rule of action prescribed and enforceable by recognized authority." The common law was brought to this country and became a part of our system of jurisprudence long before the time of Blackstone. Blackstone codified and made a complete and thorough analysis of the English common law and today Blackstone's definitions are recognized by every court in this country.

It was found that the common law which came to us from England in many cases was not adapted to our system of jurisprudence. Therefore the statutes were enacted which changed the common law into statute law, as, for instance, the laws of inheritance, etc.

Statutes were oftentimes cumbersome and are amended from time to time so that with the passing by each state in the Union of hundreds of statutes, a study of the law became most difficult and intricate. Especially was this true in criminal procedure which I shall discuss mostly this afternoon. Then, to add to the confusion, many legislators had their particular hobby and attempted to have laws enacted that would benefit their own section instead of the entire community. Thus each state enacted some laws, many of them in direct conflict with the laws of the United States. Oftentimes the interpretation of such a law became most difficult, even to the painstaking and studious practitioner.

Briefly, the result of these statutory enactments caused a partial breakdown of all laws. Therefore a general disrespect for all laws has been noticeable in the last decade at least.

Why this general disrespect for law and order? First, because the minority in many cases enacted unfair laws which control the majority. Second, because the authority of judges is limited to such an extent that the technical criminal lawyer can raise complex objections upon the record that will cause a mis-trial or reversal. Third, because a certain class of attorneys are continually looking for a technical advantage to secure the acquittal of clients whom they know to be guilty. Fourth, because judges are victims, oftentimes, of political adventurers who attempt to coerce judges and nullify their work. Fifth, because judges are not appointed for life.

A Criticism of the Profession of Law

Noticeable advance has been made in almost every profession except that of the law. Law colleges are graduating annually thousands who are prepared from the outset of their careers as attorneys in raising every possible legal technicality and thus secure an unfair advantage.

The traffic laws of this country are considered a huge joke by hundreds of thousands of citizens in the United States who openly boast of their ability to evade them and of their influence with the police departments and courts.

I am making these observations, friends, after years on the bench listening to thousands of felony and traffic cases and after nearly a quarter of a century in the practice of law before going on the bench.

I have not the exact figures but I have been informed that I have handled over 280,000 cases, some of them repeaters. In other words, I have had the opportunity of looking into the eyes of over 200,000 people.

Eighty-seven years ago England recognized the fact that in order to secure speedy and certain justice a complete change in this system of administration of justice was necessary. They thereupon erased entirely the old procedure and enacted laws which did away almost entirely with technical objections by attorneys, giving the judges far greater authority.

The result was that criminal cases which theretofore had been pending for years were disposed of expeditiously before the witnesses died or left the jurisdiction of the court. Therefore the innocent were acquitted and the guilty were punished and made to pay the penalty for their criminal conduct. Appeals were unheard of and granted only when the trial judge so ordered. The trial judge in charging the jury really made an argument for or against the defendant—for the defendant if the evidence showed that he was guiltless and against the defendant if his guilt was proven to the court beyond a reasonable doubt.

Arguments of counsel were reduced to a minimum being brief and reciting and calling the jury's attention to salient facts only in the

evidence. Prosecutors were appointed from the list of attorneys or barristers, as they call them there. No case in England is prosecuted by a prosecuting attorney, if I am informed correctly. In every instance a reputable member of the bar is chosen to prosecute each criminal case.

Today England is recognized as having the ideal system for the administration of real justice. They have judges who are always appointed for life and attorneys who have the respect of the entire community. No one can practice law there unless his character is of the highest. The people respect laws and obey them.

After 87 years, during which time England has lived under this complete change and the codification of its laws, the entire laws today are respected and commended throughout the civilized world.

Remedial suggestions, which I suggest for our own country are the following:

1. Codification and uniformity of all criminal laws patterned after the English system.
2. Stricter requirements relative to admission to the bar, making character as well as scholarship a prerequisite.
3. Appointment of judges for life.

Therefore, answering the question assigned to me, only laws should be enacted which can and will be enforced.

CHAIRMAN BROWN: Judge Bartlett, on behalf of the assembly I want to thank you for taking your time from the bench to come and talk to us.

The next subject on the program is "Safety as a Community Problem." Mr. Charles E. Hill, Vice President of the National Safety Council and General Safety Agent of the New York Central Lines, New York City, will speak to us on that subject.

SAFETY AS A COMMUNITY PROBLEM

Chas. E. Hill, General Safety Agent, New York Central Lines

In discussing "Safety as a Community Problem" we must necessarily approach the subject from a broad standpoint, having in mind not only the problems with which we are confronted today but the conditions we may reasonably expect to exist in the future. This subject is a vital one, of tremendous importance in any plan we may adopt in our efforts to check the wanton waste of human life and property due to the thoughtlessness, carelessness, indifference and recklessness that have such a hold on a small minority of the citizens of this country.

We must approach the subject from a national viewpoint, for it is one that deeply concerns every man, woman and child of America and registers its wants and its needs into the very fabric of our civil life.

The enormous loss of life, due to accidents, as a result of a lack of carefulness on the part of our citizens is appalling, and is evidenced by the fact that during last year in the United States, there were 89,000

people killed and more than two and one-half million injured, representing a casualty toll of 244 deaths and 7,000 injuries for each day of the year. This was more than 20 times the daily casualty toll to the American soldiers during the World War. Yes, the tragedies of war take their toll in frightful numbers, but the tragedies of peace register a toll beyond the comprehension of the average citizen. The direct economic loss, alone, from accidents is estimated to be at least four billion dollars per year. If these accidents could be wiped out over night our economic adjustment from this cause alone would be sufficient to dispose of our public debt in less than five years.

If these appalling losses are not sufficient to arouse the consciences of the citizenry of this country, they may be stirred to action when they realize that 21,000 boys and girls under 15 years of age went to their death as a result of accidents last year. Is there not sufficient human interest in that fact to divert public attention from matters of less moment?

Our casualty record, as astounding as it is, is made up of a large number of accidents occurring in a great many places. They do not attract the publicity of a Lusitania or a Titanic disaster and, therefore, public attention is not focused upon them. Publicity properly applied is a valuable adjunct in any well regulated safety program.

America is the Most Reckless Nation in the World

America is the most reckless nation in the world. Our fatal accident rate is nearly two and one-half times as high as that of England and Wales, and three times higher when automobile fatalities alone are considered. Yet while our country is the most reckless nation in the world, her people respond more quickly than the citizens of any other nation to appeals for aid made necessary by reason of some disaster, whether it falls on our own citizens or those on a foreign soil. This is one of the many traits that make for good citizenship, and since safety and good citizenship go hand in hand we may rest assured that the bulwark of safety is on solid footing, and may take courage in the belief that in the future we shall see a realization of progress in the development of safety far beyond our dreams of a few years ago.

There has been a gradual awakening of public sentiment which found expression through the two conferences on Street and Highway Safety under the able direction of Secretary Hoover. The carrying out of the recommendations of these conferences will do much toward the curtailment of accidents occurring in our streets and highways. A great deal of credit is due those who so generously gave of their time and energy to this very important work.

We have in the United States 120 million people, all of whom are subject to varying hazards that serve to form the basis of our casualty record. The deaths and injuries resulting from accidents to which reference has been made can quite properly be placed in four classifications, namely,—

Traffic, Industrial, Home and Other public accidents, each of these constituting about one-fourth of the problem when we consider fatalities alone.

To carry on accident prevention work successfully we must proceed along orderly lines following a pre-conceived definite program. We must not only know how many people are being killed and injured each year but we must know where they occur and how they occur. We must know the causes of accidents, having in mind that a careful analysis always precedes an intelligent remedy.

Quite successful safety performances are being made by the railroads of the country today, due to the systematized manner in which safety is being conducted in an organized form.

The Steam Railroads Were Pioneers in Safety Work

The steam railroads of this country were among the prime movers in the inauguration and promotion of organized safety in the United States, and what have been the results? Railway employment today is less than one-third as hazardous as it was 20 years ago. Employees and passenger fatalities during the past 13 years have been reduced nearly 60 per cent—this in the face of a large increase in the number of employees and also in the volume of passenger traffic. I merely cite these facts to show what can be accomplished as a result of an organized effort, for these achievements have been due to the application of constructive safety methods plus a cooperative spirit as between employer and employee.

The problem of industrial accidents, generally speaking, is one that has been recognized for several years. A careful study has been made as to the causes of accidents and remedies have been applied. However, these plants have certain limitations, particularly in the small plant where safety has not been given much consideration. Furthermore, the small plant management seldom has the technical safety engineering advice and does not ordinarily conduct as progressive a safety campaign as the larger plants. However, regardless as to how effective accident prevention work may be carried on within the plant, the safety performances are frequently imperiled by the constant addition of untrained employees. These conditions have led us to the discovery that industrial safety is not only a plant problem but a community problem as well and must be attacked on this basis. The local safety councils, therefore, are equipped to serve as a clearing house for ideas and constructive suggestions, so that the plant executives are better enabled to carry on real safety work.

The casualties falling under the classification of home accidents, of course, need our attention, since 20,000 people were killed in the homes last year through accident. The major portion of these occurred in the most poorly housed parts of the population, which emphasizes the necessity of handling this problem also on a community basis.

Until about 12 years ago the center of gravity of accidental deaths and injuries was situated in the industries, but since that time it has grad-

ually found its way to the field of public accidents. This has been due to two things: first, the effectiveness of the safety movement in industries; second, the increase in the number of automobiles.

The advent of the automobile has brought with it a new and perplexing safety problem. The number of automobiles in this country increased from two and one-half million in 1915 to twenty million in 1925. The number of automobile fatalities, alone, during the same period increased from 6,000 to 21,000. The United States has 77 per cent of all the automobiles of the entire world. New York State, alone, has more than France, Germany, Italy and Russia combined. The automobile today is an absolute necessity in the conduct of the business of this country and progress will demand not only its continued use but a greater extension of its services. Therefore, it is here to stay and the saturation point is far distant for it has been estimated that in another seven years we will have 33 million cars—one machine for every four persons.

It is by reason of this situation that it becomes imperative that we, in our attempt to provide a remedy, not only endeavor to take care of our present day needs, but of the future as well; and this will include a regulation of the use of the motor vehicle so that it will serve the purposes for which it was intended. We must not overlook the fact that if automobile fatalities increase at the same ratio during the next 10 years as they have during the past decade there will be 50,000 persons killed in this manner during 1935, and more than 300,000 of our men, women and children will have entered the dome of eternal silence as a result of automobile accidents, alone, during a brief period of ten years.

Cost of Highway Traffic Accidents 600 Millions Annually

The cost of highway traffic accidents in the United States is now at least 600 million dollars per year, and this does not include the cost incident to traffic congestion. Upon the same basis as heretofore predicted, this cost will soar to one and one-half billion dollars for 1935, and for the next 10 years will amount to the staggering sum of more than 10 billion dollars. I am stating cold facts based upon the experiences of the past. Ought not this startling sacrifice of human life be sufficient to insure to our safety program the most loyal and wholehearted support of every man and woman in this country? Is it fair that the innocent suffer due to lack of concerted movement on our part?

Traffic accidents present a comparatively new problem, but we must remember we are living in a country of progress where we have problems to solve and where we never stop until we solve them. To do so we must have a complete mobilization of community forces. We must have the full cooperation of all organizations and agencies, civic, political and otherwise coordinating one with the other, having one purpose only—the conservation of human life.

In considering the entire matter—accidents of all kinds—we get more and more to the point where we recognize the problem as one for the

community. Industries are doing great work individually—yes—but they can not succeed alone. They need the aid of the public.

Accidents that come in the other classifications are automatically a problem for the community. Therefore, the entire scheme ought to be considered in an intelligent, comprehensive manner following a definite plan of procedure.

To carry out such a plan, consideration should be given to three fundamentals:

1. Engineering; 2. Education; 3. Enforcement.

Engineering is used broadly to include—

- a. The scientific study of accidents and their causes, etc.
- b. Establishing of safe conditions and determining what constitutes safe practices, etc.

Education includes—

- a. Information showing causes of accidents.
- b. Arousing them as to need for personal carefulness.

The Public Can Be Educated to Prevent Accidents

Enforcement means compelling the heedless minority to observe safe practices, which the greater majority have adopted voluntarily through education.

I have only given a brief statement of the program that should be carried on to combat accidents successfully. This program can be elaborated upon to suit the situation.

In industrial safety our experience teaches us that after our engineering work has been done, after we have ascertained the causes and corrected the conditions, our problem is then one primarily of education. This experience should better fit the National Safety Council to meet the growing problem of public accidents. Since education is the real fundamental upon which effective safety work can be based we must learn how the public can be educated, and this brings us back again to a full realization of the fact that this is essentially a problem for the community, just as industrial safety is primarily a problem for the individual plant. Of course, individual owners of taxi cabs, motor trucks, etc., can accomplish a great deal through instruction and supervision. This is being done quite effectively by certain companies, showing after all what training, through educational methods, will accomplish. However, the most of our difficulty is with individual owners who are not directly answerable to anyone. This is the fellow we have to reach through a community safety program.

The responsibility here rests with the citizens in their individual and official capacities, both civil and political. This includes the schools, the churches, the homes, the traffic courts and other officials. It also includes the various fraternal and civic organizations and the public press. A school superintendent can accomplish much with the children under his charge. The minister can occasionally admonish his flock as to their individual responsibilities to protect life and limb, to realize "I am my

brother's keeper" in the true sense of the word. The preaching of safety is as old as the Bible. Solomon, the wisest of Kings, recognized the necessity of care when he says in Proverbs 3-23. "Then shalt thou walk in thy way safely and thy foot shall not stumble." He must also have foreseen the recklessness that infests the highways of this country and therefore invoked the admonition that is found in Proverbs 27-12, wherein he says, "A prudent man foreseeth the evil and hideth himself, but the simple pass on and are punished;" which paraphrased to meet present day conditions means, "A careful man sees the danger and stops but the reckless pass on and are killed."

We must have laws requiring a proper standard of qualifications so that operators of motor vehicles will be required to meet a mental and physical test. We must have rules of conduct governing the operation of motor cars to insure reasonable safety on our highways.

The traffic courts, through a conscientious enforcement of the law, can create in the mind of the individual a proper regard for the rights of others.

The Community Safety Campaign Must Be Thoroughly Organized

The newspapers of the country have done much to educate the public as to the causes of accidents. They have a very important part in this work for publicity properly applied wields a tremendous influence in the community by directing the attention of the public to the enormity of the human wastage and by arousing them to a realization of their responsibilities.

This community safety campaign can not be conducted successfully unless it is thoroughly organized. Back of this organization must be a group of men whose sincerity is unchallenged—men who enjoy the utmost confidence of their fellow citizens—men whose real devotion to the cause of safety is unquestioned, having as their objective the prevention of human suffering through accidents.

The cost of traffic accidents, alone, justifies the formation of a local safety council—one that is non-partisan and non-commercial—an organization such as I have described—in every sizable city of the United States.

The duty is ours to carry on this great work and it must be pursued with greater zeal than ever before. Where cooperation is greater accidents are fewer. When every individual who has a responsibility in this program, whether it be of a minor or an important nature, has finally come to a full realization of such responsibility and when his innermost consciousness is aroused to the extent that he will perform his duty as it relates to accident prevention, then we will witness an era of unprecedented accomplishments in the cause of safety.

We must face the opportunity of service with patience, courage, hope and faith, with the knowledge that our cause is just, believing that the great American people will ultimately recognize safety as their friend and benefactor.

When this situation obtains we shall see a cooperative spirit and possibilities transcending any previous accomplishments. We shall then have enmeshed in the hearts and minds of our fellowmen the knowledge that avoidable accidents are unnecessary. When this is realized we shall then have established for ourselves and our posterity a safe place in which to live.

CHAIRMAN BROWN: I think that Mr. Hill has discovered the Ethiopian in the kindling when he says, this is a community problem.

I might state that the state of Michigan has realized that it is up to each community to solve its own problems and that it has called a conference on street and highway safety for November 15 at the Hotel Statler and the program will last for two days, at which time we are going to consider certain phases of this question taken up at the Hoover Conference to see if we can improve conditions here.

ADJOURNMENT

State Officials' Session

October 27, 1926

D. C. FENNER, Chairman

Chairman, Motor Vehicle Conference Committee, New York City

THE Public Safety Division at the fifteenth Annual Congress of the National Safety Council, convened at 9:30 o'clock in the large banquet room of the Statler Hotel, Mr. D. C. Fenner, chairman, Motor Vehicle Conference Committee, New York City, presiding.

CHAIRMAN FENNER: Mr. Frank Milhollan, president of the Board of Railroad Commissioners of North Dakota, has been detained at the last minute by illness in his family and he sincerely regrets his inability to be present and preside at this meeting, as stated in our program.

The National Safety Council recognizes that the principal responsibility for public safety rests on the shoulders of the duly constituted public authorities. The functions of the National Safety Council, local councils and other influential organizations are to assist and uphold these public officials in the performance of their duties. Today there is a general realization that the public accident problem is shifting from the cities to the rural districts. Cities still have their problem, and a tremendous one, but motor vehicle accidents are increasing more rapidly in the rural districts and small towns than in the large cities. This realization is reflected in such developments as the preparation of the uniform vehicle code by the Hoover conference, the holding of state conferences and the forming of state safety organizations.

In line with this tendency there has been included in the program of this safety Congress, this special session for state officials and others interested in the state wide aspects of the public accident problem. To me it seems quite fitting that the first paper this morning should be on the administration of a state motor vehicle act and should be presented by Mr. Robbins B. Stoeckel, Commissioner of Motor Vehicles, of Connecticut. Mr. Stoeckel is nationally known as an able and fearless administrator of the very excellent law of the state of Connecticut, and also for his appreciation of the importance of public education. To those states which are contemplating the enactment of a drivers' license law as well

as to those which already have such laws Mr. Stoeckel's outline of his administrative methods will be most valuable:

ADMINISTRATION OF A MOTOR VEHICLE LAW

**Robbins B. Stoeckel, Commissioner of Motor Vehicles for the
State of Connecticut, Hartford, Conn.**

Generally speaking, effective administration of a motor vehicle law is an expression of existing public sentiment by a representative. While it is undoubtedly true that an administrator, owing to his better knowledge of conditions and appreciation of problems, often leads and possibly creates sentiment, yet the principle holds good that he can not go faster or farther than those whom he represents will allow him.

He needs support for success, and it is not enough that such support be general but it must be specific and extend to details, for every action of every person who comes under a motor vehicle law is so intimately affected by it, that each soon arrives at the attitude of mind where administration concerns him personally. He is usually not loath to undertake his part. It is a principle that government, at least as we understand it in the United States, depends upon the consent of those governed. Motor vehicle laws are more intimate than other laws, so the consent is more specific on better knowledge of provisions and is sometimes grudgingly granted with a mental reservation that the individual is himself a sort of secondary administrator, who will take his due part in daily management to what extent he can with the brains God has given him plus the learning and experience he has acquired.

So it is surely obvious that administration of this type of law, to be successful, must go into strong hands and be strongly supported.

In the old days, not so long ago, it was not uncommon to hear an administrator criticized as an "autocrat" or "Czar." But development of administration consequent to pressing problems, instead of taking power from him, has given him more and more. The trend of motor vehicle administration, more than in any other public activity, has been away from political control.

Properly to administer a motor vehicle law is a practical accomplishment. It has become a major public activity in each state and an essentially important factor in its proper government. It must be done right. The public can not afford to have it done wrong.

Set Up of Administration Office

So it perhaps goes without saying that the set up of each administration must be of the best. An enabling law might provide for an administrative head, preferably an individual, to center responsibility; for a long term, so that there will be no danger of losing him just as he learns his job; for his adequate pay; for a second in command

and such assistants as are reasonable; and finally to give, through legislative enactment, all the authority and strength which can be devised. There is no danger of over authorization, for any legislature can be relied upon to promptly dampen the ardor of an over enthusiast.

Each motor vehicle law has for objective, usually, probably invariably, two distinct and far different purposes. One is to gather taxes and the

CONNECTICUT DEPT. of MOTOR VEHICLES-1926-

other to insure safety for everybody. The safety objective is the more important of the two, but in the inception of the problems created by the use of the motor vehicle as a medium of transportation taxation had primary attention.

So perhaps it may not be out of place to outline to some extent the means and methods of taxation employed.

As a preface, a cardinal principle needs to be stated. *Motor vehicle handling is a state proposition.* The federal government has never taken and probably never will take active steps for enforcement of motor vehicle laws, except to the extent of giving advice. Advisory participation of the kind referred to is exemplified by the so-called "Hoover Conference." Such participation is essential and most helpful.

One has but to realize the range of an automobile, that practically every car travels from state to state frequently, to realize the complications which laws that are not uniform, at least in spirit, can create.

It is generally conceded that all such difficulties can be readily met in each state by adoption of uniform provisions and that there is no need for central management by the United States Government.

Under existing laws we have the method uniformly followed that each state taxes its own motor vehicles and prescribes its own regulations.

This is as it should be, for the problems of taxation and of safety differ widely in states and what is absolutely necessary in one state would possibly be a hardship in another.

A Fundamental Principle in Taxation of Motor Vehicles

As a premise to this head let it be stated that every tax taken from the motor vehicle ought, and in most instances does go to the "road." It ought to be an equitable principle that taxes taken ought to be used for the benefit of those taxed. This is almost invariably true of motor vehicle taxation which goes in about every instance for building and maintenance, repairs or construction (including reconstruction) of highways and streets, and for administration of safety laws and for policing. All of these are proper purposes within the construction and interpretation of taxing laws generally and founded upon equity and justice. That is probably the main reason why the taxpayers in this class are not heard in objection more frequently. They are "satisfied taxpayers" and it is rarely that any one of them becomes provoked or upset over a motor vehicle tax except possibly as to the individual whose duty it is to collect it.

In many attempts to discover what objections, if any, there may be to this class of taxation the main response has been, "Give us the roads and we will pay." But there are often complaints about a tax on motor vehicles if it is inequitable in the sense that one is taxed out of proportion to others. And here we arrive at the first duty of the administrator. He should see that his state taxes on that basis which is the most equitable, that his tax is as easy of collection as it can be, not discriminatory, and that the expense of collection is low. If it be generally stated that an archangel could probably not do this to the satisfaction of everybody, at least without his flaming sword, it will be no exaggeration.

Automobile tax methods have always included a registration tax, evidenced usually in the hands of the person taxed by a certificate of registration and numbers for his car, later followed by an operator's license tax, intended, and legally defensible only, as an administration tax. More lately the fuel or gas tax has come in as a prime way to get money at low cost without annoyance to the taxpayer.

The registration tax was originally based on "horsepower." The inequality of this basis became apparent when in automobile construc-

tion the cylinder was lengthened, making length of stroke an essential factor. This caused adaptation and in some states the discard of this basis for weight or value. In some instances the substitute was "cubic inch displacement." It is not the purpose here to discuss these bases, nor in fact to go into this matter further than to suggest that each has its prominent defects, either in administrative expense or in annoyance to the taxpayer and that it is the duty of the administrator constantly to study the situation in his own state with a view to meeting it. Progress along these lines of study and adaptation has been rapid. The most advanced thought seems to have supplied a flat rate for pleasure cars, weight for commercials and the fuel tax to raise the bulk of the money. But there is another thought, not yet to the fore, that it is possible to tax all motor vehicles alike on a basis of "gross weight."

After an extended investigation conducted by the Bureau of Standards at the request of and with the cooperation of the Department of Motor Vehicles and Highways of Connecticut, this method is reported on as the best and most thorough, providing alike the funds to be drawn from those taxed, equality among them and ease of collection at low expense. Its theory, briefly described, is to tax pleasure cars as "gross" by weight of car and maximum load. For example, a five passenger car at "weight of car plus five passengers at 150 lbs. each;" commercials at weight of car plus registered authorized load, etc. The system provides a basis applicable to all cars throughout. It makes no distinctions. It can be formulated to raise any desired amount of money. Tested by "wear and tear on highways" it is well nigh perfect in its possibilities of adjustment.

Fuel Tax

The fuel tax is well known, both in theory and in administration. It offers as its main feature collection through the great distributors. This is extremely advantageous and unusual in a tax; that the state taxing has the advantage of accurate bookkeeping by others before payment. The big oil companies which, as distributors, cooperate in making returns, perforce have accurate books. As a result there is little escape from collection. Collection expense is so low and the return to a state so high, and the basis so sound that it is now adopted in all but four states, and bids fair to be adopted in those.

Both the registration and operator's taxes offer valuable by-products in providing identification, the one of cars, the other of operators, so there is no chance that either, if once in effect in a state, will be discarded; but the tendency is now evidencing itself to lower these taxes gradually and to rely more and more upon the fuel tax for producing money.

For the present and pending some great change in production of fuels it seems logical to support the fuel tax as the best money producer, with the registration tax a good second, if the more modern methods of its collection are in effect. The operator's tax is mainly an identification

and police aid tax and should not be relied upon as a producing tax beyond costs of its administration for discipline.

To sum up, the duties of a state administrator in connection with taxation are to keep up with the times, to provide for his state a method which will, on a pay-as-you-go plan, maintain its highways and possibly extend them and to see that such a system has public sentiment behind it. If it has not then there is something the matter with it.

He must also keep his safety duties in mind and make a selection of whichever form of tax will aid him the most in their management.

None of the three methods of taxation described can be discarded and the whole taxing problem before administrators is to get a combination of all three which will lend itself, with the most elasticity, to the enforcement of the whole law. In other words get the money and also the help which can be had from tax laws for safety.

Safety Administration

In the early stages of motor vehicle laws, an administrator usually had few, if any safety duties. The early problem was almost entirely to issue registrations and numbers. But the registration law, and later the operator's license law, have provided such an excellent foundation upon which to base police supervision and such good identification of cars and operators that it has been natural for each lawmaking body, from time to time, as necessity for control and discipline arose, to make safety laws founded upon and enforceable through these two systems.

Each registration certificate and its accompanying number plates furnish for the police of a state a perfect method of identification of the car owner. Suspension or revocation of registration is probably the most forceful means at hand for discipline. It seems logical that it should always be used to punish offenses relating to the automobile, as for example, operating a car not in good mechanical condition. Action based on suspension of registration will have an immediate and far reaching effect on condition. This is as true for every other offense which has to do with a car.

The Operator's License Law as a Police Law

The operator's license law is the necessary foundation for control of operators by a state. It is legal (in the light of court decisions, which determine that an operator's license is a privilege granted by a state) to enforce discipline through suspension and revocation of operator's license to any extreme which conditions demand. There is no more perfect disciplinary action possible than that by which a state exercises its right to take away, temporarily or finally, an operator's license from a person who has proven himself unfit to have it. Such action is salutary.

There are many methods used to accomplish this result and there is a good deal of variance in the character of offenses for which this dis-

discipline is exercised and in the length of terms of suspensions imposed. As time goes on, terms of suspension are getting more nearly uniform, until for the worst offenses, nowadays, a permanent suspension or revocation is universally had. It has seemed in some states to be the best plan to have the actual term of suspension upon conviction stated in the law and not left to discretion. Such laws have been most effective.

In other states the administrator has had discretion and has usually been able to exercise it in such a way that there has been little or no fault found. Suspensions and revocations should be imposed in each case where any offense against the law has been committed which is other than a technical violation, so that no possibly grave offense can fail to be noted and punished. But the idea of punishment is secondary. The principle is to bring the person who has committed an offense before a state authority to determine whether his character and general attributes, in the light of his most recent action as compared with his past record, make him a desirable person to have upon the highway.

The Suspension Power a Perfect Method of Discipline

The suspension power may either be on initiative or as supplementary and based on court conviction, or the occurrence of accidents or on complaints. It is in every way a perfect method for handling discipline. Its exercise will eventually arrive at a point where every operator involved in an accident or convicted of any offense is scrutinized from the standpoint of desirability on the highway, and the state department which determines this will necessarily compare each such occurrence with former records, if any, and base its action accordingly.

Founded on these two basic laws, the registration law and the operator's license law, there are possibly a number of other disciplinary actions which can be taken by an administrator. Both of them together, and an additional requirement for the reporting of accidents, will bring to a state ample data upon which to found a statistical section. In this section there should be a bureau for newspaper clippings and for tabulation. The suspension section and the complaint section will also furnish data. All these activities together will give a statistician all necessary information to work out into daily and weekly reports to show the safety condition of every highway and street as to accidents and cover registrants and operators as to discipline. When such an activity is actually arrived at by any state, it seems proper to form a state organization section which will put out the statistical material and demand action upon it.

If it is possible, as it now is in states which have such systems, to determine why accidents recur at any location, there is no reason why the state should not be given power to call upon the municipality in which the location is, to take such remedial measures as appear to be necessary, whether by physical change in traffic surroundings or by traffic regulation, signals, etc. This is a future step in administration

of the law. It has not actually been reached except that advice is furnished in a few of the states. It needs more than advice to actually produce results. Each law must be so drafted that the administrator, with this material at hand, and with the obvious remedies in his department, can demand actual performance from the organizations whose duty it is to supervise and correct.

Compulsory Insurance

In several states the so-called "compulsory insurance" law has been praised as being a certain way to secure financial responsibility and consequently more care. For various reasons, but principally on account of the fact that public sentiment is still not widely enough aroused to compel it, such a law has never been passed in complete form, except in Massachusetts. The law which obtains there has not yet actually been administered. It becomes effective January 1st, 1927. The subject has been carefully studied there and there is an excellent report on it by a state committee. The administrator in that state, the Registrar of Motor Vehicles, is prepared to put it into effect and expects it to be useful and efficient. Just how much trouble it will make for registrants in the first year it is hard to estimate but, however that may be, should it succeed in any measure it will be copied and followed in almost every state, just as the gas tax law has spread all over the United States.

In Connecticut it has not yet been found possible to agree upon a compulsory insurance law and a compromise was arrived at, known as the "Financial Responsibility Law," which has been under actual administration since January 1st, 1926. This law differs from compulsory insurance in that nobody comes under its jurisdiction until, on account of his own offense (defined in the law as an accident for which he is held responsible, resulting in the death or injury of any person or in damage to property to the extent of at least \$100 or as a conviction for reckless driving, operating while intoxicated, or evasion of responsibility) he is required to file a certificate of financial responsibility which shows that he had either taken out a policy of insurance or bond, or filed cash or securities acceptable to the commissioner in the amount of \$10,000, covering liability for personal injury, and \$1,000, covering liability for property damage.

The Motor Vehicle Department in Connecticut has in the administration of this law taken jurisdiction over some 6,000 registrants and has qualified them. It has taken away many registrations for failure to qualify and refused to allow registration. There has been no difficulty about the administration of this law. It has unquestionably brought the percentage of insured in Connecticut, which originally was much higher than that of any other state—being around 42 per cent—to an even higher rate, and its whole tendency is toward making the most dangerous people financially responsible. It is a law tending toward a compulsory insurance law but not involving its hardships, either in

universal application or in administration all at once. Whether Connecticut is ready to follow the example of Massachusetts or not will unquestionably be determined in the next legislature, but eventually there will be compulsory financial responsibility for every one, so that each person on the highway must be financially able, either through the guaranty of a protecting company or on his own certified responsibility, to answer judgments for damage or injury done.

The making of such an insurance or financial responsibility law is an experiment. The great objection to it in legislatures has been that it may compel a state to go into the insurance business, for it would hardly be fair for a state to require something which it can not itself furnish. This particular law, in one or the other of these phases, is bound to be considered as a safety law and each administrator ought to determine from time to time whether his state is ready for a portion or the whole of it.

Complaints

In each administrator's business there are a large number of complaints relating to safety. In this particular phase of his work it has to be remembered that the observer is sometimes unskilled and that there is sometimes prejudice, but there is no reason why an administrator can not handle complaints carefully and thoroughly if these two points are kept in mind and every complaint should be welcome. It is a part of the safety business of each office to investigate and care for these as fast as they come in and where discipline is indicated, to supply it.

If the license of an operator is suspended it is fair that he have a chance to be heard as to his side of the story. The hearing authority, whoever he is, ought to have the complete case of each person before him. It should be possible for anyone to obtain a hearing in a reasonable time, for then each administrator will feel free to take licenses on any well founded rumor or complaint. This is as it should be, for a person about whom a rumor is circulating may by operation of an automobile do untold damage or the person about whom a complaint has been made may commit a crime, in the absence of prompt action by an administrator. If, as a part of an organization, there is a hearing section where any person may appear and tell his side of the story, and especially if there is an appeal provided to a high court, then no person has any excuse for making a claim that he has been unduly deprived of his rights.

A license suspension section ought to be run as a business office; all similar offenses ought to be treated alike, and so far as the actual suspending power goes, no discretion whatever ought to be exercised as to definite time or method of suspension. That part of it ought to go like clock work and the hearing section be the one where adjustments and careful investigation can be had. This again seems proper because, should there be an apparently bad actor on the highway the

first thing to do is to take away his license as quickly as possible and thereafter consider the question as to whether he is or is not so bad as to need further discipline.

Each administrator has to make a large number of rulings and interpretations of law. He should have good legal advice readily available, for many of these rulings and interpretations are as to exact meaning of words and on intent and spirit of legislation. This function ought to be under the direct management of the head. He should also conduct all relations with other state departments and take care of interstate and Federal relations. These are all now so important and so bound up with the welfare of everyone that expert advice is often needed. The administrator must have that ready at hand. Sometimes it is legal advice, sometimes it is political advice in that he needs to know what is going on in other state legislatures.

No ordinary management of routine affairs needs to be under the immediate direction of the head, but it should always be possible for any person who claims to be aggrieved or has any complaint to make, to go to the head of the department and have a conference on any subject. In other words, there should be an appeal to the head of the department on every question in connection with its management and its touch with the public.

Summary

To sum up, safety administration is woven into general administration to such an extent that an administrator needs to know every detail of possibility. He is the one who must push on into the new fields of endeavor wherever possible. He either has, in his basic laws which give him control over registrants and operators, or can get by legislative action, whatever he needs for the furtherance of his safety plans.

Every administrator constantly strives along these lines of expansion and if he has not yet received what he needs for his most effective work, it is hardly because he has not asked for it. No person is closer than he to the safety question. No public official has a more sacred duty than his. On motor vehicle safety, traffic problems both of direction and supervision, he must more and more become a specialist to an extent where he is a leader. It is not enough to mean well. The public demands that he foresee and do. If he must sometimes do unpopular things, he must not shrink. Even at this time, when the motor vehicle safety problem is yet new and unsolved in the sense of actual prevention, his work is already receiving public recognition everywhere. He, through the exercise of his powers—perhaps augmented—is the best hope for solution.

To be trusted to exercise great powers in a just manner, with full knowledge of their extent and effectiveness, is an honor second to none in the power of a state to give. It does not fall to the lot of everyone to be permitted to work for the safety of his fellow men. So the administrator will always, above all else, be an enthusiast.

CHAIRMAN FENNER: We are greatly indebted to you, Mr. Stoeckel, for your very able presentation.

One of the real problems of administration of motor vehicle laws is the proper relation between the state and the cities. Mr. Benjamin C. Eynon, Registrar of Motor Vehicles in the State of Pennsylvania, is another of the leaders among state administrators and will discuss this very important subject. At the conclusion of his address we will invite discussion by any city officials present on this particular subject, and also general discussion on any of the items covered either by Mr. Stoeckel or Mr. Eynon. I take great pleasure in presenting Mr. Eynon of Pennsylvania.

RELATION OF STATE AND CITY DEPARTMENTS IN ADMINISTRATION OF MOTOR VEHICLE LAWS

Benj. G. Eynon, Registrar of Motor Vehicles for Pennsylvania,
Harrisburg, Pa.

There is an increasing tendency on the part of Americans to think that all our economic and social problems can be solved by regulation, and to throw the responsibility for their solution on the government, whether it be municipal, state or Federal.

Nowhere is this more apparent than in the public attitude toward a problem which has, within a few years, become national in its extent—that of motor traffic regulation and the promotion of safety to users of the streets and highways. This is perhaps due to the fact that the magnitude of the problem has only recently been more fully recognized.

If there is any one thing you can not regulate by law, it is the state of mind of the driver behind the wheel of a motor vehicle. Driving is not a mechanical process, but on the other hand, calls for continued conscientiousness on the part of the operator, and his adaptability to conditions constitutes the greatest element in safety.

Any state of affairs constituting an ever-present menace to every individual requires organized effort, and the complete cooperation of all existing agencies to combat it.

The burden of responsibility would, therefore, seem to rest upon the legislative bodies and administrative officers—traffic court judges, police officials, state highway commissioners and motor vehicle administrators, and unless the power of public authority is properly brought to bear on this problem, little can be accomplished.

It is concerning the relations of some of these agencies that I have been asked to speak, and if my remarks appear to be tinged with an over-emphasis of the part the state should play, that can be ascribed to the fact that I am a state official, and is not an attempt to disparage the splendid cooperation we enjoy from local authorities. In fact, in Pennsylvania, we feel that we have developed this important contact to a high degree.

In this connection, it is interesting to note the outline of state and

municipal responsibilities presented by the Committee on Public Relations to the first National Conference on Street and Highway Safety, generally known as the Hoover Conference.

State responsibility is quoted as follows: "A state department or bureau should administer the laws applying to motor vehicles, including the issuing and revocation of licenses for both cars and drivers and also the enforcement of regulations on the highway. This may be either a separate department or a division of some existing state department. The motor department or bureau should have an adequate staff not only to handle licenses, but to examine drivers, police the highways and investigate accidents"

"Regulatory legislation should be for adoption by states and not by cities. The state enforcement division must have sufficiently broad powers to formulate the regulatory provisions necessary to the detailed control of traffic, leaving, however, to municipal authorities the formulation and enforcement of ordinances covering local conditions such as the establishment of parking areas, etc."

Municipal functions are summarized briefly in that: "There should be an adequately manned traffic division in the police department with traffic safety a major function of such bureau. In cities the common practice of enforcement by the police department is recognized and the police should enforce the state law within the city limits."

No Conflict Between State and Municipal Regulations

A comparison of these seems to leave the major division to the state authorities, and rightly so, because the state department, if sufficiently alive to the situation, is in position to attain a broad general viewpoint often impossible when local expediences are viewed individually.

There should be no conflict between state and municipal regulations governing the use of motor vehicles and, in fact, state laws should prohibit the enactment or enforcement of ordinances along these lines, with the exceptions noted above.

It is appreciated that local physical characteristics may make certain regulations necessary, but it is expecting too much to assume that the motorist from some other community in the state will be acquainted with all of the freak regulations that some city councils try to enforce.

If all municipal ordinances dealing with traffic regulation, aside from those indicating one-way streets, limiting certain streets to the use of certain kinds of vehicles, lighting and zone systems and the parking and non-parking of vehicles, were submitted for review and approval by state authorities, the result would unquestionably be a uniformity of regulation of traffic conditions, and we would not be faced with the possibility of eventually having to stop every motorist on the outskirts of each city or town and attempting to make a traveling legal encyclopedia out of him.

Much of the legislation now in effect is such a source of harassment and bedevilment to the car owner as almost to disgust him with such

ownership, and the resort to more restrictive laws will undoubtedly be met with considerable protest.

The solution is not in loading the statute books with more laws, but in proper and adequate enforcement of those we now have. For some unknown reason, state motor vehicle laws are never very generally enforced in cities, unless undertaken by the state authorities, which always gives rise to certain antagonism.

Motor vehicle enforcement and traffic regulation should be separate and distinct from ordinary police duties, and officers qualifying for such positions should be policemen only in the sense that they should have police powers.

This is not to say that in municipalities they should not be attached to the public safety division, but they should be an independent unit, and in state organizations, they should be directly under the jurisdiction of the motor vehicle administrator.

Motorists Are Usually Not in the Criminal Class

It is particularly hard for your average policeman, trained as he is to apprehend criminals and protect property, to get the viewpoint that motorists, except in isolated cases, are not in the criminal class.

Enforcement experience shows that 95 per cent of the motorists are willing and anxious to obey the laws, and in a great many instances the violations are technical, or what might be called violations where the spirit or intention to violate is not present. Nevertheless, many of them do need disciplining, which usually takes the form of a "bawling-out" by the officer. The ineffectiveness of this method is so apparent as to need no discussion.

In Pennsylvania we have a State Police force, but we have also a State Highway Patrol for the enforcement of motor vehicle laws, handling of traffic, examination of drivers and investigation, and they are specially trained in these duties.

When it is realized that it takes from six to eight weeks of intensive instruction along these lines alone, what chance has the average "rookie" on a municipal police force, who is suddenly put on a traffic post with a semaphore in one hand and a whistle in the other? Even if he is an experienced and intelligent officer, he isn't necessarily a traffic man.

Municipal police departments have assumed charge of, or have had thrust upon them, the growing traffic problems with which the cities are confronted, and while much commendable ingenuity and patience have been displayed by police officials, the prevailing theory seems to be that as traffic congestion increases, all that is needed is simply more laws, more traffic men—and more and bigger traffic courts.

Not until these cases are placed in specialized hands for diagnosis and treatment will the cure be found, and mutual cooperation between state and local authorities be evident.

The establishment of traffic courts is a popular movement at present and again the necessity for state supervision is emphasized. Special

traffic courts under that supervision should be established to insure uniformity of administration and interpretation of the law in handling traffic violations, both rural and city. There should be the closest possible contact between these courts and the state department, since in that way only can the authorities remove from the highways wilful or habitual violators, by withdrawing the driving privileges.

Experience has shown this to be the most effective form of punishment—in many instances fines mean nothing. They are rather something to be hoisted of.

Too often the dockets of local magistrates and police courts are filled with such a multiplicity of cases that the true perspective of the continuous flow of motor vehicle violators before the bar is lost sight of, so far as it relates to any other than local application, and even then, in the absence of any specialized agency for the consideration and relief of the situation, to whom is the already over-worked magistrate to turn?

The suggested elimination of the minor judiciary, so far as motor vehicle cases are concerned, is no reflection upon their honesty or integrity, and many of them have done and are doing wonderful work, but the greater proportion are not "learned in the law" to the extent that they are skilled enough to meet the problems arising from present conditions.

The state department can become, and should be, a valuable clearing house not merely to administer the motor vehicle laws justly and to perform the daily routine of collecting fees and fines, but to educate the public to a realization of how far this subject goes beyond the mere enactment of laws and their enforcement.

This state agency must be readily accessible at all times to the people who created it, and must make an effective appeal for cooperation between the individual and the administration of the law.

Many Local Communities Doing Fine Statistical Work

Many local communities are doing wonderful work in the collection of reports and statistics on traffic accidents, and these efforts should by no means be discontinued or scrapped in favor of a state-wide accident reporting system, but nevertheless, the same condition often holds true in this connection as is prevalent in the minor courts. The very people who should have the data for disciplinary action or comparative purposes often never see it, and when it is published at the end of certain periods, it is then perhaps too late to take action towards withdrawing the driving privileges of the persons responsible.

At the risk of repeating, I say again that nothing is so successfully deterrent to reckless or careless driving as the suspension of licenses, and unless the data necessary for this action are available to the state department, either through a uniform accident reporting law, or by close cooperation with local agencies, this "big stick" is little more than a toothpick.

In states having large registrations of motor vehicles and operators,

the administration of such a law presents its own problem of detail and routine, and yet unless the leading factors contributing to accidents can be determined, little progress in reducing the annual toll can be made; and unless the results can be summarized in a central bureau, the experiences and corrective measures of one locality are not available for any others.

On the particular points mentioned where the state and local interests touch or overlap, the state should assume a paternalistic attitude, and while the questions of "home rule" and "decentralization" may be raised, the local interests must be subservient to proper standardization of traffic laws and proper administration of motor vehicle regulation.

I can close with no better paragraph than a quotation from an address delivered by Mr. John D. Hertz, one of the present day pioneers of motor transportation, to the Hoover Conference, in which he says:

"No one can tell which is the most important, regulation by law, regulation through a sense of sportsmanship or regulation through common sense. We would attach equal importance to all of them. But we just as surely must have the education of the public. We must educate ourselves up to the point where we know how to use automobiles and use them with safety to human lives. We must have a motor age education, and a motor age sense of responsibility toward our fellow men and the protection of their lives."

Constitutional Questions Would Be Decided by Courts

CHAIRMAN FENNER: As announced we will now throw this meeting open for discussion on anything that was brought out by Mr. Stoeckel or Mr. Eynon.

H. O. ROUNDS (Bureau of Public Safety, Detroit, Mich.): Is it constitutional to forbid any one a driver's license, and is it constitutional to take it away from him and forbid him the use of the road? In other words, if this question was taken to the highest court could he beat us to it?

CHAIRMAN FENNER: Mr. Eynon, have you had any experience along those lines?

MR. EYNON: Never; that is the first I have heard of it. I would imagine if that came up, the court, regardless of law, would use its own good judgment. If the person who made the application was a careless and reckless driver, as shown by the motor vehicle law of the state, it would probably uphold the state authorities.

CHAIRMAN FENNER: Are there any other questions? If not, the next item on our program is the brief review of progress during the year in state legislation and also in safety organization. We all realize this past year has seen a great development in organized safety educational campaigns, including public legislation on a state wide basis, and the names of some of the states in which such work has been undertaken are printed in our program. We will now call for reports from persons present representing each of these states, and also from any other states

that are not listed. To conserve time we will ask each speaker to limit himself to three minutes, if possible, and to report actual developments along one or both of these two specific lines: first, the improvement in motor vehicle legislation in a state; and, secondly, actual progress made toward a state safety organization and a continuous educational campaign. I will call first on Mr. Louis E. MacBayne, of Massachusetts.

Massachusetts and New York Report Year's Activities

MR. MACBAYNE (General Manager of Massachusetts Safety Council): Speaking first generally on the question of legislation we have in force 85 per cent of the recommendations of the Hoover Conference. We have the examination of applicants and control by the registrar; so I don't know that legislation is necessary under the general recommendations. Through the year we have passed 13 acts in the motor vehicle law; some of which are minor and are referred to briefly; others refer to punishment for certain motor vehicle crimes, the stealing of autos, and operating after suspension or revocation of a license. The penalty is state prison, not more than 10 years, or jail or house of correction not more than two and one-half years.

Also division of highways to designate through ways and regulate traffic at intersection of such way. Motor vehicles used in the commission of certain crimes are reported forthwith to the registrar. I might say that the position of the registrar of motor vehicles on the Compulsory Insurance Law, is that it should result in a reduction of serious accidents next year by the elimination from the highway of drivers who, after two accidents, are found to have been responsible for them. There is a reduction of accidents in the state as compared with a year ago up to September first.

In May the governor of the state called a state conference on highway safety as a follow up to the Hoover Conference in Washington, that was attended by delegates from 34 cities and towns; some 520 persons; and as a follow up to the recommendations made at that conference it offered six specific recommendations by resolution. The governor has appointed a permanent committee on state and highway safety. The chairman of that committee is present and also one of the members of the committee. In the state are three fully organized safety councils with paid staffs who are geographically situated so that they influence practically the entire state. There have been, as a result of the Hoover Conference, many local campaigns undertaken by mayors and police departments, and there is a gradual coordination of such activities which will be tied up under this committee recently appointed by the governor.

CHAIRMAN FENNER: The next is the state of New York. Mr. Leon Aronowitz of the State Motor Vehicle Bureau!

MR. ARONOWITZ: During the past year New York state held its first Safety Conference. For the first nine months of 1926 New York state shows 22 fewer fatal accidents than the corresponding period a year ago.

This decrease is remarkable in view of the fact that the state has shown an additional registration of automobiles over 200,000, and shows an additional number of licensed operators numbering 150,000.

In addition to the educational phase of the work, New York state has been planning traffic surveys of the cities, the preparation of spot maps and increased care for examinations to drive. Applicants for drivers' license now are required to pass an eye test in addition to being able to operate a motor vehicle. This test is being conducted by the inspector as part of the regular examination. The following specific recommendations are going to be made by the commissioner for legislative consideration during the coming years. First, to enforce the driving law which does away with the distinction between chauffeur and operator. The present provision acts as an occupational tax, and for that reason is unfair. Second, the issuance of a license for three years, which will eliminate the burden of handling and filing approximately 2,000,000 applications a year. Third, the granting of power to the commissioner to create traffic courts in the more populous counties to handle traffic violators. Fourth, plates to be designed so that they will be easily readable both in the day and at night.

CHAIRMAN FENNER: Next is Ohio. Mr. Norman Anderson of the Ohio Belle Telephone Company, active in the Cleveland Safety Council, also in the Ohio State Safety Council!

Report by Norman Anderson, for Ohio

Our efforts in Ohio this year are being confined to the adoption of a drivers' license law. Preparatory to introducing this bill this fall in our legislature a state safety council was organized. The membership of this Council is confined to associations. In other words, it is an association of associations. The sponsors of the state council and the members are composed of representatives of the following groups:

Ohio Farm Bureau Federation	Ohio Society of Safety Engrs.
Ohio State Grange	Ohio Automobile Association
Ohio Railroads	Ohio Committee on Public Utilities
Ohio Good Roads Federation	Ohio State Chamber of Commerce
Toledo Safety Council	Ohio Council of Automobile Dealers
Cleveland Safety Council	Ohio Council Retail Merchants
Ohio Federation of Labor	Assn.
Ohio Manufacturers Association	

It is felt that through the cooperation of this group this law will be passed. I shall not go into the details of our proposed law because that will be covered by Judge Lee E. Skeel, chairman of our legislation and law enforcement committee of the Cleveland Safety Council, who is also the author of the bill.

I believe there is a great deal of value to be had through the organization of a state safety council. The object of the Ohio State Safety Council is to create an atmosphere of safety throughout the state; to carry on

activities, through the member organizations, which will reduce highway, industrial, school, home, rural, and other accidents; to promote the avoidance of danger and waste from fires, and to act as a clearing house for the correlation of safety activities of the member groups. The organization consists of members subscribing to the objects of the state council.

The following are some of the things accomplished during the past year through the Cleveland Safety Council:

1. Published a textbook on the question of School Safety for teachers and distributed 6,000 copies to public and parochial schools in Cuyahoga County.

2. Published each month a set of loose leaf safety lessons by grades for the teachers covering a definite hazard for the month. For instance, in October the subject covered was "Fire Prevention" and for November it will be "Street Accidents" and December "Home Accidents," and so on. Six thousand copies of these lessons will be distributed each month. Approximately 36,000 boys and girls make up the membership of the Junior Safety Councils in our 258 schools.

Details of the Regular Safety Program

3. Our Home Safety Program is carried on through the Federation of Women's Clubs. We are featuring a series of bulletins on the various hazards in the homes to be distributed through the safety committees of the various women's clubs belonging to the federation. These bulletins deal with such subjects as burns, scalds, electrical hazards in the homes, vacation hazards, and so on.

4. Each month we mail to our entire membership a bulletin regarding the accident situation. The list includes 650 factories and business houses in addition to the other members of the Council.

5. We have featured a series of radio talks furnished by the National Safety Council and revised by our radio committee for local broadcasting. These have been broadcasted each day as a part of the noonday program.

6. Fire prevention is a big part of our work and in addition to our observance of Fire Prevention Week, home inspection campaign through the children, the committee is constantly active.

7. We hold a drivers' school for the education of commercial vehicle drivers and these meetings are held each month and are attended by 1,500 drivers.

8. Our committee on public education from time to time issues special pamphlets on carbon monoxide gas and other hazards including those of traffic for the information of the public.

9. Our churches' committee has distributed material on the subject of safety and fire prevention to some 500 ministers in our city.

10. Our industrial activities are under the supervision of a special committee of 54 men. These consist of monthly mass meetings for foremen and superintendents, special school for safety supervisors and safety engineers of plants, fire prevention course, and other lectures. Other

activities include safety surveys made through our engineering department, information on safety standards and practices, meetings and conferences of our members, distribution of five-word-slogan posters throughout the city on the question of public accidents, safety campaigns to help fleet owners, taxicab companies and firms employing a number of truck operators. Public safety meetings, and other such items comprise our program.

11. The staff of the Safety Council consists of seven people and our annual budget is about \$40,000. It is really but nine months old, having been reorganized the first of this year. We operate as a branch of the National Safety Council, affiliating with the Chamber of Commerce as a bureau, and are a non-profit-making organization of public spirited citizens, interested solely in the promotion of accident prevention to human life and limb.

Safety Organization for Every County in North Dakota

FRANK MILHOLLAN (President North Dakota Safety Council): I am pleased to bring to you greetings from the great state of North Dakota. One of the purposes of this meeting is to advise you of the progress made in state legislation and safety organization. You already know that North Dakota leads the Nation in the production of small grains, and we are here to tell you that we are among the leaders in the safety movement.

Following the Second Hoover Conference, the Governor of North Dakota called a state safety conference which was attended by representatives from practically every county in the state. Two days were devoted to a consideration of the Uniform Vehicle Code adopted by the Hoover Conference, and consideration was given to the entire problem of safety. At its conclusion the Conference resolved itself into the "North Dakota Safety Council" and selected officers and an executive committee. The executive committee subsequently adopted by-laws and authorized the appointment of committees on legislative, finance, membership, public education, statistics, and railroad grade crossings.

We have thus far been successful in arousing public sentiment in favor of such an organization, and the spirit in which the committee chairmen are assuming their responsibilities is most gratifying. We will, of course, concentrate on a legislative program during the next few months, endeavoring to have enacted into law the principles embodied in the Uniform Vehicle Code.

It is the plan of the North Dakota Safety Council, when thoroughly organized and functioning, to have a local organization in each county. With this in view, the membership committee consists of a chairman and one member from each of the 53 counties. The members of this committee will be designated as "county representatives" of the Safety Council.

We find no adequate machinery established for the purpose of ascer-

tafning the nature and causes of accidents. The statistical committee of the organization will have some interesting data to present at the next annual meeting of the State Safety Council, which will be held in May, 1927.

The matter of financing an organization of this kind has its difficulties. Our finance committee has three plans to propose to the executive committee at a meeting to be held about the middle of November, at which time the chairmen of all committees will meet with the executive committee. We estimate that it will require at least \$25,000 annually to carry on the activities of the organization, and our finance committee is confident that it can raise this amount.

While our safety council is still in the process of formation, we are determined to go forward. We assure you of our desire to cooperate in every way.

CHAIRMAN FENNER: State of Michigan. Mr. L. J. Van Schoick, Detroit Automobile Club!

Detroit Safety Work From an Educational Standpoint

MR. VAN SCHOICK: I am going to touch very lightly on what is being done through our state. I might say that through developing a spirit of cooperation between the state, city and county officials we hold conferences; we held two last year and we will meet again on the 15th of next month. At the last conference held in October, we had over 50 per cent of the municipalities in the state of Michigan driving under one ordinance or one uniform driving rule.

Along the lines of safety work from an educational standpoint, we have a cooperation between our state department of police and our Michigan state police, which details 23 men in charge of our good Lieutenant Arnst which is carrying a safety message into practically every school in the state of Michigan. These boys visit about 112 schools per day. We plan on visiting these schools every 90 days with a safety message, posters and safety literature. We have what we want, an organization of junior state police made up of the boys, and this is a new angle that we are taking. We started out by organizing junior state police from the best boys in the schools; but now we are taking the rough-necks, the boy that has the poorest standing in his studies and deportment, and we are putting them as leaders in their schools, and the development is wonderful. We had several cases of boys that the teacher could do nothing with, who were just unruly little tyrants; and one of them was put in as captain of his patrol and his department standing was 100 last month. We have in our other schools 13,000 school boy patrolmen, making a total of 29,000 on duty in the state of Michigan. That work is carried on directly through our department and the department of state police.

In connection with that we are visiting every theatre, whether in a small town or city, with a two reel picture developed and

for the purpose of giving direct lessons in safe driving. It shows the principle of ~~safe~~ driving, and then the results of driving and noticing cars on ~~curves~~ ~~etc.~~, and so on. This picture is accompanied by a uniformed ~~state~~ ~~police~~ man and a lecture is given. This is being done as an educational ~~project~~ ~~subject~~ to the citizen of the state, and the first of the year we are giving an intense drive on reckless driving, because we feel that ~~by~~ ~~giving~~ we will have reached enough people so that they will ~~know~~ ~~why~~ and how they are expected to drive. That will give you just a ~~small~~ ~~outline~~ of what we have accomplished in Michigan so far.

~~CHAIRMAN~~ FENNER: We would like to hear from Mr. F. W. Matson, Commissioner, Minnesota Railway and Warehouse Commission.

The Stop Crossing Law in Minnesota

~~MR.~~ MATSON: Motor vehicle registrations of Minnesota are increasing at a rate of over 100,000 a year. Many are tourists, coming from every state in the Union to see our 7,000 lakes, and we have a real ~~problem~~ ~~up~~ there. The last legislature passed a very comprehensive traffic law for the use of the highways. We found, after the ~~former~~ ~~conference~~ committee reported; that we were in line with most of their recommendations, but not meeting all of them. We have a committee composed of representatives of our leaders of Minnesota municipalities, a very active organization made up of the representatives of all the towns of the state, representatives of the Governor's office, and state highway department, the legal department, and all of the safety bureaus, who are drawing new uniform laws in line with the Hoover recommendations. Our governor has called a state wide safety conference to be held on the 19th and 20th of November, at which these proposed laws will be discussed, and some plan prepared to meet the situation.

The last legislature passed the stop-crossing law. I think that is a very unique law. The only other state that has anything like it that I know of is North Dakota. This law gives the Warehouse and Railroad Commission the authority to designate certain railroad crossings in the state as stop crossings and requiring every driver to come to a full stop before crossing. We have only marked about 10 per cent of the crossings where the conditions were dangerous. We prepared a pamphlet that we put in with every state license plate that goes out. We distributed almost a million of these warning cards in the state. We have perceptibly reduced the number of accidents at railroad grade crossings. We have very good records in our state on account of the principal cities showing a marked reduction in the number of fatalities in 1925 over 1924; so far in 1926 over 1925. We have three very active branches of the National Safety Council in our principal cities working constantly along educational lines, having schools for drivers, fire prevention weeks, and other activities of that sort. I think those are the outstanding

features that we have had in Minnesota in the ~~past~~ year. We are doing everything that we can and following every ~~good~~ example that we can follow as set by the other states.

J. H. HARVEY (Kansas City Safety Council): In the state of Missouri our program today is largely of a legislative ~~nature~~. Immediately after the National Conference on State and ~~Highway~~ Safety last March, Governor Baker called together the ~~delegates~~ and discussed with them the principles of a state wide conference. ~~The~~ conference was held in the state capital in May and during its ~~deliberations~~ was attended by 100 per cent representatives of every ~~geographic~~ district in the state and every organization within the state. ~~By~~ that conference reports were submitted on the various legislative ~~measures~~ of the modern law and adopted.

Missouri and Kansas Programs During the Year

Another recommendation of the ~~conference~~ unanimously adopted was the creation of a permanent organization ~~to~~ be known as the "Missouri Association for Street and Highway ~~Safety~~". That body has acquainted itself with various phases of the ~~problem~~ and its activity today has been largely concerned with the ~~preparation~~ and final form of the legislative bill which will be ~~submitted~~ to the next state legislature in 1927. We are therefore fortunate in ~~having~~ a chairman of that particular committee, and ex-secretary of ~~state~~ who in the eight years in which he served in that capacity, has ~~given~~ a great deal of study to this particular problem. We are now ~~ready~~ to put up in form to be printed: the proposed law in one column ~~and~~ the present law in another. In the average state legislature, ~~particularly~~ in those states where your problem has not been so intense, ~~you~~ find a great deal of opposition to certain phases of the program ~~and~~ we feel that if we can furnish the legislature with exact knowledge ~~of~~ the changes and the additions in the legislation, it might ~~beat~~ some of the opposition we would otherwise have. It is our ~~purpose~~ as time goes on, of course, to carry on a definite educational ~~program~~. As a means of building up public sentiment in our passage of ~~the~~ ~~law~~ we sent to 350 newspapers throughout the state, educational ~~material~~ which we believe will aid most materially in affecting the ~~decision~~ when it comes before the state legislature.

JESSE GREENLEAF (Railroad ~~Commission~~, Topeka, Kansas): Early in July the governor of ~~Kansas~~ invited the heads of about 50 state wide organizations in Kansas ~~for a~~ conference. We had the president of the farm bureau, the president ~~of~~ the bankers' association, the head of the American Legion, and ~~all~~ the line. We had no program. Mr. Sidney J. Williams of the ~~Legislative~~ Council was present and a great help to us. Mr. Harvey, our ~~representative~~ from Missouri, was in attendance. As a result of that meeting ~~we~~ called a safety rally nine weeks later, the 9th and 10th of September. ~~We~~ had a program and a banquet the first evening. We were ~~fortunate~~ in having Mr. Julian Harvey, who

has had a good deal of experience in safety work, and we used him to the limit. We had him give us an address in the morning. At noon the rotary club had a safety program; he addressed that; and in the evening we had him speak at the banquet.

We were very highly gratified at the enthusiasm with which the safety movement was received. We had asked each of the presidents of the state wide organizations to send us in the names of 10 men whom they would recommend we invite. That made us a list to start with of about 600 or 700. We also invited the mayors of our cities and representatives and senators. We had the meeting in the house of representatives. We had a registration booth on the first floor. We did not stress the registration, but there were 462 registered from all over our state, and we probably had 600 or 700 in attendance. We had four very enthusiastic sessions. Now, we organized a safety council; we passed resolutions endorsing the recommendation of the Hoover Conference, which we hope to enact substantially as recommended at our next legislature in January. We are encouraging the organization of local safety councils, and several of our cities have the matter under consideration now and one of them is forming a local council.

CHAIRMAN FENNER: State of Oregon, H. P. Coffin!

Compulsory to Report Every Accident in Oregon

MR. COFFIN: Gentlemen, I am from the great state of Oregon out on the Pacific Coast. You might know that we are on the map. We have one road that is 1,765 miles long, and it is paved the entire distance, except 60 miles in the mountains, and this is being closed up as quickly as possible. In conjunction with the chairman of the State Highways Committee and the chairman of the House of Representatives we were appointed by the governor to draw up the first state automobile law, and in that law we made it compulsory on every person having an accident to report that accident, and any injury or property damage to the nearest sheriff within 12 hours, and we put that immediately in force. All convictions under this law have to be reported to the secretary of state, and they are on record. We have also a list of all convictions in the Municipal courts.

When a man is called into court his record is looked up to see if he has had a form of conviction, and that is placed on the judge's desk for his consideration. We also are now putting into effect a system of three cards. The first is a white card, issued to the driver, and is his license. If he is convicted of traffic violation, or has a serious accident, he is given a green card by the secretary of state; and on further violation is given a third card, which is red; that is his last fall. If he has another one the card is taken away from him and he can't drive for the balance of the year. He can start again the first of the year with a new card, but there is an endorsement, made on the card, of his former convictions or violations, or accidents. So that we have a complete check of automobile accidents and convictions. I might say that we are fol-

lowing are the up-to-date regulations, rules of the safety conventions and meetings and we are on the map and doing good work.

Details of the Texas Program for Safety

W. E. JAMES (Director of the Texas Council of Safety): I am submitting with a report concerning the activities of the Texas Council of Safety which gives a brief account of the work done the first six months of active operation. The report also gives a suggestion as to future activities and a statement relative to the financial situation of the organization. We shall be pleased to have you look over the report and offer any criticism or suggestion that you feel might aid us in our work.

We have met with considerable difficulty in our efforts to get the message across, to the extent of arousing the people to action in accident prevention, we feel that much progress has been made. Development is but substantial. We are convinced that, with adequate help in the form of money and with sufficient funds, much greater progress could be made.

Queries concerning our organization and its work are coming to us daily and we believe that the outlook for the organized safety movement is more promising than ever before. We are entering upon the second six months of our task with increased faith in the gospel of safety and with renewed determination to spread this gospel to every community possible for us to reach.

Activities of the Council

Addresses delivered by the director before civic organizations, churches, automobile clubs, student bodies, institutes, associations, conventions, picnics, safety meetings, etc.....	28
Approximate number of people addressed.....	10,000
Number of typewritten letters sent out by director.....	325
Number of mimeograph letters mailed.....	6,000
Pieces of literature, safety folders, booklets, accident report blanks, program sheets, outlines, safety stickers, etc.....	43,000
Number of safety articles, reports on safety addresses, and other statements concerning the work of the organization that appeared in papers.....	20
Local safety councils organized.....	4
Cities and towns now seriously considering organizing local safety councils.....	5

Future Activities Planned

- Continue safety addresses.
- Distribution of safety literature, stickers, posters, etc.
- Organization of community safety councils where possible.
- Organization of junior safety councils in the schools.
- Propose and work for safety legislation in the next legislature.
- Increased newspaper publicity.
- Introduction of safety instruction in the schools. Outlines for this work are now being prepared.

Propose safety rallies for a number of the towns and cities.

CHAIRMAN FENNER: Gentlemen, the session in this same room this afternoon will be practically a continuation of this morning's session, and at that time representatives from other states will be given an opportunity to report progress in their various communities. This room is required for a luncheon and we will now proceed with a very interesting paper on head light regulations and enforcement by Mr. J. H. Hunt, General Motors Corporation, Detroit, Michigan.

HEADLIGHT REGULATIONS AND ENFORCEMENT

J. H. Hunt, General Motors Corporation, Detroit, Mich.

(Accompanied by Lantern Slides)

Although I have been announced as being affiliated with a certain corporation I want to tell you that I am not presenting an official viewpoint of that corporation. I am also very closely allied with the automobile industry, but I can't speak for that industry. The viewpoint then of your speaker is simply that of an engineer who is in contact with the industry and who is very much interested in this problem, who would like to do something in it, if possible, and finds himself confronted by an exceedingly confused situation.

I want to take this opportunity to say that as far as I have been able to find out in my contact with men of the industry, all of the responsible heads in the automobile industry look at the headlight problem as an exceedingly important safety problem. Regardless of what is said about them, they do feel, however, in a great many cases that they are in a very hopeless mess at the present time. They hardly know which way to turn; and what I am going to attempt to do today is try to make you see some of the situation that the industry finds itself in.

I will frankly admit at the start that the industry has been careless on the lighting question in the past. We have not paid the attention to that question, possibly that we should have; but you must remember that we started out with the question of how we could make something that would get you home a reasonable number of times without being hung up for major repairs, and we have gradually progressed, making our machines better and better, making them good enough so that people are willing to drive them at night. You didn't dare take those early machines out at night. You were afraid to take a lantern around them with the kind of gasoline we had in those days. Now, we have got the machines so that they run at night, and we have put on lights.

We started out without knowing very much about the lighting question. We have learned a lot of the difficulties of the lighting question today and find that we haven't learned much about the lights yet. Now, on account of the intolerable situation that very soon came about, the very large number of cars on the road at night, regulations came about;

state laws were passed which usually specified that substantial objects on the roadway should be visible a certain number of feet ahead of the car; the usual distance was 200 feet; the law usually went further and said that these lights should not be glaring. Sometimes a law specified what a glaring light would be. Where some specific law regarding a glaring light was made it was usually stated that the bottom of the light should not rise more than a certain distance above the roadway. Some were set 42 inches; some 36 inches; some said about the level of the head lamps. Now, most of the states still have laws that are somewhat indefinite the same as these statements I have just made. Other states have much more definite laws to guide the administrators who felt the need of assistance. The Illuminating Engineering Society drew up a set of specifications.

But those specifications are a compromise. No compromise is very satisfactory to the majority of the people and sometimes it isn't satisfactory to very many of them. That was the compromise of the man behind the lamps. It was where he was going and what he had to avoid to meet the objection of the men in front of the lamp who didn't want to be blinded so that they couldn't see anything at all. There has been more or less complaint. The complaint was more active with respect to glaring than it was with respect to inability to see. Furthermore, a car is not an object, as you all know, possibly to your grief, that travels always on an even keel without any variation whatever. A car shows a tendency to bob along on the highways. With even the best of them the result is that this high candle power light (while it specifies 7,200 minimum, the S. A. E. recommendation calls for 25,000 candle power—three times as much) may be thrown into and out of the eyes of the man coming along the road.

Three Important Changes Affecting the Light:

Since these specifications were adopted there have been three important changes affecting the light. One is the tendency to put the passenger down closer to the road. We have been compelled to lower our cars, because the public wants that kind of a car. The public wants a lower car, and all our cars have been made progressively lower so that the eyes of the driver are coming down nearer and nearer to the ground. The public also wants a better road than they used to have. The roads are getting better; we don't have a springy car and severe shocks. The springs are softer; as the result, the average five passenger car today will rock only a small degree. Motor vehicle commissions have made an attempt to enforce laws requiring that the light be pointed down one degree. It is a fact that cars are being driven very much more with only part of the load than they are with the full load, and I sometimes think that is particularly true of these cars that go out at night. As a result they drive along with a very bad spot in front of the car, which is more or less difficult to see, and they haven't got a safe light.

It is my personal opinion that the original S. A. E. specifications are just powerful enough for an alert driver on a good road; they are not enough on roads where road conditions are bad like wet surfaced roads, rainy conditions, and they are not enough particularly with people whose adjustment is a little bit slow. You have all had experience, I think, with the driver who lurches in front of you and then discovers something close to the edge of the road which he tries to dodge in his excitement.

Now, that is the situation so far as the regulations are concerned on the type of lamps we had up to about a year and a half ago. At that time, it was felt that there was need of improvement and that there should be an opportunity to get better light on the road. More and more people were driving, and with this increase in the number of people there were more and more people driving who needed a longer time to plan out a course of action than the average driver. It may be that some day we will sort individuals and limit some of them as to when they can drive. People that might be perfectly safe to drive under certain conditions are very likely to do very erratic things under stress. But in any event it was felt that the lighting problem was not being satisfactorily met; and the so-called double filament lamp came along, which provided a means of depressing the beam on meeting another person. That gave an opportunity to have a real driving light; also to change the lighting conditions when meeting some one, so as to give the other fellow a chance to get by. Now, we have had that for about two years. But the thing was nearly four years in getting across.

ADJOURNMENT

Drivers' License Laws

October 27, 1926

ERNEST N. SMITH, Chairman

General Manager, American Automobile Association, Washington, D. C.

The second session of the Public Safety Division convened at 2:15 o'clock in the large banquet room, Statler Hotel, Detroit, Michigan, Mr. Ernest N. Smith, general manager, American Automobile Association, Washington, D. C., presiding.

CHAIRMAN SMITH: I suppose there are more individuals in the United States interested in the possibilities and development of a driver's license law than perhaps any other general law referring to general conduct.

As a background for the meeting this afternoon, I am going to point out one or two very brief features before introducing the first speaker, in order to give you an idea of the situation that is confronting the United States.

In a recent survey made by the American Automobile Association, we found that in 18 states and the District of Columbia, all drivers of automobiles were required to have licenses. In the remaining 30 states there were no such provisions.

In connection with this investigation we also inquired into the provisions in the various states covering the examination of drivers as a prerequisite to licensing. The results showed that in nine states and the District of Columbia examination is compulsory; in six states it is optional with the motor vehicle officials, and in 33 states examination is not required, except of operators of public vehicles or vehicles for hire.

In our investigation we also inquired into the practices in the various states of suspending or revoking automobile licenses. We found that each of the 18 states and the District of Columbia requiring licenses, except Virginia, permitted either the suspension or revocation of licenses, or both, for cause. Under the Virginia law a license is automatically given when a vehicle is registered. This license entitles not only the registrant to operate the vehicle but anybody in his family, or anybody employed by him, to operate the vehicle registered. We also found that in 15 states which have no provision for the issuance of licenses, any driver of a motor vehicle who has shown himself to be reckless or who

has been involved in a serious accident may be deprived of the right of driving on the highways.

The Committee on Traffic Control of the First National Conference on Street and Highway Safety recommended that there be both the examination and licensing of all automobile drivers, that new drivers be required to undergo a probationary or instruction period of 30 days or more, and that there be provision in every license law for suspension or revocation of the license where the driver was shown to be dangerous, incompetent, indifferent, or reckless.

The report of the Committee on Traffic Control was adopted by the general sessions of the Conference, and the report of the First Conference contains references to licensing and examination of drivers which I shall read at a more appropriate time this afternoon.

The exigencies of politics have made necessary a slight change in the program for this afternoon. According to the printed program, Mr. David Fenner was to speak first on the developments of the past year, to be followed by Mr. L. B. Palmer, and then by Judge Skeel, of Cleveland. We are placing Judge Skeel first on the program. I think I ought to say in behalf of the Judge that he is not anxious to leave this meeting were it not for the fact that a political campaign is on in Cleveland.

In order to insure his attendance at a meeting before some veterans tonight, Judge Skeel is trying to cover two places. I take pleasure in presenting Judge Skeel, chairman, Legislative and Law Enforcement Committee, Cleveland Safety Council, Cleveland, Ohio.

A PRACTICAL LICENSE LAW FOR AN AGRICULTURAL STATE

Judge Lee F. Skeel, Chairman Legislation and Law Enforcement Committee, Cleveland Safety Council, Cleveland, Ohio

All life is a response to a stimulating urge to do more, to get there faster, to secure more of the comforts of life and its luxuries: in short, a desire to move more swiftly and more easily in the direction of personal progress.

The equipment and accessories you see on the 1927 model automobile are all collateral pacemakers; they are designed to convey their cargoes with greater speed, greater comfort and greater safety.

This unprecedented haste of men and machines constitutes what we now know as our "traffic problem."

But just as in all things, this speed tends to become extreme; hence traffic signals for humans and four wheel brakes for engines.

Yet mere cautions seem not enough for humans nor mere accessories for machines. Intelligence and education must carefully adjust people and automobiles to the new conditions.

We must understand that safety is not to be applied by means of brakes; it must be used mentally by bipeds.

After all, traffic rules are not meant to retard progress but to conserve and assist it; not to impede it but to speed it on when the danger is past; not to restrain but to guide it. What are the problems that confront us today? As Grover Cleveland once remarked, "We are confronted by a condition, not a theory."

The advent of motor transportation has revolutionized the economic fiber of our daily life to a greater degree than the industrial revolution of England or the French revolution changed the daily life and habits of the inhabitants of those countries. The life of the average person has been made bigger and fuller and the average man is now able to take his family into the country to enjoy and appreciate the grandeur of nature when 20 years ago this would have been impossible. People are able to go from one locality to another and their breadth of vision is increased by a knowledge of how things are done in other places.

The automobile industry in 1923 became the largest industry in this country. In fact it is now the largest industry in the world, surpassing even the steel industry. The National Automobile Chamber of Commerce in its report of 1925 states that for the year 1925 there were 3,445,682 employed directly or indirectly in the automobile business. This represents approximately one-tenth of all the people employed in gainful occupation in this country.

The Extreme Importance of Motor Transportation

Nineteen million nine hundred fifty-four thousand three hundred forty-seven cars were registered in the various states of the United States last year, representing an investment of over six billion dollars, or a sum half again as large as the total indebtedness of the United States Government at the close of the Civil War. Approximately one out of every five people in the United States owns an automobile, and the amount of taxes paid last year amounted to \$666,944,340.98. On January 1, 1926, \$258,136,775 was paid in insurance premiums and \$972,000,000 in negotiable paper was outstanding on motor vehicles; 9,362,094,000 gallons of gasoline were consumed and \$1,002,000,000 was expended on highways. A prominent economist of the University of Iowa estimates that "about ten billion dollars a year covers the operating cost of the country's twenty million motor vehicles. This is based on the average figures of ten cents per mile and 5,000 miles per year. The country's annual highway expenditures amount to about one billion dollars a year; motor vehicle transportation involves an annual cost of about eleven billion dollars."

A rough perusal of these figures will give a general idea of the extreme importance of motor transportation.

It has been said that one of the greatest difficulties to be found in the pacification of Europe is due to the tariff walls between these countries and the lack of commercial and social intercourse between the peoples. We have never been troubled with tariff barriers in this country and the intercourse between people in the city and in the country

and between the citizens of various states has grown to such an extent that our people now understand the peoples of other states much better than ever before. The city, county and state lines have been eradicated in so far as the motorist is concerned. The inhabitants of the eastern states no longer have the popular conception that all of the men west of the Mississippi River are cowboys and the people of the west now realize that something good can come out of New York after all. Even the inhabitants of the Dominion of Canada now fraternize and treat as relations our citizens who travel into that great country on their annual vacations. It has been estimated by the Statistical Bureau of the American Automobile Association that approximately nine million automobiles were touring at some time this year, representing 36 million people who have been able to enjoy the beauties and advantages of their localities.

The extensive use of the automobile has been in a large measure responsible for the eradication of our social unrest. Seventy-five per cent of our cars are purchased with time payments. The average owner of an automobile does not desire a revolution or great economic change until his automobile is paid for. Private ownership makes an universal appeal.

City People and Country People Are Obsolete Terms

Country people no longer look askance at city people and city people are no longer accustomed to look at country people other than with an eye of envy. The hardships of the country in the old sense of the word no longer exist, and in nearly every state of this union a person living in the country is only a few hours distant from all the advantages of the city. These people are no longer country folks but suburbanites.

In view of the very extensive intercourse between country people and city people, the tendency of the country people to motor into the large cities and the practice of the city folks to spend their vacations in the country, the day of community legislation has passed. As has so often been remarked, the automobile has ceased to be a plaything of the rich man, it is now an article of necessity with the farmer and with the urbanite.

Local legislation with which visitors are not familiar causes great hardships. Different municipal regulations are becoming increasingly unpopular. The tendency is to have uniform laws and uniform rules whereby a motorist may be able to know and to abide by the law, no matter where he goes.

With the advent of extensive travel comes the necessity for personal regulation in order that the maximum of safety may be had and the maximum use obtained from our highways. Since the foundation of this country it has been instilled into all of us that a minimum amount of regulation for the individual is desirable. This is a great principle and should be preserved and cherished by us, but in every body politic there comes a point where there must be a certain amount of personal regulation in order to secure the greatest good for the greatest number. There

is a twilight zone where regulation may or may not be offensive but there can be no question that the need of the regulation of the operators of motor vehicles is imperative if the greatest benefits are to be derived by the greatest number.

It has been reported by the National Safety Council that 22,500 people were killed last year and 675,000 were injured through the operation of automobiles. Of course the number killed can not be reduced to a zero, but steps can be taken to reduce this amazing sacrifice of human life. The right to drive an automobile is now a question of public concern. Safety on a highway largely depends on three things: first, how well drivers are informed as to the rules of the road; second, with what degree of care they abide by and live up to such rules; and third, the capacity or lack of capacity of a driver to operate a motor vehicle.

While on the traffic bench at various intervals for a period of over three years, I frequently asked defendants when they had last read the book of traffic rules, and in about 50 per cent of the cases they very frankly stated that they had never read the rules at all and many did not know that books of traffic rules could be had. It could only be deduced that a great number of drivers learn what they know about the rules of the road by watching the other fellow. This, at least, is a most dangerous way to obtain correct information.

Few Laws and Made as Simple as Possible

It has been the purpose of legislative bodies having to do with the enactment of laws and rules regulating the use of the public streets and highways by motor vehicles to make such laws and rules as simple and as few as is consistent with public safety. This being so, no especial burden is placed upon drivers to know just what these rules are. Every driver, in fairness to himself as well as to others who are compelled to drive upon the public streets, should first inform himself as to just what the rules of the road are and then do his utmost to live up to them.

In addition to a lack of knowledge of the rules of the road and a somewhat inattentive observance of them by those who are informed, one of the most frequent causes for accidents is congestion. Police records show that about 30 per cent of all accidents occur between the hours of 5 and 6 p. m. This is the hour when traffic congestion is at its peak. It is at this hour that the most vehicles are upon our streets, and to this must be added the fact that the mental alertness of the driver is undoubtedly at its lowest point. At this hour the homeward bound traffic crowds our streets. The drivers, being impatient of delay, fight over places of advantage, drive at as many rates of speed as they are able, and weave in and out of the regular lines of traffic with the inevitable result of thousands of accidents. In the direction of this great volume of traffic, traffic departments of our large cities are seeking to keep vehicles moving at a universal speed and to insist upon slow moving vehicles moving near the curb.

Much has been done to make our streets safe, such as the installation

of signal lights and adoption of the boulevard stop laws. Both of these laws have been important factors in reducing accident hazards. The boulevard stop law should be enforced to the letter. There is only one way to comply with this law and that is to make a full and complete stop so that one's entire attention can be directed to the condition of traffic on the main thoroughfare. Anything short of this should be a violation of the law. It is desirable to form the habit of making a full and complete stop. The habit is a good one. Police records show conclusively that these two factors, together with the elimination of parking during the rush hours on main thoroughfares, have directly caused the reduction of accidents more than 25 per cent.

One more thing, and a very important one, is needed to help make the streets safe; that is the universal enactment by the various states of a driver's license law. So far all efforts made in the interest of such a law in our state have resulted in failure because of the feeling very prevalent in rural communities that the automobile driver has already been over-regulated, and that this additional burden should not be imposed upon the operators of cars, and especially upon the younger members of the family who have to run errands and drive the children to school. It is hoped that these people in rural communities can be made to appreciate the necessity to sacrifice a little of their freedom to the universal desire to save life, limb and property. To close observers of the traffic problem, a drivers license law must be enacted and enforced if we would do all within our power to make life and property safe upon our streets.

All Right Thinking People Will Support Public Safety

Every American citizen abhors unnecessary restriction upon what he believes to be his inalienable right to the pursuit of happiness, but the right to use the highway is not an unrestricted one and the right to avail yourself of the use of our thoroughfares can not be obtained without making some sacrifice. When it becomes apparent that an unrestricted right is abused by a few to the detriment of many, police power of the state must step in to preserve public safety. This is now true of the right to operate a motor vehicle. All right-thinking people who are familiar with the problem are agreed upon this, the only question being to what extent the right should be restricted and the method by which it should be done.

A driver's license law should be made as simple as possible with no greater restrictions than are absolutely necessary to accomplish the purpose intended. The law should provide that everyone be issued a license to operate a motor vehicle as a matter of right, except those who by reason of serious impairment, either mental or physical, are apparently incapable of operating a machine. It would be impractical to require a rigid mental or physical examination of every applicant for four reasons. It would be impossible to examine every person who is now operating a car within many months, the expense of such an examination would be unpopular, the examination would place an unnecessary burden upon

the great majority of careful drivers and the force required to make such examinations would constitute another undesirable and powerful bureau in our state governments.

Require every applicant for a license to fill out an affidavit in which he swears among other things to the presence or absence of physical defects and the number and character of convictions for violation of the traffic laws. Every statement in the application should be made a material allegation for the purpose of a prosecution for perjury. If the affidavit does not disclose any defects that might make the applicant incapable of driving, and there are no apparent defects, the applicant should be granted a license. If the appearance of the applicant or his affidavit disclose physical defects that would put in doubt the question of his ability to drive, or the record discloses a conviction for a serious traffic offense, the applicant should be required to demonstrate to authorities appointed for that purpose that he is capable of operating a car. In the event of a refusal to issue a license, an appeal should be open to the courts to review the decision. An age limit is desirable. A provision should be inserted permitting children in the country under the required age to drive to school and perform similar duties.

Make It Easy to Get and Easy to Lose Your License

In other words, make it an easy matter, comparatively speaking, to get a driver's license and then make it just as easy, if not easier, to lose it.

The power to suspend or revoke the driver's license should be in the Judge or Court of record having jurisdiction to enforce and punish violations of motor vehicle laws. Make the traffic court responsible for the restricting of the right to drive of those who by their actual driving record show that they are unfit and unwilling to curb carelessness. You restrict, by this simple method, only those who by their actual driving record, unnecessarily and thoughtlessly, or by reason of unfitness, cause damage or injury to others. They have demonstrated that they are unfit to be entrusted with the great privilege of operating a motor vehicle. The right to suspend or revoke licenses should be permitted only upon conviction of the operator for the violation of one of the five principal motor vehicle rules, which I conceive to be speeding, careless driving, driving while intoxicated, passing a standing street car while passengers are getting on or off, and failing to stop after an accident.

The great majority of drivers do their utmost to abide by the accepted rules of the road and drive with that margin of safety which will insure against accident even when an unusual emergency arises. Those who take greater privileges upon the streets than are consistent with safety are a very small minority. These drivers must be eliminated for the good of the overwhelming majority. The license law as herein outlined and suggested is a most effective, positive and economic means of placing in operation this much needed restriction without placing a burden or undue inconvenience upon the great body of sincere law-abiding motorists.

The time is now here, with regard to motor vehicle driving, when

incompetency and willful recklessness must be stopped. Our streets are so busy, the loss of life so great and the injury and damage to property so costly, that those who drive vehicles must be competent. Ignorance and thoughtlessness can no longer be accepted as an excuse. Safety and utility are now the underlying factors upon which must be founded the right to use a motor vehicle upon our public streets.

The last question which I wish to discuss is the traffic court itself. It is here that good or evil may result by virtue of the conduct of the judge. Law enforcement has been and always will be a very difficult and troublesome problem. This is particularly true of the traffic court because the great majority of those who, for one reason or another, find their way into this court are not criminals, nor was the mistake which caused them to be called before the court the result of criminal intent. For the first part I would say that they are there because of thoughtlessness, perhaps better described as lack of attention to the operation of their motor vehicles. The court, it is true, must impose penalties that are commensurate with the offense, in so far as this can be done within the realm of human judgment.

Certainty of Punishment a Sure Deterrent of Crime

Certainty of punishment for violations of the law is an absolute deterrent, and is the only means known to protect society from the wrongful acts of the individual. But fear of the court should never be the reason for right-thinking persons obeying the law. Observance of the law ought to be by desire of the individual. The traffic judge should therefore not only strictly enforce the rules of the road without fear or favor, impose appropriate penalties for their violation to the end that the streets shall be made safe, but he should also, with all his strength and vigor, sell traffic safety to all that come before him. When they go out from their experience in court it will then be with a better understanding of the need for observance of the rules of the road, with a solemn resolve thereafter to become exponents of traffic law observance and to hold in contempt those who, by their carelessness and disregard for the rights of others, make our streets unsafe.

I have attempted to point out to you the tremendous growth of the automobile industry and the revolution that it has brought about in our way of thinking and in our way of living. Sectional lines have been eradicated. The country has been brought to the front doors of the city and the city has brought itself to the back doors of the country. Like the Colonel's lady and Judy O'Grady, we are all motorists under the skin. The price which we are paying is too great, the toll in human life is too heavy. A spirit of personal responsibility, the idea of individual competency must be our goal. Success is to be achieved not by working from the top to the bottom but by working with the individual—from the bottom up. Those of us who preach must practice. You are not performing a great service to the community when you preach from the street corners, like the Pharisees of old, about safety and then impose upon your friendship with the court and ask him to be lenient with your

friends. A driver's license law, simple in its requirements and effective in its application, enforced by an independent, intelligent and courageous judiciary, will achieve in a large measure the desired results.

CHAIRMAN SMITH: I think we are particularly indebted to the Judge for his able discussion. I was greatly interested in it because I knew that he had been chief counsel for the Cleveland Automobile Club for a number of years and did such a good job there that he was elected to the bench and is now fining a lot of people who used to help pay his salary. Does anybody want to tell the Judge what he thinks of him?

New York Is Making Laws More Severe Each Year

LEON ARONOWITZ (New York State Motor Vehicle Department): The tendency in New York state is becoming such that we are having more severe license laws than we have had in the past. We are making requirements more drastic each year. We have found from our experience that more public accidents are due to inexperienced driving than from experienced. The great percentage of new drivers have more accidents than those who have driven over two or three years.

In New York, in addition to making a man pass a test to operate the motor vehicle, he has to pass a sight test. The examiners are now devoting more time to the examination. We license approximately half a million each year and have been able to accomplish that with about 100 inspectors.

CHAIRMAN SMITH: There we have testimony from one of the largest states in the Union. I understood Judge Skeel to say that if some people had been injured or were deformed or had some infirmities that possibly they ought not to be licensed. That calls to mind the fact that the head of the department in Pennsylvania had to meet the problem of licensing deaf people and had to decide whether or not they should be given licenses. His experience told him that people who were deaf seemed to have another sense: that their eyesight was more acute. He solved the problem by appointing a committee from the deaf school to pass upon the licenses of other deaf people. That board which he set up was much more active in its examination than any official board of the state.

I am mentioning these points to bring out discussion. I recall not long ago in the state of Iowa a legislator said he was going to introduce compulsory state liability insurance because there were altogether too many accidents in his state for which no compensation was given to the injured person. I prolonged the discussion for a little while, and then asked him if they were going to introduce the drivers' license law.

"Not at all," he said. "We farmers don't like it. The farmer doesn't want to take out a license for his three daughters and four sons, hired men, so they may take the car to town. The farmer doesn't want to bother with a license law."

I then asked him if his solution, as far as his state was concerned,

meant he would let all unregulated traffic go over the state. The only compensating feature he could offer to a person was that if injured he would be paid a lot of money, but he didn't make any provision to first prevent the injury.

After I finished he said that put a little different angle to the situation.

I have had the same discussion in other parts of the Union. Possibly some of you people may have had the same experience. I bring up the question of compulsory liability insurance here because I think it is linked up with the question of a drivers' law. I do know from our experience over the country that many people are advocating liability insurance for the protection of motorists, but they don't want to adopt any law which would make it hard for a motorist to get his license in the first place.

H. P. COFFIN (Portland, Ore.): I don't altogether agree with Judge Skeel in regard to calling attention to violations of the driver. This woman should have been called down. If the man had been a careful driver himself and had called attention to this woman's violation, I think he was doing nothing more than his public duty. If many more citizens would take upon themselves the task of calling down careless drivers it would tend to assist the police department.

One Driver Who Violated Five Rules Rounding a Corner

I remember one day in Portland that a driver violated five of our rules in turning the corner. He failed to put out his hand and several other things. I was in my car and called him on it. He told me to go where it is nice and warm. I followed him down the street and asked him to stop at the curb and said, "Now tell me that again." And I showed him my authority.

He said, "I will take my hat off to an officer."

I told him that he was making a mistake, that I might have been a private citizen who was simply warning him of what he was doing. He thanked me very much and said he was a stranger in town and did not know the rules. I promptly handed him one of our traffic books and he was happy.

As I say, the public citizens ought to take upon themselves the duty of helping the public officials, for it might help out some of our bad situation.

MR. POWELL (Buffalo): In New York state there is a very simple way of handling the situation. All that would be necessary would be to take the number of the car that was offending the rules, report it to the local police authorities and it would be recorded against the car, would result in a summons being issued against the owner in the locality, or the revocation of the driver's license in the state. It is a very simple matter to handle.

CHAIRMAN SMITH: I know that in some places the cities have secret committees of 200 or 300 business men to watch for infractions of the law. On the other hand, that has the aspect of an espionage system.

I can't say as far as our experience and observation go that it has been a satisfactory solution. I think it is better to reinforce the public officers, but there is no reason in the world why an infraction shouldn't be called to the attention of the proper officials.

In Washington we have had nine recent calls for emergency road service. Our service men reported in almost every instance that the man had been drinking and that the car had been seriously damaged. That man's membership was cancelled because we didn't want to have him on our roll. In addition we reported the incident to the police, and his license was withdrawn.

It has been said that a man who has one arm or a wooden leg or only one eye shouldn't be permitted to drive. Very well, what will you do with several thousand veterans of the war who sacrificed themselves for their country who in other respects may be in perfect health? If they can pass the tests should they be penalized and never be permitted to drive because they have lost an arm or a leg or an eye?

CARL SMITH (Cleveland Safety Council): I should like to say to those who are interested in the drivers' license law (particularly what is being contemplated in Ohio in the way of a law), that copies of this proposed bill for introduction in the legislature this fall are on file at the National Safety Council office. So anybody who desires can get complete information, particularly in relation to Judge Skeel's idea on a drivers' license law.

The Problem of Cincinnati and Kentucky Licenses

A. E. MITTENDORF (Cincinnati): I might add that the state of Ohio is now engaged through its Legislative Committee in trying to suggest and have a proper drivers' license law enacted. I agree with the chairman in stating that the drivers' license law should not be tied up with a compulsory insurance law. In other words, I should hate to see compulsory insurance a part of the law. Compulsory insurance does not make for safety. It has nothing to do with safety. Rather, in a measure it makes the driver feel more secure in taking chances.

In Cincinnati we have 250,000 people across the river who get their licenses in Kentucky and take their pleasure in the city of Cincinnati. Their cars are on our streets all the time. What are we going to do about it? I should like to know the possibility of having some sort of national instead of state license law.

CHAIRMAN SMITH: In answer to Mr. Mittendorf, I will again take up this report from which I made some quotations earlier in the afternoon and state for your information that the Committee on Traffic Control of the Hoover Safety Conference adopted some resolutions. The first paragraph of the report is as follows:

"No unlicensed person should be permitted to operate a motor vehicle. A reasonable length of time after the passage of the law requiring operators to be licensed should be granted operators already qualified in which to secure licenses without examination. The de-

partment or division administering the motor vehicle law should have full authority to refuse an operator's license to any persons and to suspend or revoke a license already issued for any reason deemed sufficient."

The second paragraph reads:

"Before granting an operator's license, the department or division should determine the applicant's ability to operate a motor vehicle safely by ascertaining his physical and mental fitness and his knowledge of the laws, and by requiring an actual demonstration of his ability to operate a motor vehicle. It is recommended that all states designate the minimum age limit, but that no person under sixteen years of age, and no person who can not read English, should be permitted to operate, drive, or direct a motor vehicle."

States That Now Require a Drivers' License

Speaking of the drivers' license, I had an examination made for this Conference of the number of states that required a driver's license, which I read. In addition to that, we had a list made of the states in which an examination is required of operators not for hire. Briefly, let me read to you the states in which drivers (not for hire) are required to have licenses. These are the states in which a license is compulsory:

Arizona, California, Connecticut, Delaware, District of Columbia, Maine, Maryland, Massachusetts, Michigan, New Hampshire, New Jersey, New York, Oregon, Pennsylvania, Rhode Island, Vermont, Virginia, Washington and West Virginia.

That constitutes 18 states and the District of Columbia.

Now let me read the names of the states in which an examination is required of operators (not for hire):

Connecticut, District of Columbia, Maryland, Massachusetts, Michigan, New Hampshire, New Jersey, Pennsylvania, Rhode Island and Vermont.

That constitutes nine states and the District of Columbia. Just one-half of the group that issues licenses require examination before issuance. The list which I am now going to read is one of six states in which examination is optional with designated officials:

California, Delaware, Maine, New York, Washington and West Virginia.

If there are any representatives here who want to take issue with this report, I should be glad to have you call any discrepancies to our attention if there be any.

MR. ARONOWITZ: New York State requires an examination for both operators and chauffeurs. That requirement has been in effect since 1924.

HOWARD BROWN (Detroit Automobile Club): The examination is required in Michigan but it is optional as to what examination is given. In other words, there are certain officers in the state that can give an examination to secure an operator's license, but there is no provision in the state law requiring a certain examination to be given by those officers. It results in very good examinations being given in Detroit and in sev-

eral other cities, like Grand Rapids, and some of the large cities. But in some of the smaller cities, sheriffs and deputy sheriffs give the examination. They are not uniform. We have reason to feel that there are parts of the state in which operators' licenses may be secured very easily.

CHAIRMAN SMITH: With respect to refusing to grant licenses unless the operators can speak English, I was driving in Canada last year and I came to a section of the country where all the road direction signs were in French, and there was practically no English spoken. I don't suppose I could have traveled very far if I had been a resident and couldn't speak French. I proceeded further and came to a section where the French flag still flew and there were very few English flags. As I went along the road directions and danger signs were given in both French and English. There I had the feeling that it was perfectly safe to go on my way, and I entered a small town which was mainly of French population. A street car stopped in front of me suddenly and 14 laborers got off on the left-hand side and I was in the midst of a crowd that was jumping and shoving in every direction. I heard the cry, "Let's go and call the police." So, you see, there are some difficulties in traveling on this continent.

Courtesy Extended the Driver From Another State

MR. COFFIN: What is the attitude assumed by those states requiring examination for drivers of machines toward states where there is no examination?

F. F. GILMORE (Louisville Safety Council): In making a study of drivers' license laws a year and a half ago, we found that generally speaking the driver of a car from the state not requiring a license was given the liberty of driving within that state if he had his own car and could show ownership of the car for a period of anywhere from 30 to 60 days, but any length of residence in the state requiring a license required him to take out a special license.

CHAIRMAN SMITH: The situation may be a little bit complicated in that respect. Eventually there probably will be complete reciprocity all over the states so that a license from one state will be accredited in all others for as long as they choose to remain there. Then again we will have a little complication.

Miss R. H. Brooks (Patterson, N. J., Safety Council): I know that in New Jersey anybody who remains in the state longer than 60 or 90 days has to go through all the process of getting a new license. He has to take all the examinations of a new driver who has never driven a motor car before to get out a license plate for his car.

JAMES KELLY (Trenton, N. J.): There is a 15-day reciprocity stipulation in the Jersey Act as long as you comply with the laws of your own state while in Jersey.

FRANKLIN ZELLHOEFER (Milwaukee, Wis.): I just want to endorse the remarks made by the gentleman from Ohio. It seems to me that this

discussion brought out very strongly the one big point that we are all going to bump up against when we try to fix up our respective state laws: the matter of drivers' licenses from one state to the other. We, like the state of Ohio, have been working on our drivers' license law. We had it through the legislature two years ago and the governor didn't like it. But we are going back with it. The biggest problem we had in all the discussion was: what sort of tolerance are we going to allow the fellow from Illinois who comes up to Wisconsin to catch our fish and hunt our game? We like to have them come, but how are we going to control them if we have one sort of drivers' license or law in Ohio or Illinois and another in our own state? Therefore, I agree with the man from Ohio: let us attack the problem as a national issue.

CHAIRMAN SMITH: I should like to say with respect to this proposed law as drafted by the Hoover Safety Conference, that there are 42 state legislatures meeting in the United States this winter. This model code drafted by the Hoover Safety Conference will be introduced into those 42 state legislatures, I think. An attempt will be made, at least, and I feel safe in saying the bill itself will be put before all the state legislatures, or at least the principles incorporated in that model code will be placed before the state legislatures either for adoption as a whole or for the adoption of such parts as are not already contained in the existing code. I believe this winter will see us further on the road of progress with respect to unification of our motor vehicle laws than at any time within the last 25 years. I think that it reflects a sane opinion when I say that many people will make great progress this winter. If we can't get the code adopted as a whole in 42 states, we will make very substantial progress, and then in the succeeding state legislatures we will be able to iron out some of the wrinkles left as a result of the action of legislation in 1926 and 1927.

Minnesota's Lakes Draw the Summer Motorist

B. N. WHEELER (Commissioner of Public Safety, Duluth, Minn.): Up in Minnesota we got in touch with the Hoover Conference and we discussed back and forth these various problems we are discussing today: and we now have a committee that has been with us for more than six months working with the various departments of the state in order to make our state law in harmony with the Hoover Conference law. If the other states will do the same thing, we will get together without any difficulty.

We have 10,000 lakes in Minnesota, and it makes a wonderful short drive from Duluth to Canada, and we expect automobiles by the thousands next summer, as they were up there this summer. But first we have got to have reciprocity. The Hoover Conference proposition takes that into consideration. If we all get together we won't have any trouble at all.

CHAIRMAN SMITH: Mr. David Penner, who is chairman of the Motor Vehicle Conference Committee, which comprises a group including the

National Automobile Chamber of Commerce, representing the manufacturers, the American Automobile Association representing the owners, the Rubber Association of America, and one or two other groups, is greatly concerned with uniform acts as carried out all over the United States. Mr. Fenner is going to talk about the developments of the past year. I am curious to hear that speech myself, because I recall that Mr. Fenner spent quite a bit of time during the past year heading a most distinguished delegation of Americans who toured South America. I understand that he was involved in numerous accidents owing to the fact that he turned to the right and the rest turned to the left. I take pleasure in presenting Mr. Fenner.

DRIVERS' LICENSES AND EXAMINATION LAWS

D. C. Fenner, Chairman, Motor Vehicle Conference Committee,
New York City

In any discussion of the drivers' license system one must bear in mind, first, its origin and purposes; second, the form of such laws to date and their accomplishments, and, third, having in mind the experience gained from those laws already enacted, the form in which such new laws should be adopted.

Michigan was the pioneer state in the enactment of drivers' license and examination laws, "blazing the trail" toward the adoption of operators' regulatory measures in 1919.

At that time, with but some eight and one-half or nine million motor vehicles registered in the United States and some four hundred thousand of these in the State of Michigan, it had become apparent that if automobiles were to increase in number in the future as rapidly as they were then increasing, immediate steps must be taken to regulate their operation to promote public safety.

This idea of public safety has always been the motive behind all legislation regulating the automobile and its use, and with this in view, it may safely be said that all operators' license and examination laws have been enacted for three main reasons:

- (a) To insure that those who drive automobiles will be eminently fitted for that responsibility.
- (b) To insure that, once the proper parties to operate them are found, automobiles will be properly operated.
- (c) To determine the right to operate an automobile and to enable the state, through its police power to govern and control such operation.

With these needs in mind, from 1919 to date, 33 states have incorporated in their motor vehicle laws some form of operators' license law. These states are Arizona, California, Connecticut, Delaware, Illinois, Maryland, Massachusetts, Michigan, Minnesota, New Hampshire, New Jersey, New York, Oregon, Pennsylvania, Rhode Island, Tennessee, Washington, West Virginia, and the District of Columbia.

The form of these laws must not be confused. They are by no means uniform, but as a whole they have brought about a change in the operation of the automobile and in the personnel of the operators in the direction desired. The main variance in these laws is not in the regulation of the operators, once they are determined, but in the determination of who they shall be. A survey of these various laws shows that in the states of California, Connecticut, Delaware, Maryland, Massachusetts, Michigan, New Hampshire, New Jersey, Pennsylvania, Rhode Island, Vermont, New York, and the District of Columbia, all applicants for an operator's license must take and successfully pass an examination before receiving such license. In the other states it is left discretionary with the enforcing authorities whether an examination is required; and in the states of California, Delaware, Maine, Michigan, Oregon, and West Virginia they do not require such an examination except of those who are manifestly physically or mentally deficient. The state of Utah does not require an examination in any instance.

In all states, however, the operation of the law is practically uniform in that all operators must obtain a license, and once having obtained this license, must comply with the law or the authorities may and will avail themselves of their powers of suspension and revocation, which powers are the "teeth" of these laws, in the endeavor to so regulate these operators that only those who are fitted for, and who continue to prove themselves worthy of, the privilege conferred upon them when a license is issued, may be the ones who operate motor vehicles.

There is again a marked lack of uniformity in respect to the term for which a license is issued.

A One or Two-Year Period for the Driver's License

The chief obstacle to the issuance of an annual license is the great burden it places on the State Motor Vehicle Departments and the great amount of time necessary in getting approved licenses into the hands of all applicants by a given date in the more thickly populated states. The Motor Vehicle Department of the state of New York is now considering a recommendation to the state legislature that the license period be extended from one year to two years because of the great task of licensing two million or more drivers each year.

To just what extent the public has been benefitted by these laws is impossible to determine, in view of the fact that no complete data can be obtained. Accurate records are not kept of accidents with a view of showing the responsibility of the operator in most states. In the few states where such records are kept one is hampered in obtaining data from which an accurate survey can be made because of the form in which these records are kept. There must, however, be some benefit from simply knowing who are operating automobiles, and there must be still more benefit derived through the ability in the beginning to weed out those manifestly unfit and suspend or revoke the licenses of those who later prove themselves unworthy of the privilege to drive.

Developments along this line have been slow, due, no doubt in most

instances, to the fact that the public is always averse to any law which in any way hampers its freedom. The whim of the individual must be considered. It would seem, nevertheless, that when the public understands this problem it is solidly behind such a movement. This is evidenced by the stand taken by the American Automobile Association, made up of individual motorists, which has gone on record as favoring the enactment of these laws in all states.

In the past year no new developments have taken place and no new enactments along these lines have been made. Only 12 state legislatures convened this year and none of these touched upon the operators' license and examination law, except to amend slightly laws already existent.

The attitude of the automobile industry is perhaps best shown by the part it took at the National Conference on Street and Highway Safety, commonly known as the "Hoover Conference," which met in Washington in 1924, representing there the entire country as a unit, in an endeavor to promote legislation which will make for safety in the operation of automobiles. At that meeting the automotive interests along with the other groups favored the adoption of a uniform drivers' license and examination law. Again in 1926 these same interests assisted in drafting a uniform law, which has become part of the Hoover Code.

What Can Be Done to Perfect Legislation

So much for what has been done. And now, what can be done in an effort to perfect legislation along this line?

It is but common sense that the greatest variable factor in the problem of safe operation of motor vehicles is the ego, the personality, the individualism of each operator. Just how far our laws should go in the selection and regulation of this operation is a question, and since there has not been devised any method by which all applicants may be examined and their exact individual ability accurately and unfailingly determined, the best that can be done is to devise an examination which will, at the outset, determine from those applying for a license, who are best fitted to receive the same, and, through the powers of suspension and revocation, weed out, from those to whom licenses are issued, the ones who prove themselves unfit to continue to enjoy this privilege.

Such an examination should, therefore, determine as to each applicant.

- a. His mechanical ability to drive.
- b. His mental qualifications.
- c. His physical qualifications.
- d. His moral qualifications.
- e. His age.
- f. His reactionary ability.

By "mechanical ability to drive" is meant the ability of the driver to operate a motor vehicle under ordinary conditions—his ability to turn the same in limited space; to drive in heavy traffic; properly to handle the vehicle on steep hills and to handle it at a reasonably rapid rate of speed.

"Mental qualifications" would include a knowledge of the law pertaining to automobile operation and the ability to determine right from wrong, coupled with the ability to respect the rights of others.

To ascertain "physical qualifications" would mean learning whether the applicant had control of all his limbs or of sufficient of them to enable him to operate a vehicle safely.

Under the heading "moral qualifications" we would determine whether the applicant is a habitual drunkard, a drug addict, or has some other vice which will numb his sensibilities and make him unfit to be allowed control of an automobile.

The question of "age" is a mooted one. There are no figures, based upon experience, by which we can determine at what age a person is best qualified to drive an automobile. There are many in their 'teens who can and do drive better than those of mature age, and vice versa. The consensus of opinion seems to be, however, that no license should be issued to those under 16 or 18 years of age.

Coupled with the foregoing, and particularly with the mechanical ability and mental, moral and physical qualifications, enters the additional test of the applicant's reactionary ability.

There are those who advocate a psychological examination, having principally in mind the fact that, while a person may be of apparent sound mentality and perfect physically, there may be lacking that inherent something which enables some of us to react immediately to a certain situation, while others cannot. This is one of the particular questions to be considered in a discussion of this subject. Just how it is possible to determine and weed out those whose reactionary instincts are such that they do not and can not act immediately in a case where split-second judgment is demanded, it is hard to say, and, perhaps, it is impossible, but in any case, whatever mode of examination is adopted it should be such as to indicate those best fitted, as an average, to drive under conditions as we have them at present.

Two Operators Use Every Automobile in the Country

There are today undoubtedly two operators for every licensed automobile in the country. This means there are some 40 millions driving automobiles. To examine and license these, even taking into consideration the large number of licensed operators in those states having license laws, is a colossal undertaking. The time which would be consumed must be considered. At best we can probably only hope to issue licenses to all those now operating automobiles without examinations, and trust to the powers of suspension and revocation to weed out those who should not have been licensed in the first place.

The expense in connection with such examinations and licenses is a controlling factor in winning or losing public approval. At the present time the rates charged vary from no fee and 50 cents for duplicate licenses in the state of California, to \$1 or a perpetual license in Oregon, and \$3 annually or a license and \$2 for each examination in the state

of Connecticut. West Virginia issued a license good until revoked for a fee of \$1. It has always been the contention of those most interested in this question that the motorist is now paying sufficient for the privilege of operating an automobile, and should not be taxed more than will cover the expenses involved in issuing the license. This plan has not been favorably looked upon by the state authorities. At any rate the lower these fees can be kept, the sooner the public may be won over to favor such laws.

In the enforcement of these laws lies the ability to restrict operating privileges only to those who should be so privileged. In the case of those proven careless, reckless or heedless of the responsibility of the task and unimpressed with the duty which rests upon their conduct, the state, through the proper authorities, should be empowered to suspend licenses, as a warning, and in the case of repeated misconduct, to revoke their licenses altogether. This phase of the subject has met with, and will always meet with, strong opposition because there are always individuals who insist upon doing as they please regardless of the other fellow's rights or privileges.

The Wolves in Sheep's Clothing Among Drivers

If a driver's license and examination law is to be worthy of the name of a "safety measure," enacted to protect pedestrians from automobilist, and automobilist from pedestrian, other automobilists and himself, there must be some method by which those "sheep in wolves' clothing" may be culled from the operators' fold.

There should be the power of suspension placed in the hands of competent authorities to punish those, otherwise capable, who carelessly commit minor violations of the law. In most instances a warning is sufficient for this class and for those who will not heed a warning the power of suspension is effective. After a suspension the license may be returned to the driver and he may be given another chance to prove himself worthy of having the same.

Statistics showing the number of suspensions and revocations during the year 1925 in those states having operators' license and examination laws are interesting, even astonishing, in that the numbers are so large.

Connecticut shows a total of 8,434; New York, 10,899; Pennsylvania, 2,571; Michigan, 1,819; Massachusetts, 16,249; and New Jersey and California, 2,886 and 444, respectively. California authorities state most violations of its laws takes place in cities where the civil authorities impose fines instead of revoking licenses.

Figures for the first six months of this year for these same states show a marked increase in the number of both suspensions and revocations.

An analysis of the reasons for these suspensions and revocations reveals that at least 75 per cent of them occurred for the four following reasons:

1. Driving while intoxicated.
2. Reckless driving.
3. Leaving scene of accident without revealing identity.
4. Speeding.

If this condition now prevails in those states where drivers are first selected and where the shadow of suspension and revocation always hovers over their heads, it must be more serious in the states having no such laws.

The thought is surely not consoling to those of us who take this matter seriously and are willing to forego a minimum of convenience to attain a maximum of safety, but it should prove conducive in bringing about, in so far as is humanly possible, the removal from our highways of the driver who now flagrantly violates not only our laws but the rules of common courtesy and decency as well.

Tests of Drivers Determine Liability to Accident

CHAIRMAN SMITH: We have in Mr. Fenner's paper specific evidence of the variety of laws which we have in the various states. I will now turn the meeting over for discussion. Has anyone anything to add?

E. C. HAZELTON (Federal Mutual Liability Insurance Co., Boston): I want to ask if you have had any experience with psychological tests on operators which might be helpful to the rest of us?

CHAIRMAN SMITH: Dr. Cattell, that is perhaps a question you can answer. The speaker wants to know whether you have used any psychological tests for the issuance of drivers' licenses.

DR. CATTELL: In the taxicab companies in Chicago, those who pass the tests are three times less liable to accident than those who do not. We hope to carry on the experiments, of course, and ultimately be able to make a really valid examination. At present it is only a statistical possibility.

MR. HAZELTON: If you develop it to the point where it is practical, what is the nature of the test?

DR. CATTELL: In our report to the Hoover Conference we recommended that we thought it was pretty difficult to test everybody for a license, but we thought that professional drivers, drivers of buses, public service drivers, etc., should be tested. We also thought those involved in accidents should be tested and that those who had special disabilities, such as the loss of an arm or a leg should have tests. We took these three groups and tested them. That was as much as we could possibly do at the time.

CHAIRMAN SMITH: I might say further that a number of taxicab companies in the United States have made some rather exhaustive tests with their own drivers which might in some respect go into the realm of psychology. Also Professor Moss of Washington has made some such tests.

DR. CATTELL: Also in Philadelphia and Pittsburgh.

C. E. ROBB (National Safety Council): I should like to call attention to the splendid record made in Massachusetts and Connecticut over the past four or five years. I know more about their records than some of the other states where there are license laws. Their death rate in the past year, 1926, as compared with the same months of 1925, has shown an actual reduction in the number of deaths. We attribute that largely to the efficient administration of the motor vehicle laws of those states.

CHAIRMAN SMITH: I have heard it said that one reason for our difficulty in controlling accidents is that with the great extension of credit facilities in this country it has enabled many people to drive automobiles who under ordinary circumstances might not be able to acquire one for some considerable period of time. I refer more especially to the foreigners who come to this country, who speak English very slightly, and who upon an investment of as low as \$25 can secure an automobile and start driving. I think perhaps that might interest you and be worthy of some discussion.

Also, on the question of whether drivers' licenses should be taken away, it has been said that in the case of speeding, in order to secure convictions, they would have to have specific speed limits and then arrest a man for exceeding those speed limits. A superintendent of police of New York state told me a year or two ago that his motor police did not have speedometers. What they arrested a man for was reckless driving. He said that his officers might not touch a man who went 40 or 45 miles an hour in the open country, while on the other hand several minutes later the police would pick up that man for driving 25 miles an hour past a schoolhouse at recess time. Perhaps some of you may want to discuss that side of the situation.

Peculiarities of South American Traffic

MR. FENNER: Since Mr. Smith has mentioned my trip to South America, I might make a few statements in that regard. I might explain that this was a trip of delegates to the first Pan-American Highway Congress in the Argentine. We started early in order that we might gain a little knowledge of some of the countries on the way to the Conference, so instead of going direct to Buenos Aires, we went down the west coast of South America. Actually, our first stop was in the Canal Zone and in the City of Panama, in the Republic of Panama. There we found a national law that vehicles must pass to the right. But as a matter of fact, there are so many vehicles, especially taxicabs and buses upon the streets of Panama that are driven by men who come over from Kingston, in the island of Jamaica, where the English pass to the left, that in Panama they actually pass to the left, although the law says they must pass to the right.

In Peru vehicles pass to the right. In Chile they pass to the left. In Argentine they also pass to the left. In Brazil they pass to the right. So we were very glad to drive as much as possible in hired cars with

native drivers and not try to figure out the regulations for ourselves. There seemed to be absolutely no limitations as to speed. Everyone drove as fast as he could, and drove to beat the other fellow at the intersection.

A peculiar thing I might mention is that in the cities many of the streets are paved with sheet asphalt. Much of this was laid at the height of the summer season, when the temperature runs very high. Cars passed over this soft green asphalt with tire chains on and left an imprint of the chain on the pavement, so that the authorities immediately secured ordinances in the cities prohibiting the use of tire chains. Most of the automobile drivers were hired chauffeurs. It is beneath the dignity of the average South American to drive his own machine. He doesn't get a car unless he can get a man to drive it for him. Since they couldn't use chains in the city, they argued what was the use of having them at all? Perhaps they could use them in the country but they would have to take them off when they got to the city limits, so they might as well not have them. So it got to the point where chains were rarely used. We happened to be down there in the rainy season, and half a dozen times we were stalled because there wasn't a single machine in the whole country that had a chain that would enable us to get up the hill.

How Will the Criminal Driver Be Prohibited From Driving?

MR. HAZELTON: I should like to ask if there has been any attempt in the other states, such as we have tried in Massachusetts, to ascertain how many unlicensed operators there are on the road. Mr. Goodwin, our registrar, estimates there are 25,000 such operators in Massachusetts. On two occasions, I believe, during the past year he has endeavored to line up every man who is driving a car simultaneously on one given day, with the assistance of the local police. Is that true in other states, and what measures have been taken to combat that situation?

MR. MITTENDORF: I want to ask one question that might probably be considered foolish or carrying this discussion to a point where it is unnecessary. But Mr. Fenner's paper has interested me. In framing a law which has as its outcome the revocation of licenses, I should like to know just how the framers of that law figure they will actually prohibit the driver of a car whose license has been revoked from driving? In other words, I have in mind the criminal driver; I have in mind the undesirable citizen. I have in mind the reckless driver, the drunken driver, the bootlegger, the law violator. Is the revocation of a license going to prohibit them from driving?

In brief, we have evidences today of people jumping into cars and running away with them—boy joyriders and all that sort of thing. They have no license to drive. How are we actually going to prohibit the criminal and the undesirable citizen from driving by simply revoking his license? If he is a law violator he is not going to hesitate on that account one moment.

CHAIRMAN SMITH: That is perfectly true. If the license is revoked in Cincinnati the culprit may try to take out a license under a different law or go across into Kentucky. So far as I know, it is purely a question of police follow-up and the infliction of an unusually severe penalty if the man is ever caught driving again. We know that of necessity there must be a thousand cases of licenses revoked in which the operators were caught driving again. I think possibly the representatives from New York state have had some experience on that. I am going to ask how they handle the situation there.

MR. POWELL: Of course, we come in contact with that every little while. When we catch anyone who violates that regulation, he gets a pretty severe penalty in consequence. In other words, we put him in jail.

The Attitude of the Farmer Toward the License

CHAIRMAN SMITH: I am interested in knowing whether any severe penalty is made if a man gives a false name originally when he takes out his license.

MR. POWELL: That is included as a misdemeanor.

CHAIRMAN SMITH: I can see where a culprit might go to different parts of New York state and take out a driver's license under four or five different names. It would seem to me that that is not an impossible situation at all. He could be like a cat with nine lives. He could lose several licenses and keep on driving. Again, I think it is a matter of police control.

MR. MITTENDORF: In Ohio he is subject to perjury. When he takes out his license he swears that he has given his proper name and residence and that all the facts he has given are true. If he is caught at this game he can be brought up for perjury.

CHAIRMAN SMITH: We will now proceed to the last part of the set program. The next paper is going to be upon the attitude of the farmer with respect to a farmers' license, which has been of considerable interest to the governing bodies and the Hoover Conference. In the eastern states, where there are many thousands in the congested district, the farmer's voice has not been quite so prominent as in the middle west and far west where the states are largely made up of farming communities. I know that some of our own clubs have reported in the middle west that it would be impossible to get a drivers' license law through because of the opposition of the farmers. Yet we know in the last two or three years that the feeling the farmers have against a drivers' license law seems to be abating. I feel safe in saying that farmers seem to be coming to an appreciation of the fact that a drivers' law is needed. I am not trying to seek a support for an argument of my own, but am giving facts as reported to us around the country. However, the matter of the farmers' viewpoint is naturally of great importance in a gathering of this kind.

When we decided to have a speaker on this subject, we asked for the next speaker, Mr. L. B. Palmer, president of the Ohio Farm Bureau Federation. I now take pleasure in presenting Mr. Palmer.

THE FARMERS' VIEWPOINT

L. B. Palmer, President, The Ohio Farm Bureau Federation, Columbus, O.

I realize fully the importance of the subject under discussion. All of us are so constituted that we think just a little bit more seriously about problems which deal directly with the saving of human life than we do about those which at times seem important but in which no actual saving of life or prevention of permanently crippling accidents is at stake.

At the same time, it is important that we do not allow sentiment to call us too far from the practical application of any suggestions we may make for the prevention of accidents through regulation of motor traffic or examination and selection of those who place themselves in its stream.

I well realize the almost impossible task placed upon me of giving you the farmers' viewpoint. Most of you are well acquainted with the fact that farmers as a group are not as well organized as other groups here represented. We have not had the opportunity of getting the expression from as many states as we desired.

It is to be regretted that the agricultural population has tended to remain, economically, socially and politically, a group apart and relatively unorganized in both its thought and active role in national life. Through the Farm Bureau units, township, county, state and national, we are endeavoring to unite the leaders in all lines of agricultural pursuits in one large organization through which we can get sentiment expressed and can better cooperate with other groups in the formation of legislation and other policies essential to progress and development of our national life.

Right here I would like to say that I have behind me no official action of the organization with which I am identified to support the things I have to say. While automobile traffic, road building and allied subjects have formed an important part of the discussion at many of our meetings, the particular subject assigned to me has never been discussed nor acted upon formally.

The opinions I am giving this afternoon have been secured largely through correspondence and contact. I am aided in this by having talked during the past month with a representative group of mid-western farm leaders at Chicago. This, with the special effort I have made to get in touch with farm leaders on this subject by mail, forms the basis of the ideas I am bringing to you.

May I first call your attention to the fact that the rapid industrial and commercial development of the United States during the past quarter of a century has tended to obscure somewhat the changes in the position of American agriculture, to divert public attention from its problems and to make their importance less clearly and generally understood?

I am glad today for this opportunity to represent agriculture. It has many times truly been called our basic industry. On the purchasing power of its products and the relation of its land values to values in other lines depends much of our national prosperity. Agriculture normally exerts a purchasing power of two billion dollars worth of goods and services annually. It purchases each year about one-tenth of the value of the products of our manufacturing industries. It supplies materials upon which depend industries giving employment to half our industrial workers. It pays indirectly about two and one-half billion dollars in wages to urban workers.

Agriculture supplies about one-eighth of the total tonnage of freight carried by our railroads with its products and much more in supplies carried out to its farming units. Its products constitute nearly half the value of our exports. It pays in taxes one-fifth of the total cost of Government. The capital invested in it in 1919 more than equaled that invested in our manufacturing industries, mines and railroads combined. It represents about one-fifth of our national wealth and normally contributes about one-sixth of the national income.

Thirty Per Cent of Total Population is Rural

The farm population forms about 30 per cent of our total population and constitutes a reservoir from which must be drawn a large part of our future citizenship. The standards of living and social welfare of this group can not but have an important effect upon the national quality of our people. The population of our cities is renewed every fourth generation from the farms of America.

I am just calling to your attention a few of these important facts in leading up to why the farmers' viewpoint is essential in considering the adoption of any license law. It will be more greatly affected than other groups since the percentage increase in transportation during the past two years has been greater in rural sections than it has been in cities. This is due largely to the fact that we are spending billions of dollars in the improvement of our main highways.

With the improvement of these trunk lines in our highway system new forms of transportation, such as busses and trucks, as well as the increased uses of privately owned automobiles, is greater in the rural sections than anywhere else.

Probably the most detailed and complete traffic survey ever made was recently completed in Ohio. It showed that only 12 per cent of the traffic on our state highway system was contributed by farmers. In any direct state tax levy those farmers would pay 28 per cent of the costs, and during the past we have paid nearly 60 per cent of the cost of building that system. So, in Ohio at least, you city automobile owners owe quite a bit to the farmers.

This bears out the point that while the large portion of the traffic comes from cities, the rural population is continuously endangered, not so much by its own traffic as by that of the traffic which comes from

cities. This traffic problem then is one in which our rural people are vitally interested.

Statistics show that on December 31, 1925, there were in the United States, 4,332,482 farm owned motors as compared with a total of 19,954,347. This includes trucks and pleasure vehicles. While this shows one-fifth owned in rural sections, the mileage traveled by these is not as great as that traveled by the other four-fifths.

The compulsory licensing of all members of the farmer's family who are eligible to drive would meet with objection on the part of our rural folks. I have asked the leaders in different states for an expression as to what they felt the viewpoint of the rural population would be as to the application of compulsory licensing of all drivers. While I have not heard from all states everyone that has replied has expressed this same viewpoint. At the same time all of these leaders have expressed themselves as desirous of cooperating in whatever traffic regulations and policies could be enacted to assure safety on our highways.

Many have said that compulsory insurance, which would carry proper liability, would be more preferable than compulsory licensing of drivers. This, they believe, would provide protection and financial assistance in case of accident, and if no one was allowed to drive on our highways except those who could obtain liability insurance, that would tend to relieve the danger of those who would not be permitted under a license law to obtain licenses.

More Children Are Driving Cars in the Country

It is true in rural sections that more children are drivers of automobiles than in the city, because they are active participants in farm operations at a younger age than the average child in the city. In driving cream trucks and delivery of produce to nearby towns, as well as in transporting themselves over rural roads to schools, it would be a decided disadvantage to eliminate children between the ages of 16 and 18, as is proposed in some license bills.

One survey of motor accidents showed the rate per thousand vehicles to be 2.06, due to faulty operation by driver. Of this percentage 1.43 was due to recklessness and carelessness, which would be controlled by licensing only to a very small degree. Only one one-hundredth of this 2.06 rate per thousand vehicles was due to children drivers.

Our rural folks also feel it essential to maintain a strong highway police system for patrol on roads. Several states already have such systems. Improvement of highways has thrown open the farming country not only to the professional criminal but to the property damaging trespasser.

But from the angle of public safety on the road our rural folks feel that a system of rural police furnishing proper patrol of the roads will add much to the safety of all drivers. Unless proper provisions are made for enforcement it would be of no advantage to have the drivers' license law, and farm folks put this need for policing ahead of that for licensing.

More could be done for the protection of automobile drivers and for public safety in general by enforcing present rules of the road than by adding another law without provision for enforcing it.

We are very much interested in the formation of our State Safety Councils, and feel that through this agency and with the cooperation of all groups, we will be able to work out satisfactory laws to safeguard the public. There are two purposes raised in the licensing program. One is for the purpose of regulation in the interest of public welfare, and courts have held quite generally that Legislatures have the right to impose reasonable restrictions upon those following out occupations or performing certain acts such as the driving of a vehicle upon public thoroughfares. This may be done as a safety measure. The other purpose is to raise revenue, and I feel that our rural folks would be opposed to this as a revenue raising measure. Of course, we recognize that in the administration of this department a certain fund must be provided to which no one would object if the overhead of the organization would not be too great.

Points of View as Gathered in Several Localities

In a reply from a president of one of the states, he reports the sentiment of the farmer representatives at a meeting held to discuss the question of the drivers' license law, that it seemed to be the general opinion that we should have a drivers' license law of some sort, but that it should provide for a nominal fee, if any, and that there should be no examination requirements for the issuance of the license. The main object of the drivers' license law would be to give police officials power to revoke the license of anyone who is extremely careless or in the habit of driving while intoxicated or otherwise incapacitated as a driver. He further stated that it was his opinion that the farmers would stand for a license law along those lines, and it will probably call for some stringent regulations in regard to railroad crossing signals, as it seems a large percentage of accidents occur at railroad crossings.

We received information from another state to the effect that they would oppose the licensing of drivers because many would contend that licensing of drivers would not make a poor driver a good one, nor an intoxicated driver sober. He emphasized the need for restricting the privilege of driving to exclude those who had physical or mental defects, and also the need of eliminating grade crossings and passing stringent laws which would protect folks from many accidents now occurring. He also expressed himself as feeling that a better system should be adopted before any of these measures could be properly enforced.

Another state representative makes this statement: "Whether the licensing of drivers has proven to be practical and helpful, I am not able to say. If, however, experience has demonstrated this to be a successful device I shall of course urge that this be favored. In short, I will say that whatever is practical in the increasing of safety on our public thoroughfares should be favored. I realize that there is some objection to

the licensing of drivers on the score of difficulty and experience of administration."

From another state this reply came: "I think we should be very careful in giving approval to licensing of auto drivers which would require each member of the farmer's family to take out a license. I think all reasonable precaution should be taken to safeguard the interests of the public, but it should not be a system that would work an undue hardship on the very class of people who are the most careful and considerate of drivers."

Farmers Usually Support the Public Interest

CHAIRMAN SMITH: I think we will all agree we have had a very frank expression of the farmers' viewpoint with respect to these various matters.

One of the things that has attracted my attention during the years I have been interested in automobile work is the fact that in the final analysis the farmers have nearly always voted upon motor vehicle matters in the way that is most to the public interest. You will recall many, many years ago the farmers were generally considered and actually were against good roads. They had the feeling that they were being taxed to permit the city people to speed past their territory. I don't suppose there is any part of the country now where you will find a very pronounced opposition from the average American farmer against good roads. There are instances in the far west in which there is opposition against good roads. It has come in some instances from sectional railroad interests. It has come in others, such as Montana, from the sheep and cattle men, so it is reported, who feel that tourists and road travelers are not wanted in that part of the country because they will interfere with the great domain over which they rule with their stocks.

Many years ago those same people went up against the movement of the American public to such an extent that they had to give up their great ranges and the land suitable only for grazing and divide it up into farms, upon which now live hundreds of thousands of contented people. I believe the opposition which the farmer has had to the drivers' license is gradually being stamped out, because the farmer is being educated, or, rather, he is educating himself to the necessity for certain safety measures. It seems to me from our experience that he is coming more to an acceptance of some measure of caution in the issuing of licenses generally.

Mr. Palmer, if I heard him right, came out in favor of compulsory insurance—which is another very interesting viewpoint to be presented. I should like to throw the meeting open for discussion. Has anyone anything to say?

HOWARD BROWN (Detroit): Mr. Palmer made some comment on connecting up the amount of compulsory insurance with an operators' license law. There has been a great deal of comment on this compulsory liabil-

ity, and I believe one state has enacted such a law, to go into effect January 1.

I think there is a great deal of bunk being spread around about compulsory liability insurance. I happen to represent an automobile insurance company, and we have found out that the man having such coverage isn't likely to be so careful as to whether or not he might bump another machine. He becomes a little irritated. He knows he is not going to pay the bill, and he may be a little more careless than he would otherwise be. If he doesn't endanger his life, he is taking the chance.

It depends upon what we want to accomplish by compulsory insurance. If we want to protect the public and make the public more safe and reduce the great accident toll that everybody is talking about, due to automobiles, then we have to take such measures as will tend to reduce the accident hazard. In other words, is our problem one of protecting the public or is it one of compensating the injured party? If we take the attitude of compensating the injured party, then we have to abide by all the rules of negligence as they may go into effect in the various states.

Contributory Negligence on the Part of Both Parties

My experience has been that in a great many cases with pedestrians and also the occupants of either car being injured, that there is contributory negligence or neglect on the part of both parties. Following that out logically, neither party can recover. Now, if we want to compensate the injured party, is it not the logical thing to carry an accident policy?

I carry an accident policy, also a liability policy, on my car. We have found out that in the state of Michigan every man, woman, and child could carry an accident policy for approximately \$1 a year or a little more. It would amount to about \$4,000,000 for the accident insurance companies. If you are going to compel every automobile driver to carry liability insurance, it will cost approximately \$20,000,000. We figured that out on the basis of the cars that are insured.

In other words, if a man has an accident and carries an accident policy, there is no question of negligence. It is a contract between him and the insurance company. If he is killed, the maximum amount of coverage is paid to his beneficiary. So I think that we are confusing the issue when we talk about compulsory liability insurance. We are not going to protect the public any more than we do now. If we want to compensate the public for injuries received, then let's attack the question on the other hand and require every man, woman, and child in the state to carry an accident policy. To my way of thinking it is a blame sight more logical if that is what we want to do.

MR. PALMER: In presenting that as I did, I tried to make clear the viewpoint of a lot of people, bringing out the need the way some people look at it. I would not for a moment want to be quoted as saying that compulsory insurance would take the place of licensing. I think that we ought to get back to the idea and arrive at an understanding of what

those things mean. The president of the automobile insurance company knows something of the record brought out. In connection with those who have made offenses in licensing, if the insurance companies would be more careful to whom they give insurance, I think there would be fewer accidents committed.

CHAIRMAN SMITH: Do insurance companies get reports from the state departments showing whose licenses have been taken away and showing those who have had accidents?

MR. PALMER: To a certain extent, yes. Do you think it has been the practice of insurance companies to refuse to renew policies to the average person who has had an accident?

MR. BROWN: Not in the past.

CHAIRMAN SMITH: The impression I had was that too many insurance companies will issue the policies anyway. I remember a safety man who was president of the Safety Council in his town and was also the general counsel of one of the large railroads in our region, who became exceedingly exorcised when he met an insurance friend and asked him to join in the movement, and the friend did not appear to be particularly interested. When the gentleman in question taxed him on his reluctance to join, the other responded, "It's a darn good thing we pay an accident policy once in awhile. It helps build our business."

A Misunderstanding of Compulsory Insurance

MR. PALMER: I should like to say that in a meeting in Chicago last week representatives of the midwestern states were discussing this question. I want to give their expression to you, and I want to say that the officials from Michigan, in which state you are having the license law, spoke favorably for it. The expression came from those other officials and some of those which I quoted saying that they wanted to give that as an expression, that they wanted to get in on the program in an educational, constructive way and to carry it back to the membership, that is, to bring out the thing that needs to be emphasized.

CHAIRMAN SMITH: Would you agree that it is vitally important to present to the farmers both sides of the compulsory insurance matter? Don't you think there has been some misunderstanding as to what is to be accomplished by a compulsory insurance provision?

MR. PALMER: I think there is a complete lack of understanding.

CHAIRMAN SMITH: For instance, I believe there is a failure to understand the difference between compensation and liability insurance. As Mr. Brown said, you can provide your own insurance accident policy for approximately \$1, but an accident policy against the other man will cost approximately \$20.

MR. BROWN: Mr. Chairman, I think that would be determined considerably according to what territory you live in.

MR. FENNER: Have you seen the schedule of rates to be enacted in Massachusetts on the first of January?

CHAIRMAN SMITH: Yes, that is one reason I live in the District of Columbia.

J. M. CLANCOY (St. Paul): I should like to ask if any of the states that have compulsory insurance as one of their features of a licensing law would give us some information on that?

CHAIRMAN SMITH: There is only one state in the country that has that provision, and that is Massachusetts. There it has not yet gone into effect.

MR. CLANCOY: I should like to ask if they have done anything regarding the fixing of the insurance rates?

CHAIRMAN SMITH: State insurance is not involved. My understanding is that the commissioners have power to reduce rates over the states, and have announced that the rates of the insurance companies will be approximately 16 per cent less than before. It remains to be seen whether a state insurance commissioner has that power.

MR. FENNER: That schedule is merely a guess and will be revised at the end of a year's experience.

Compensation Insurance Quite a Different Matter

MR. HAZELTON: I am from Massachusetts, and I am not here to defend the insurance law. In fact, I have some doubt as to the working out of the scheme. But in principle it seems to me it is something we have got to come to. It is on the same principle as the workmen's compensation act, that a man who is injured has the right and may fairly expect to be compensated by the man who causes his injury. The same doubts and very much the same arguments were used at the inception of the workmen's compensation act, and yet that act has spread until now I think it covers all but three or four states.

I think that the same thing is going to take place with regard to compulsory insurance. Our Massachusetts law is far from perfect. I haven't seen anybody who claims it is perfect. My particular company thinks so much of it that we are a little hesitant about accepting new business. We want to see how it works out. But I do believe that most of us feel we are working along the right line, that if I am a poor fellow walking along the road and am struck by an irresponsible driver I should certainly expect him to provide some property or some money with which to pay my doctor bill and hospital bills; just as if I am working in an industry and am injured, I may fairly expect my employer to compensate me. I should like Mr. Brown's opinion in that regard.

MR. BROWN: There isn't any comparison, because in the workmen's compensation act, I believe, in most states the matter is taken care of by the fact that the workman employed in a certain factory if injured is paid on a certain schedule of payments which the statute gives. For instance, so much is given for the loss of an arm, so much for the loss of a hand, and so much for the loss of an eye—according to the injury.

You have removed entirely the question of negligence. If you are going to create a state fund and have every injured party paid when he is

injured, then you are going to have an entirely different compulsory insurance law than is advocated at the present time. I have tried to follow this question as closely as possible to see if there has been such a law advocated any place. In other words, what you are going to do is to put the thing on an accident policy basis, the same as your accident policies are written. You are going to pay a man when he is injured. How he was injured or who was at fault is not a pertinent question. The mere fact he was injured and what was his injury are the issues at stake. But I do not think that the advocates of the compulsory insurance law are recommending any such measure as that.

MR. WHEELER: It seems to me as though we are getting away a little bit from the question. The drivers' license law, to my mind, is the one thing we are almost unanimously in favor of. If we tie up the drivers' license law with the compulsory insurance law, we are likely to lose both. Wouldn't it be sound sense to go straight ahead with the drivers' license law and then take a little more time and consideration on the other issue until Massachusetts really works it out?

CHAIRMAN SMITH: I think Mr. Wheeler's statements are really very pertinent. We are not here to discuss compulsory insurance. Your chairman brought that in himself and is somewhat responsible for it, because the matter is being discussed all over the country and I thought that no harm would be done in discussing it, particularly when Mr. Palmer brought it forward.

It shows that people are thinking of two things.

The Junior Patrol an Adjunct of the Police Department

Mr. Palmer also brought up another matter which you might say was not strictly on the program, and that was the matter of additional police protection. He pointed out the necessity for it. It immediately recalled to my mind the fact that in many parts of the country the police forces are being supplemented by school boy patrols. The National Safety Council in various parts of the country is setting up most valuable aids in this way. In that connection, I recall some figures which I got just yesterday in Detroit and which might interest you. The Detroit Automobile Club has many thousands of boys, I think approximately 20,000, in the schools who are protected by school boy patrol. Wherever that patrol has existed, there were only two children injured during the time that school boy patrol has been in effect.

You spoke particularly about the farm distribution and the highways outside of the cities. I understand that every country school has a junior state policeman on the buses where they are driving buses and collecting for schools and that those boys who are going to the schools will constitute the junior police force, ride these busses, and will not permit the bus to cross the railroad tracks without getting out and going ahead.

I also ascertained that in one Detroit school where one child was killed

and seven injured in three months' time, the school boy patrol was established and 15 boys were made that particular patrol. No accident ensued for 13 school months thereafter.

In Watervliet in southern Michigan I discovered two accidents occurred at one school. The ministers of the community asked that the school-boy patrol be instituted, and since March, 1925, which was the date of the inception there have been no accidents whatever in that school.

ADJOURNMENT.

Police and City Officials' Session

October 28, 1926

**MORGAN A. COLLINS, Chairman
Superintendent of Police, Chicago, Ill.**

The meeting of the Police and City Officials' Session of the Public Safety Section convened at 10:00 o'clock in the Large Banquet Hall, Statler Hotel, Detroit, Michigan, Mr. Morgan A. Collins, Superintendent of Police, Chicago, Illinois, presiding.

CHAIRMAN COLLINS: It is well that we understand just what is meant by the term Safety Council, or rather Community Safety Council. It is the getting together of the local civic organizations, public utilities, schools, trade organizations, and others interested in good government, that they may stand at the back of the constituted authorities. The Safety Council must be understood as an educational project in safety.

There is a growing interest in traffic accidents as a municipal and community problem, one that city officials and all good citizens must get together on. A meeting of this kind was held last year for the first time, with a large and representative attendance.

Accidents are so numerous, especially in highly congested sections, that next to the prevention of accidents and the means to prevent them comes the necessity of properly tabulating accidents when they occur.

In the City of Chicago, through the aid of the National Safety Council, we have recently adopted what we believe is the most complete form of tabulating accidents that has ever been gotten together anywhere in the United States. I don't know that Chicago was the first place to adopt this form, but I understand that many other communities have adopted it. We are able to show from day to day just how many accidents occurred, where they occurred, why they occurred; and from this analysis we are able to learn the things that we should know in order to adopt means to prevent accidents.

The part that the courts play in traffic violations is so important that unless they function 100 per cent, the other law-enforcing agencies, such as the police force, highway commissioners, etc., have their work nullified; and later on we will discuss in open meeting the relation of the courts to motor vehicle accidents.

In order that we have uniform ordinances in all of our cities which suffer from congestion of their thoroughfares, the Hoover Conference, a national organization called together at the instigation of the Secretary of Commerce, Herbert Hoover, turned out what is known as a model motor vehicle act, one that we are going to ask every state in the Union to adopt.

In Chicago the Association of Commerce spent \$50,000 in making a survey of our rules and traffic conditions, and that survey was based upon the recommendations of the Hoover Conference.

I understand that this model motor vehicle act is now ready, copies of it are now ready for distribution, and it is an excellent guide for us to follow in our efforts to make uniform city ordinances, in regulating the movement of vehicles on our city streets. We will also discuss speed limits and enforcement.

At the different gatherings that I have attended I have always introduced the subject that if we are to prevent accidents, we must curb speed. Experiments have shown that speed is the prime factor in at least three-fourths of all accidents. If the operator of the machine were able to control his vehicle when the occasion for the accident opens in front of him, there would be no accident. The motor vehicle operator is the first to discover that an accident is imminent. The momentum of his machine is so great he is unable to stop, and the result is that accidents happen, serious accidents happen.

We will do the best we can at this meeting to devise some way of controlling the speed of motor vehicles, especially in congested sections. That is, we will do the best we can in making recommendations and in adopting resolutions relative to that point.

We will hear first from Superintendent of Police William F. O'Neil of Providence, Rhode Island.

A PRACTICAL SYSTEM FOR REPORTING AND TABULATING ACCIDENTS

William F. O'Neil, Superintendent of Police, Providence, R. I.

We have listened to many an interesting and instructive talk on the relation of the police department to community safety councils. My remarks will point out perhaps a little more in detail one phase of cooperation between our organizations in Providence which has proved especially helpful to all concerned.

I like the phraseology of the subject assigned to me because I believe that the method which we now use is a practical one for any police department. In order that I may properly present the feeling of our department in regard to automobile accident statistics, I should like to sketch briefly the history of our experience, in hope that it may be helpful to those of you who have not as yet undertaken any standard method of classifying your traffic accidents.

One of the first steps taken by the Providence Safety Council, in the fall of 1923, was to extract periodically from our police blotters informa-

tion regarding automobile accidents. The amount of detail that was available on any one accident case varied decidedly with type of patrolman who made the original report. This meant that the facts which could be summarized from such a digest of our reports were extremely meagre. They did, however, serve to give us an idea of the size of our problem in the prevention of traffic accidents.

In the summer of 1925 our safety council officials called to our attention the standard reporting system advocated by the Statistics Committee of the National Safety Council. We believed, after study of the system, that it could be applied to our situation, and with the assistance of the safety council developed a report form for our local use which embodied all of the essential elements of the card suggested by the National Safety Council. Our reporting system was put into effect on September 1, 1925, and each month finds it working more smoothly and more effectively.

Statistics Are Useless Unless They Promote Action

And now that we have them, what do we do with them? Statistics whether they relate to accidents or what not are useless unless analyzed and action taken to correct the conditions found.

Each month the information from the several hundred reports received is summarized on the report form provided by the National Safety Council. The facts developed by these summaries form the background for the preventive work being carried on by both the Providence Safety Council and our own department. Knowledge of facts lends a business-like aspect to this work of accident prevention that commends it to the citizens of any locality. For example, we *know* that during the first nine months of 1926 we have had a 33.4 per cent reduction in the total number of accidents, a 20.3 per cent reduction in personal injuries and a 46.5 per cent reduction in fatal cases as compared with the same period last year. We do not have to *guess* at it.

As a basis for our constructive work we know that 68 per cent of all automobile injuries in Providence involve pedestrians—that 57.5 per cent of these pedestrian injuries are sustained by adults and that 67 per cent of all pedestrian injuries occur between intersections. I could cite you endless figures which would at once appeal to you as being necessary for a proper understanding of the public accident situation in which we are all so much interested.

So much for the general use of the statistics made possible through our reporting system. We have another specific use for these statistics which, to our minds, is as important as the general application I have just outlined to you. I refer to our spot maps.

I do not believe that there is anything which presents a more striking picture of the automobile accident problem than a well-prepared spot map. We have standardized on our spot maps after a series of experiments as to just what procedure would best suit our requirements. At the present time the following maps are prepared:

- 1st: A monthly map of the entire city showing—
 - A. The number of property damage accidents.
 - B. The number of personal injury accidents.
 - C. The number of fatal accidents.
- 2nd: An enlarged monthly map of the congested area showing the same information as the city map.
- 3rd: A yearly map of the city (size 4 by 5 feet) which shows the following:
 - A. Child pedestrians killed.
 - B. Adult pedestrians killed.
 - C. Riders killed.
 - D. Child pedestrians injured.
 - E. Adult pedestrians injured.
 - F. Riders injured.
 - G. Considerable property damage accidents.

We have studied the several requirements of a good spot map, such as type, the size and color of pin, etc., keeping in mind the difficulty in the photographing of spot maps for permanent records.

Making Good Use of the Spot Map

Now as to the use of these spot maps. Each month as the maps are prepared they are analyzed to determine the trend of our accident experience and to locate any sore spots which may be appearing in new locations. When we find that the accidents in any particular location are increasing, a study is made of the situation. We can readily tell from our permanent spot maps the number and type of accidents that have occurred at any particular location. If we want to supplement that information by further detail, for example to determine whether or not there is a similarity in the causes of accidents at any particular location, we have but to go back to the original records. In order that the records for any particular location be readily available we have adopted the system of filing these cases by arterial streets. For this purpose we have selected 38 streets which cover 90 percent of the important intersections in the city. The records are then filed by street number for these arteries, making reference almost instantaneous.

Let me cite you one specific instance which illustrates the purpose to which the spot maps may be put. When the spot map covering the experience for the year 1925 was completed the Traffic Committee of the Providence Safety Council found from study of it that accidents on our traffic arteries and in our outlying sections were increasing in the face of a splendid decrease in our congested area. After considerable study it was concluded that additional motor patrol was necessary on these arteries. Six weeks after the Traffic Committee recommended the change the men were on the job and the condition has been much improved. Without statistics and our spot maps with which to back up the request of the Board of Police Commissioners to our City Council, I doubt if the men would have been forthcoming—certainly the action would have been delayed.

I do not want you gentlemen to misunderstand me. The introduction of our present system was not without certain discouraging incidents; but in the months that have passed our card has graduated from the status of a bugbear to that of a piece of real equipment. At first, the policemen, with pudgy fingers, mostly thumbs, looked upon this accident card as "Another piece of imposition", another burden without apparent necessity for its existence.

You must bear in mind that our subordinates were men of varying educational capacities. Some had no schooling, some had primary school training, some had been through grammar grades and a few had been through high schools. They were not clerically inclined: that is one reason why they went into police service. We had men who were in service when there were no automobiles; a great many more entered police work when there were fewer than 15,000 cars registered in the state of Rhode Island. Our younger men have come into the department since the total in the state of Rhode Island has mounted to more than 100,000.

All this, in the smallest state in the Union, where your after-supper-ride may take you clear around the entire state. We have come to believe that 50,000 to 75,000 cars daily pass in and through the jurisdiction of our police department. This volume of machines, repeatedly nudging each other, has brought to the department a vast amount of clerical work, with which we have no adequate force of trained men to deal.

Our department records suffered continually. The information which our own city solicitors or our captains and lieutenants needed in the preparation of evidence seemed, repeatedly, to be sadly lacking. It brought embarrassment to us as much as to outsiders. Patrolmen, on the scenes of accidents, without knowing what to watch for, failed to observe crucial facts and, neglecting to record them, showed faulty memories on the witness stand.

Endorses Card Reporting System of the Council

We have found in our card just the thing we wanted. It showed the men on posts, the sergeants, and even lieutenants and captains a catalogue of things to be observed. Men with a stock of cards in their pockets came to learn that they were handy, even handier than note books. After they came to memorize the questions, which happened soon after they were "caught" without cards once or twice, they were inclined to look upon the procedure more favorably. It has given us a basis for instruction in our police school which has proved of incalculable value and we have applied the same principle to reports on stolen cars. Our men do not now say that they forgot to look for this or that. We have the information. It is fixed on the card and in the police witness' memory.

I can heartily endorse the accident reporting system advocated by the National Safety Council. I can go even farther; I can say that its instal-

lation in our department has reached the same heights of satisfaction that have all of our dealings with the Providence Safety Council, with whom we work in perfect harmony.

CHAIRMAN COLLINS: You have heard a splendid paper by Chief O'Neil of Providence on the tabulation of accidents. Its many good points should be well dwelled upon by delegates in attendance.

I would like to ask Mr. Robb to take one of the accident reporting cards and go over it, dwelling upon each question asked by the reporting card, what it means, and explaining how, after the information is compiled, it is tabulated in the general office and our report of the accidents made at the conclusion of each month.

Detailed Description of Accident Reporting Card

C. E. ROBB (National Safety Council, Chicago): The Standard Accident Report System is composed of three forms. First, the accident report card, which is filled out by the patrolman, either at the scene of the accident or immediately following the accident; second, the accident tally sheet upon which is tallied the information obtained by the patrolman on his report card; and third, a summary or monthly report form giving all the details of all accidents which have occurred during the month.

The Accident Report Card was designed to give all the important information concerning any accident in logical form with the minimum of writing required. Provisions have been made for reporting, by means of check marks, as much information as possible.

The accompanying illustrations (Figures I and II) show the front and reverse sides of the accident report card. The first two lines give the date and location of accident. The next section "Vehicle 1" gives essential information concerning the vehicle, owner and driver of car involved in the accident. Provisions are made to check mark the classification into which the accident falls as "Pedestrian," "Motor Vehicle with Motor Vehicle," "Motor Vehicle with Railroad Train," etc. The next section "Vehicle 2" provides for the information concerning Vehicle 2. In this section may be entered the information concerning the railroad train, street car, horse vehicle or whatever other vehicle was involved.

Spaces for names, addresses and other information concerning the injured persons and the witnesses are also provided on the front side of the card.

The reverse side of the card is given over exclusively to description of the accident. By selecting the proper items for check marking, the accident may be quite accurately described. However, in some cases it is necessary to supplement the check marks with further data. Additional lines have been provided for further details.

The arrangement of the items on the tally sheet (the large form) simplifies the combining of information obtained on the report cards.

FIGURE 1

Vehicular Accident Report		Date.....	At.....	At.....	A. M. P. M.
No.	Reg. No.	Owned by.....	At.....	At.....	
Vehicle 1	Driven by..... Operator's License No.....	Age..... Sex..... Experience.....	Direction Yrs. of Travel.....		
Did Accident Involve: Pedestrian..... ☐ Railroad Train..... ☐ Bicycle..... ☐ Other Vehicle..... ☐ Non-Collision..... ☐ (Check X which) Automobile..... ☐ Street Car..... ☐ HorseDwn.Veh..... ☐ Fired Object..... ☐ (Describe Under Rem.)					
IF ANOTHER VEHICLE WAS INVOLVED, GIVE FOLLOWING INFORMATION FOR VEHICLE 2:					
Vehicle 2	Driven by..... Operator's License No.....	Age..... Sex..... Experience.....	Direction Yrs. of Travel.....		
Names and Addresses of Persons Injured or Killed					
1.					
2.					
3.					
Injured Were Taken To.....					
Names and Addresses of Witnesses				Age	Phone No.
1.					
2.					
3.					

At the end of the month, the tally marks in each space are counted and placed in the corresponding space on the monthly report form.

It is intended that one copy of this monthly report form shall be sent to the National Safety Council for inclusion in their combined monthly report showing the experience of all cities reporting.

National Safety Council, 1927

Because of certain local conditions, ideas and wishes, certain changes have been made by some cities in drawing up forms for use of their local police departments; but the information on these cards is practically identical with this standard form.

The logical method of filing criminal records seems to be by serial

number. Finger prints, photographs, and other features of information concerning criminals may be most efficiently handled by serially filing. However, for best results accident reports must be studied to determine what conditions exist at particular locations that the appropriate remedies may be applied. In order to obtain quickly and easily the information concerning conditions at any particular location, it has been found that filing accident reports by location produces the best results.

Much of the success of the Grand Rapids and Providence Police Departments is due to their studies of accidents at particular locations. The best picture of the conditions existing at any location can be obtained from a study of the original reports of the accidents which have occurred there. Filing of the original reports by location makes such studies possible.

Getting as Complete a Picture as Possible

CHAIRMAN COLLINS: In compiling this information we had in mind getting as complete a picture of what happened when the accident occurred as is humanly possible to get. In many instances these reports point out exactly who is to blame and give the law-enforcing authorities an opportunity to correct the things that bring about accidents of that kind.

ALEXANDER K. GAGE (Assistant Prosecuting Attorney, Detroit, Mich.): Mr. Chairman, I would like to ask two questions: first, whether every patrolman, every man on duty on the streets, is given a package of these cards; and, second, what instructions are given to him in the use of those cards in case an accident occurs?

WM. H. KILLEEN (Captain of Police, Chicago, Ill.): The officers in Chicago are furnished with loose-leaf books. These take care of any sort of reports the men are required to write. In the accident form of the loose-leaf book we have the same information we use on our accident form that comes from the district headquarters. All the classifications are there. The officer turns his form over and makes his check mark. On the front of the book there is a sheet of instructions explaining to him the use of every form on that book.

If an officer appears on the scene of an accident, all he has to do is fill in the same form as this form here, only in smaller size, turning the page over and making his check marks under the classification. He turns that in to the desk lieutenant, who from that information makes out this form in triplicate.

The original and duplicate come to my office and the triplicate copy is kept by the district station for their records. When we get it we can tabulate it in the card system and run it through the tabulating machines and make our own analysis.

From our analysis we make these charts and graphs and it gives a picture of what transpires during a certain period. The ordinary report has a lot of figures and is dry reading, so we put our analysis in the chart form, by monthly periods, three and six-month periods.

CHAIRMAN COLLINS: As the Captain explained, on the inside cover of

the loose-leaf volume are printed full instructions relative to every form in that binder. That binder contains arrest notifications, accident reports, and other violation reports. We have five reports in that loose-leaf volume. That serves the purpose of getting them all in the one book so the officer has only that one book to carry and can report any of five different things; in fact, everything he comes in contact with during the day can be reported from that loose-leaf volume.

The Private Citizen Might Help a Great Deal

MR. GAGE: I take it from that there is no specific instruction from the officers in reference to his duty in case of accident other than the instructions given in the book. No training is accorded the average patrolman, for instance, in connection with this information?

CHAIRMAN COLLINS: Of course, this training occurs from day to day.

MR. GAGE: It seems to me a great deal of the difficulty we encounter in the matter of law-enforcing comes from the fact of inadequacy of the initial investigation. It is the patrolman on the beat, and the man in the street, who fail to give us the information that makes it possible to carry through the proper enforcement of the law, and which these cards represent to the patrolman and the man on the street.

If every citizen carried a pack of cards in his pocket and felt the duty resting upon him to give this information, we would soon have the information we want; but without that information, the enforcement officers really are at a loss for the necessary evidence.

CHAIRMAN COLLINS: I clearly understand you now. Of course, when an accident occurs there is no previous announcement, and they just happen. Then, of course, everyone who witnessed the accident or who is around the locality in which the accident occurs is interested and will give as best he can his version.

Now then, in order that no detail be overlooked, we have compiled these cards that embrace every conceivable question that can be asked of the person from whom we seek information. You must bear in mind that the police officer seldom witnesses the accident. He comes upon the scene after the accident has happened, and the picture he draws on this card is the picture from the person who witnessed it.

It is true that we don't get as useful information as we should, but we never will be able to do that, because if we knew an accident was going to happen, it wouldn't happen.

MR. GAGE: May I ask the Commissioner of Rhode Island to answer my question, as to whether or not each man carries cards?

MR. O'NEIL: I will say that every patrolman has what we call his own memorandum, and in that memorandum book he has one of these cards, and when he comes upon an accident, he checks up from the people around him on this card, and he also makes out a report that comes to headquarters. They also put it upon what we call a record-book in the station. He takes this card and makes out his report, a regular report, and turns it in to his superior, which is checked up by the clerk in the station

from his original card. There are three cards, one retained in the precinct where the accident happened, one on file in headquarters, and another sent to the Providence Safety Council.

H. P. COFFIN (Safety Council, Portland, Oregon): In addition to these reports we have a blank form of street intersection attached to the report, so the investigator or the policeman that arrives on the scene can fill out at that intersection just how that accident occurred, the position of the car, machine or street car, and the distance from the point of contact. We find in studying the problem that that is of great assistance to us, so we have a double form instead of a single form.

T. B. WILLIAMS (New York): Having just come from the direction of an extensive traffic survey in Providence, the information the Chief has given is of particular interest to me. One of the things was the fact that it was used in the study of traffic systems which lead finally to the recommendation of a \$40,000,000 program.

These charts were analyzed by sections. You see what the cause of the accident was, why sustained, whether there was too much traffic, whether it was a case of intersection being blinded or whatever the cause. The basis thereby laid was used as a design for devising the system.

Suggestions in the Training of Police Officials

I would like to submit two suggestions in reference to such maps as that and the training of the police officials in making observations. Most communities which have had some experience start on a given date, wipe off all the lines, and build up from month to month thereafter. It makes a complete study from the time things are entirely wiped off throughout the year. The suggestion is that only those things be removed which correspond with the date and periods. For example, if you are tabulating day by day, if you find an accident on the 17th of October, remove those of last year according to your records of the previous 17th of October. If you are tabulating the whole month of October, remove those of the previous October and you will have a complete record of all accidents for 12 months.

Having been called in on several occasions to analyze photographs of accidents, it occurred to me that the training given in the police schools should be carried out in a movie, or large photographs of an accident should be shown. Certain individuals would be trained to answer questions, representing the driver, the person who is involved in an accident, and each member of the school actually would make an examination of the picture and question these witnesses.

MR. GAGE: At the end of last year I had some experience with the Police Department in the city of New York. We didn't use the same type of cards as distributed here, although we did have a card of similar characteristics, but not containing so much detailed information.

We issued a general notice to all precincts, outlining some 15 or 20 specific accident headings that had been developed through our analysis

of accident records for the previous year, and patrolmen were instructed specifically to see that every accident they investigated included in the report full information as to whether any of these specific causes contributed to this particular accident.

We then felt that, although these men under Police Department regulations would receive these instructions and do the best they could to compile them, yet they would perhaps be more efficient in making out the reports if they would be better sold on the idea that was back of getting the information, and if we would call them together and explain more in detail.

Education of the Police Officer in New York

So the Police Commissioner of New York arranged for a number of large mass meetings, where they were called together in groups of 800 or 900. At these meetings I was present and explained in detail that the reason back of the idea of obtaining all this detailed information was to conduct a campaign of safety investigation along scientific lines, in order that we might acquaint the children from the school and drivers of automobiles and pedestrians as to the things they were doing to contribute to accidents. I think that educated the patrolmen in getting this detailed information, because we found that immediately accident reports began to come in in a much more intelligent way than before.

Now on the question of spot maps, we found it very advantageous to draw red boundary lines on the maps that would indicate the boundaries of the school districts, and from these maps the monthly report was sent to the principal of each school, showing the number of accidents actually occurring within the school district month by month, and frequent delegations were sent to the police headquarters from various schools to study these spot maps, and we got a great deal of valuable assistance from the school and a great deal of benefit by indicating the location by school districts.

CHAIRMAN COLLINS: The principal information that the gentleman from Detroit was seeking was what information or what instruction we gave to the members of the police department in relation to the collection of this information.

I must explain that police officers in Chicago are given a 30-day intensive, instructive course in the things that they should know when they are to become regular police patrolmen. They are taught the laws and ordinances coming within police jurisdiction, the rules and regulations of the police department, and laws and ordinances relative to traffic. They are taught military maneuvers; they are taught how to handle their revolvers; they are given instruction in honesty, sobriety and obedience, and that they are to apply themselves strictly to their business.

Whenever we make a change in tabulating forms, that change is forwarded to the members of the department in a letter of instruction. This letter contains everything that we can think of that the police officers should know in relation to the new form. When this card was adopted,

that letter of instruction was given out to the members of the police department at least two weeks before the card was introduced.

I want to say that for nine years I was a desk sergeant. (We call that position desk lieutenant now.) It was the duty of the sergeant to take reports of accidents from the patrolmen or sergeants that were out on the street doing duty. You would be surprised to learn the degree of efficiency that the police officers obtain in the collection of evidence, in the collection of information.

The training of a patrolman or sergeant or other member of the department in the collection of information relative to an accident is one that must come upon him gradually. You could not take a desk book and say, "Now here are all the things that you should know," and have him read them. After he finished he would go out and do the thing his own way anyhow. So the training can only be drilled into him day by day, and as each new accident happens he learns something new, so that police officers, as a matter of fact, are especially well trained to gather this evidence.

True, reports do not show exactly what happened. They seldom do, because nobody knew what was going to happen, and nobody analyzed it right on the spot with a clear mind. I am free to say that many of the things that are reported as the cause of an accident might be a contributing factor, but the real reason behind it all is speed. When a man operating a machine is unfortunate enough to have an accident, and is asked how fast he was going, he says, "Fifteen or 18 miles an hour."

Nobody Ever Drives Faster Than 18 Miles An Hour—?

A newspaper man from New York City was sitting in one time at a coroner's inquest in Chicago and the deputy coroner took him to two or three other inquests where fatality occurred by a motor vehicle. At the conclusion of his day's investigation, he asked the deputy coroner, "What kind of a machine do they use in Chicago?"

He said, "They use all kinds of motor vehicles."

The newspaper man said, "They must be different from those they use everywhere else. In the three or four cases reported here today not one of the motor vehicle operators would acknowledge going faster than 18 miles an hour."

As a matter of fact, if one measured the speed of that automobile, he would find that it was decidedly in excess of 18 miles an hour.

So those are the things we have to contend with in the gathering of information. I am frank to admit the information is not complete. The true picture is not painted. But it is the best we can get under the circumstances, and if that is the best we can get, that is all we can expect.

MR. GAGE: Mr. Chairman, at the risk of wearying the delegates present, I want to be quite plain on the proposition that I am not making any inference in reference to neglect in the preparation of this matter. I realize, as you have stated, that the whole proposition is a flash-back of memory, but I realize also that special training is necessary in the gathering of this kind of evidence.

There is no one in this room who has a higher regard for the capacity and ability of the police officer in the collection of evidence in other classes of matter, cases that are brought into the law-enforcing officers, than I. I yield to no one in my estimation of their capacity and ability in that particular, but here is a particular class of evidence that requires special training, it seems to me, to gather it, because nobody is prepared to know that the accident is going to happen. There is no preparation for it, and from a very limited study of this problem, I have come to the conclusion that the great difficulty in the proper enforcement of these regulations is due to the inadequacy of initial investigation, and we must, it seems to me, face that problem. There must be devised some means by which that situation can be met, and this conference is for the purpose of bringing out some idea, some method by which that situation may be met.

Methods Employed in the City of Cleveland.

I have raised the question here at this time, because it seemed to me that the Commissioner might answer it so we could perhaps get some constructive suggestion as to how this initial investigation might be carried out.

I had the great pleasure not long ago of going to the city of Cleveland. I don't know whether there is anyone here representing the department down there, but they have a most excellent method of supplementary and almost instantaneous investigation. Besides the necessary help available to take the injured party to the hospital and bring the party involved to headquarters for questioning, they immediately send out to the scene of the accident a man who is trained especially for that kind of work, who asks these questions in reference to speed. If there is any evidence available, he finds it out and brings in a report. The driver says he was driving 15 or 18 miles an hour, and here are two witnesses who say where and how fast he was going. They have that evidence and they can use it without delay. They get the measurements which afterwards become obliterated. They are there within a few minutes after the accident and find out what the facts are, and those facts are presented to the law-enforcing officers, and something can be done.

Then if the law-enforcing officers fail in their duty, it is easy to put the responsibility where it belongs. It seems to me some definite suggestion might come which would help us all in getting the facts of this situation, because on account of the manner in which it takes place, it is very difficult to get at the truth, and that is what we want.

CHAIRMAN COLLINS: I want to say that I have attended court in many instances where someone was being sued for damages, and if there was anything left uncovered by either side, it was something that I couldn't see could be covered.

As a matter of fact, immediately upon an accident happening, in our city at least, we go right to the bottom and try to get all the information we possibly can.

In answer to the question, "What is the cause of accidents?" a well-

known damage attorney in Chicago, who probably handles 75 per cent of the cases, stated to me, "In 75 per cent of the cases I handle, speed is the cause."

MR. O'NEIL: I would like to answer this gentleman. He says the law-enforcing officers should have the full amount of information to choose from.

You know and I know that when an accident happens it is always confusing on the highway. There is always a different story to tell. That confusion makes a thorough investigation difficult. If the parties were taken to the station the same as in crime, we would have a better investigation.

We have a little city in population but large in area. Sometimes accidents happen when there isn't anybody around, so we have followed this simple plan: Every time there is an accident we send two of our plain-clothes men out, and they get information.

MR. COFFIN: We have trained investigators out in Portland. The minute we have a call that there is a bad accident where a person is injured, this investigator is sent out, but in going over the records for the last two or three years, we do not find that speed enters into it.

Eight per cent of the accidents are caused by speed, but it is the reckless driver. Eight miles an hour in one section might be speed, or it might be 12 miles an hour or 15, and out in the outskirts a man might drive 30 miles in safety, although he may be violating a law. We find that most of our accidents are due to carelessness, not to speed.

UNIFORM CITY ORDINANCES AND REGULATIONS

H. O. Rounds, Supervisor, Bureau of Public Safety, Police Department,
Detroit

The reports from available sources show that 77,000 citizens were killed in traffic accidents in five years. What are the causes of these terrible accidents? Well, Mr. Robb, statistician of the National Safety Council, made an analysis of the accidents reported from 71 cities with a population of over 32,000,000, and he gives us the following result.

The first and chief cause of accidents is, taking the right of way from the other fellow.

Second. Failure to give signal of intent to stop or turn.

Fourth. Cutting in ahead—not waiting until well past the other car before turning, and so driving him into the curb or ditch or into parked cars.

Of course, we could say all these are just a lack of courtesy; but if I did you would not know what I mean, for "Courtesy" is a word that has been dropped from the vocabulary of the average driver.

The third cause of accidents is exceeding the speed limit.

As I understand it, this does not necessarily mean driving 50 or 60 miles per hour. In fact, when driving on a country highway with no other automobiles in sight, if you desire to drive 100 miles per hour, it

is all right with me. It is your car, and your hands steering it, and if it skids and runs up a telegraph pole, that's your business, not mine; you got what you were looking for, and as long as you are satisfied, the rest of us should not complain. Only, I think such an occurrence should not be charged up to accidents—it should be classified as suicide.

But in the cities where cross streets are only 300 to 500 feet apart, the conditions are different.

No driver ever left home in the morning with the firm intention of killing or injuring some one during the day. All accidents happen in emergencies; therefore, I maintain, any man who drives so fast he can not stop in time to prevent taking a life, when that emergency arises, is "exceeding the speed limit," I don't care if it is but 10 miles per hour.

Difficulties of the Motorist With Parked Cars

In the residence districts where cars are parked both sides of the street, and children are playing on the sidewalk or lawn in front of their homes, any man who drives so fast that he can not stop in time to prevent killing one of them if he should run out from between cars is exceeding the speed limit, even though he may be traveling only five miles per hour. When children are present anywhere on the landscape, take that foot off the accelerator and put it on the brake—don't blame the child!

Fifth. Driving while drunk.

It is often difficult to prove a man is drunk. We have 10 judges in our Municipal Court, and no two of them agree as to just what condition a driver shall be in, to find him "Drunk" under the law. Those who are found drunk, you can better believe are DRUNK. But you and I will agree that if a driver is in such condition that an approaching car looks like two cars, and he tries to drive between them, he is sufficiently drunk to be a menace on the streets and should be removed.

This stuff sold in bottles bearing wonderful labels, showing it is the regular goods (and, of course, there can be no mistake about it, as it was purchased from an honorable, upright law-abiding bootlegger who would not stoop to crooked ways) I say, this stuff is so poisonous that one drink often will so daze a driver that when the emergency arises his mind is not in a condition to function properly, and an accident occurs, a life is taken. But we can not prove to the satisfaction of the court he was drunk—it is therefore charged up to one of the former causes.

Well, what will help to alleviate this sad condition?

If all drivers were compelled to become as familiar with the rules of driving as they are with the rules of their lodge, club, society or church, before allowing them to drive a car, and if they would then obey them, 50 per cent of our troubles would be over.

One of the obstacles in the way of carrying this plan into full operation has been the numerous and conflicting rules thought to be necessary by each individual municipality and state. Although one became thoroughly familiar with the ordinances in his own town and drove accordingly, and was recognized as a careful law-abiding citizen, he fre-

quently became a violator when he drove in a neighboring municipality. Thirty years ago each municipality had a few rules governing the acts of horse and ox-drawn vehicles, and that was all that was necessary; for roads were poor, almost impassable in the spring, and a 50-mile trip was an event in almost any man's life. Then the automobile appeared. Roads were improved—a 50-mile trip became just around the corner, and we began to run afoul of each other's rules of driving. We started out on a pleasure trip to wind up in some station house, our car impounded if we didn't happen to have \$25.00 on our person.

We are a long suffering people, and we have stood this condition about 25 years longer than we should, but now that we have put our shoulder to the wheel, let us "carry on."

The Hoover Conventions are familiar subjects to all; it is needless to go into detail. There was handed to us, as a result of careful painstaking work of the committees over the course of a year, a set of fundamentals in traffic control, which was entrusted to all present to take back into their own states and weave into law, so that tourists from far distant points would not run afoul of a strange regulation for driving in every state they entered.

Keynote Should Be "Uniform Traffic Laws"

It is my opinion that the key note of the Public Safety Division of this conference should be, "uniform traffic laws in every state."

Michigan has stepped out in front and blazed a path, and I know other states will take up the work and carry it through.

Through efforts of the Detroit Automobile Club two conferences were held, following the first National Conference on Street and Highway Safety, which were attended by a representative from nearly every village, town and city in Michigan; a set of rules was edited that could be adopted by all of the municipalities represented, and at last report 150 had so adopted them. And it may be of interest to you to know just how we went about this.

The Safety and Traffic Division of the Detroit Automobile Club, with Mr. L. J. Van Schoick, director, took over the arduous task of getting the representation together.

A meeting room in the General Motors Building was secured for a certain date, then letters were sent to the Mayor, Chief of Police of every municipality, and Sheriff of every county in the state, stating the reason of the meeting, and inviting them to attend.

A tentative draft of the desired uniform ordinance was made, and when the 250 delegates assembled and organized for business the tentative draft was read item by item. Those items that met with unanimous approval were adopted, and those that met with an argument were referred to a drafting committee appointed by the chairman, which committee acting on suggestions brought out in the argument, went to work to redraft those sections; and the first meeting was adjourned after partaking of a banquet as guests of the Auto Club.

On invitation from Grand Rapids the adjourned meeting was called at

the Hotel Pantlind there three months later, with a larger attendance than we had at Detroit.

At this meeting the disputed items were taken up one by one and disposed of; then a two-hour recess was taken to enable the drafting committee to whip it into shape and during this period we were guests of the Grand Rapids Motor Club at a splendid luncheon.

When the meeting was called together after luncheon the completed draft was read, section by section, and a vote taken on each section; and at the end the chairman called a short recess while the representatives from each municipality could caucus and select a chairman to cast the vote for that municipality.

The Pedestrian Has Rights in the Streets

Then the meeting was called to order, and roll call made, each town having but one vote. This roll call showed the uniform ordinance adopted unanimously, and we adjourned feeling we had taken one step forward.

The Detroit Automobile Club had the ordinance printed and sent every official in the state a copy.

A trip made by me through the state during the summer convinced me that all the principal towns and cities had adopted it and were enforcing its provisions, and it was a great help to traffic. But of what use are traffic laws, if the law-enforcing bodies are lax or indifferent?

Sidney J. Williams, director of the Public Safety Division of the National Safety Council, has well said, "There must be a definite continuous effort to mobilize and organize and mould public opinion, and to support those police departments and those courts that are doing their duty, and to stimulate those that are not."

No truer word was spoken, for public sentiment, after all, is the ruling force in the enforcement of law. The people can have just what they demand, if the demand is made strong enough.

Then how about the pedestrian? He has rights on the streets, of course, but in many cities he has been given to understand that his rights are paramount. While a few have educated their pedestrians to make it 50-50, and while the Conference on Street and Highway Safety did not give us a positive recommendation, I believe some uniform law on this subject would save us embarrassment when in some other municipality.

Now, we have left that small percentage of people who are indifferent or reckless and who care nothing for you or your rights on the street.

I believe there is but one thing that will cause them to change their ways, and that is the assurance of swift, ample punishment without quibbling on technicalities when they are brought before a court.

I am firm in the belief that the record of the city of Detroit proves this.

From 1916 to 1926 the traffic killings in our city increased each year from 25 to 55 more than the previous year, with the exception of two years, 1921 and 1922.

In 1920 there were 240 killed; 1921 there were 134 killed; 1922 there were 185 killed; 1923 there were 266 killed.

During a large part of 1921 and part of 1922 we had a traffic court, and a judge who won international fame for the severity of his sentences; and again the same judge was persuaded to take over a traffic court this year, assuming his duties May 15.

Let us look at our record for this year.

Killed in January, 17; February, 16; March, 24; April, 36; May, 19; June, 22.

Many cities have had the same experience; and once again I state, let us have uniform state laws, and insist they be effectively enforced, and the years to come will not leave a trail of blood, dead and the dying from traffic accidents from coast to coast.

The Citizens of St. Paul Are Proud of Junior Police

CHAIRMAN COLLINS: I am going to ask Mr. Clancey of St. Paul to put on the pictures.

MR. CLANCEY (St. Paul): I wish to say just a word or two. A year ago I was at Cleveland, seeking information as to how to take care of the unsafe conditions on the streets in St. Paul, just like you are here today.

The question of the schools came up and I explained in a few brief words our organization. I took the question up with the secretary of the National Safety Council of showing those pictures at this convention. He listed them for the Junior Safety Meeting, Friday, but I felt that the pictures should be shown before the police chiefs and the city officials, and he agreed with me. So this morning those pictures are here.

Lieutenant Hetznecker, who is in charge of school police work, will explain those pictures as he goes on, and when the pictures are over I want you to ask him all kinds of questions, because he has been with the school police since 1920 when they were first organized under Commissioner Smith; this work was then carried on by Commissioner Matson, who succeeded Commissioner Smith, and who was here yesterday representing the railroad commission, and the work is now being further carried on by myself.

I want to say that the citizens of St. Paul are proud of their school police, are backing them up to the limit, and these pictures will be at the disposal of the National Safety Council to be used wherever they may want to use them after this convention.

LIEUTENANT E. J. HETZNECKER (Director of School Police, St. Paul, Minn.): I am never going to get old, as I have been working with children for the last few years. I find there is no more essential work in solving the problem of safety among school children than that of teaching and acting as director of safety in the various schools.

To bring this about, it might be explained that in inaugurating the school system we started out with 750 school police. This organization

carried on for a year. In fact it took a year to make up the activities of this organization.

The following year I had taken it up with Colonel Matson, at that time Commissioner of Public Safety, and explained to him the needs of the organization in order to carry on the safety work to the last letter. In doing this, we passed an ordinance making it just as effective for school police to handle traffic as for an ordinary police officer.

At that time I had no idea how to stop them, how to warn the people. You oftentimes see children out in the streets, boys with their hands up in the air, begging rides. How are we going to get away from that?

When visiting one of the schools, an educator mentioned to me we ought to have something to let the drivers know the business end of this organization. He mentioned the flag. I didn't think a flag would show very well on a rainy day. I had a long conference with that educator. In leaving that school I had to cross a railroad track at which place they had a man stationed holding up the stop sign. That gave me the idea of this sign which we use.

(Lieutenant Hetznecker exhibited the sign carried by the school police in St. Paul.)

It Is a Serious Matter to Disobey the Stop Sign

Today this sign, I believe, is being used in numerous cities of the United States. If anyone is caught disobeying it in St. Paul, I am telling you, gentlemen, he gets the limit. His fee at the present time is \$25, and his fine and punishment may be \$25. There hasn't been a case this year where a man hasn't been fined \$25 for violating this rule.

I want to say, gentlemen, that this organization is a business from start to finish. It isn't only traffic, it is everything in the line of a boy's life in bringing up that boy to become a good citizen.

The children are taken care of in the same way going to school as coming from school. It isn't only for a block or two. I get out in the communities and make arrangements with the parents in certain districts, and we have school crossings at a distance of eight blocks from school, and these streets are crossed in the same fashion as your children march into the lobby or hallway of your respective schools.

This is all done without the eyes of the principal or teacher or police officer watching them. The only guide is that little director of safety, the police officer.

We have 1,475 members among these junior police officers at the present time. They are all recognized by this star. It is the same star that the members of the regular police department have, with the exception that it is a trifle smaller. This star is a captain's star. Each school has its own captain.

It is interesting to see on election days at various schools, the interest school children take in selecting their leaders to become guardians of that school. This star signifies leadership.

Now, gentlemen, don't let me impress upon you that we give these

boys the same star we have, expecting them to be out at night looking for trouble. The authority of this star is for school police work only, and that is from the time they go to school until they reach home. In some schools it may be from 8:00 o'clock in the morning until 4:00. Again it may be from 7:30 to 4:00.

This star is also used on various occasions where there happens to be an entertainment of some kind for the education of children, if it happens to be a school day or holiday or during vacation time. These boys are sacrificing their time and are willingly doing it to help their friends along. They are doing this gratis for safety.

I have seen these pictures twice. They were snapped in St. Paul without my knowing it. As to the pictures of the children themselves, I want to say they did not pose for one of them, with the exception of one part, and that is where we wanted a violation of a boy explained in these pictures. The children themselves are all acquainted with the rules of the school police and know that if they break such a rule they are apt to be brought to court.

Disciplining the Child for Traffic Carelessness

As I explained before, it is a business organization. They have everything for themselves. They have their own courts. This court session is held once a week after school hours. They receive punishment in this court from the judge. That judge is usually the captain of the school police. I wish police courts would get the same action. I haven't found a case yet in school police court where the party was not found guilty.

This punishment is carried on in such a way that it is going to be a lesson for the boy as long as he goes to school. It is carried on with the punishment of missing his recess time, with the punishment of compelling that boy to write the bad effects of breaking whatever rule it may happen to be. After this is made up it is given to the judge. The judge has a copy and the boy has a copy. This is checked up, and a copy is taken home to the parents. Oftentimes parents don't hear of these things until after court proceedings. Parents put their signature on this punishment, and see that it is returned to the school court. Oftentimes I notice in going along to these various courts that the parents themselves take an interest in the case and are a part of the audience.

I don't want to take up much more time. I would like to have the operator prepare the films and we will go on with the picture.

The interesting feature of this organization is how the city of St. Paul has benefited by it. Since it was inaugurated the parents actually call up the Police Department and ask, "Have you got school police at this school? If you have, all right. I am going to send my child to that school."

(Moving pictures were then shown of the school police in action.)

LIEUTENANT HETZNECKER: We brought two of our boys with us today. Will they please come forward.

(The two boys from St. Paul came forward.)

I want to say regarding these boys, they have set a rule that every time they are called upon to do something, the first thing they do is stand up straight so they can be seen; next, talk loud so they can be heard; and third, shut up so you will like them.

I wish to introduce Leonard Hazelman, captain of the parochial schools.

LEONARD HAZELMAN (Captain of School Police, Parochial Schools, St. Paul, Minn.): Mr. Chairman and Delegates: I did not come here to make a speech, but to listen, observe and learn. As a representative of the 26 parochial schools of St. Paul, I am proud to be permitted to greet you, and offer our hearty cooperation in this great movement of safety first.

The School Police of St. Paul, a Serious Business

The School Police organization of St. Paul is no joke or fad. It is a serious business.

I want to say to the children of Detroit and the nation: obey your teachers and the officers of the safety organization, observe the rules of safety, and you will never be brought home on a stretcher.

LIEUTENANT HETZNECKER: I wish to introduce Harold White, chief of the public schools.

HAROLD WHITE (Chief of Public School Police, St. Paul, Minn.): Mr. Chairman, Ladies, and Gentlemen: This is indeed a great honor to be shown a school pupil. For myself it is a great pleasure to have the honor of becoming a delegate at this convention. This opportunity for a boy comes but once in a lifetime. You can bet your last dollar that I will remember my trip to this convention in Detroit as long as I live.

I wish to say that you will find the school division an organization for safety in all its branches in St. Paul, and in behalf of the St. Paul school system, I wish to extend greetings to the National Safety Council for the work it is carrying on.

H. O. ROUNDS (Supervisor, Bureau of Public Safety, Police Department, Detroit, Mich.): On behalf of the school patrols in Detroit, I wish to invite these two boys to the luncheon tomorrow noon, at which there will be 455 school police from Detroit and from Toledo. If you folks would like to see the quality we have in this section, be in the lobby tomorrow between 11:30 and 12:00 o'clock, but you will not be admitted to the banquet, because we will have 455 in a room that will permit only that number.

CHAIRMAN COLLINS: We are greatly indebted to St. Paul for this object lesson in school patrol.

DR. B. L. CORBETT (Secretary, Milwaukee Safety Commission, Milwaukee, Wis.): Who is responsible in the event of an accident to one of these children who is in the middle of the street directing traffic? We have asked that question throughout the United States in the various cities

we have visited. I was wondering if anyone here can tell us of any experience in that line. Since in St. Paul it is covered by an ordinance, the city would not be responsible.

MR. CLANCEY: I would like to ask Lieutenant Hetznecker how many deaths we have had in St. Paul at corners since the school police were organized in 1920?

LIEUTENANT HETZNECKER: There has been but one death of a child, when going or coming from school, and that was a boy who disregarded the rules of the school. The school police were on the job and had the children in formation. The small boy for some unknown reason started out from the rear ranks and started to cross the street. He wasn't run over by the car, but landed at the side of the car. That particular case happened last year. The child died five days after the occurrence.

MR. CLANCEY: I never had a report of the school police being injured. They use their judgment as to the proper time to cross, and that is the time when they themselves would cross in a walking gait, in such time as they wouldn't have to run. They raise up this sign and the autos stop. The children do not start to cross the street until the traffic has been stopped both ways.

MR. MARSH (Pittsburgh, Pa.): I would like to ask the gentleman from St. Paul what the effect has been upon the ratio of all child fatalities from injury in the city? In other words, what proportion of the injuries have been actually removed?

Police Officers Must Have the Support of the Courts

MR. ROBB: Reports from St. Paul indicate that the pedestrian is only 47 per cent of their problem. The usual average is 69 per cent. The child problem is 21 per cent of that 47 per cent. The usual per cent is about 43 per cent of the pedestrian problem. Last year, or perhaps the first nine months of this year, there were seven deaths of children, all of which occurred during the vacation period.

CHAIRMAN COLLINS: No doubt that answers the question, and it certainly is a splendid record and speaks for the accuracy of the system in operation in St. Paul.

The hour is growing late and we still have some work to do before adjourning.

Unless police officers are given the support of the courts, we are helpless in our campaign for safety on the public highway. Too much stress can not be laid on this particular point. The laws in Canada are much more rigidly enforced than they are on this side of the line. The accident rate is considerably less than it is in the United States.

The courts depend upon political prestige for their existence. It is very seldom that we find a man is big enough to lay aside the things that he believes might affect him in a political way and go in day after day to the administration office without fear or favor, meting out punishment where punishment is deserved in the enforcement of the law.

I am sorry to say that in Chicago it has been my experience that it is

a very difficult matter to get the courts to stand behind the enforcement of the traffic laws, the enforcement of the laws relative to speed, in the manner in which they should be enforced.

I am free to say that if all the courts in the United States would stand behind the police officers in bringing in violations of the motor vehicle act, that we would be able to show a decided reduction in the number of accidents each year. In going around the United States, from one large city to another, I can tell after 10 or 15 minutes observation on their prominent thoroughfares, whether or not the courts are behind the police officers.

I am not going to mention any specific locality, but in the east I noticed the drivers were very, very careful about what they did on the highway, notwithstanding the fact that at many intersections there were no stopping regulations and no police officers. Traffic was going at a pretty rapid rate, but they were careful when they came to an intersection to see that they got over without injuring or offending anyone. In this particular city the accident rate has shown a steady decrease.

Automatic Speed Registering Devices in Europe

Before concluding our work this morning, I would like to have the delegates express themselves freely on the two subjects that have not yet been dwelt upon. That is, the relation of the courts to the enforcement of the law, and exceeding the speed limit.

ERNEST P. GOODRICH (Consulting Engineer, New York City): While in Europe this past summer, I had occasion to do some investigating work along the patent regulation line, and discovered in the office of the Chief of Police in the city of Stockholm an experiment was being tried with reference to automatic speed indicators of the registering type.

A special device was arranged, which was also applied to the motor truck and taxicab. This consisted of a disk which rotated at uniform rate, and every quarter of a mile a pencil placed a dot there. This could not be tampered with, and in case of an accident or a question as to speed, this automatic registering device was adjusted as to what the conditions were in different sections.

We have in this country certain suggestions about the limitation of speed by automatic devices so that a man can not exceed the speed limit of so many miles an hour. This has been pointed out very well by the presiding officer today. If the facts registered on this machine could be used, the problem of speed, I believe, would be very largely reduced. The consideration of some such automatic device might be objectionable to many drivers, but it is one which the police officials should consider.

W. H. WISE (Canadian National Safety League, Toronto, Canada): With reference to your remarks about the courts and the traffic laws of Canada, I want to suggest, as a probable reason, our judges are appointed for life by the Lieutenant Governor.

F. B. HENRETTA (President, Yellow Cab Co., Inc., Roanoke, Va.): Mr. Chairman, a prominent automobile manufacturer in this country. after

spending a great deal of time in getting up a book as to the proper care and use of the car, threw the whole thing away and got out a poster. The fact remains that you have got to get down to the simple rule, "Run under control." Until that is accomplished, no good will come.

I think that brings in clearly this matter of the relation of the police to the court. When a man is absolutely found to be reckless, make the punishment so severe that he will be a startling example for others.

MR. COFFIN: Mr. Chairman, I might add an instance that happened in Portland. We found a great many of our violators, through political pull or stand-in, were able to get out of appearing in court. It became so flagrant that a meeting was called by our mayor and at that meeting were the chief of police, the prosecuting staff, and others that were interested in the enforcement of the laws; and they all stood up, with uplifted hands, and swore there would be absolutely no political pull that would enter into the enforcement of the law.

Every man or woman that has been arrested since then has gone to court and the judges mete out proper punishment.

CHAIRMAN COLLINS: Now in conclusion, I desire once again to repeat that everyone should get behind the model motor vehicle act, the outcome of the Hoover Conference. As you all know, the Secretary of Commerce, Herbert Hoover, recognizing the great toll that automobile accidents were causing every year, caused this conference to convene. Everyone that was interested, either in building an automobile or in its operation, or had to do with enforcing the laws, or had to do with it in any capacity, was drafted into this service. They were all in attendance at these two conferences. Many committee meetings have been held. The result is that we have today a model vehicle act, something that has been devised free from politics, free from influence, free from the interest of anyone except the general public, and it behooves us all in every state in the Union to get behind this act and see that it becomes a law, so we may know in California as well as we do in New York what the laws relative to the movement of motor vehicles are on our public highway.

ADJOURNMENT

Traffic Regulation and Control

October 28, 1926

ERNEST P. GOODRICH, Chairman
Consulting Engineer, New York City

The meeting convened at 2:15 o'clock, Mr. Ernest P. Goodrich, Consulting Engineer, New York City, presiding.

CHAIRMAN GOODRICH: This meeting is in a partial sense a continuation of certain investigations which were carried nearly to a conclusion by the last two Hoover Conferences. One or two of the committees of that conference reported recommendations with reference to the items which are on this afternoon's program.

One of the sub-committees of the Hoover Conference made careful estimates of the cost of accidents and the delay in street traffic difficulties, and came to the conclusion that each individual citizen was charged at least \$20 per annum because of those conditions. It means then that it is worth \$20 personally to each of you to get this thing worked out. It may be worth a great deal more to you if you happen to miss a train some time because of street congestion, or if you happen to be in that particular branch of the engineering profession which is now interested in this topic.

The topics can be divided into two main groups. The first has to do with traffic survey and traffic control, which might be called the explicit side of the question. The last paper has to do with organization, which covers general traffic matters.

We should like to hear from Mr. Powell, of Buffalo, at this time.

TRAFFIC CONTROL BY SIGNAL LIGHTS

**W. B. Powell, Consulting Engineer on Traffic, Police Department,
Buffalo, N. Y.**

Traffic signals today are an outgrowth of the very rapid development of traffic congestion in our city streets. As soon as this began to infringe upon the consciousness of the city police departments, they did the very natural thing—they began to put out men at the different

intersections and of course, police departments being under-manned, they quickly got to the point where they didn't have an available man to take care of the increasing traffic.

They also found it a burden for a man to stand and wave the traffic with the motions of his arms and hands, and the second stage was to give him a mechanical device, which he could turn by a simple movement of his wrist. That didn't serve the purpose for a great length of time, for presently we found that even then we were not able to keep up with the increasing density of traffic, and so we began to have various types of automatic-control signals offered by ingenious manufacturers, and there were as many different types of devices as there were manufacturers, and that is quite a few.

The city of Buffalo, with which I am connected, was rather early in this field. One of our own citizens developed a traffic-control light in the early stage of that activity and was successful in getting one of them put up in our city streets about four and a half years ago. The signal is still working today, although it is considerably out of date.

Now the first and obvious method of adopting one of those signals was to set one color for the vehicles to move through the intersection, another color to stop them, and a third color to indicate there is going to be a change from one color to another. Even today I think that general system is in use throughout the country.

We fortunately managed to coordinate on green to go, red to stop, and yellow or amber for the change light. However, I don't think that is the last word in signal control, by any means. So we go on to find there are difficulties even with that method of signalling, which we can perhaps overcome by some ingenious changes.

Drivers Invariably Want to Jump the Signal

Buffalo has found as soon as you use signals of that type a great many of your drivers want to jump the signal. If he is standing still on the red, as soon as the warning bell sounds he is in a terrible hurry to get to his destination and so he steps on the gas before the signal actually changes and gives him the release color of green. That would be all right, perhaps, if it were true that the fellow moving on the green, when he saw the warning light, was willing to stop going and wait. But the unfortunate thing we find is that when a man moving on the green sees the yellow light and is about 100 feet from the intersection, he takes that as a jolly good chance to get through before the change actually comes, and he steps on his gas, too, and the two meet in the street with disastrous consequences for everybody.

The first thing we tried in our town to overcome that difficulty was a direct change from red to green and green to red simultaneously. It didn't work very well because the time between the two changes was hardly sufficient to clear the intersection. The next thing we tried was to cut out the yellow warning on the red side and only provide it for the man on the green side. That was some improvement, but, neverthe-

less, the fellow standing still on the red managed to get some idea of the fact that yellow came on the other side, so he hopped the signal just the same as before.

Ultimately we tried the scheme of changing directly from red to green and green to red, but brought the change from green to red on a definite interval ahead of the change. In other words, we overlapped our reds. After a little experience we found that five seconds was a reasonable time of overlap to clear our intersection.

Our first experiment was made a year and a half ago. It was put into effect in January, 1925. We tried it in one of our busy intersections, one having trolley lines in both directions and motor traffic and pedestrians. We were so thoroughly satisfied with the net results we got by that method of operation that we tried it on other corners under different conditions in various parts of the city, and eventually, about the first of this current year, made up our minds that was a good standard to adopt, and now we have every signal in the city, with the exception of one or two that can't, operating on that basis.

So if you visit Buffalo in the near future, you will find instead of having a warning, the change is made directly without any warning as to bell or light.

The Average Individual Observes the Red Warning

I believe the psychology of that is correct for this reason: your city ordinances generally require a reduced speed limit at intersections. In our particular case the standard speed limit in the city is 20 miles per hour, on the outskirts 25 miles per hour, and at the intersections 15 miles per hour.

If you use the warning light and the man steps on the gas to get across, he speeds up for the intersection instead of slowing down. If on the other hand, he is driving on our system, and he approaches a light which has been green up until he comes toward it, instead of stepping on the gas to get by, knowing it is going to change directly from green to red to hold him up, he approaches with caution.

Our experience has been that we have had considerably fewer collisions and near-collisions at street intersections controlled in this way than we had before. It is a very well-established fact that the psychology of that method of changing from red to green and green to red is correct.

Now it is true that even with the red changing to green and green to red, some ambitious drivers still jump the signals, but it is a remarkable fact that red holds the average individual better than the ordinary coloring. We have an ingrown belief that red is a dangerous thing to monkey with.

So the percentage is greatly reduced, and with a little police administration to back this up, which we administer with plain-clothes men on scattered intersections, we have succeeded in holding that down to a minimum.

That, however, is not the final solution to our whole problem. As we

increase the number of signal-controlled corners, we get to the point presently where the motorist begins to complain because he has been held up unnecessarily.

The average motorist thinks an automatic speed control is a speeding device to move traffic more quickly. I believe it is primarily a safety device and not a speeding device. However, you can use your safety devices so they will move traffic advantageously.

The next move was to figure out at his given rate of speed, if we alternated the colors we could let the driver go right on through without being stopped at all. We have several notable examples in the country of that method of operation, generally known as the progressive system.

We find the flow of traffic is not always uniform, some require a longer time in one direction than in others. So we go one step further, as they have in Chicago, where they vary the time interval as well as having the progressive system of movement.

Even then I don't believe we will have reached the final outcome of our problem, because even now we hear rumors of various schemes for still further refining the methods of controlling our traffic.

More Traffic Control Signals Change Traffic Stream

One curious by-product we have observed, and probably you have, too, in the introduction of traffic-control signals in a considerable number, is that you diffuse your traffic to other streets. The foxy motorist does not drive where there are control signals. He devises other routes to take him around the signals, and one of the very interesting results of the installation of traffic-control signals at any particular corner is immediately to decrease the traffic at that point.

However, I am rather inclined to think we may go a stage too far in this direction. I know one or two cities of my acquaintance where they think they have too many signals and want to take some out. It is difficult to take a signal out, because once the inhabitants have it in, they think it is the worst corner in the nation, and must necessarily be under control. Of course you can let the signal get out of repair and not fix it.

Another thing might be said along that same line. In our town we tried every kind of signal ever invented. Cleveland looked us over and said that Buffalo was the worst traffic-controlled city in the world because they had every system ever invented, which was true.

CHAIRMAN GOODRICH: We will continue this particular phase of the subject by listening to Mr. E. J. McIlraith, Engineer of Chicago Surface Lines. They have a particularly well worked out program.

If you will permit a personal reference first, some 15 years ago, while in charge of traffic in New York City, I took all the inspectors we could get and put them on cross streets in Fifth Avenue for about 30 blocks. In those days each police official was a law upon himself, he regulated traffic at his intersection as he saw fit, and you can imagine the helter-

skelter movement up that avenue, which was about as congested then as it was thought it could be.

RECENT DEVELOPMENTS IN TRAFFIC SIGNALS

E. J. McIlraith, Staff Engineer, Chicago Surface Lines, Chicago, Ill.

In interpreting the subject that has been assigned to me, I wish to change it slightly, and instead of "Modern Development in Traffic Signals," let's say "Modern Development in Traffic Signal Application," because I don't think we need any discussion of the type of signals or desirability of different types, or of the salesman's points, in discussing the merits of various types of red or green signals or red, green and amber sets of lights.

The real question in traffic-signal application is the justification—what is the excuse or reason for applying signals? If we apply to that question, engineering judgment, and real technical skill, there can be a good application of signals to improve the conditions at whatever intersection is selected, if the study shows that any signal is required.

I want to make it very clear that what was brought out in the previous speaker's discussion is all too prevalent in the United States. There are too many signals installed at the present time where they do not apply and have no business to exist. I think Mr. McClintock has expressed it very nicely when he says that a signal should not be installed in any location unless its presence will expedite the freedom of movement in that intersection.

If a signal is actually going to reduce the freedom of the intersection, it should not be placed at that point. A warning signal may be necessary. Some indication of the dangerous point may be needed, but the stop and go, which is the usual means for traffic signaling, can only be excused if tangles of traffic are going to be relieved by the use of an alternate stop and go.

There are many locations where a traffic signal may be desirable for two or three hours of the day and undesirable for the rest of the 24 hours. In such conditions it can be arranged that the traffic signal only operates at those periods of the day. It may be at some of the country locations traffic signals are needed on Sundays, but they can, and often should be, completely eliminated on other days of the week. Such conditions are peculiar or special.

All conditions have need for very careful examination before the signals are installed or put into use. It is that present-day tendency to give specific analysis to the problem before buying signals, that is the most promising feature of signal development.

Until there is real care given in the timing of signals, they usually become a handicap, and they are a handicap in the major portion of the installations in the cities of the United States. They do not promote the speed and comfort and freedom of movement as they were expected to do, and when they do not promote speed, comfort, safety and street

capacity, they have fallen short of what they might be doing, and have fallen short of what they will do if a little engineering skill is put into the idea of tying them together, correlating their indications, and timing them according to the problem they have to solve.

There is no question but that an individual officer at an individual intersection, who is working with good judgment, can handle that intersection more effectively than any traffic signal which can ever be installed.

I would like to wipe out any ideas that may prevail that signals can do something better than human beings can, if the human being is using the right and proper judgment and is not subject to inquiries for directions, etc., not subject to the faults and failings of his own mental lapses, or his anxiety to get away from the crossing, or anxiety to promote or enforce some of the ordinances with which he is especially concerned.

The officer has something else worth while doing besides the mere timing of the intersections. He can watch the people, to keep them safe; he can inspire a little moral persuasion in the minds of those operators of vehicles and pedestrians who would otherwise take advantage of the signals; he can guard against all sorts of traffic violations, and the officer really becomes available for street regulations when the signal does the timing automatically.

A Big System of Traffic Signals Brings Big Problems

If an intersection is by itself, not correlated to any others, it would still function very well through the entire period of control, even if the officer fails to use his best judgment all the time, and the best traffic officer is usually discovered as failing to use good discretion through the major portion of his time on duty. A single isolated intersection does not create serious trouble, even if poorly handled.

When the individual control, however, becomes a group of individuals, as in a large business area, and we have intersections over a half dozen or dozen or 50 different blocks of the city, all needing to work together in harmony, and each trying to play into the other man's hand, then you have a much more serious problem of officer's lapse and officer's failure, because no individual there slips ever so little without immediate reflection on the operating condition at the four corners adjacent to him. The officers are not able to give their individual attention to the timing of their intersections even if they would. There are continual questionings, happenings and incidents to disturb and delay them.

Further, they are bound to grow careless or indifferent, or one might call it hardened by the continuing strain of the job, and the natural thought that traffic gets along even if they do not worry much about it. The tendency is to develop to an automatic practice in which they really think very little. When the various mistakes and carelessness of the individuals are multiplied by all the individuals at adjacent corners, it is easy to understand how cumulative confusion results so that properly

timed signals are far superior to individual officers. Orderly movement results from groups of signals.

When signals are installed many officers are released from a timing job, to be available for observation of traffic violations and enforcement of traffic regulation, and the threefold advantage has accrued: reduction in cost of enforcement of traffic law in areas under signal control, improvements in speed and street capacity due to orderly movement and safer movement.

It is very desirable in traffic movement installation that the ultimate purpose of the traffic movement may be served. If the ultimate purpose is that, starting at the beginning of the section of the street, we wish to go the entire length of the street without delay, without stopping, the signals should be so set, and so controlled that the majority of the vehicles can move through the entire area without stopping because of red lights or traffic interference.

Coordinated Control Simplifies the Freedom of Crossing

There are sometimes mechanical interferences with such an ideal. Occasionally cross streets require unusual treatment to prevent either left turns or straight through movement on the cross street. Occasionally some particular restriction may have to be made to fit special street layouts, but in general traffic movement of any area, when thoroughly analyzed, when reduced to its logical parts or groups of intersections, can have for each of those parts a signal control so arranged that traffic will move across the area at the maximum speed which the conditions of the streets normally will permit, without red lights interfering.

Proper coordinated control will simplify the freedom of crossing intersections, simplify traffic at intersections, and should speed up traffic movement over anything that can be introduced by ordinary officer-control.

However, very few cities have put engineering analysis into this problem to discover the logical sub-divisions into which controlled areas should be divided.

It is inevitable that when high-speed boulevards are beside a business district, the high-speed boulevard can not be treated in the same way as the business district. If the two are thrown together and tied up together in control, there is bound to be a serious sacrifice to one or the other or both.

However, by carefully picking out the factors that are involved, by laying out the itemized movements, classifying them, determining speed, time, intersection interference, and the controlling factors involved in the movement, it is quite possible to lay down in advance of signal installation, the exact detailed results that will be accomplished by that signal installation.

It should be as easily demonstrated as the engineering features of a building, because you can detail just what is to be done in traffic movement with much the same certainty that you can detail the steps in

construction of a building. You can determine the possibilities of it and you can control some of the difficulties.

In making an installation in Chicago for the central area, controlling 49 intersections, it was necessary to go into a very detailed study, and the results accomplished there are almost identical with what were expected. Yet to any casual observer it now seems like an ordinary city. It does not seem seriously different in the operation of the control there than would be observed in Cincinnati or Cleveland. To the casual observer there would seem to be similar features in the results from the two methods of control. Actually there is a material difference in results, and one can not from street observation differentiate fully between the two systems. The smoothness of operation in Chicago gives the streets the appearance of light traffic. The usual type of synchronized control would create serious blockades.

Reversed Synchronized Control in Some Cities

The freedom of movement may seem to be good in many cities because of the relative density of traffic, but if the more careful observations, timing and planning are developed in the setting of the control movements of the individual intersections, progressive timing will do marvelously better than the ordinary method, and it costs very little more in comparison. It can be done at a cost not to exceed \$300 in each intersection as compared with the synchronized timing, and the results may be as much as 100 per cent better, depending upon the type of city.

In speaking of the difference between types of signal control, progressive timing is merely a method of timing signal control that permits each individual intersection to have its timing individually set up as compared to all others, in order that when vehicles move from one intersection to the next, in as many cases as possible, the signal will change for the vehicle just at the time it arrives at the next intersection and is ready to go.

This is somewhat the same as is done in Washington, D. C., or Cincinnati, Syracuse, Minneapolis, and several other cities, but it is not exactly the same. The cities mentioned above use a reversed synchronized control. A synchronized control is one where all lights of the group change at exactly the same instant and all lights indicating movement along a given street are set green at the same time, and then change and become all red at the same time. The reversed synchronized type of control may be illustrated by saying that all lights are changed at the same instant, but numbering the intersections along the given street, Numbers 1, 3, 5, etc., will be all green at the time when numbers 2, 4, 6, etc., are red. In the next change numbers 1, 3, 5, etc., will become red while the others become green, or it may be that 1-2, 5-6, 9-10, along a street are green while number 3-4, 7-8, 11-12 are red, and then these two sets reverse at the same time, keeping the groups of two intersections always paired out as shown above. Sometimes groups of three are so coupled up.

The purpose of this reverse control is to so arrange the timing that the leading vehicles entering the control zone will be permitted to travel at the desirable rate of speed, say 20 miles per hour, and the red lights ahead of the driver will change just before the driver arrives at the first intersection of the group that has been red. If these control groups are three successive intersections, then when the change actually comes, only one-third of the vehicles operating through the three blocks, that are under green light control, will have passed the last green signal of this group when the change comes, provided there is uniform distribution of traffic along these three blocks. It is obvious, then, that only the first one-third of each moving group can go through without a stop. Further, when signals are so arranged in reversed synchronized control the time split at each intersection must be arranged on a fifty-fifty split, in order that each street can have the same portion at successive intersections.

This is a great waste of time where a main street is crossed by a succession of minor streets, although such a system does get along fairly well on most of its present installations, due to the volume of traffic, and because it is an improvement over what was previously in existence.

Each Intersection Timed to Individual Requirements

With the coordinated or progressive system each intersection is timed according to its own requirements, and the start of the red or green signal for a given direction of movement is such as to permit vehicles arriving at that intersection to continue passing without delay, because it changes at the time when the correct speed of movement will bring the vehicle to that intersection from the last control intersection. The control permits the time of change at one intersection to occur at the exact instant best suited to the operation of the system, and this change need not happen at the same instant as any other change is occurring. Such flexibility is the great asset of this method of control, and enables the engineer to obtain the maximum usefulness for the streets and to give the greatest freedom to the users of the streets.

There is about to be started in East Cleveland such a system of progressive timing, where it is hoped that 25 miles per hour or thereabouts will be the speed of automobiles moving along the streets, and once they start, there will be no red light to stop them if they proceed at approximately that speed.

There are about to be installed in Chicago, two such systems, one on Michigan Boulevard and the other on Upper Broadway, where there will be installed for two and a half miles such progressive control. In each installation vehicles will go the entire direction without material change of speed, and we can guarantee that when they start they will not have to change their speed until they pass that controlled area.

Such movement is a true traffic control that expedites movement and is the only type that can be usually tolerated, and it is the principle on which traffic movement should be set up in so far as it can possibly be

done consistent with the type of business. In an intense business center where the streets may be narrow and the cross streets may be in large numbers, and the control necessary in speed is determined to a large extent by the movement of the street cars, their stopping and loading keeps the speed of vehicles lower than it might be otherwise. However, in busy areas vehicles can not attain high speeds even if no street cars operate.

If the people served by the street cars are in greater number than the people served by the automobiles, it may be desirable to set the signals so as to give the maximum speed to the street cars, for it may be that the vehicles can not go any faster than the street cars due to street widths. That is true in the more congested areas without safety zones. Under such conditions it may be considered that the speed is set for the street cars, while as a matter of fact, it is actually set at the highest speed at which all vehicles can move. Today with the present system of traffic regulation and of parking and delivery of vehicles, etc., that prevails in Chicago, the street car is actually able to move through faster than vehicles can normally move through, so the speed happens to be the speed of the street car; but when we come to an installation like Broadway, where the street is wide and the number of street cars is relatively lower, then the street car will make a faster speed than before signal installations, and probably 12 miles per hour, including stops, while the automobile can go through at 22 or 25 miles per hour. This district will not seem to be affected by the street cars as Chicago's downtown district now seems to be.

Emphasis Laid Upon Flexibility of Control

It is this flexibility of control and the recognition that is being paid to it throughout the country that is the feature I want most to emphasize today. It is an engineering analysis of the peculiar situation with which each control installation is confronted, that should be given the most serious attention.

It matters relatively little what type of lights or standards one wishes to put in, whether there are two lights or three lights in the signal post. These are controversial points on which I may have definite opinions, but as long as there is a reasonable standardization of meaning of signals throughout the country, detail of design or location is not so very important. The important thing is to use engineering analysis and engineering skill in arriving at a way that will expedite traffic movement instead of slowing it down. Unless that skill is used and that result is accomplished, traffic signals are going to be handicaps and many of them should come out. Many of them must come out, and the traffic control systems in many cities must be turned inside out before real basic satisfaction in the handling of traffic is obtained.

I regret that I have talked so long. The other items that are involved are standardization of this particular type of signals, such as control of boulevard traffic streets, or control at such intersections that are pecu-

liarily dangerous or peculiarly subject to traffic accidents. Standardization should, therefore, always prevail, and a particular type of sign needed has not yet been generally adopted, and it has not had enough systematized attention to decide what is best. It is open for discussion and should be developed so all cities will have the same meaning for flashing red signals and the same meaning for flashing green signals or amber signals.

There are other somewhat controversial points, too. The question of pedestrian control has not been satisfactorily settled and is being handled in different ways in different parts of the country. It is very necessary to get a good solution, but in small cities you can get away with some things which can not possibly be taken into consideration in larger cities.

These are all controversial questions, and I can not express my views at this time, but if I can induce any greater attention to the planning and induce attention to the traffic engineering idea in city management, or produce for traffic engineering a better status, or encourage getting into it much more engineering skill, I will have served my purpose.

It is Possible to Vary Traffic Speed From Block to Block

CHAIRMAN GOODRICH: My own studies of this particular system have led to the belief that it is possible to vary the speed of traffic from block to block so as to take account of the different periods of cross traffic. Of course you need a considerable number of signs.

It is also possible in some instances nearly to double the speed of the vehicles compared with the street car so they run in different periods, the street car going half as fast, and therefore skipping each period.

There are numerous other schemes of that variety which can be included in this progressive system.

DR. B. L. CORBETT (Secretary, Milwaukee Safety Commission, Milwaukee, Wis.): Mr. McIlraith, did you recommend signals to operate on a 24-hour basis or turn off between the hours of 12:00 and 6:00 in the morning?

MR. McILRAITH: They are turned off any time. It may be some signals will work 12 hours, some 24. For instance if you have red, green and amber alternating, you can flash steady amber all night long.

There is one other feature I neglected to mention. That is, if it is set for 20 miles an hour speed, there is no chance of your overrunning that speed. It has the additional safety argument that you can not speed 25 miles an hour down a street which is set for 20 miles an hour. In the ordinary simplified system where they are all green along the street, at one time, there is a premium on fast driving, and you can introduce the hazard of the fast driver. Under the progressive set up, the driver gains nothing by speeding.

C. E. REDERER (Windsor, Canada): I want to ask a question with reference to automatic signals, where you have two or three blocks in sections of 300 feet, the next block 800 feet, another block about 300 feet. How do you handle that successfully? It is a matter that seems to be somewhat complicated.

NORMAN ANDERSON (Cleveland, Ohio): Under the direction of the City Railway Company there has recently been installed on Euclid Avenue in Cleveland a system of progressive signals such as has just been described. I drive that East Cleveland distance, probably three or four times a day, and can go from one end of East Cleveland to the other at 25 miles an hour without interruption.

CHAIRMAN GOODRICH: I would like to take a moment to answer our friend from Windsor. You have a 300-foot block. We will say it takes two seconds to travel that at the given speed. The green signal on the second block is set to start two seconds after the one on the previous block. The next block, being 300 feet, would also have a two-second interval. If the succeeding block were 900 feet, it would have three times two, or six seconds, so a progressive wave or green light would appear before the eyes of the motorist as he is operating down the street.

It is simply a matter of setting the signal to start the red or green at a given time.

H. S. BUTTENHEIM (New York): Would it be possible, before we change the subject, just to have a show of hands? I wonder if any city here represented, which has not been mentioned, has a progressive system in operation?

CHAIRMAN GOODRICH: I wish each one would stand and give the name of a city where the progressive system is in use.

(The following cities were named: Milwaukee, Wisconsin; East Cleveland, Ohio; Lynn, Massachusetts; Minneapolis, Minnesota; and Chicago, Illinois.)

CHAIRMAN GOODRICH: Washington has a partial system, Detroit has a partial system and so has Los Angeles a partial system. There are some others.

We will take up now the paper by Dr. Miller McClintock. If you will pardon the quotation, the first shall not be last, but pretty nearly so in this particular part of the program. Dr. McClintock is the man who wrote the first real book on traffic. He is Director of the Albert Russel Erskine Bureau for Street Traffic Research, and is attached to Harvard University. He has been doing excellent work in Los Angeles where a new code has been prepared, and he has been retained by the Chamber of Commerce of Chicago.

HOW TO MAKE A COMMUNITY TRAFFIC SURVEY

Miller McClintock, Director, the Albert Russel Erskine Bureau for Street Traffic Research in Harvard University, and of Metropolitan Street Traffic Survey, The Chicago Association of Commerce

The type of survey I will discuss is one designed primarily for the purpose of collecting facts which will assist in rational plans for the reduction of accidents and congestion upon city streets, through a better use of existing facilities. It should not be confused with community studies which are made as a basis for city planning work, that is, as a

FIGURE NO. 1

foundation for the improvement of street traffic conditions through the provision of new and more adequate facilities.

It is apparent that the traffic and physical conditions of American cities vary so widely that it is impossible to lay down detailed survey plans which will be universally applicable. Each city, because of its local peculiarities, presents a special problem. In the preparation of this discussion therefore, an attempt has been made to select methods which would be suitable to communities which may be considered typical.

Further, a statement of the details of a survey in a sizeable community would consume all of the available time with their mere listing. An attempt has been made, therefore, to give the general outlines of the survey and the principles which should govern it.

The Reason for a Traffic Survey

A question which naturally arises is: "Should a community feel it necessary to undertake a serious study of its traffic conditions?" The answer is that while the weight of the street traffic problem in the form of accidents and congestion is generally recognized by public officials and business men of most cities, those in charge of the problem are too apt to overlook the most obvious causes of the difficulties. Guess work in street traffic control is no more fruitful of beneficial results than in any other engineering problem.

And this brings me to the kernel of the situation. If the control of street traffic is to be dealt with as a purely political problem, as too frequently it is in American cities, then a serious attempt to collect facts is merely a waste of time and money. On the other hand, if the street traffic situation has reached a point where it can be considered as one demanding thoroughly rational action, it is time for the application of sound engineering technique. Such technique may be described as the process of collecting accurate data, and on the basis of these facts drawing warranted conclusions. There is no republican nor democratic method for handling traffic, but there is usually a fairly simple solution for most traffic difficulties, once their causes are understood.

This entire discussion is based, therefore, on the assumption that the street traffic control problem is similar in its general characteristics to the other physical problems of municipal administration, such as, water supply, sewage disposal, street maintenance, and city planning, and that its solution or relief is to be found in a similar type of approach.

With this principle in mind I want you to think of a traffic survey, not as a study which is to be made, printed and filed away, but a study which is designed for the purpose of collecting information from which immediate results can be obtained. Moreover, it should be conceived as merely a first step in a rational method of dealing with the difficulties of street accidents and congestion. A single survey, no matter how skillfully designed, can not be of perpetual value. It should serve merely as the basis for a continuing and intelligent study of traffic difficulties.

The principles and methods of traffic surveying are by no means new

nor original except in their application. They have been used by public officials and public utilities for many years in dealing with the knotty problems presented by local transportation, telephone, gas, electric, water and other fields of public service.

FIGURE NO. II

Filed in ST & T Survey - general -

A successful survey requires both liberal public support and funds. These necessitate a suitable organization. The first problem, therefore, is to provide a body capable of sponsoring the work. Rather limited experience thus far appears to indicate that non-governmental groups are more apt to be successful in the initiation and support of such work. This is illustrated by the activities of the Los Angeles Traffic Commission, a group of prominent citizens with actual monetary interests in the traffic problem; in the conduct of the Metropolitan Street Traffic Survey by the Chicago Association of Commerce; and in the Traffic Survey of the city and county of San Francisco, under the direction of a committee of leading business men appointed by the mayor.

In all of these instances the entire cost of the engineering work has been carried by private subscription. The non-governmental character of these groups has made possible a liberal financing, and a freedom from some of the limitations incidental to official operations. The conclusion is by no means drawn, however, that public officials could not successfully engage directly in such work.

One of the advantages which results from a private group is to be found in the opportunities it presents to bring together the numerous and often antagonistic traffic interests. As your own experience will indicate, questions of traffic control are highly controversial. Matters relating to parking, the relation between motor vehicles and street cars, the operation of motor buses, the position of the pedestrian, and many others, often create real and sometimes bitter differences of opinion. Opportunities for free discussion, under the restraining influence of the facts which are revealed in the survey, frequently show many of these differences to be more imagined than real, and to open the way for mutually acceptable adjustments.

In the non-official plan to be followed for the body sponsoring the survey it is essential that care be used in its organization. It should be widely representative of all of the interests which feel that they have a stake in the use of the public streets. A list of those agencies which under no consideration should be left unrepresented might be given as follows:

Street Railways.	Motor Coach Operators.
Motor Car Dealers.	Insurance Companies.
Automobile Clubs.	Cartage Companies.
Retail Merchants.	Building Owners.
Taxicab Operators.	

The financing of the survey may properly come from this group, and a wider representation which may be added to it. More or less casual groups of business men who form organizations for the consideration of traffic problems are too prone to pass resolutions and let the matter lie at that point. On the other hand, when a business man goes into his pocket for \$4,000 or \$5,000 to support a project he is going to demand something more than talk. It will be apparent from your experience that local safety councils may serve readily as the basis for a survey organization.

The sponsoring body outlined above will serve as a jury, or perhaps more accurately as a board of directors to pass upon the facts and conclusions resulting from the survey. The agreement of such a representative and responsible group upon proper recommendations naturally carries weight with public officials, and expedites the application of remedial measures that may be proposed.

The Technical Staff

Business men who may willingly give their time to such a committee as that outlined above, have neither the time, nor generally the inclination to engage in actual survey work. The next step, therefore, is the organization of a technical staff.

There are a number of courses that may be followed. In the recent past a number of engineering firms, especially those operating in the adjacent fields of city planning, or local transportation, have been manifesting an interest in the problem of traffic control. The services of a

FIGURE NO. III

At this point it may be well to clear up a misapprehension that has arisen in some quarters. The Albert Russel Erskine Bureau for Street Traffic Research in Harvard University was not designed for the pur-

pose of rendering professional traffic engineering service to American cities, but rather to assist in an approach to the problem through the collection and dissemination of sound information, and through the training of young men for professional activity in the field. Such surveys as have been conducted directly by the Bureau have been primarily for the purpose of developing a practical technique, and demonstrating the advantages of rational methods.

Conducting the Survey

Methods for the collection of data, will depend somewhat upon the funds available and the organization of the technical staff. Many of the investigations will be in the form of innovations, and these will require direct action by the staff. Large counts of vehicles requires the services of several score men for a considerable period in the larger cities and this naturally involves large expenditures. Where funds are available the best results will be obtained by a paid personnel, selected and trained for the work. Where conditions are favorable—and they are more likely to be in the smaller cities—volunteer workers can be used to advantage as checkers with definite instructions and adequate supervision. In one city members of the Chamber of Commerce gave their time for this service. In another a very effective check was made through the services of the Boy Scout organization.

Fortunately much of the information of basic importance to a comprehensive survey is already in existence in the average American city. The city departments should be able to provide information regarding the general physical characteristics and conditions of the streets. Efficient city planning organizations usually possess detailed data that are applicable to the problem of traffic control. The street railways, taxicab companies, motor coach companies, and trucking concerns normally keep useful reports of their operating conditions.

Their representation on the sponsoring body, and their understanding of the purpose of the survey will facilitate the acquisition and use of this material. Earlier studies of traffic conditions, even though local and special in character are serviceable where their accuracy is dependable for the drawing of comparisons. A full use of these and similar sources of information will greatly reduce the cost of a comprehensive survey, and will expedite its completion.

The physical scope of the survey will depend upon local conditions. Where funds permit, the investigations should extend out from the center of the community, so far as traffic effects local conditions. Little or no attention should be paid to political boundaries, for traffic does not heed them. Intensive investigation within the city will naturally be directed to those localities where traffic has proved to be burdensome, the principal arteries leading into and through the community, the more important outlying business districts and the central business district.

The subjects to be covered by the survey will be determined by local problems to some extent. There are certain data, however, which are

of general importance. For the purpose of conciseness the suggested subjects are listed below in outline form:

I. The study of existing traffic:

- A. A census and analysis of traffic flow at important points throughout the city, including data on the following factors:
 - 1. Volume.
 - 2. Direction.
 - 3. Speed.
 - 4. Types of vehicles.
 - 5. Hourly variations.
- B. A study of the operating conditions and problems of various vehicle types:
 - 1. Street cars.
 - 2. Commercial vehicles.
 - 3. Private passenger cars.
 - 4. Taxicabs.
 - 5. Buses.
- C. A study of the concentration of traffic in the central business district through the making of a cordon count on a typical business day:
 - 1. Total number of vehicles entering the district.
 - 2. Total number of persons entering the district.

II. An analysis of the parking problem; a study especially applicable to the central and outlying business districts:

- A. Capacity of the districts for parking.
- B. Current practice in parking.
- C. Amount of traffic obstruction offered by parking.
- D. Existing and potential off-street storage facilities.

III. Collection of accident statistics:

- A. Collection and tabulation of existing data.
- B. This is not a study that can be completed satisfactorily in a short period. The collection of accurate information over a period of months, and even years, is requisite for confident generalization. The report forms and methods of the National Safety Council are recommended.

IV. The relation between traffic and business:

- A. A computation of trucking and other transportation costs attributable to traffic congestion.
- B. The effect of traffic upon accessibility of retail establishments.
- C. The relation between parking and retail trade.

V. A study of physical obstructions.

- A. Street design.
- B. Pavement conditions.
- C. Private use of streets:

1. Merchandising.
2. Signs, posts, boxes, etc.
3. Building encroachments.
4. Storage of materials.
- D. Street openings.
- VI. The effectiveness of existing regulations:
 - A. Through street—stop regulations.
 - B. Left turn rules.
 - C. Operation of signal lights.
 - D. Overtaking movements.
 - E. Relation between street cars and vehicles.
 - F. Pedestrian regulation.
- VII. Study of police operation:
 - A. Enforcement methods.
 - B. Directive methods.
 - C. Adequacy of personnel:
 1. Numbers.
 2. Training.
 3. Equipment.
- VIII. Functioning of the courts:
 - A. Volume of cases handled.
 - B. Classification of cases.
 - C. Disposition.

Concluding the Survey

The materials of the survey when collected and analyzed, should be set forth in a clear and concise report. Emphasis can not be laid too strongly upon the necessity to present the data in such form that they can be readily understood. Several charts are incorporated in this report from the Metropolitan Street Traffic Survey recently conducted by The Chicago Association of Commerce to indicate graphic methods for the display of factual results.

The drawing of conclusions from the materials collected presents, of course, the most difficult and delicate part of the survey work. Few suggestions can be offered as to procedure. With sound facts available, however, reasonable men, even without a large degree of technical training, are likely to come to similar conclusions.

Recommendations to be drawn from the survey material will naturally fall into two classes: First, those rules for the regulation of traffic, which have been indicated as necessary. These should be formulated into a simple traffic code. Secondly, there will be inevitably recommendations for administrative changes to make the future control of traffic more effective. Specific details of such proposals will vary according to local political conditions. In all cases, however, provision should be made for the placing of definite responsibility over traffic control in some official or group of officials, and for the provision of suitable traffic engineering services for the future.

CHAIRMAN GOODRICH: I think we should tell Dr. McClintock we have enjoyed hearing his paper, also Mr. McIlraith's paper.

MR. REDEKER: There is a question that came up to me in Windsor. We instituted the automatic system and it has taken, as one of the speakers said, considerable traffic off the main streets. This particular situation has arisen: the complaint has come from business men, that due to the fact that much of the traffic now is taken off that street in order to avoid the automatic system, it does materially affect the amount of customers that come to these places of business. They have felt it to such an extent that some of them are objecting to continuing to pay the amount of rent for those places of business.

CHAIRMAN GOODRICH: The chairman had one such experience as that at least, in a certain city in the state of Massachusetts. After the traffic system was installed, which was recommended, the newspapers almost immediately came out with headlines that the main street was now simply a country town street instead of a congested city street.

The merchants, probably largely influenced psychologically by the newspapers in that instance, complained against the system, saying they were losing business. The facts were that business was being lost by other people in the city as well as by those merchants. There was simply a momentary depression throughout the community.

Merchants Often Mistaken About Automobile Business

Surveys made under my direction have disclosed that there is a wrong idea on the part of retail merchants as to the amount of business they get from automobile patrons. In one community, a relatively small town where the country people drove in on Saturday afternoon to do their shopping, complaints were made that the parking privilege which had heretofore been in existence and which was changed through the new regulations, actually drove patrons to other communities because the farmers had to walk one or two blocks to get to the downtown stores.

It happened that complaint was made on a relatively cloudy, rainy Saturday afternoon, and that in succeeding months there was no diminution shown in the amount of traffic. In fact they did more, because more people could get to the stores, rather than less because they had to park further away.

MR. POWELL: I might add a little testimony to that.

Our main street is also our principal shopping street, and at one time was our main thoroughfare. Our recent traffic efforts have been directed in driving through traffic away from that street so local traffic, which wants to patronize the stores, can get there.

Not long ago we undertook to clear up the street in the late afternoon, so when the traffic peak was on it could move faster. The store-keepers came to us the first week after the operation of that ordinance and claimed they were getting no customers after 4:30.

We had anticipated that and made a count. I asked them if they had,

and they said, "No." I compared our figures and they showed they were getting more business than they got before.

MEMBER: We are having a great deal of trouble in our community on the subject of left-hand turns. I am wondering if this is an appropriate time to ask what the cities are doing in left-hand turns?

CHAIRMAN GOODRICH: Left-hand turn practice at the present time is not standardized. There are a good many different schemes being employed in as many different communities.

JOHN J. GALVIN (Inspector of Police, Minneapolis, Minn.): I would like to ask the gentleman from Cleveland if the red light means, "stop and get killed by the man making the left-hand turn?" The question just asked is really a case for the Safety Congress and not the question of expediting traffic.

CHAIRMAN GOODRICH: This is primarily a question of safety. Safety, however, is coupled almost as closely as two things can be tied together with the handling of traffic. If traffic is delayed, it has been proven by statistics there are more accidents. If traffic is expedited too much, there are also more accidents, so there is a happy medium.

Making the Left Hand Turn in Dense Traffic

I will answer the first question first. Left-hand turns are permitted in some cities to be made from the center of the street and some from the right-hand side of the street. In some cases they have to be made around the center of the street and in other cases out of the center of the thoroughfare.

In some cases left-hand turns are permitted with the traffic. The complaint against that is that pedestrians are also moving with the traffic and are liable to accident from those vehicles making the left-hand turns.

In some communities the left-hand vehicles are not turned until after the vehicles have passed. In other places the left-hand vehicles turn before the vehicles pass, or whenever there is a gap in the traffic coming from the opposite direction.

We need standardization in traffic control, and the left-hand turn problem is one which is going to be as big a question as any. Some communities absolutely prohibit left-hand turns at any time.

My personal opinion is that red should mean absolutely nothing but stop.

MEMBER: How about the right-hand turn? If you stop, can you proceed on the red on the right-hand turn?

CHAIRMAN GOODRICH: That is a question differently handled in some communities. In some communities the vehicle can proceed and in other cases it must wait until the traffic has passed. It will depend entirely on local conditions, just as the two previous speakers have indicated.

The traffic at any intersection, and by and large, throughout the community, must be based on conditions in the community. Where a police official is on duty in addition to the red light, it is sometimes within his

discretion to indicate where the vehicle may turn, to left and right. Where there is no officer on duty, it is wise to make a rule and to adhere to it, and maintain it, perhaps change the rule after a few months' experience has been secured.

The best scheme seems to be to keep both turning vehicles back until just before the other traffic moves, and let them turn both right and left. So there would be introduced into the signal system, as at one point in Boston for example, the green to go, another combination of color to make the turns, another combination to stop and let the other vehicles pass on the intersecting street. In that particular case in Boston there is a still further signal for the pedestrians to move when all vehicles stop.

The Problem of the Pedestrian Always With Us

MR. PACKARD: Red always means stop, and when they put their signals in, that is the theory. Then we got a lot of complaints, as I guess everybody has, and we tried a new idea. We painted aisles in the streets. On a certain aisle the cars were supposed to go when they wished to make left-hand turns. Other aisles were for right-hand turns. We painted those aisles and permitted the left-hand turns on the private cars when the signal was red against them. The number of accidents caused by cars making left-hand turns was reduced 48 per cent over a similar preceding period of time when red meant, stop absolutely. Still we get the objection. What the answer is going to be, I don't know.

BERT N. WHEELER (Commissioner of Public Safety, Duluth, Minnesota): How are the pedestrians going to get across if they do not have the automobile traffic stop on the red?

MR. SHORNS (Detroit): I think along with your traffic discussion you will have to take into consideration the pedestrian. You have a problem here of vehicles that are traveling 20 to 25 miles an hour, and pedestrians going four miles an hour. I believe in Cleveland I was told that on a street extending 35 feet in width the average time of the amber light signal is insufficient for pedestrians to cross streets, and the inclination in our larger cities is toward wider streets, so we will have to give the pedestrian a separate way in which to cross.

CHAIRMAN GOODRICH: That is a very interesting problem, and one which has been discussed from time to time by practically every traffic engineer in traffic survey.

When I was in London a year ago, I went to examine the situation at the intersection known as the Elephant Castle. Five or six streets come in from varying directions. There is a very complicated movement on the surface. Pedestrians were almost taking their lives in their hands to cross that at the congested time of day. The authorities, therefore, built subsurface radii like those above, with a control area into which all pedestrians would feed and then take the turn which would lead them to their own streets.

I chose about 4:30 in the afternoon, when I thought the traffic would

be dense on the surface, both vehicle and pedestrian, and found it was as I had surmised. I was much interested in discovering how many people were using the surface. Two children on roller skates and I were the only people in the subway.

In the olden times in New York City congestion used to be very heavy at the intersection of Broadway and Fulton Street, and there was in those days a bridge over Broadway. I have a photograph of that bridge with one man leaning on the balustrade and looking at traffic below.

There is in New York what is known as "Death Avenue," along which the New York Central operates trains to a grade and on which there is a great deal of heavy trucking, and across which many people have to go at different points to reach the waterway on the west side of the thoroughfare.

The New York Central erected an overhead bridge for pedestrians. When this question was under discussion in New York City some years ago, I used to take some time about once a week to investigate conditions at "Death Avenue" crossing, where this bridge was erected, and on at least half a dozen occasions saw a total of one person using the bridge.

Many of the subway stations in New York are so designed that a person can go down on one side, cross under the street, and not have to pass through the turnstiles. On days of dense traffic it is very rare that a person uses those means of crossing. They prefer to take their lives in their hands, rather than go downstairs and upstairs. The question is whether such under-surface crossings should not be more used, but I personally believe until we put up fences which are pedestrian-proof, we won't be able to get them to go over or under thoroughfares.

Are there any other questions? If not, we will take up the regular order of business and listen to a paper by Burton W. Marsh, Traffic Engineer, Department of Public Safety, Pittsburgh. We have been discussing the physical side, and will now discuss organization.

ORGANIZING FOR THE CITY TRAFFIC PROBLEM

Burton W. Marsh, Traffic Engineer, City of Pittsburgh, Pennsylvania

From two and one-half million automobiles in 1915 to nearly twenty million registered today in the United States is a tremendous increase. This avalanche of some seventeen million automobiles is of course largely responsible for the modern traffic problem—one of the most serious problems cities have ever had to face, and a problem which, with its ever-increasing growth and complexity, threatens economic calamity to cities which do not courageously and effectively attack it.

The magnitude and costs of our unsolved present-day traffic problems are staggering. In traffic accidents alone, we yearly kill what would amount to one person from every thirteenth family in the city of Detroit and seriously injure about one-half as many people as live in that great city. Including property damages, it is estimated that traffic accidents represent an annual loss of \$600,000,000. If congestion, time losses, increased maintenance and operating costs, and similar losses are added,

the Hoover Conference estimates an annual total loss of \$20 for every person in this country, or a total of more than two billion dollars. Here are costs and losses we do not easily comprehend in magnitude. And the figure grows larger every year! Surely considerable expenditures are warranted in minimizing such losses.

What are cities doing today towards coping with their traffic problems? Numerous cities have realized that much of their present trouble may be traced to their inadequate streets and outlet arteries, irregular layout, and other inherited city-building faults. They have, therefore, made City Plans to correct some old errors and to avoid, as far as possible, mistakes in the future. In very large cities, rapid transit has become necessary. All such future planning now seeks to improve traffic conditions, and whereas some plans emphasizing centralization probably will complicate traffic problems, the best of such city plans embody real solutions to traffic ills.

But such plans are largely very costly, and even if they can be financed, they require long periods to be carried out.

In the meantime, there is always the "current traffic problem"—that of securing the most efficient and safe use of available streets and arteries. In this limited field there is much confusion. Common experience in cities and dissatisfaction of citizens indicate the general inadequacy of efforts to cope with the fast-growing current traffic problem. The muddle of opinions as to parking, the disorganized and confused use of streets, the wide variety of traffic signs, the inadequacy of knowledge of the fundamental causes of traffic accidents and how best to prevent recurrences, the generally unsolved pedestrian problems, the general ignorance of the public at large on many basic traffic matters—these all illustrate the need of—what?

Method of Attacking the Problem

In the first place, the need is for facts to replace opinions! There is a very evident need of more light on the various involved traffic problems. What are the real effects of no parking restrictions in certain districts? What are the extents of various demands on streets and how can they most justly be met? How does the elimination of certain turns affect the general traffic problem? What are the fundamental facts about the traffic problem?

Having the facts, the next steps in a logical attack on the problem are:

- (1) Effective analysis.
- (2) The development of improvements, remedies, solutions.
- (3) Putting the remedies into effect and checking results obtained.
- (4) Throughout all of these steps, a most vital work must not be neglected—that of "keeping the public informed." For the public must understand (if proper results are to be obtained) what is being done and why, and how to act under various conditions. It is in this field, perhaps more than in any other, that cities have the greatest opportunities for improving traffic conditions.

The above-outlined, common-sense procedure must be a continuous program to be adequate. There are constantly new problems arising, new factors entering the picture: new street car and bus routes, new streets and bridges, subways, pavement improvements, grade separations, new theaters, new ramp-type parking garages. Traffic counts must be kept up to date. The whole procedure is a steady job.

The question of the most effective way of carrying on this job—of coping with current and "immediate-future" traffic problems—is one which cities must seriously consider.

A first essential is proper organization, and few cities even including the largest, would claim that they are today adequately organized for their traffic problems.

What does constitute the usual present-day organization for coping with these complicated problems? Largely, the traffic police—a group of generally hard-working officers who largely through the hard school of experience have come to know much about how to handle traffic.

Complexity of Traffic Situation Demands Special Police

The traffic police, in general, have done and are doing excellent work. All over the country, however, those in charge of traffic police are crying for more men. The need for large increases in the numbers of traffic officers is quite generally realized, although the question of whether the existing personnel is being used to the best efficiency is frequently raised. The demands upon city budgets are so tremendous, however, that it is becoming quite generally obvious that other methods must be devised to aid in handling the traffic situation, because cities are not financially able to add sufficient numbers of men.

The increasing complexity of the traffic situation has brought out the need of specialized squads within the traffic police organization. Thus Detroit, Cleveland, New York and other cities have very effective accident investigation squads. Squads especially trained for brake, headlight, and over-weight testing, are needed. Officers trained for educational work exclusively, are also sadly needed all over the country—such officers to be teachers in traffic officers' training schools and to aid in the general traffic education of the public by talks in schools, in garages, at various safety meetings, etc. Detroit and New York are examples of cities which have provided such men. The demands for "special details" have become so important that they need special consideration.

In summary, the traffic police divisions in most cities are faced with a problem growing by leaps and bounds, and constantly becoming more complicated, with the needs of specialized activities emphasized. At the same time, these traffic police divisions are in general being forced, partly by lack of real appreciation by municipalities and the public of the true magnitude of their work, and partly by the financial limitations of the city budget, to attempt to carry on this ever-increasing work with, if any, only few and decidedly insufficient increases in the number of men to handle the job.

The need of developing other methods to aid in coping with the situation is a positive one. Many fundamental phases of the modern traffic problem are decidedly technical in nature and require careful engineering studies for their solution.

Just as "city planning" was found necessary in the problems of city building, it is becoming appreciated that there is another function which should be carried along to aid and supplement the work of the traffic police. This function may be called that of "Traffic Planning." The development of this work does not mean the elimination of traffic officers, and should not conflict with their proper work, but should rather aid and supplement it. If provisions are made for such planning work, the traffic police are enabled to concentrate more completely on their primary work of dispatching traffic, educating citizens on traffic matters, preventing violations where possible, and enforcing laws where necessary.

As mentioned above, the primary need in solving traffic problems is to secure the essential facts and then effectively to analyze them. For this work a traffic planning staff under trained technical direction is the proper type of organization, though in all such work the officials in charge of traffic police can be most helpful. A previous speaker has outlined in admirable fashion, "How to Make a Community Traffic Survey." The carrying out of such traffic surveys, including traffic counts, speed tests; the preparation of necessary maps and charts showing actual conditions, are all matters which can be handled best by some engineering traffic planning organization. Similarly, the design or selection, and erection of traffic signs, signals, and other equipment are matters where the engineer can be of real service. Analyses of traffic accident data, charting of results and development of preventive measures are all problems for which the engineer is best suited. Studies of segregation of types of traffic, street car, bus and truck routings, and the development of various inter-district routes, along with the preparation of necessary maps and charts on these subjects, are also traffic planning functions.

Methods of Traffic Planning

As stated above, other means of traffic control must be found than the constant addition of traffic officers, if for no other reason than the purely financial one. The recent development of electric traffic control signals and interlocked systems is the most promising step in this direction yet devised. In the development of the proper control system for any important district or thoroughfare, the experiences of several large cities have shown the tremendous importance of making a careful engineering study of how most closely to approximate the ideal in the system devised. The excellent downtown Chicago traffic control system and the good system on 16th Street in Washington, have been the product of careful engineering study. It is reasonably safe to say that the main future progress in this art will come through such studies. Here again are examples of proper traffic planning functions which many cities are today entirely incapable of carrying on in an effective, continuous fashion.

(1) There are at least three methods of organizing the traffic planning work. The first consists of employing an outside consultant to make a detailed traffic survey, building up a more or less temporary organization for the purpose. The usual conclusion of such a survey is a report containing many excellent recommendations. One important drawback to the outside consultant is the usually unwarranted, but frequently inescapable, aversion of local officials, and even citizens, to somebody from the outside telling them what they should do. Such pettiness may be on the decrease, but still exists.

Another great danger of this method is that those who should use the recommendations will be so busy with other affairs that they will not give the report proper consideration, and will file it away instead of carrying out its recommendations. This danger can be greatly minimized or eliminated (as evidenced by the outstanding accomplishments of Dr. Miller McClintock) by the consultant "carrying along" with the development of the plan, a sufficiently strong group of directly affected and prominent officials and citizens so that when the final report is submitted, this group will take up the work of getting it put into effect. Under such an arrangement, a logical step would be to have certain of the staff used in the survey, remain as permanent employees to aid in devising ways and means of getting the recommendations carried out, and to keep data up to date.

A Traffic Planning Organization Part of Local Government

Traffic planning work can not end with the presentation of such a report, or even with the execution of its recommendations. New studies must constantly be made and further solutions devised for the modern traffic problem is developing with almost hurricane speed. Hence it seems logical that there should be some permanent traffic planning group within the city government.

(2) This is the second method of organization—a traffic planning organization developed within and as an integral part of the local government. The greatest difficulty at the present time with such a plan, is to find the proper person to lead the technical staff.

No college turns out traffic engineers today, although some are beginning to give special work along this line. The only alternative is, therefore, to select some engineer who has had experience in some sort of traffic work (such as city planning traffic studies). Through study and experience he can develop effective leadership in such work. With only a small staff the engineer can begin to study the local needs, but he will very soon need an adequate working staff.

The staff should be of sufficient size to enable it to carry on continuously the necessary surveys, counts, investigations and studies, and to aid in putting them into effective use.

Under such a plan of organization, it may, of course, be advisable to have occasional consulting service from experts on particular phases of the problem. Thus, Pittsburgh may employ some outside consulting service on certain details of the downtown traffic control system.

(3) A third method of organizing traffic planning work, and one seemingly well adapted to smaller communities, is that of employing intermittent, or continuous part-time local consulting engineering service. At least one large city, Buffalo, uses this plan.

Other units in what seems to be a proper organization for traffic work, would include:

1. A responsible traffic head;
2. A traffic court (or in smaller communities, all traffic cases heard before one judge);
3. A traffic committee (or other means of securing active citizen and governmental support).

Each of these three divisions will be considered and then comparative descriptions will be given of the functional relationship existing between these various units in several of the larger cities which have been developing what now seem to be reasonably complete traffic organizations. In these cities most of the various divisions outlined are covered in one form or another, but the relations between them differ somewhat.

Advantages of a Special Traffic Court

It seems to me absolutely essential that there be some one official in responsible charge of all planning, administrative, and executive phases of the traffic work, including both the traffic planning organization and the traffic officers. The importance of centralizing responsibility on this as on any other important work does not need to be enlarged upon. Of course, such an official could not properly be in charge of the traffic court.

It is probably fair to say that the advantages of a separate traffic court are becoming quite generally recognized among the larger cities at least. The ever-increasing numbers of traffic violations of various sorts and the increasing complexity of the laws and ordinances governing traffic, call for a judge to become a specialist in this field, if even-handed justice is to be given and cases are to be handled with the necessary dispatch. A judge exclusively on traffic work comes to develop a technique for getting at the essential factors in the case. He quickly comes to detect flaws in arguments and to know those who are "repeaters", and to govern his decisions accordingly.

For most effective work, such judges should be removed in every way possible from the danger of political pressure and should not have short terms. Where such a traffic court is set up, good systems for keeping records are usually devised and plans worked out so that either as a direct adjunct to the traffic court or in a separate so-called "violations bureau", minor violations may be handled without the necessity of a hearing before the judge. Thus the judge is relieved of minor cases and can give his attention to the vastly more important major violations, such as speeding, reckless driving, failure to stop after an accident, etc. In smaller cities where a separate court is not warranted, considerable of its advantages may be gained by having all traffic cases heard by one judge.

It must be realized, of course, that only a small proportion of drivers are frequent traffic law violators, and only a much smaller proportion are intentional violators. In other words, the vast majority of citizens are law observers. Improvements in observance of traffic laws are brought about largely by a better understanding of simple and reasonable regulations by the public. This is one of numerous examples of the importance of active citizen support.

Especially in the early stages of working out an effective traffic improvement program, the importance of the active cooperation of citizens is too generally minimized. Though such cooperation and advice are needed most until an adequate official organization is fully developed and firmly established, it is my belief that such cooperation and advice should prove of inestimable value as a permanent policy.

Securing Active Support of Influential Citizens

In the solution of practically all traffic problems, there is the unavoidable clash of conflicting interests. The various types of conflicting interests may be grouped, however, and recognized representatives can frequently by discussion around a common table, come to an agreement after realizing all phases and analyses of the problem. Thus the necessary action is taken: whereas, the usual method of submitting an ordinance commonly results in concerted attacks on the proposal, and frequently a sorely needed improvement fails to be put into effect.

As to the method of securing such active citizen support, there is considerable difference among the cities. The following description relates to the method very effectively used in Pittsburgh. In other places, entirely different methods may be preferable.

Pittsburgh has a so-called "Better Traffic Committee" appointed by the Mayor. This advisory committee is made up of representatives of the main business interests directly affected by traffic, and of representatives of civic and trade groups. It also includes those representatives of the city government who must, by virtue of their positions, be the officials to aid in carrying out plans for improvements.

Much of the value of this committee has been brought about by the careful selection of prominent, active, civic-minded members.

The Committee's work is carried on by four sub-committees: (1) Engineering, (2) Traffic Flow, (3) Laws and Enforcement, and (4) Education and Publicity. These sub-committees consider and act upon recommendations of the Traffic Engineer and other city officials, and suggestions from citizens. They also initiate numerous projects, and develop ways and means of getting results. The sub-committees report at general committee meetings, where final committee action is taken. Certain recommendations are then forwarded to the proper municipal department or bureau for direct action or for transmittal to city council. Some are actually carried out by the sub-committee themselves.

The following two examples illustrate the valuable work of this committee:

(1) Pittsburgh was, it is believed, the first large city in this country to eliminate on a large scale, parking in its main business district. A critical street car service problem, narrow streets, an irregular lay-out, insufficient outlet arteries, bridge problems, and other factors made it essential that this step be taken. The recommendations were carefully considered by the committee and the desirability of the step agreed upon.

Ordinances were presented covering "no parking" and certain street car routing changes. The opposition which developed was tremendous. Had not this citizens' committee supported the Council and taken much of the burden off its shoulders by holding a considerable number of hearings with complaining groups, and effectively explaining the need of the no-parking rules, the regulation might have been defeated, or rather quickly rescinded by the insistence of the temporary opposition.

Instead of forcing traffic away from the downtown district, as it was stated would happen, counts showed that there was an increase in the traffic, comparing the period before the regulations were put into effect and one month afterwards. Instead of putting merchants out of business because of loss of private-car trade, investigation showed that, whereas there was a general business depression in the whole western section of Pennsylvania during that year which caused a falling off in the volume of business in the entire Pittsburgh district of three per cent, business in the district where parking was restricted fell off only .8 of one per cent.

The Better Traffic Committee Did Good Work

The Better Traffic Committee was very largely responsible for getting this measure adopted. Council and the mayor frequently want to do the right, but temporarily unpopular, thing to improve traffic conditions, and it is often of the greatest value to them to have a strong, non-partisan, respected committee willing to sponsor such recommendations, and to hold hearings, attempt to adjust differences, and explain the necessity for measures.

(2) Another illustration of the value of the committee is in important educational work now being undertaken. A large proportion of traffic difficulties in cities undoubtedly result from the fact that citizens do not know how they should act under various conditions, why various regulations are passed, and what they mean.

In the field of traffic accident prevention, the need of education is tremendous. The Better Traffic Committee is shortly to publish some 22 short illustrated, single-sheet statements concerning various fundamental traffic and traffic safety matters, 150,000 to a set. These will be widely distributed, and will, no doubt, produce most valuable results. Further, realizing the awful traffic accident situation, a Prize Essay Contest for school children is being inaugurated. Substantial prizes are being offered, some 100 in number, totaling some \$900. A one-year scholarship at a local college is also being offered.

The committee also aids in securing one of the most important con-

ditions for efficient development and prosecution of traffic movements—close cooperation and coordination between various affected city departments, commissions, etc., on all matters relating to traffic work. As has been stated, representatives of most of these departments and commissions sit on the committee itself, and are in this manner kept in close touch with projects under consideration. The importance of preventing over-lapping and of securing coordination can not be minimized.

The committee carefully avoids over-stepping its advisory capacity, and instead refers matters properly coming under departments or commissions sit on the committee itself, and are in this manner kept in close touch with projects under consideration. The importance of preventing over-lapping and of securing coordination can not be minimized. City Planning Commission and of a Department of City Transit, have a marked effect in determining what the proper scope of the traffic committee and the Traffic Planning Bureau should be. In cities where such functions are not provided for, it may be necessary for the traffic committee and the traffic planning staff to take over such functions, at least temporarily.

The support of the mayor and city council are, of course, essential. The committee, with its numerous prominent citizens and with constant evidence that it is not seeking to serve the advantage of any special interest or faction, has enjoyed most excellent cooperation from both the mayor and city council. Council has been quite liberal in providing funds and in setting up necessary positions, including the addition of 125 policemen, has shown a willingness to enact ordinances requested by the committee, and quite generally refers important traffic matters to the committee.

Points of the Adequate Attack on Traffic Problems

The Pittsburgh Traffic Committee had been operating so successfully that no need was felt, when the Hoover Committee on Metropolitan Traffic Facilities report was made public, to add any Official Traffic Commission. The plan of having the Traffic Engineer responsible to one official who also has the final control of the traffic officers, is believed to have many advantages over the arrangement under the above-mentioned Commission set-up. Other objections to the commission plan are divided responsibility, and the danger of the officials named being so busy as not to give adequate thought and consideration to traffic needs. Some of these objections may be only theoretical. At any rate, Pittsburgh has never formed such a commission. The suggested officials are mostly members of the committee.

Through experience, Pittsburgh is learning what changes and adjustments are necessary in its traffic organization, and is gradually improving it. It is believed that the general organization is one which will enable an "all-around" adequate attack on the various current traffic problems constantly arising, and with gathering momentum will bring about the development and execution of plans for traffic improvements, including:

- (1) The determination of causes of and contributing factors to traffic accidents and the gradual reduction of traffic accidents by applying remedies;
- (2) The determination of the most effective means of traffic regulation and control and the enactment of necessary regulations, and installation of necessary men or equipment;
- (3) The determination and execution of remedies for parking problems.
- (4) The effecting of the necessary minor street and roadway changes and improvements;
- (5) The absolutely essential education of the entire public on the fundamentals of traffic and traffic safety.

It is not claimed that the present Pittsburgh organization is perfect, but it is believed that it represents, as do the organizations of other cities to be mentioned, a tremendous step forward compared with the present very inadequate organization in most cities.

Supplement

Comparisons in Organization Forms in Pittsburgh, Detroit, Washington and Buffalo

The inter-relations of the various organization divisions mentioned above constitute an important functional question which has not yet, perhaps, been worked out ideally in any city. The following is a brief comparison of this functional relationship in Pittsburgh, Detroit, Washington and Buffalo:

In Pittsburgh, the Director of Public Safety is the responsible traffic head. To him reports the Traffic Engineer for the traffic planning phases; and through the Superintendent of Police, the Traffic Inspector for the traffic officers' division. An important point to note here is that the Director of Public Safety under this plan has direct authority over both the traffic planning function and traffic dispatching function. This point will be amplified in relation to the Washington organization. The director is a member of the Better Traffic Committee. All planning, statistical and technical matters are handled in the Bureau of Traffic Planning under the Traffic Engineer. All matters of traffic dispatching, assignment of officers to corners, educating of the public by officers, and enforcement, are handled by the traffic division under the Traffic Inspector.

The Better Traffic Committee is entirely voluntary and advisory, with a citizen chairman. The traffic engineer acts as the engineer and secretary of this committee, though the secretarial duties are in most ways an undesirable feature.

Traffic Court is under the direction of a magistrate appointed by the mayor.

Coordination and cooperation between city departments and bureaus are secured through membership on the Better Traffic Committee and through informal meetings and discussions.

With the present Pittsburgh organization, the following objections are noted:

(1) The duties of the Director of Public Safety are so considerable and exacting that he does not really have sufficient time to devote to consideration of traffic matters. The suggestion of the Traffic Engineer of Washington that an ideal organization would provide a Deputy Commissioner of Public Safety as Director of Traffic, who should either himself be a traffic engineer or have a traffic engineer as his principal assistant, is worthy of consideration.

(2) Insufficient personnel and funds in both the traffic planning bureau and traffic division.

(3) Not altogether satisfactory coordination between city departments carrying out functions relating to traffic.

The present Detroit organization consists of a Committee of Traffic appointed by the mayor, with a traffic engineer (who has a small staff) reporting to the committee in weekly meetings. The committee, and hence the engineer, are responsible to the mayor. The committee acts in an advisory capacity to the Director of Traffic. The traffic police are under the direction of the Traffic Inspector, who is the Director of Traffic.

Under this arrangement there is the danger of conflict between the dispatching and enforcement branch (the police) and the planning and legislative branch (the committee and its traffic engineer).

The accident investigation and prevention work in Detroit is one outstanding accomplishment of the organization there. The drivers' school to educate prospective operators before issuance of a license, and the violations bureau for minor traffic ordinance violations, are other outstanding features in Detroit.

The Organization Functioning in Washington, D. C.

Washington has a traffic court. In considering the remainder of the Washington organization, it must be constantly borne in mind that the problem is quite different from that of any other city in the country because the traffic organization, in addition to covering the customary city functions, must also occupy a position corresponding to the motor vehicle division of a state.

Washington has a Director of Traffic with an Assistant Director of Traffic who is the traffic engineer, and who has a working staff though, an evidently inadequate one. The traffic police are under the customary police head. It is understood that an at least potential difficulty with the original Washington organization plan has been the question of authority of the Director of Traffic over the traffic officers. As a matter of fact, there is a strong spirit of cooperation between the traffic bureau of the Police Department and the traffic director. It is understood that at one time, consideration was given in Washington to the creation of a distinct Traffic Department with traffic officers entirely separated from police in general. This would have certain executive and other advantages, but it would have serious disadvantages in the relations between the two separate police units, and in the questions of jurisdiction

between them. The separation of police units in such a manner is not generally favored.

Washington has an advisory traffic council composed of two members from each of the following organizations: Board of Trade, Chamber of Commerce, Merchants' & Manufacturers' Association, Commercial Vehicle Owners' Association, Automotive Trade Association, and American Automobile Association. A Washington official states that the value of such an organization depends entirely upon its makeup. If the appointees of the various organizations are men who have knowledge of traffic conditions and are selected for their fitness they can be of great assistance. If, however, they are merely picked on account of their personal prestige, without regard for any particular qualification, they are naturally of less value as advisors to the Director of Traffic.

Those working with the problem in Washington believe that better results can be obtained with the Traffic Bureau of the Police Department reporting through the Superintendent of Police to a Deputy Commissioner of public safety holding the position of Traffic Director, than would be possible with an independent force of traffic police reporting directly to the Director of Traffic.

The Buffalo Organization Has Several Differences

Consideration of an ideal organization in Washington has led to the belief that there should be a statistical division under the traffic engineer, charged with the preparation of comprehensive reports on causes of accidents, traffic counts, traffic flow maps, etc. Also it is believed that the installation and operation of electric traffic signals should be exclusively in the hands of the Director. The further suggestion is developed that the ideal organization should include an additional division for organizing school boy patrols, taking care of children on streets, and educating the public in general. The importance of a Violations Bureau as an adjunct to the traffic bureau or traffic court, is brought out.

An outstanding recent accomplishment of the Washington organization is the 16th Street traffic control light installation, which has brought about a reduction of traffic accidents of 58 per cent in the past six months as compared with the same period before the traffic signals were in operation.

The previous three organizations are either much similar or are developing towards a similar governmental organization. The Buffalo organization has several differences:

There is no active citizens' committee, cooperation being secured largely through numerous personal contacts. Buffalo had a citizens' committee, but for certain local reasons it did not make much progress. The mayor of Buffalo is the Director of Public Safety. The traffic division is in charge of the captain of traffic who reports through the chief of police to the mayor. The chief of police has a consulting engineer acting as his traffic engineer. In Buffalo there are weekly meetings of a "traffic committee" composed of the chief of police, the captain of traffic, the secretary of the safety council, the president of the motor

club, and the traffic engineer. This group to some extent constitutes a citizens' committee. To this committee all recommendations are submitted, and are discussed and voted upon. Authoritative action follows when the chief of police (with the approval in major cases of the mayor) issues orders based on the committee's recommendations. In general, no changes in traffic regulations are made without the sanction of this committee.

Buffalo reports substantial progress with its form of organization and cites numerous accomplishments. In general, it may be said that even this form of organization is not so different from the other cities' organizations, save that the planning function is carried out under a sort of contract with private local consulting service, and that the planning function is actually under the police department instead of being a separate function reporting directly to an administrative head in charge of both the planning function and the police department.

Making Efficient Use of the Present Street Facilities

E. J. REEDER (National Safety Council, Chicago, Ill.): It seems to me there is one point that applies particularly and ought to be investigated in connection with this question. That is, a distinction which ought to be drawn between the immediate problem of traffic engineering and the less immediate problem of city planning. In the last analysis they are one and the same thing, but we must remember that the purpose of city planning is primarily to lay out the picture of the way the city is going to be when eventually all these things are accomplished.

The problem we think of as being a problem of the immediate present is largely one of making most efficient and safe use of the present street facilities for moving.

I believe that is specifically the thing Mr. Marsh had in mind in presenting his paper. That is one of the problems that are of immediate importance in the present day and one which we must take into consideration when we are reaching out into the field of traffic engineering.

There are several ways, of course, to go about that thing. There have been surveys of various kinds conducted. I was glad to hear Mr. Marsh say that the specific and individual survey that is to close today and to be left up to the local people to carry on as they see fit, is not likely to be the most successful one unless there are proper facilities provided for the follow-up, and that constitutes the reason for men in the positions of Mr. Marsh and Mr. Simpson and others in traffic engineering in different cities.

The problem is one that is constantly changing and one which must have attention almost from day to day. We can make a survey that will represent the best judgment of the present day upon this rapidly increasing problem of traffic, and we may find that in a year and a half or two years the situation is quite different. That is the reason it needs constant and every-day attention.

The survey of the type Mr. McClintock and Mr. Marsh have spoken of is of particular importance to show the large pictures of the problem;

but I want to emphasize that we must at the same time set up machinery for handling the follow-up of that particular study after we have obtained the first picture, and carry it through to make the individual studies from time to time.

AUGUST VOLLMEYER (Chief of Police, Berkeley, Calif.): I should like to ask the delegates, if there are any here who have had experience in educational work, what success they have had with traffic in their cities, and what has been their program?

I will say Grand Rapids has had considerable success in organizing the Professional Drivers' Club. St. Paul has had success with their boy patrols.

I should like to know what other activities there are in existence in other parts of the country that would be useful to us in carrying on the educational work. Obviously the engineering problem is first, but all the engineering work is practically useless unless we count that in the human element, in our traffic problem. I should like to know what is being done to educate the public?

Educational Programs on File in the National Council

CARL SMITH (Cleveland Safety Council, Cleveland, Ohio): This gentleman has just asked for a large order, and we could spend all the rest of the evening and all the next day and two or three more days discussing it; but let me say this, for the benefit of some of the new ones here, that there are organized at the present time about 65 cities that have an educational set-up in the form of a Safety Council.

Now about 50 per cent of those cities employ a safety director, and in some cases, as in Cleveland, a staff of seven people. If I were to attempt to give you a set-up of our educational program, I would consume the next hour, and it would be the same way with St. Louis, Kansas City, and Grand Rapids.

I would like to say this: on file in the National Safety Council is a complete set of these educational programs, and they can be obtained, all that information can be obtained by anybody who wishes, by writing to them; or they would be glad to have someone visit your city and explain the value of the work that is being done by these councils.

I might point to the statistical report that was presented in this conference two or three days ago by Mr. Robb, where he pointed out that for the first eight months of this year analysis of accidents showed in 27 cities that had Safety Councils they had succeeded in having a decrease of five per cent in all traffic fatalities. Where they did not have Safety Councils backed by the communities, the reverse was true—they had a five per cent increase in accidents.

C. C. VARNUM (St. Louis Safety Council, St. Louis, Mo.): I would like to ask one question of Mr. Marsh. I would like to know what his experience has been in Pittsburgh on the segregation of various classes of traffic? I have reference particularly to the segregation of traffic such as street cars.

I know there is a situation that has arisen in St. Louis recently, which concerns this particular problem, and it has been our view that wherever traffic can be so segregated, there is a decided beneficial effect as well as a reduction of accidents.

MR. MARSH: We have not had anything in particular along that line. I will say that scheme of segregation does bring up one little point which I think might be of general interest. It is a special problem entirely, and relates to the entire segregation of the section between two parallel streets in Pittsburgh.

We have a big stadium there which seats about 70,000 people. We have developed a traffic plan for the big games at that stadium. We have the Boulevard of the Allies, so-called, leading from our downtown district. It unfortunately leads into another street before it gets out very far. On the Boulevard of the Allies only vehicles operate. Therefore, we have a high rate of speed on that street. There are few cross streets on either side. We have a very good situation, but all vehicles stop when they get to Forks Street.

We are routing street cars entirely on Fifth Avenue and allowing the Boulevard of the Allies during those particular hours to continue through the open district by taking all the street cars off, with the most unusual results. We have made a new record I believe in the recent game when about 50,000 people were able to leave that game in 18 minutes.

CHAIRMAN GOODRICH: To supplement perhaps what Mr. Marsh has said about segregation, we had some experience in Jersey City and also in Springfield, Massachusetts, which may be of interest to you in St. Louis.

Jersey City is located on a narrow tongue of land parallel to the Hudson River with relatively low land, a sharp bluff, and low land again to the west. To negotiate that bluff several viaducts and zigzag streets have been constructed from time to time.

Traffic Surveys Made in Jersey City and Springfield

A traffic survey was made in Jersey City some years ago, and it was decided to initiate an entire segregation of these several streets mounting the bluff, street cars being kept practically entirely on one viaduct, heavy motor traffic and motor trucks using the incline which was less steep but a rather longer route, and pleasure automobiles or the passenger cars being permitted to make use of certain other more direct thoroughfares. That was found highly satisfactory to the people in Jersey City, also to the motorists of each kind and to street car riders.

In Springfield, Mass., an endeavor was made to improve traffic conditions on Main Street. The through traffic was first given an opportunity to use a parallel thoroughfare close to the river. Then a number of street car lines were proposed to be shifted over onto an adjoining thoroughfare, leaving Main Street practically the shopping street through which the pleasure and passenger automobiles would go.

When the shifting of street cars was suggested, the merchants on Main Street protested vigorously because they wanted all street cars to go past

their stores. We told them they were narrow-minded and insular and various other things, but they still believed they were right. The shifts which were made in a few lines, however, showed that just as many people came to those stores after the street cars had been moved one block away as formerly. It is largely a matter of fear. If the segregation is carried out on a logical basis, it has been found in my experience invariably that it was eventually received and believed to be of advantage to the community.

Are there any other experiences? If there are not, I think we can consider we have had a very pleasant afternoon, and give the speakers a vote of thanks.

ADJOURNMENT

Home Safety

October 29, 1926

MRS. JAMES N. DOWNEY, Chairman
Chairman, Women's Safety Committee, Detroit, Mich.

The Home Safety Section of the National Safety Council convened at 9:30 o'clock in the Ball Room of the Hotel Statler, Detroit, Michigan, Mrs. James N. Downey, chairman, Women's Safety Committee, presiding.

CHAIRMAN DOWNEY: It is indeed a privilege to have been invited to preside at this first home safety session. When I tell you of the struggle we have had here (and perhaps you have had it in other places) to get a five minute speech on a program, perhaps you will realize that we feel we have almost arrived on this question. We have with us this morning the wife of the president of the National Safety Council and she has asked me to let her have just two minutes, so I am going to call upon Mrs. Scott at this time.

MRS. CHARLES B. SCOTT: - Madam Chairman and Ladies: having in mind the many courtesies extended to us through your gracious chairman, Mrs. Downey, and her able assistants, we visiting ladies thought it only fitting and proper that we should take this opportunity to present her with a small token of our appreciation.

Mrs. Downey, on behalf of the ladies of the National Safety Council, it gives me great pleasure to present to you this little remembrance. The flowers may wither and lose their sweetness but our regard and esteem for you and your co-workers will last always.

CHAIRMAN DOWNEY: Mrs. Scott, I haven't words to express my appreciation. I thank you so much and I am certainly overwhelmed.

This morning's program has been planned for the specific purpose of first pointing out the economic and social importance of home hazards and then for the discussion of the actual concrete method of solving the problem in the community.

To men must be given the credit of starting the safety work and they say, as the old saying is, "There is nothing new under the sun." I have been under the impression that until recently home safety hadn't been given any attention, but I was told this morning that it had been given attention in a little different way quite a long time ago.

I believe that the first safety work was started from an economic point

of view and so it is very fitting that our first paper should be along this line. We have two very able men in New York City, statisticians of the Metropolitan Life Insurance Company, who have prepared papers. We will hear at this time from Mr. E. W. Kopf, of New York City.

WHAT DO HOME ACCIDENTS COST THE NATION?

**E. W. Kopf, Assistant Statistician, Metropolitan Life Insurance Company,
New York City.**

We have all been accustomed to look upon the home as a haven of rest, security, and protection from the stresses of the external world. And yet there are hazards to life and limb in and about the American home which bring an annual toll of death and injury almost as great as that which arises in industry.

In fact, the 17,000 deaths or more which occur each year in and about the American home equal the deaths which arise in industry; they almost equal the deaths from hazards on our streets and highways. The one agency in society which exists for the protection of the very young and the old, the helpless and dependent, gives rise almost to the same number of deaths which have been the focus of attack for more than 20 years by the organized safety movement in American factories and workshops.

The hazards in industry have been brought sharply to public attention because of the interest of sociologists, economists and the managers of industry in humanizing the productive and distributive processes of society. The number of serious industrial injuries and deaths has been materially reduced, especially for certain of the large scale enterprises where the more dangerous processes are carried on. This includes such industries as the fabrication of iron and steel products, the steam and electric railroads, mines, and other important fundamental industries. The death toll on our streets and highways has also engaged the attention of our statesmen to such effect that two National conferences have been called under the auspices of the Secretary of Commerce for the development of ways and means for reducing the annual toll of about 22,500 deaths.

But with respect to the heavy toll of about 17,000 deaths and three million serious injuries in and about the home, little, if anything has been done. The facts, themselves, have not been brought to public attention. Would it not seem that as much attention ought to be directed to the chief agency for life and health conservation—the home—as to those agencies which deal with the production and distribution of physical goods?

In the field of domestic accidents, not only is there a lack of any statement of the facts, but there is even no definite approach toward the problem at the present time. We sorely need a definite recognition of this tremendous drain upon our vital resources and a broad-gage

approach on the part of agencies whose work can be brought to bear on this problem. We should recall that little more than one-third of these domestic fatalities occur among children under 15 years of age and a little more than a fourth among persons at ages 65 and over. There are organizations in the field at the present time which have facilities for reaching the home because of their interest in other social problems which affect the lives and destinies of children and of old people.

Close to two-fifths of these fatalities in the home are found to occur between the ages of 15 and 64 years, the main working period of life. Here there is an opportunity for all agencies which affect the lives of intelligent adults. All that is needed is the recognition of the extent of this problem of tremendous waste of life and a realization of the gravity of the serious disabling injuries which occur in or about the home.

The safety engineer in industry has done a good job, especially in specific locations. The movement for greater safety on our streets and highways is about five years old. Especially effective productive work has been done by safety engineers who have gone into communities and used the data such as now are available from the National Safety Council uniform reporting system, and injuries have been reduced on the streets and highways, and deaths averted. But with respect to the study and prevention of the 17,000 deaths in and about the home, and three million serious injuries, little, if anything, has been done in an organized way.

That more than one-third of these deaths, 34.4 per cent, occur among children in an environment which is expected to provide protection for the dependant and helpless should arouse the active efforts of every organization interested in the promotion of child health, child safety and child welfare in the United States. These young lives which are extinguished through exposure to domestic hazards are valuable lives, not only in the sense that economic productiveness has been cut off, but in the wider sense that possibly important cultural and higher values have been extinguished. Deaths from accidents among children occur among all classes of the population.

Early Text Books Upon Organized Safety Work

Much could be said also about the deaths from the exposure to needless hazards in adult life; the deaths of mothers and fathers which, in so many instances, occasion resort to agencies for the dependent, the disabled and the crippled. The large number of deaths in old age shows also the existence of preventable hazards for persons who have again become dependent upon the family circle for care and support.

I can recall very definitely about 1895 when the first text book on elementary hygiene and physiology was introduced in the grade schools, and I recall also the chapter on first aid and on accidents and injuries in and about the home. I also recall possibly 20 minutes of instruction from the grade school teacher at that time on what to do in case of injury in and about the home. That was organized safety work because those texts on physiology and hygiene were encouraged by the American Physiological Educational Association. Right now I want to say that the

work of that association has never been appreciated in public health or safety work. No one has ever given credit to those physicians and teachers who first began to teach hygiene to school children 30 years ago.

From our data for the industrial department of our company we estimated this figure of 17,000 deaths in and about the home each year. That checks in fairly well with the figures produced by Mr. Robb. He estimated 19,000. I suppose we could say that it is not less than 17,000 nor more than 19,000 a year.

Now, the problem of considerable interest to women is shown by this fact, that of the 17,000 deaths 9,000 are deaths of females and 8,000 are deaths of males. We were asked to prepare a figure on the economic loss from these domestic accidents. We were able to do that fairly roughly for males only and our figure is that there is an annual loss of about \$120,000,000 a year, and that loss means this: it is that amount which males contribute to the national wealth annually over and above what it costs to maintain them. It is not what these males would have produced, but it is the excess of the value of what they produce or contribute over and above the value of what they consume. One hundred twenty million dollars a year for males only. We haven't any idea of what the economic losses are from the deaths of females, but it must be at least that figure, or more.

Tracing the Causes of Accidents in the Home

We also have some facts on the nature of the accidents which give rise to this death toll in and about the homes.

We find first, that one-tenth of these domestic deaths is due to falls. Another tenth is due to accidental burnings and falls. Another tenth to accidental drownings in and about the home. Two per cent of the domestic fires. Two per cent of those deaths were due to accidents by fire. That, of course, excludes deaths by burns and by scalding. Two per cent, therefore, of the domestic deaths arose in the course of domestic fires. Two per cent of those deaths was due to accidents by poisoning and some three per cent to the accidental discharge of firearms.

There seems to be wide scope for the development of means for the study of the hazards which lead to falls. I looked over one of those very early text books—got it out of a second-hand book store, and one of the paragraphs had a slight discussion of this question of falls in and about the home. It warned against the rickety step ladder—against the defective stairway with no hand rails—the stairway with the hang-over, jagged metallic guard. The substitute for the step ladder—the rickety kitchen chair and sometimes the rocking chair. And it also warned against the bad placement of articles of domestic equipment. That was in 1895 and all of that, of course, holds true at the present time. These facts in respect to falls in and about the home ought, of course, to interest architects and experts in home economics and home design.

The next important group of injuries was the drownings; especially the drownings of young children which could have been prevented

Every day we hear about the tragic blunders which are made in abstracting articles from the family medicine chest.

There is also to be considered the hazards from cleaning substances used in and about the kitchen—the proper disposition and use of lye, ammonia, and strong soaps. Some efforts have been made to safeguard the dispensing of poisonous substances, such as carbolic acid, bichloride of mercury and other items which find their way into the family medicine chest. But this movement is still sporadic; no one has taken hold of it in a way which would make safety publicity continuously available to the public.

In our experience last year, out of 228 deaths from accidental poisoning in and about the home, we found that 104, or nearly one-half, occurred among children under 15 years of age. What a field there is for determining ways and means for keeping poisons out of the hands of children! Perhaps some of you will recall the epidemic of bichloride of mercury poisoning which spread over this country seven or eight years ago, following the first case of an accidental poisoning in and around Atlanta, Georgia. We kept track of the deaths which arose in the course of that epidemic in the nation due to bichloride of mercury poisoning. I suppose within six months we had 40 deaths, a cause of death which up to that time was comparatively infrequent.

One-Half the Accidental Poisonings Are of Children

As I say this movement is still sporadic, no one has taken hold of it in a way to make it available to the public, but this could be taken hold of by the manufacturers of pharmaceuticals, by associations of retail druggists and by agencies entering the home. That this affects children largely is shown by this fact that out of 228 deaths from accidental poisoning in and about the home, as I say, we found that 104 or nearly one-half, occurred among children under 15 years of age.

Another important group of deaths in and about the home, where public discussion with respect to it has had some publicity for more than 30 years, are those from illuminating gases. Three per cent of our domestic deaths were in this class. During the past five years health departments have endeavored to establish a standard code with respect to tubing used in and about the home to convey gas from the pipe to the hot plate. The engineers of the American Gas Association have been active in studying the manufacture of domestic gas appliances and the development of the devices attached to those appliances which would make their use much safer. Illuminating gas, one of the most useful substances in household economy, can be made entirely safe for use and the solution of this problem depends largely upon cooperation between the manufacturers of gas appliances, the engineers studying the proper use of such appliances and the general public.

The domestic conflagrations or building fire hazards have been attacked by the fire insurance group, especially by the National Fire Prevention Association of Boston. Each year there is a fire prevention week

and no doubt this work has done much good. Our committee on public accident statistics estimates there are about 2,600 deaths each year from fire in buildings. And, of course, in the control of the domestic fire hazard one must consider the situation. This phase of domestic hazards should appeal to architects, the city planning movement, real estate owners, the electric industry and other important groups in the further improvement of domestic construction and equipment.

Through the courtesy of the secretary of one of the largest accident insurance companies we were able to determine some of the facts on domestic accidents which occurred among adult males insured in their preferred risk department. Their classification of fatal accidents shows that the most important cause of death in their experience was poisoning by plants, insects and infections. The next important cause of death in and about the home for these adult males was falls from benches, ladders and roofs; and burns in burning buildings, falls on stairs, falls on steps, lawns and ice. There evidently is some very close connection between father and the family step ladder. The accident insurance companies have ever so many claims each year where householders in hanging pictures use the treacherous step ladder or some substitute for it.

The statistics for non-fatal domestic accidents are of prime interest. The chief cause of disability in non-fatal domestic accidents in this accident insurance experience, was cuts on bottles and sharp instruments which accounted for 16 per cent of the non-fatal accidents; and then falls on steps, lawns and ice, caused 20 per cent; falls on stairs, eight per cent; working around barns and gardens, six per cent, and collisions with inanimate objects, six per cent. The inanimate object is chiefly bed room chairs and all sorts of obstructions which crop up at night in the dark which are not there in the day.

The Council Is Taking an Important Step Forward

Now, in view of this very heavy death toll each year what should the National Safety Council do about it? The Council has taken an important forward step recently in instituting its effort to study and to encourage prevention of street and highway accidents. It took a most important part in industrial safety movements. As far as I have been able to determine this is the first session held under Council auspices, where the problem of domestic accidents is given attention. You say from the figures which I quoted that domestic accidents account for more deaths than occur in industry and for almost the same number of deaths which occur on our streets and highways.

Our suggestion is that the National Safety Council, temporarily, under its division of public safety, appoint a committee of representative persons; draft a program for consideration of the Executive Committee of the Council, and that program should be a statement of the facts available—of the facilities available for entering the homes of the entire nation; relationships which could be set up in respect, particularly to

organizations such as the American Gas Association, also the home economics groups—groups of teachers and the family case workers and agencies. Many details will have to be worked out in a consideration of this program but we are confident that shortly that program could be put into effect and that perhaps we could utilize agencies which are, at present, attacking the problem of public safety. It is quite possible that in teaching public safety it would also be possible to develop and teach domestic safety.

We therefore recommend that the Council take under consideration the formation of a committee broadly representative of the several interests in the Council and that that committee be requested to bring in a report on plans and scope and facility at the next meeting of this Council in 1927.

CHAIRMAN DOWNEY: I am sure we all appreciate that very fine talk. Not long ago in Detroit there appeared in one of our leading papers this startling headline, "The Street Is Safer Than the Home," so I am sure it will spur everyone of us, especially the women, to be interested in this home accident prevention campaign.

Our next speaker is one of the leaders in social service work in America. I think very often we lose sight of the close community of interest between safety workers and social service agencies. It is an honor at this time to present to you Doctor John A. Lapp of Chicago.

WHAT ACCIDENTS MEAN TO THE FAMILY

**Dr. John A. Lapp, President, National Conference of Social Work;
Director, Department of Social Action, National Catholic Welfare
Conference, Chicago, Ill.**

Madam Chairman, Ladies and Gentlemen: I beg your indulgence this morning. I have to tell you that I have arisen from a sick bed to come to speak to you here, and I am not able to give you a written paper such as I had intended to do.

The subject is a most interesting one—the relation of accidents to the home, and it is especially interesting to me because of my connection at the present moment as President of the National Conference of Social Work—for social workers are interested in the family—interested in the family above all else. In a fashion, our entire interest centers around the stabilization, protection and promotion of the family. Anything that interferes with the family—breaks it up, destroys it—therefore breaks up the home, is a disastrous thing in the life of the nation. And I believe most social workers devote most of their attention to means of keeping families on their feet, to means of protecting them against those causes which would break them down, and to means which would make them function just as complete as possible for the purposes they have been granted by nature.

We must remember that the home and the family is the basic institu-

tion of this country. Away back as far as we can trace in history we find the family, far back beyond any other institution that we can trace, and we know not how much farther back it goes, but we are assured that it must have gone far back, certainly, to the beginning of human relations. And so the home is in all respects the most vital thing in society, and, of course, in connection with the home comes the individual in the home. We must protect him, not solely for his own sake, but for the sake of his part in the family, in making the family do its part in the world's work.

I was very much interested to hear the previous speaker mention the fact that the first safety work began back in the teaching of hygiene. That fits in with what I have to say because that tended to strengthen the individual—tended to make him able to play his part; to protect him from breakdown and thereby protect the family from breakdown.

Things That Break Down the Individual's Resistance

There are many other things of a similar character that work constantly for that end. I have seen some very good movements for the betterment of the feeding of people. I have seen some very good text books, past and present, for the guidance of those who would feed the family, but this morning coming up on the train I saw a new one and I am not sure but what this will go a long ways toward stabilizing the family and certainly stabilizing the individual of the family. I found an advertisement in Harper's Magazine this week of a new book on foods and feeding and recipes and so forth. It was prepared by two very distinguished women and it was entitled "Feed the Brute." So we may expect in the future that we will have the brute better protected and, therefore, capable of performing his functions and preventing the breakdown of those functions in the family.

Now, then, social work centers around the individual in the family and what are the things that break the individual in the family? Well, first of all, there is sickness and I have come to the conclusion this week that sickness is an accident. I know it is an accident. I did not will sickness. I did not neglect anything that I knew how to prevent and yet sickness comes as an accident, but I am not going to discuss sickness today, although sickness is the great cause that breaks men down and makes it impossible for them to maintain families.

Secondly we have this question of accidents. We have accidents as a very important, a very significant cause of the breaking up of the family. And we see the very spectacular in accidents; we see it even more than we do in sickness. We see it so well in accidents that we have been legislating against the economic disaster of accidents so far as they occur within industry, but we haven't done anything with respect to sickness yet. That is largely because accidents are so spectacular that we can't get away from the sight of them. Even when we read about them, they spring up before us. We visualize them and therefore we are horrified at the conditions and we do all we can—first, possibly in prevention, sec-

only, in the economics of the situation, even going so far as to provide in many spectacular accidents to take care of the victims.

We have provided, under workmen's compensation laws, for accidents within industry, and some states are doing fairly well in protecting the family against breakdown due to accidents in industry. They haven't gone far enough yet in any state and they are far from being far enough in most of our states, but they are approaching the ideal, namely, that no person injured in industry need apply for charitable relief on account of that injury. An ideal workmen's compensation law would hold that as its motto, that no one need apply for charity because from the fund created by insurance they are paid the cost of their medical care; the cost of their hospital care; a goodly portion of their wages, sufficient to maintain the family during the time, and, therefore, they should be in no need, such as requires the intervention of social agencies, with the exception of need for temporary care.

But we come now to this question which you are discussing today. We find that the home which is to be protected against accidents is the one source of the worst kind of accidents that could possibly take place.

The Home a Great Factor in the Accident Totals

Accidents outside of the home take place largely with respect to workers and we have been providing so many protective measures that we have learned much of the way to protect the family. For example, when the worker is killed in an accident and leaves dependent children we have the workmen's compensation law, but when the mother is killed in the home and there are dependent children under 14 years of age, there are no means of keeping the family together.

But we find now that the home is a great factor in accidents. Seventeen thousand deaths in one year. Seventeen thousand, a large part of which consist of people between the ages of 15 and 64. Mr. Kopf mentioned that something over half of the accidents were among women. So we find that in the home this very greatest of disasters is the injury or death of the mother and in all probability in a good many cases, a large part of them in fact, the person injured or killed is the mother.

Consider the great extension of machinery in the home; the great extension of just such things as the electric wringer. In my own experience I have seen case after case, and heard of many, many others, of children and older people having their hands dragged into the automatic wringers and crushed, many of them thereby being handicapped for life. And that is only one of the modern automatic machines that is being put into the homes. These machines must necessarily be operated by unskilled hands—the most unskilled hands, and must be there where children and others who can not possibly foresee dangers are going to have access to them, and the only way in which we can prevent results of a disastrous character is by education of the parents to keep these things safeguarded (but after all it is a long job to reach parents and teach them to keep things safeguarded); and secondly, a campaign to get just as much of this

machinery made foolproof as possible and just as much proof against children—just as much proof against those who can not be expected to protect themselves.

So it is a very fortunate thing that the National Safety Council is approaching the subject of home safety, and from my point of view as president of the National Conference of Social Work, I should like to see this same idea brought forcefully to the attention of social workers throughout the country, for they are in a position to reach vast numbers of people. I have in mind that body of near-social workers at least, the public health nurses who reach the homes of the poor and the middle classes, and those who perhaps most need education; they are in a position, if anybody is in a position, to teach safety. Get the Public Health Nurses' Association on this job, as well as the teachers of the schools. I think probably in all respects the public health nurses and the family welfare agencies will reach the people more effectively, that you want to reach, than even the schools can possibly do.

There is the other aspect of this question which I want to bring to your attention because it is on the program of the National Safety Council—the Michigan Conference on Rehabilitation. Aside from this question of death which we have talked about, we have the three million people who have been injured in the homes, more or less seriously. Probably if we knew the facts we would find that a very considerable percentage of the three million are having some sort of a handicap put upon them for the rest of their lives, and among three million injuries we will find thousands of cases that need rehabilitation. And it is fortunate that social workers have been in modern times the leaders of public opinion, and have developed the plan of rehabilitation. It is very fortunate you have meeting with you the Michigan Conference on Rehabilitation. In the past I believe you have had a meeting of the National Conference on Civilian Rehabilitation.

Social Work Is Very Largely to Help Prevent Accidents

As I finish what I have to say, I feel inspired to write a better speech than I have given—to write more completely my views upon the subject that I have dealt with here necessarily in a cursory sort of way, because it does seem to me that we are right at the very heart of social work. I would like to have safety people impressed with the idea that they are social workers, too. I would like to have them impressed with the idea that it is a large part of the program of social work to prevent accidents; to rehabilitate the injured, put them on their feet physically and vocationally and I am very happy to have had the privilege of participating even informally in the discussion.

CHAIRMAN DOWNEY: I am sure you will all agree we are very fortunate in having Doctor Lapp on the program. We have a gentleman from Michigan with us this morning and he has just a little different angle from which to tell you about this home safety work, and I am going to

Introduce at this time Doctor Sidney G. Davidson, Superintendent of the Butterworth Hospital, Grand Rapids.

HANDLING ACCIDENT CASES IN THE HOSPITAL

Dr. Sidney G. Davidson, Superintendent of Butterworth Hospital, Grand Rapids, Mich.

Madam Chairman, I confess at this time a woeful lack of information and a great amount of ignorance with reference to the work of the safety council. I presume that your work is largely educational and as an evidence of the advance of the educational work, may I say that having been connected with hospitals for a great many years, it was only within the past three or four weeks that I was educated to the fact that there was a place in the safety council work for hospitals?

I can't bring to you the figures that Mr. Kopf has brought to you this morning nor perhaps much of the message that Doctor Lapp has brought; but let me take you down to a little town in Michigan with three hospitals, and just outline the work that is being carried on in one of those institutions.

A great many accident cases are brought there. In 1922 there were 749, and they have increased each year until, in 1925, there were 1,194 accident cases. And from September, 1925, until September, 1926, it had increased to 1,393 for that period. For 1926, from the first of January to the first of October, there were 1,039, of which 412 were due to automobiles, leaving a balance of 771 accident cases due to other causes. Of the automobile accidents during last year (and I am sorry to say that the hospital has not kept a very accurate record), up until 1925, 231 persons were struck by automobiles on the streets.

Fifty-five accident cases were brought in due to individual automobile accidents, that is, where the automobile ran off the road and hit a tree or telegraph pole or turned over in the ditch or something of that sort. Eighty-nine were injured in automobile collisions. Nineteen were injured when the automobiles were struck by trains and three when the automobiles were struck by trolley cars. Of this group of 231 people so injured, 39 died, 21 of them within 24 hours. One hundred and forty-seven of these people were hospitalized at a cost of \$15,000 in hospital bills, for which they were able to pay only \$7,000 and the community had to make up the difference.

A man buys a second hand Ford car for \$125 and he is working two days a week or three whenever he can get a job, and he pays for the Ford as he can and buys a little gasoline; takes two working girls out driving, and of course he drives recklessly. He has an accident. He is not injured but the two girls are. They are in the hospital for eight and ten weeks, and they have no funds. It is a community problem. The community has to pay for their care.

Only three of the accidents last year were due to children being injured by automobiles while going to or from schools, which is an evidence of the very fine work that is being done along that line.

Of the accidents for a year from October 1st, 1925, to September 30th, 1926, 444 were automobile accidents, 268 home accidents, 304 accident cases of people employed in manufacturing places, and then the balance—323—due to such causes as being bitten by dogs, falling off bicycles, playing basket-ball, volley ball and so forth. Fighting only one, fire-cracker accidents one; only three hunting accidents; 26 poisonings of one kind or another. Of this group 407 were hospitalized at a cost of \$34,000 of which less than 50 per cent was paid by the injured person and for which the community had to foot the bill for the rest. On the balance of those injured, 937, there was a cost in hospitals, for dressings, X-rays and first aid, of nearly \$10,000.

The education of these people, it seems to me, as Mr. Lapp just said, is a tremendously big job which is going to cover many years. Just Tuesday night a man and his family were driving out of Grand Rapids in an automobile, going to their home in a town 15 or 16 miles away, driving through another small town in the early evening. It wasn't raining either; it was a fairly clear night, and he drove his automobile into a moving locomotive on the main thoroughfare of that small town through which he was passing, and his nine-year-old son was seriously injured and died the next day. I don't know how you are going to educate a man of that kind.

Another Little Child Horribly Burned

As to the home accidents of which Mr. Kopf has just spoken—Wednesday there was brought into the hospital a little child of three years, horribly burned. Its muscles were hardened and charred. It had no feeling at all and died within a half hour after being brought in. The father, a poor crippled man, was out looking for work and the mother was hunting for some work so as to get some funds with which to keep the family together. There were several other children. The little three-year-old child was left home alone and got hold of the matches and set itself on fire.

We have, I should say, three different types of individuals to educate: the man of average or more than average intelligence; the person with less than average intelligence; and then that great mass of people who are loose in all of our communities who haven't any intelligence; and we ought to know when the accidents happen what type of intelligence it is on which to base a program of education for those different types of people.

Go back to the man of more than average intelligence. Doctor Lapp said that sickness was an accident. I think it is to a very large extent, and perhaps it might be necessary to educate that tremendously intelligent group of people—the physicians of our country. I have been trying

for three years to get the physicians connected with the hospital in which I am superintendent, to see the value of making that hospital a center for the physical examination of employees in the many factories in Grand Rapids. As soon as I mention it they say "State medicine," or some other such thing as that, or, that I am crazy and that nobody will stand for it.

I have been going around lately interviewing the employers and I think in time we might educate the employers to the advantages of that thing, for it has many, many advantages. I had the opportunity some years ago of being in the health department of New York City when we began physical examination of the employees in that department, and the first year I think less than 30 per cent of the employees would submit to physical examination. At the end of three years, all of the employees were coming in for their yearly examination. I talked with several employers of labor last week in Grand Rapids and slowly that thing is beginning to interest them, and the next big job for the public of Grand Rapids is to so interest the medical profession of that community that they will fall in line with a suggestion that means tremendous savings for the people and for the community.

The Hospitals Can Aid Safety Councils Greatly

I have come to the belief that the hospitals can add tremendously in giving to the safety councils of their communities information which will be available upon which to base an educational program, and it would seem to me that perhaps in those communities where there is a safety council, contact should be made with the hospital or hospitals in that community and they be asked to keep a separate record of the accidents. We are doing it at the hospital where I am. A record slip is kept of every accident case coming in—age, name, residence, sex, married or single, occupation, brought in by, from where, employed by, injured while at work, nearest relative, address, telephone number, surgeon attending, conscious or unconscious, serious or not serious, cause of the accident, whether the case was hospitalized or not, whether he was sent home, and when he died. And then, going on into the hospital, if the patient has been hospitalized the record of that patient is kept separately from the other records so that any time we are able to give the figures on our accident cases.

Now, that is not difficult. If you can not make contacts with the local institutions, contact can be made with the state hospital associations. There is one in nearly every state and contact certainly can be made with the American Hospital Association at its national headquarters. We, long ago, in the National Association, decided upon a standardized accounting system. This work very largely fits in with our accounting system and with the statistics we have to keep, and I am certain that when the contact is well made with any institution and standard forms are prepared and the institutions are asked to keep their accounts in that way, that they will realize the value, not only to the Safety Council and

the community, but the value to themselves, because there is a tremendous loss to the hospitals on these cases, unless there is, as we are so fortunate in Grand Rapids to have, a community chest which takes up the burden.

CHAIRMAN DOWNEY: We have now come to the discussion of the topic of reaching the home. It will not be necessary to discuss specific home hazards, as I think most all of us are familiar with that subject, but we will have discussions on what is the best method or how we can reach the community. We will have to limit our discussion this morning to six minutes, because it is very necessary for this room to be vacated at 12:00 o'clock.

A Center of Information Upon Employees' Health

LEWIS MACBRAYNE (Manager, Massachusetts Safety Council): I am very much interested in the remarks that the last speaker made relative to endeavoring to establish in his hospital a center of information on the physical condition of employees. It ought not to be difficult to sell that idea. In my own city of Boston we have in our membership one very large corporation that last year selected a group of 1,000 employees and gave them all a very thorough physical examination. What the examining physician did was to re-assure them as to the condition of their health or point out trouble which was about to develop and indicate the change of diet or whatever might be needed to correct it. The other group of employees, numbering about 1,000 was not examined.

At the end of a period of about 10 months the lost time due to sickness was computed in the two groups. In the group of 1,000 employees who had been examined and had received advice, there was a very large saving in lost time as compared with the other group. Translated into dollars and cents there was a very important saving, both to the employee and to the company in the group of people who had had that human engineering done.

The doctor spoke of the people who have almost no intelligence. We conducted in the Massachusetts Safety Council the first study I know of made of the habits of pedestrians. We examined the habits of 19,000 pedestrians. We selected five cities. The people in charge were usually trained police officials—lieutenants and traffic sergeants, and they stood on the intersections and watched what pedestrians did under two circumstances: when there was a traffic officer in charge of traffic, and when there was a heavy flow of traffic with no light control and no traffic officer. We found that out of the 19,000 pedestrians, 10 per cent in the five cities did absolutely nothing to prevent an accident. If the traffic officer said to pedestrians, "Stop!" the 10 per cent pushed their way through those who did stop in order to walk by the traffic officer; and sometimes when he said, "What are you trying to do?" they did not even know the traffic officer was there; and the corresponding group, where

we have the heavy flow of traffic and no officer, pushed their way through and walked out into the stream of traffic.

Now, at our general session here on Tuesday the statement was made that 10,000,000 Americans—relatively 10 per cent—passed through the hospitals of this country last year, and I wonder whether there wasn't a relation between the 10 per cent of the pedestrians we found and the 10 per cent of people passing through our hospitals.

The Army used to give the Binet Simon test and some 87,000 were found defective and they were told they could not go over the top. If we applied the same test in the hospitals and in the home, of course we would find the same proportion and the problem is how to reach them.

I have one interesting example that may be helpful. In one of the fleets of automobiles in our membership, the manager said, "What is the type of man whom I should discharge? I believe that a small group of my drivers are responsible for a majority of my accidents." And the engineer on the job said, "Discharge any man who has two driving accidents in one year for which he is responsible." Well, the manager said, "I have a chap who has had three accidents in six months for which he is responsible." The engineer said, "That being an unusually interesting case will you turn it over to me?"

Handling the Habitually Careless Employee

He interviewed this chap and he said, "Are you married," and the fellow said, "Yes." "Have you any children?" and the man said, "You bet your life, I have got five now and I expect another." The engineer said, "You can't afford to lose your job?" and the man said, "No, why should I?" Then he said, "We have decided that you are in the class of drivers whom nobody should employ. You should be discharged now. Of course that is the theory of these scientists and they may be all wrong. My own idea is that some of you chaps are having accidents just because you have accepted no responsibility, and I am going to arrange your discharge on this basis: you remain at work until you have your next accident and then you lose your job automatically."

The six months has elapsed since then and the man is still on the job. Now, if it were possible for us to say in the home, "You are going to lose your standing in the community the moment you are involved in another accident through your own carelessness," possibly we might salvage something out of what appears to be the "nut" 10 per cent of the community.

I have pretty nearly used up my time except to say that in the city of Boston in the last nine months we have had 75 deaths from automobile accidents, and 107 deaths from falls. We have had in the last three years a steady reduction in home fatalities from accidental causes and the only way we have been able to get into the home there is through the district nurses—the school nurses, social service workers and through the play ground.

We delivered a message in some 15,000 homes in the congested areas

this summer. In a previous year we reached some 20,000 homes through a little booklet, entitled "Common accidents in the home," which was written for the poorer people. There is an approach to the home through the social service worker and the nurse, provided we can put into her hand the message in such simple, direct form, that the mother will be able to understand it. In one of our cities once, I had 25 policemen ringing 2,500 door bells in the area where we had our accidents, and the policeman said to the woman—and she might be one of seven nationalities—"Read that carefully; there are too many children being injured on this street." The policeman being in uniform probably arrested the attention of the mother when I would not have done it if I had gone and talked to her as I am talking to you here. The problem is to dramatize and translate in such a way that the busy mother in the home will get something practical out of it.

Getting the Women to Help in Better Home Safety

FRED ROSSELAND (Manager, Newark Safety Council): We found in Newark, as I presume many have found in their own home city, that we have many more home accidents, both fatal and non-fatal, than industrial accidents, and we have just about as many home accidents as we have public accidents. In the non-fatal group the data are very insufficient and we can only proceed on what we believe to be an authoritative estimate rather than actual statistical information. We have found we were not getting very far with the home accident situation. As in so many other cities, we have a large foreign population. We have many Hebrews whose knowledge of English is very limited. We have many Italians and many Polish to say nothing of the other good people who come to us from foreign countries. These people do not seem to be interested at all in English printing, and our printed matter did not get very far with them.

We found that through the schools we were getting pretty good results, but that was not going far enough. We found that pretty generally the accidents occurred—those about which we secured a record—in the homes of what I presume social workers would call the middle class, and the lower class; not that the third group didn't have any accidents, but they did not seem to have so many of them, and we found that our attempts to work with the organized women's clubs of the community (and we have some splendid ones) did not get results particularly.

So now we propose to get one of these women's club leaders—and we have the matter already arranged—who has had experience in organization and who is a real leader, to undertake to organize some of the other women who have not had this organization experience, and carry out a rather simple and, we believe, a direct program for home safety.

The first thing they have already agreed to do is to conduct a series of meetings which Mr. Corn, the field secretary of the National Council, has originated and which I, for my own purpose, call a safety instruction course for social workers. That struck home with our people. They said

that we have such splendid social workers they would like to help, but they don't know just what to do about it. So we propose, through these lectures, to teach them what to look for—what to say and do to help in preventing home accidents—to help in teaching home safety.

Then we will ask that committee to go into the wards and districts of the city and distribute these printed safety instructions, hints and so forth, about which we have already talked. They will be printed in the different languages of the particular peoples to be approached. We are going to ask them to make a special effort to report dangerous conditions and dangerous practices. We have national surveys and community surveys and some of us know pretty well just what the dangerous conditions and dangerous practices are that may be found in the homes of the community; but I have found that people like to find out those things for themselves, and with the information which has been made available for me, I can direct their investigations and help them to see most quickly just what the hazards are—just what the dangerous practices are, and in the meantime they will be developing the data themselves and I think will be the prouder of their work and the more interested in it.

A Special Fire Prevention Campaign to Follow

Then we propose to carry on a special campaign which might be called a fire prevention campaign, although actually from my standpoint it is more of an accident prevention campaign, for we have found a number of these people, and there is no distinction as to who they are, are still using some of the dangerous materials for home cleaning. We have had a number of persons, grown up men and women, who were seriously burned, and I think in two cases very recently burned to death, through our old familiar and long-condemned practice of home cleaning with gasoline.

Then these women's committees will conduct what you might call safety mass meetings. In those meetings we will have the people addressed in their own languages. I am going to try to suggest to them what they shall say and I hope they will say it. That is much the same as with our foreign language newspapers. We provide them with material and others tell me that they use it.

We believe the home safety mass meeting following the safety courses for the social workers will be truly effective; and then, somewhat contradictorily it may seem to you, we propose to have this committee conduct our next women drivers instruction courses. Those courses have proven to be very interesting and well responded to in our territory; and again we find that automobile driving seems to have no boundary lines, and where a family may need many other things they also have an automobile and they contribute to the street accident hazards and are involved in them.

CHAIRMAN DOWNEY: We have with us this morning a Detroit man who is about the most enthusiastic safety man I have ever met and it is a

pleasure at this time to present Mr. Paxton Mendelsohn, who is chairman of the Fire Prevention Committee of the Detroit Board of Commerce.

HOME FIRES AND THEIR CAUSES

Paxton Mendelsohn, Chairman, Fire Prevention Committee, Detroit Board of Commerce

I have divided my important subject into four divisions. The first is, to compare the home fire hazards with industrial hazards. You do everything possible through the safety council and chamber of commerce organizations to protect the theaters, the hospitals, the factories, and the stores with all modern devices that possibly can be put into them or used in these places, but what do we do for the home? I don't think we do anything. The person at home has not even in most cases a fire extinguisher and has no sprinkler system. It is too expensive and he can't afford it or won't afford it. So what must we do? We must educate the people in equipping the home.

The next point is the things happening in relation to home hazards and accidents and in relation to fire, because fire is, as our previous speaker said, an accident. Mr. Kopf, I believe, told us there were 22,000 or more people killed in public accidents, and I am sorry to have to add to that by direct fire losses in the United States last year, 15,000 were killed and 17,000 more, more or less permanently disabled and disfigured; and out of those 15,000 deaths and 17,000 injuries it is appalling to note that 85 per cent are women and children.

Does that strike into the home or doesn't it? And furthermore while we have been sitting here this morning, every minute we have been here, there has occurred a fire some place in the United States, and also, strange to say, 85 per cent of these fires are home fires. One big factory fire of \$1,000,000 may be a tremendous loss financially, but against that one fire there are 85 home fires. In the home fires there may be only small losses and no accidents, but every fire in the home is a possible injury or death. That is why I talk to you about fire in relation to home accidents.

Now, what happens in the home? There are three places in the home where fires start. I know, I go to them. In the basement, poor housekeeping, rubbish and dirt. In the attic, again poor housekeeping—rubbish or dirt. Defective chimneys or so-called defective wiring in the walls, and it has been found in many cases that the so-called defective wiring is not defective or it was not when it was put in. Maybe it is made defective by the occupant of the home who is not an electrician and doesn't know when he is making the wire defective—overloading lines and putting in extra base plugs and so forth.

How to prevent these accidents requires education—absolutely only education. Do you know, ladies and gentlemen, that the great majority

of home deaths from fire last year were from inflammable liquids? I have been on a committee of the National Fire Waste Council which has been making tests on losses of life and accidents by fire; and we find that the greater number of the home fires are due to inflammable liquids, and second, electric light appliances. I wish I could tell you of an accident I knew of where a lady was cleaning her chamois gloves in a bowl of gasoline. In rubbing the gloves it made static electricity and burned her arms off. I wish I could tell you of the day I helped to take a burning baby out of a crib.

Now, how are we going to get in contact with the home? We can't go from door to door like a postman delivering mail. It is impossible. It might be done in a small town, but where you have a city like Detroit, or Chicago, or New York or Boston you can't make a door-to-door canvass to tell each mother and each servant maid and each occupant of that house what is there that they don't recognize or what they are doing that they don't know is dangerous.

Education Through Visiting Nurses and Children

There is one possible chance, as I see it—and that is through some of the ladies I see here—the visiting nurses; and I am going to get to their superintendents because if they were in fire prevention work and we could get the visiting nurses of the big cities to go from house to house and get them to teach what we know, we will get a closer contact than by any other means.

The next thing we have to do is get to the school children. That is old stuff, but if you will get to the school children you will get into the home. I know that you can not go to the school child with a high-tone serious talk, that you must do this thing or that thing; but play with them—make them interested in what the subject is, and they will go home and tell daddy and mother about what happened in school because they do it. My children do it. Your children will do it. They come home and tell you what happened in school and if it is funny or if it is interesting they will pay attention to it and remember it.

Perhaps some of you know Chief Rogers, the Fire Clown, who teaches by this method: He falls off of step ladders and he does everything in his act that he should not do, and the children and teachers think he is great. Then when he does all these things he reviews the subject and tells why he fell off of the step ladder and why the mop exploded under the stair steps. He first of all did all of these things that he should not do and made the children scream with laughter, and then he gets serious and tells them those things happened because of certain things. I happen to know a case down in Wichita, Kansas, where four years after Chief Rogers talked to a little girl she caught herself on fire and she saved her life by remembering from four years back what this funny, stupid clown told her to do.

I happen to be the chairman of a fire prevention committee in Detroit.

I am very glad to say our chairman of today is also a member of that committee. Why is she a member of that committee? Because she, as a woman, is interested in the work of public safety. Mrs. Downey is one of our points of contact with the home through the clubs of the women, because women will discuss things among themselves. They are interested if you will get to them. We have also on our committee of 20 people Miss Harriet Beard, whom you probably all know, Supervisor of Safety work in Detroit schools. Why is Miss Beard on the committee? Because she is interested, not alone in Public Safety, but in any type of safety. She is supervisor in the schools and our committee can only contact by having people who are interested and have in turn the contact to carry on.

CHAIRMAN DOWNEY: You have heard from all these gentlemen and I am going to call upon Miss Rose Brooks of Paterson, New Jersey, to tell us something about her work.

Paterson Women Interested in Safety Work

MISS ROSE BROOKS (Paterson Safety Council): We have started some constructive work in the prevention of accidents in the home. We really started it in a very indirect way when last spring we conducted a safety instruction course for women automobile drivers. We had a splendid turnout for that and over 500 women were enrolled in the course. At the end of the course we asked the women whether they would care to do permanent safety work and called their attention to the fact that there were more accidents occurring in the homes than on the streets or in the shops—our statistics which had been compiled, showed that very clearly—so we got together a group of the women and have organized what has been said to be the first women's division doing active safety work in the homes in the United States. The group has its own board of control. They meet once a month and are planning some constructive work. We have with us today Mrs. Shrantz who was a representative of that group of the women's division and I think she could tell you more than I know about it.

MRS. JULIA SHRANTZ (Paterson, N. J.): The Paterson Council pointed out to the women that there were many, all too many, deaths resulting from accidents in the home. When the women investigated the conditions they found the figures astonishing. For instance, the women's division found at the end of nine months, ending September 30, there were a total of 65 deaths from accidents in Paterson, and out of those, 35 were due to home accidents. It was more than 50 per cent of the total and something was wrong. We therefore started our campaign of education.

The first thing we did was to make a poster. We distributed it first by means of the Paterson Council poster bureau and then women carried the posters to their neighborhood stores. We have a volunteer group of women who will visit women's clubs at all times and tell the story

of these home accidents. In order that the women may tell the story well, each one of these volunteers—there are 12 of them—will all learn the same speech.

In addition to this we plan for the fall and winter to send a letter by means of the school children into every home and this will tell the mothers and fathers of the dangers there are in the home from falls, fires, burns, asphyxiation, piling things in the attic, stairways, lack of light in the stairways, misuse of gas and electricity. Altogether we have developed an ambitious program and we feel that in a year or two we will have educated home makers as to the danger of accidents in the places where they live. We also have an emblem and a pin that indicate the connection of our order, and we have our distinctive poster. We are placing it in all public places and we are asking the women to put it in all the stores and wherever they can find a place to exhibit it.

A Few of the Things Accomplished in Kansas City

JULIAN HARVEY (Kansas City Safety Council): All of the managers are intensely interested in the development of our home safety program. We have realized and we have talked for many, many months and years, I might say, of the only effective method in reaching the home and I hate to throw a discouraging note into any discussion, but I think we all agree it is one of the most difficult problems with which we have to contend.

I don't know what to tell you except a few of the things we have done in Kansas City—not nearly all the things we should have done. I hope the managers who are here this morning will pardon me for telling a story that I tell every time we meet. It concerns the matter of home inspection campaigns, and we are very proud of the record we have made through these campaigns, the ninth of which closed last week. To give you a concrete illustration of the results I might quote the figures Mr. Vernor used in the general session the other afternoon, which are to the effect that in Kansas City in 1922 there were 2,217 fires and after the campaign in 1923 it was reduced to 1,931, the succeeding year to 1,633 and last year, 1,430, and this year I am confident it will be under 1,100.

The first of these campaigns resulted in the return of 11,000 of these inspection blanks. The one that has just closed goes to over 60,000. These boys and girls in the different schools are not content with simply 100 per cent returns based on the enrollment in their schools, but in many instances they go out and canvass the neighborhood. We have had schools that go as high as 350 per cent, based on their enrollment.

The matter of home inspection blanks is a more or less routine proposition and if we have had any success in Kansas City, I attribute it to the fact that we have thrown into the campaign many stunts of various kinds to stimulate the children. We don't believe in asking any home owner to answer 25 questions for us. We confine it to five or possibly 10, picking out the principal causes of fire or accidents in the home. We award prizes. Some people may not agree that we should offer prizes.

Some people think it creates a wrong attitude on the part of the children or the school. I do not believe that at all. I think that regardless of our age, we always have an objective and if we can hang up as an objective before one of our young junior safety councils a banner or bulletin board, or something for them to strive for it is going to increase their interest. That has been the experience with us.

I wish I could tell you of the effect the campaigns have had on the matter of accidents in the home, but unfortunately we have not been able to assemble that information. We intend to continue the campaign in the future as we have in the past because of the success that these figures indicate.

We have had some discussion in reference to the lessons prepared by the National Safety Council on the subject of home safety and designed to reach the social workers, and I think that is one of the most distinctive forward steps that has been taken by our National organization in a long time. I think it presents a great opportunity, if we will go back to our respective cities and take this matter in hand.

The National Council will prepare the materials, but we all know that it is useless to have that material unless we will constructively go to work in our various communities and do something with it. The material, if properly used, will have wonderful results, not only along this line, but many others as well, and it means enthusiasm and optimism on the part of every community if we are going to get any place with it. Our visiting nurses association and many other organizations in every community present a wonderful opportunity for us to go to them with this course of lectures and instill in their minds great possibilities that can be accomplished.

Most Accidents Occur in Homes of Poorly Housed

E. WILLIAMS CORN (Field Representative, National Safety Council): Those of you who are not acquainted with me don't know that this is my hobby. I began thinking in terms of home safety immediately upon my relationship with the National Safety Council, partly because of the tremendous problem that it presents, and partly because of my past experience in family case work and family reconstruction.

I found myself confronted with the two horns of a dilemma, as I thought. In the first place the 75 per cent of these accidents we find occur in the homes of the poorly housed. I don't say they are poor, but they do occur in the homes of the poorly housed. The second place is that the homes of the poorly housed are occupied by people who are not easily reached in group life and do not have at present organizations that can be easily made accessible. The hill sections and the brown-stone fronts have their wealth and their societies, but Mrs. Marchinski doesn't have anything of that kind and generally her entire domain is the four walls of her home with the possible addition of the picture show.

So it seemed to me, knowing these groups as I know them and knowing

the people who have worked in these groups and with whom I have been associated for the last 10 or 15 years, that if we, through education and inspiration, could fill their minds full of this tremendous problem—the minds of the family case workers, the minds of the visiting nurses, the minds of deaconesses and assistant pastors, the minds of settlement workers and in certain instances the minds of the men who are doing the collecting for the industrial insurance companies of the United States—that we will get a group of people who are professionally going into those homes; and it was pursuant to that end that I took my pen in hand and tried to lay out a course of six lessons. I believe that if we are going to do anything in a large way in home accident prevention it is going to be through such a definite course of instruction.

Planning an Educational Series for Home Safety

I am going to tell you briefly what that course is—just merely give you the titles and tell you; if you want further information, write to the National Safety Council, 108 East Ohio Street, Chicago.

The first lesson I have chosen to use as a more or less inspirational lesson on the social aspects of home accident prevention, in order that we can get the picture. The second lesson is upon home engineering and equipment, preferably to be handled by an architect or engineer, who knows the tricks of the trade—the right kind of house building or rebuilding. Third lesson, preferably to be handled by a housekeeper, is entitled, "The house we live in," it is a lesson on good housekeeping and after all there are more accidents caused by bad housekeeping than any other one thing. The fourth lesson is entitled, "Out-guessing the children," preferably to be handled by a mother. It outlines the tricks in handling that little lad who is two or three or four years old, who has not come to the point of judgment or discretion, and keeping the hazards out of his way. The fifth lesson, with due respect to our fire prevention people, covers fire hazards and fire protection; and the sixth lesson is entitled "When accidents occur."

I am not trying to give first aid in this sixth lesson at all. A reasonable expectancy in the arrival of a physician in the case of an accident is from 15 to 20 minutes. The problem, therefore, is to keep your patient in comfort and out of danger until the physician can arrive. Resuscitation will be described. As far as fractures and sprains are concerned, I don't care if they know whether it is a fracture or a sprain or not. The treatment is exactly the same: demobilization. Hemorrhage—we don't want to fool with tourniquets or pads or anything of that kind. I am endeavoring to set out the pressure points so that we can take the patient by the arm or wherever the point of pressure should be placed to stop a hemorrhage, and through that I try to run in the idea not to get scared (because most of us are scared at the sight of blood) by saying that we have about four quarts of that kind of liquid in us and it won't all leak out of a little hole in a few minutes, so if you don't hit it the first time, feel for it again until you do stop it. In other words, I am trying to

give in my sixth lesson, just the little simple tricks of the trade that are necessary for the protection of the patient until the physician comes. I am decidedly interested in the problem, and I will be glad if I can give you any help as the months go on in the programs that you may undertake.

H. H. COFFIN (Oregon and Columbia Basin Division, N. S. C., Portland, Oregon): We began our safety work in Portland, Oregon, 20 years ago, both in the school and in the home. We have a letter there from the Japanese Government, from their educational department, asking how we are accomplishing results in our city. I have two or three concrete examples that I desire to leave with you, and possibly they will help.

In the first place we try to have one child in the various rooms write on the board a composition which is copied by the children and taken home. In that way we reach the home with some subject upon safety in the home. Then every morning the teacher asks the pupils, "Now, children, have you had an accident in the home since we met yesterday?" If there has been an accident the child is asked to make a report, and those reports are sent to the principal and turned over each week to the administrative department. If they were serious they are immediately telephoned in to our department and the visiting nurses department is notified, or the police officer may be notified. We use the firemen of Portland to reach every home. They make an inspection and if they see a hazard in the home they report that to the National Safety Council and in that way we reach every home in Portland.

The Insurance Toll Necessary for Fire Inspection

CAPT. G. R. G. FISHER (Illinois Manufacturers Association, Chicago): I would like to say a few words on this matter of home accidents. Of course, we all agree that the great thing is education. Do you know that the insurance companies of this country are paying six cents on the dollar for inspection alone? Just let that sink in. Six cents on the dollar for inspection alone. Now, inasmuch as there are five times more accidents in the homes than all the railroad and steamship companies of this country, I think we have a subject that ought to grip our hearts.

When you think of burns, accidental poison cases, falls, and so on; we have something we should try to remedy, but I just want to say a word or two about infections. The unfortunate thing is that in most of our homes we have too many substances that are absolutely dangerous. I wonder how many of you ladies or gentlemen know that when iodine is dark it is not safe and the trouble is when you go to the trouble to buy iodine you get it three times stronger or twice as strong as it should be and very often it is in a deteriorated stage.

I wonder how many here know that peroxide should not be used three days after the cork is taken out of the peroxide bottle? It is dead. The only thing it is good for would be to bleach the hair—I won't say anything more about that. Here is a thought I want to give you. When you buy a so-called infecticide or bactericide or germicide and the bottle is

colored, don't buy it. The fact that the bottle is colored shows it is not stable. I am sorry to say we in industry are being a little wary of mercurichrome because even those who are advocating its use say that it must be fresh when it is used. Therefore it is not practical either for the small industrial shop or the home because it may not be safe after 72 hours.

ADJOURNMENT

Junior Safety Council Representatives

(Luncheon)

October 29, 1926

H. O. ROUNDS, Toastmaster

Supervisor, Bureau of Public Safety, Police Department, Detroit, Mich.

The meeting convened at 1:00 o'clock in the Ball Room, Statler Hotel, Detroit, Michigan. Mr. H. O. Rounds, supervisor, Bureau of Public Safety, Police Department, Detroit, Michigan, acting as toastmaster.

TOASTMASTER ROUNDS: I take pleasure in presenting to you a gentleman known throughout the United States as one of the chief educators of the nation, the man who is the head of the public schools of Detroit, Superintendent Frank Cody.

FRANK CODY: Mr. Chairman and Boys: Here is where I am going to make a world's record for a short speech. I have enjoyed looking into your clean faces and have enjoyed hearing you eat. It has all been fine.

I particularly wish to congratulate you boys in this community and all other communities on the fine work you are doing for your classmates, not only in this state, but in every other state in the Union.

I look upon the work of safety education as just as important, perhaps more important, than any other subject taught in the schools. I know in Detroit last year we have had a fine record as far as protection is concerned. I think we had only about three fatal accidents in the school systems of this city. I am sure that to you, and to this organization, go the thanks of fathers and mothers all over the community.

TOASTMASTER ROUNDS: I see you all like to yell. They have a yell master down there, and I wish I could do as well as he can. We have a safety yell, and I want you to learn it, if you don't know it.

I am going to read it to you and you listen

"Stop, look, listen,

Before you cross the street,

Use your eyes, use your ears,

Then use your feet."

(The boys then gave the yell.)

TOASTMASTER ROUNDS: Fine! Now please be very quiet once more.

We are honored this afternoon by having with us a gentleman who is well known, and the society he represents is known all over the world, Monsignor John Doyle, who is Chancellor of the Diocese of Detroit, and who has charge of the parochial schools of the diocese.

RT. REV. MGR. JOHN DOYLE: Mr. Chairman, Ladies and Gentlemen, and Boys of the Patrol Squad: I am honored in having the opportunity to address a word to you of commendation for the splendid work that you boys are carrying on, in each of the schools throughout the school year. You boys, because of your youth, I believe, can not fully realize the responsible task you have and the tremendous good you are accomplishing.

I know that there are perhaps thousands of mothers in this city who every morning are worrying about their little ones on the way to school, but since the patrol boy has been placed near the school and is there to safeguard these little ones of tender years, that mother is relieved of her anxiety.

I believe also that that work is building your character. It is developing in you during these years when you are molding your character, an early sense of responsibility, of the obligation you have to your fellow men and the spirit of sacrifice that you must build up in your character if you are to be useful agents in society later on. These, I believe, from a selfish point of view, are the great benefits that come to you individually and personally.

Accomplishing a Good Beyond Estimation

You are accomplishing a good that is beyond all human estimation. No one will ever be able to tell the lives that have been saved through your efforts. No one will know how many have been saved from permanent injury throughout their lives, because of your efforts and because of the merits of your splendid work.

TOASTMASTER ROUNDS: I just discovered a gentleman in the house whom I want you all to meet. I want you to meet him this way; I don't want you to meet him in a business way, for I know you never will, for school patrol boys don't do things that make it necessary for them to appear before a judge. I want you to see Judge Bartlett, of Detroit.

JUDGE BARTLETT (Detroit): I only wish I was up there playing the violin instead of speaking here. I am a much better violinist than a speaker. I used to play first violin in Mr. Rounds orchestra, and I really can hold a position as violinist.

I didn't expect to talk here this afternoon, but as probably most of you know, I have a decided interest in children, young men especially.

I have sat there in court for a great many years and listened to the stories of frightful accidents and losses of life of beautiful children in our communities, and elsewhere. What a wonderful work, boys, you have started on! How many lives this will be the means of saving, not only in this community, but in other communities!

I spoke at a meeting at Battle Creek, Michigan, recently, gotten up by the Automobile Club, and there in a space of 12 to 15 blocks there were 18 or 20 thousand people in a small city like Battle Creek who were interesting themselves in this great, life-saving problem. Battle Creek, a small city, probably put on the greatest safety parade ever seen in the United States. It certainly was a great safety gathering, and every man, woman and child in that small city is sold on safety.

Boys, I am just going to give you a few little hints on how to be successful. I receive hundreds of letters during the year from young men who want to know what they can do, and I always try to answer them. They want to know how they can start life, how they can make headway, and I reply in this fashion to most letters:

Advice to Any Boy Starting Out in Life

Boys, you are starting now upon your careers. Remember that the boy who does anything wrong or takes anything that doesn't belong to him, or does anything selfish, is bound to make a failure of life. A fine boy will make a fine man.

You must take care of your health. You must study. Above all, you must work hard. The boy who is a drone and doesn't work hard accomplishes little.

You must, above all things, use every effort to secure a good education. What little education I got, I got through playing a violin at country dances, and I paid my way through Ann Arbor. I started out, boys, at 40 cents a week, pumping the organ in the Episcopal Church. I wasn't satisfied, so I struck for a raise of 10 cents a week and they wouldn't grant the raise, so I resigned promptly.

Then I was ambitious. I went ahead and worked myself through business college and high school and secured a position as bookkeeper, and I worked for over six years as bookkeeper. I tried to do that which was given to me, well. I tried not to slight anything. The boy who feels that he can get by in this world either on his parents' reputation or his good looks or pleasant manners is bound to meet with disappointment.

Boys, all of you want to make a success, I am sure. Father Doyle has covered most everything I can cover. You are on a great, life-saving work, boys. Don't forget that. Perhaps your efforts will be the means of saving 40 or 50 lives in the city of Detroit and hundreds of accidents next year.

You must remember that every eighth or tenth car contains either a reckless or drunken driver. This car is liable to strike you any minute. Last week I had seven cases of drunken drivers, where they went up on the curb and hit people, hit little children. So you are not safe, even on the sidewalks.

Carry this great safety work on! Remember the little children that were torn to pieces by automobiles in the United States last year. The loss of life was appalling. It is a national problem, boys. It is a problem you should interest yourselves in. When you see a man driving reck-

lessly, it is your duty to report him, get his license number and report him, because that man may kill one of your classmates.

Remember this, every time you write up one of those drivers or assist in apprehending him, you may be saving a human life. So let's continue this work. Let's protect the lives of the people in this community and in other communities. Let's fight for the lives of these children, and let's have a real "Father and Son Week," a real "Mother and Daughter Week" in the City of Detroit, not the kind of Father and Son Week where the father and son sit at a banquet and nothing is accomplished. Let's have a Father and Son Week where the father and son will pledge themselves to each other and not only protect each other's lives but protect the life of every child in this great community.

TOASTMASTER ROUNDS: In connection with the Safety Council there is a magazine called *Safety Education*. I presume you are familiar with it. It carries up-to-date ideas for safe thought and safe teaching that are available today. The editor of that magazine is present. She came all the way from New York, and I want you to see Miss Idabelle Stevenson, who is going to speak to you.

Greetings From the National Safety Council

MISS IDABELLE STEVENSON: I want to tell you that I am not the editor of that magazine. She is here, but I don't know where she is.

However, I do want to bring you greetings from the National Safety Council, and tell you that in the Education Division, the division that publishes the magazine, we feel that we absolutely could not do our work if it were not for you.

During the last four years I have been in every state east of the Mississippi river, and I would like to say to you that in every city I visited where they were getting a reduction in accidents of children, it was because the boys and girls in that community had gotten behind the work.

I am glad there are some girls here. You know, of course, there are about 20,000 children killed accidentally each year, and we know from the work we have done that you can cut that down 50 or 75 per cent. So I hope next year your goal will be to bring the number of deaths down to 10,000 instead of 20,000.

I want to congratulate you on the splendid work you have done in Detroit, and other cities in Michigan, and in Toledo. I hope you will all keep in touch with us, so we may tell other people what you are doing.

TOASTMASTER ROUNDS: Next I want to present to you a man who has been working days and nights and Sundays to carry on the safety work throughout the state. He is the representative of the Detroit Automobile Club, and is known as the Director of Safety and Traffic.

I take pleasure in presenting Mr. L. J. Van Schoick of the Detroit Automobile Club.

L. J. VAN SCHOICK: Mr. Chairman, Ladies and Gentlemen, and Life-Savers: We feel that the group of boys we have before us today are life-savers.

Before I go on with the program, I would like to have our group of state troopers over at that table please rise.

(The state troopers rose amid applause.)

They make up part of a group of 23 who are insisting on the school boy patrol and junior state police throughout the state. It is our habit to keep an interest in our boys, keep them on the job, and to put up three prizes, a loving cup and two American flags, for the school boy patrol in the state which does the most efficient work while on duty.

This is the time that we are repaid for the time that we put forth, when we can gather with a group of boys like this, who are out on the streets looking after school children. We feel we are repaid when we bring them together and see their smiling faces and the enthusiasm they show.

I am going to call on Wayne Hesseman.

(Wayne Hesseman then came forward.)

We are pretty proud of Wayne. He is the captain of Helmar School Patrol, of Jackson Michigan, which is the state winning patrol. It is with great pleasure that I present to the Helmar School and to Wayne, the captain, the cup we offer as the efficiency prize.

Helmar School Captain Receives Efficiency Prize

WAYNE HESSEMAN: The boys of the Helmar School State Patrol, of Jackson, Michigan, are very happy to accept this cup from the Detroit Automobile Club. We surely think it is far better than anything we have really earned, though we tried to do our very best.

This cup will be kept at the Helmar School so boy patrols may see it and try to live up to what it stands for.

MR. VAN SCHOICK: The second prize goes to No. 5 School of Battle Creek. We have a group of boys from Battle Creek who are running very close to the Helmar School at Jackson. In the group of boys we have from Battle Creek today are boys who have won the meritorious service medal.

They are: Roy Jarvis, Carl Dobel, Wayne Cornwell, Harry Wagner, Milton Winans, Wayne Brockway, Kenneth Ellerton, Mauray Selley, Charles Zeller, Joe Mellick, Jack Hill.

I would like to have those boys rise.

(The boys rose amid applause.)

I would like to have Hiram Tresenberg come forward.

(Hiram Tresenberg came forward.)

Hiram represents the school patrol of the Vine Street School of Kalamazoo, winning third prize. So it is with great pleasure and honor that I present your school with the American flag.

HIRAM TRESENBERG: Mr. Chairman, Fellow Patrol Members, and Safety Patrol Members, and Friends: In behalf of the Safety Patrol of Vine

Street Junior High School of Kalamazoo, I wish to thank you for this honor you have shown us. It is to the untiring effort of each member that we owe our success.

Although meeting with many difficulties in the beginning, we finally succeeded in organizing a patrol. We will try to make a better patrol for the coming year.

Mr. VAN SCHOICK: Will Wayne Cornwell of No. 5 School, Battle Creek, please come forward.

(Wayne Cornwell came forward.)

Wayne, I am happy to present to you the American flag, as second prize for doing your duty.

WAYNE CORNWELL: Mr. Chairman and Friends: In behalf of the patrol boys of Battle Creek, we accept this flag in recognition of our service on patrol.

I am sure I am expressing the sentiment of all the boys when I say each of us is glad we served on the patrol, because it has given us a greater sense of responsibility, loyalty and adherence to safety.

Mr. VAN SCHOICK: Sometimes the old folks wonder if these boys are doing a real good. It is hard to measure the amount of good work they are doing. It is hard to measure the number of accidents and lives they save. But in our school boy patrol in the state of Michigan last year there were 263 who won service medals. There were five who won medals for actually saving a life. So we know that through the work done by these boys five children are playing today that would not, had it not been for the patrol.

The groups that you see from Battle Creek, Kalamazoo, and Jackson are just a few of the 18,000 school boy patrols on duty in villages and cities throughout Michigan, and 11,000 junior state police in the country schools.

The Gold Medal for Saving a Human Life

Through his quick-thinking, Patrol James Kane, of Dearborn, Mich., saved a boy from being electrocuted, and I can not tell you the sincere honor it is to place upon this boy's chest the meritorious gold medal, the highest medal we give, for this act. So with great pleasure, I present you, James, with the gold medal. (Applause.)

I hope at each of the following Congresses we may have the chance to get together a group of boys and girls such as we have today. I want to assure you that I appreciate the opportunity and the honor of making these presentations.

TOASTMASTER ROUNDS: Will Ward Keith come up here? The last number on our program will be just a word from Master Ward Keith, of Toledo, who is going to speak to you for just a moment.

WARD KEITH: Members of the National Safety Council, Pupils of Detroit Schools, and Friends: On behalf of the Toledo Presidents of the Junior Safety Council, I want to thank you for this splendid dinner.

We are doing our very best to make Toledo safe, and we are here today to learn how to do better work this coming year than we did in the past year. Last year in Toledo there were 31 fatal automobile accidents. So far this year our deaths due to traffic accidents were reduced 60 per cent of what they were last year at this time.

This year we are paying special attention to home hazards and the prevention of accidents in the home, and through the efforts of our secretary, Mr. Jay E. Thompson, we are very hopeful that we may reduce the accidents in the home as well as on the streets.

Again I want to thank all those who have in any way made it possible for us to be here today.

(Cheers from the Toledo group.)

TOASTMASTER ROUNDS: That is fine. You can't imagine how much pleasure it has given me to be able to preside over this assembly.

We have now reached the end of our first luncheon, and I hope we have one every year whenever the National Council meets.

Before closing I want you all to stand and sing "Hail, Hail, the Gang's All Here."

(The boys rose and sang.)

ADJOURNMENT

School Safety and Junior Safety Councils

October 29, 1926

MISS HARRIET E. BEARD, Chairman
Supervisor of Safety Education, Public Schools, Detroit, Mich.

The program of this session, held on Friday afternoon, October 29, at 2:00 o'clock, in the Ball Room of the Statler Hotel, consisted entirely of pictures, demonstrations, and plays, making it impossible to present a detailed stenographic report.

The session opened with a showing of the film, "St. Paul School Police," accompanied by a description given by a representative of the St. Paul Police Department. This interesting film showed how the school patrols in St. Paul are organized and how they operate to protect the lives of the school children going to and from school.

The next number was a demonstration of safety instruction in the class room, presented by Miss Marie Sibley and children from the Hillger School, Detroit, who gave a delightful demonstration of safety games and the use of other safety material in a kindergarten class.

This was followed by a demonstration of a Junior Safety Council meeting, put on by the American Civic Club of the Balch School, Detroit, and Miss Mary McSweeney, teacher. The boys and girls of this club went through a regular Junior Safety Council meeting, including the discussion of various safety problems in the school and the trial and discipline of offenders against the safety rules.

Miss Doris Greenwood, Massachusetts Safety Council, then spoke briefly on the value of Junior Safety Council work and described the work of this nature that is being done in Massachusetts by the schools and the Safety Council.

The program closed with three charming safety plays—

"Bruin's Inn"

"How Knowledge Driveth Away Fear"

"The Runaway Ball"

These were acted by children from the Franklin and Poe Schools, Detroit, under direction of Mrs. Mabel Foote Hobbs, Consultant, Community Drama Service, Playground and Recreation Association of America, New York City, assisted by Miss Ethel Ann Cumming, Miss

Rhea Dalrymple and Miss Helen Doremus, of the Detroit schools mentioned. The plays presented striking evidence of the value of the dramatic method in expressing the safety idea, especially by and for children.

It is worthy of mention that the rehearsing of the plays, including the learning of parts by the children, did not begin until the preceding Monday, only four days being consumed in this work. In spite of this short time for preparation the plays were presented in a most excellent manner, due to their simplicity and naturalness and the splendid direction by Mrs. Hobbs. The costumes and stage settings likewise were effective but simple and prepared at very little cost. Copies of these plays with suggestions on costumes and stage settings may be obtained from the Education Division, National Safety Council, 120 W. 42nd St., New York City.

The entire program produced a deep impression on the hundreds of children and adults who witnessed it. One could not help feeling that through these demonstrations and plays both the actors and the audience caught the true spirit of safety to an extent that is rarely produced by formal addresses.
