MR. REID: I wish you would be good enough to tell this board what you know about this accident. You have been in investigations before and you understand the purpose of this sort of investigation. It is not to criticize anybody or try to get anybody in bad, or to have anybody disciplined, but to determine the cause in order that we may be able to prevent such accidents in the future, if possible. Will you just be good enough to tell the board what you know about this accident?

The Conductor Was Busy Collecting His Fares

MR. OLIVER: I don't know anything about the accident. I was working in the back end and about eight or ten passengers got on at Winnetka. I was having some argument with some bird back there about paying a dime fare. Finally I got tired of fooling with him and I walked up to the front end of the car and a fellow up there didn't have a ticket and I had to cut a seven cent duplex; then he and I got into a jam, and then just as I looked up I saw this black thing come out of the train and Jack hit him in the rear. Of course, Jack and I jumped out, took care of the injured, got all the witnesses I could, and that is all I know about it.

MR. REID: How long had Mr. Thomas been operating as motorman with you?

MR. OLIVER: We have been together for the last three sign-ups.

MR. REID: What length of time would that be?

MR. OLIVER: About a year and a half.

MR. REID: Have you ever noticed a tendency on the part of this motorman to recklessness in speed at dangerous places?

MR. OLIVER: No, I never paid attention to it.

MR. REID: Would you consider him a competent motorman?

MR. OLIVER: Yes.

MR. REID: As conductor of this train, what are your responsibilities?

MR. OLIVER: To get the passengers on and off the car and to collect the fares.

MR. REID: Do you feel that you are responsible in any way for the safety of the people that ride on the car?

MR. OLIVER: Yes.

MR. REID: We would like you to tell us just what your responsibilities are?

MR. OLIVER: I have got to collect the fares, see that the passengers get on and off the car, and that they don't get hurt.

A Little Lesson Upon Public Relations

MR. REID: What would the patrons of that line know about the Chicago, North Shore and Milwaukee Railroad except as they see that railroad through you?

MR. OLIVER: I don't know.

MR. REID: Are you in the habit of arguing with passengers?

MR. OLIVER: With some you can't help but argue.

MR. REID: Did you ever have any arguments with your motorman?

MR. OLIVER: No.

MR. REID: Do you consider him cool-headed?

MR. OLIVER: Yes, he's all right.

MR. REID: Do you attend safety meetings held on the property?

MR. OLIVER: Some of them.

MR. REID: What do you mean, some of them?

MR. OLIVER: Well, whenever I get up there in time to go in for a few minutes.

MR. REID: How often do they have these meetings?

MR. OLIVER: Once a month in Milwaukee and once a month in Highwood.

MR. REID: At which place do you attend?

MR. OLIVER: If I am in Milwaukee I attend there, and if I am in Highwood I go there.

MR. REID: What sort of a program do they have at those meetings?

MR. OLIVER: I don't know, they do too much talking.

MR. REID: Have you ever offered any suggestions as to how those meetings should be conducted?

MR. OLIVER: I sent in a recommendation one time and then I quit. They said something about it at one of the meetings but I wasn't there.

MR. REID: Then apparently you take just about as much interest in the safety work on your property as you do in the safe operation of your train. I mean so far as the education of your part of the work is concerned.

MR. THOMAS: They want you to go to safety meetings of the E. M.

C. A., union meetings, and other meetings. That is all there is—meetings.

MR. REID: Do you realize the question of human life is involved in this discussion?

MR. OLIVER: Yes.

MR. REID: Any questions, Mr. Harmon?

MR. HARMON: You say your safety meetings are not interesting?

MR. OLIVER: I have been to some that were and others that weren't.

MR. HARMON: Is that the reason you don't take an interest in the safety movement?

MR. OLIVER: They want you to go on your own time. Why don't they pay us if they want us to attend regularly?

MR. HARMON: Aren't the meetings for your own benefit?

MR. OLIVER: Partly, yes. It isn't all one-sided.

MR. HARMON: Did you ever have an accident on the rear end of your car?

MR. OLIVER: Yes.

MR. HARMON: What is the worst accident you ever had?

MR. OLIVER: I had a fellow fall off the rear end and break his leg. It was his own fault, though.

The Motorman Had Been in a Card Game Last Night

MR. HARMON: Did you notice any unusual action on the part of this motorman on the day of the accident, and was he acting normal?

MR. OLIVER: I thought he was all right, except that he was a little excited because he won five bucks in a card game.

MR. HARMON: Did he tell you that?

MR. OLIVER: He told everyone in the barn.

MR. HARMON: Was that the only conversation you had with him that morning?

MR. OLIVER: I asked him when we were going to get into Chicago.

MR. HARMON: How long did you remain in the front vestibule of the car?

MR. OLIVER: I wasn't in the front vestibule. I was in the front of the car about four seats from the front vestibule.

MR. HARMON: This was your regular motorman?

MR. OLIVER: I had him for three sign-ups.

MR. HARMON: Do you know anything about this bulletin that has been posted with reference to speed ordinances in towns?

MR. OLIVER: I know there is a bulletin that these fellows can't whistle through certain towns. It is not an ordinance, it is an order.

MR. HARMON: Why was this order issued?

MR. OLIVER: It was requested by the people in those towns because they did not want to be disturbed by the whistle.

MR. HARMON: How do the motormen take that bulletin?

MR. OLIVER: I never heard much jabbering on it. It looks as though they make them so they could hang something on the motorman.

MR. HARMON: Do you think that was a good bulletin?

MR. OLIVER: I don't know. You take those towns that come out with an order such as that. They want crossing protection and we have any number of those wigwags down there. They don't want any noise and yet they want protection. They want the guys on the cars to do all the protecting; they won't do any themselves.

MR. HARMON: You don't like those people in those towns very well, do you?

MR. OLIVER: They are not reasonable.

MR. HARMON: Do you ever think the passengers you are always arguing with are unreasonable?

MR. REID: Any questions, Mr. Jeffries?

MR. JEFFRIES: Mr. Reid asked you whether you thought the motorman was competent and your answer was that he was a good man?

MR. OLIVER: He is a good motorman.

MR. JEFFRIES: Do you think him competent enough to operate his train?

MR. OLIVER: Yes.

MR. JEFFRIES: Do you ever have any arguments?

MR. OLIVER: Not about operating.

MR. JEFFRIES: What do you argue with him about?

MR. OLIVER: About the world's series.

MR. JEFFRIES: You are on friendly terms with him.

MR. OLIVER: Yes.

MR. JEFFRIES: Do you think that you could contribute in any way to the promotion of safety on this road? Do you think you could do anything?

MR. OLIVER: Well, I think after this accident that I will probably attend more meetings and jump into some of this discussion that they talk about.

MR. JEFFRIES: You have plenty of time to attend these meetings.

MR. OLIVER: No, I don't have.

MR. JEFFRIES: What do you do with your time?

The Conductor Also Did Not Attend Safety Meetings

MR. OLIVER: We leave Highwood at 11:09 and our call time is 10:50. I have half an hour to get my lanterns and to get my trip slips, take a look at the car to see that it is cleaned of any papers, and then I have about ten minutes to slip into the meetings. Why don't they hold them when a fellow can get to them? Let them hold their meetings earlier in the morning.

MR. JEFFRIES: Do you do everything on your road that you should do for the benefit of the road and for the improvement of the service?

MR. OLIVER: I do all they pay me for.

MR. JEFFRIES: You are not underpaid, are you?

MR. OLIVER: Well, it is a good road to work for.

MR. JEFFRIES: Do you like to stay with this road?

MR. OLIVER: Yes.

MR. JEFFRIES: Do you ever have an idea that you would like to have another position with the road, a promotion or something?

MR. OLIVER: I never thought of that.

MR. JEFFRIES: Don't you think that if you offer a few suggestions and take an active part in these meetings that you might have an opportunity to get into a better position?

MR. OLIVER: I think you are right.

MR. JEFFRIES: How would it be for you to take an active part in the next safety meeting?

MR. OLIVER: That would be all right.

MR. JEFFRIES: I think you turned in a report with only one witness. What was the reason you didn't get any more witnesses?

MR. OLIVER: They wouldn't give me their names. I had plenty to do to take care of the people that were hurt.

MR. JEFFRIES: Don't you think that attitude of the three or four arguments that you had with the passengers had something to do with your not getting your witnesses?

MR. OLIVER: No. There was one man that I argue with regularly once a month.

A Suggestion About Conducting Safety Meetings

MR. REID: Mr. Oliver, we appreciate your coming out here. I trust that you understand the purpose of this investigation and that you are going to look at this effort that the Chicago, North Shore and Milwaukee Railroad Company is making to prevent accidents, in a different light. I hope you appreciate that you have some responsibility, not only with respect to the operation of the train you are on, but in helping to create a strong public sentiment in favor of accident prevention. Now, I say a strong public sentiment is very essential if you are going to help in reducing the accidents on this property. We thank you for coming out here.

MR. OLIVER: Can I make a suggestion? It is about this investigation that you fellows hold. Of course there are only a few of us that have been in it, and I think that the safety director ought to work up something like this and put it in a safety meeting. Sometimes I sit there for three hours and hear nothing but supervisors and department heads talk. Why don't you put up something like this at a safety meeting?

MR. REID: I think it is a good suggestion and we will recommend that to the safety department.

MR. OLIVER: Well, can I go back to the barn?

MR. REID: Yes sir, thank you.

If it were not so near 12:30 we would put the superintendent on the stand and interrogate him with reference to this bulletin that has been issued forbidding the blowing of the whistle in certain places, but I think we will have to dispense with that.

(The audience indicated that they wished the investigation continued.)

All right. Mr. Burke, we will ask you to take the chair. Mr. Burke is the superintendent of the Milwaukee Division of the Chicago, North Shore and Milwaukee Railroad, and as such he knows something about bulletins; he knows something about supervision; he knows something about what the men should do to prevent accidents, as shown by his good record. I don't know how much he knows about the attitude of the people in this community in regard to the blowing of the whistle. At any rate, we are going to find out what he knows about this bulletin.

Now, Mr. Burke, will you be good enough to tell us about this bulletin which was issued around the time of this accident?

The Public Is Quick to Criticize Whistle Blowing

W. H. BURKE: Some years ago when we started the effort of reducing grade crossing accidents we impressed upon our motormen the importance of proper crossing signals being blown, and the majority of our motormen took it very well and used plenty of whistle; but in these small suburban towns the public was ready to criticize the unnecessary noise that the interurban railway was making through the village. The city managers of these small villages got together and appointed a committee. The committee met the management of the company and requested that the whistle not be used while operating through one, two, or three of these small villages. It was necessary for us to meet our public relations and meet them right, and so we advised the people in these communities that some instructions would be issued to eliminate some of the nuisances, so-called.

A bulletin was issued on the unnecessary blowing of the whistle in these different towns named, and it stated that the whistle was only to be used in case of emergency. That would go on very well for a short period and then we would get some more complaints that our motormen were using too much whistle, so another bulletin would have to be issued calling their attention to the fact that there had been some complaints about the unnecessary blowing of the whistle and that the whistle should be used only in case of emergency. From time to time it was necessary to re-issue that bulletin. Even though we have had accidents at those crossroads and the management has met the city managers of these different villages and talked it over, yet we have been unable to get permission from them or get them to agree that we can use plenty of whistle through the villages.

MR. REID: Let me ask you this question: If you hadn't issued this bulletin about blowing the whistle and this man had blown his whistle back here, 600 feet, when he first saw this automobile coming from the west, and there had been a complaint from some of the citizens in this case, would you have reprimanded the motorman for blowing that whistle when he explained to you that he considered this an emergency?

MR. BURKE: No.

MR. REID: Would you have made any effort to explain to the citizens

of that community that the blowing of this whistle meant the saving of somebody's life? If there was a complaint made, would you have made an appointment to meet the city managers and lay the facts before them and show them the reason why it was necessary to blow the whistle and the good work on the part of the motorman in saving a life? Has that ever been done?

MR. BURKE: It has. Still it is a hard thing to get them to agree that the whistle is absolutely essential through those small communities.

MR. REID: Which do you think is the more important—a few minutes' sleep of some fellow that lives along here or the life of this fellow that is going over the crossing?

MR. BURKE: The life of the man going over the crossing. We are attempting in our safety program in our schools, in our civic organizations where we have motormen and other men, to put the message over to the public.

Bulletins Are Thoroughly Explained to the Men

MR. REID: Let me ask you another question. When you issue a bulletin of this kind do you explain to the men who get it, either individuals or in groups, just what is meant by an emergency and how they are to determine whether or not there is an emergency?

MR. BURKE: Yes. Probably the motorman and the conductor of this accident have said that they didn't get it at the safety meeting.

MR. REID: Are these things explained at the safety meeting?

MR. BURKE: Any bulletin is open for discussion.

MR. REID: But it is not discussed unless somebody asks a question with reference to it?

MR. BURKE: No.

MR. REID: Don't you think it would be a good idea to explain to the men just what is meant by such bulletins as this and others governing speed of trains, and so on?

MR. BURKE: I do.

MR. HARMON: What do you think of the attitude of these trainmen in this investigation?

MR. BURKE: I did not think very much of their attitude. The motorman is not a motorman anymore, and the conductor has since changed his attitude.

MR. JEFFRIES: Have you ever taken it upon yourself to check up on the men who attend these safety meetings? Have you said anything to Thomas or Oliver about attending these meetings?

MR. BURKE: It is a matter of record.

MR. REID: Thank you, Mr. Burke.

Now, my friends, one of the things an investigating board should do after an investigation of any kind is to arrive at some definite conclu-

sions. Now, it goes without saying that these conclusions had to be arrived at previous to the meeting because we could not take your time. Therefore, these conclusions have already been prepared beforehand, but our idea is that when an investigation of this kind is being made and the witnesses have been here, that the members should then get together and consider everything and arrive at some definite conclusions as to the cause of the accident and what might be done to prevent a recurrence.

Now, the conclusions that we have made may not be entirely in keeping with the testimony that was brought out by these three witnesses, but it will serve its purposes and give you some idea of what is meant by coming to some conclusion when you do investigate an accident. So I am going to ask the secretary to read these conclusions.

Conclusions of Board of Inquiry

1. The motorman should have taken into account the possibility that some motorist would take it for granted that it was safe to cross the tracks after the northbound train had cleared the crossing. When he saw the automobile approaching the crossing he should have recognized the existence of an emergency and therefore would have been justified in blowing the whistle and reducing the speed of the train. In this instance if it had been a fraction of a second later the accident would not have occurred.

2. When two trains meet so near a highway crossing the motorman should be on the alert, ready to blow his whistle and reduce speed if necessary in order to prevent an accident.

3. When complaints are made by village authorities or neighborhood authorities that there are times when the blowing of a whistle is necessary in order to save the lives of the citizens.

4. When operating officials issue such bulletins as the one involved in this accident they should take such steps as may be necessary to inform motormen just what is expected of them and what is meant by the word "emergency."

5. Thousands of people are killed annually at grade crossings. There is one sure and immediate remedy. That is for all motor vehicles to come to a full stop at all railroad crossings. No effort should be spared to educate the public with respect to this greatest of all hazards.

W. H. BOYCE (Pittsburgh Railways Co., Pittsburgh): Mr. Chairman, I would like to know if any representatives here can tell us whether on their property they give an explanation when a bulletin is issued for the issuance of that bulletin?

R. M. READE (Quebec Railway, Light, Heat & Power Corp., Quebec): In our company no man is permitted to take his car out unless he is thoroughly conversant with the bulletin that has been issued. He has to sign his name if he does understand it and if he doesn't understand it he applies to the superintendent to give him an explanation of the

bulletin in question. He is not allowed to take his car out unless he understands it thoroughly.

MR. BOYCE: We tell our motormen and conductors why a certain bulletin is issued.

MR. BURKE: In all our bulletins issued the first paragraph tells why it is used and underneath that, in the second paragraph, is the order.

VICE-CHAIRMAN KOEHLER: Gentlemen, this has been a most interesting demonstration. I know that you all feel as I do, greatly indebted to Mr. Reid and the other members of the board, and to the motorman conductor, and superintendent for this feature.

ADJOURNMENT

WEDNESDAY MORNING SESSION, OCTOBER 27

R. W. EMERSON, Vice-Chairman
General Manager, Cleveland Railway Co., Cleveland, O.

The meeting convened at 10:00 o'clock, Vice-Chairman R. W. Emerson, general manager, the Cleveland Railway Company, Cleveland, Ohio, presiding.

VICE-CHAIRMAN EMERSON: In the first place I wish to apologize for my failure to arrive yesterday morning in time to take charge of the meeting. I heard Mr. Hellmuth was unable to preside. I was in Canada and my train connections went bad, but I think this Section is very fortunate in having a man such as Mr. Koehler to step into the breach as he did. The enthusiasm, the pep, and the interest that we all got out of yesterday's meeting were due in no small measure to the manner in which Mr. Koehler handled the meeting.

The secretary has a communication which I will ask him to read at this time.

SECRETARY EASTHAM: The communication is as follows:

Members of National Safety Council,
Electric Railway Section.
Gentlemen:

In order to record ideas which may be suggested at any session of the Electric Railway Section conference, the 30 representatives of the Pittsburgh Railway Company meet for one-half hour after each session.

At the noon gathering, Tuesday, October 26, the favorable opinion expressed by many of the delegates was so spontaneous that it was suggested a minute be made in the official record concerning the value of the idea presented through the playlet, "A Board of Inquiry in Action."

This little sketch sparkles with safety thought and suggestions and tells the story in a manner new and interesting. It holds the interest of all present until the very end and gives each something concrete to develop on our respective properties.

It is resolved therefore that the members of the committee which

developed and presented the idea be commended for their successful effort; that the delegates be urged to avail themselves of the unique method and give it wide publicity as a recommended means of stimulating cooperation and in keeping interested both employees and executives in accident prevention work.

Respectfully submitted,

W. H. Boyce, Chairman,

Central Safety Committee of the Pittsburgh Railways Company.

VICE-CHAIRMAN EMERSON: I am sure we all appreciate the spirit in which the communication was sent and it will be made part of the record of this conference.

The first paper this morning is to be presented by John J. Connors of the Tennessee Electric Power Company, Chattanooga, Tennessee.

SUCCESSFUL METHODS OF SAFETY

J. J. Connors, Assistant Safety Director, The Tennessee Electric Power Company, Chattanooga, Tenn.

The ordinary methods of conducting safety work, such as bonus plans, awards and safety committees have all been used to good advantage by The Tennessee Electric Power Company in Chattanooga.

We do not claim to have reached a state of perfection in Chattanooga, but we have made great progress in safety work and accident prevention. The total accomplishments can not be accurately compiled, many advantages, such as improved morale, individual efficiency and public relations, are incalculable, but with the aid of a few tabulations and statistics I will attempt to show what improvement has been achieved in the way of reductions in accidents, and in cost of damage suits.

For several years prior to 1918 the number of accidents occurring on the street railway lines of Chattanooga and the resulting expenditures had been constantly increasing. The maximum was reached in 1918, when as a result of 2,793 accidents and held-over claims we expended \$152,604, or 17.7 per cent of our passenger revenue. Late in 1918 our safety first organization was founded and intensive accident prevention work actually started about the middle of October of that year.

A study of the records shows that the average cost of our claim department for the ten years preceding the organization of safety work was 12 per cent of the gross revenue earned. The cost of the claim department for the years 1919 to 1925 inclusive shows an actual saving of 6.68 per cent of the gross revenue, in the street railway division. Our safety first efforts reached their greatest efficiency in 1925. In that year only 2.95 per cent of gross revenue in the railway department was expended for accidents.

In my opinion, no methods of safety work can be successful without the whole-hearted cooperation of the platform men. The safety director must win and also merit the confidence of these men or no methods offered will meet with success. Considering the hazards existing on city streets today, it is my sincere belief that during each period of eight or nine hours that a car operator is on duty, he will undoubtedly save a human life.

With a 100 per cent increase of automobiles on our streets during the past five years, the problem of operating a street car safely has become extremely difficult. Also there is hardly a property that has not, because of public demand, increased its schedule speeds during this period. So the successful street car operator must possess a double track mind and a couple of switches and cross-overs additional, in order to meet present day conditions. The safety director's job is to keep the operator's train of thought on the track of safety, and all switches and cross-overs well lubricated with safety first methods.

Show the Operator His Daily Responsibility

A survey made during a nine hour run showed that the operator of the car actually prevented 35 and possibly prevented 516 accidents. The foundation for safety work must be laid on the front platform of your street cars, and any method formulated which does not consider the human factor can not be successful.

If you can increase the operator's stock of patience, if you can bring home to him the realization that he is truly a servant of the public as well as a non-commissioned officer of the company, if you can convince him that the only solid foundation for him is his safety record and if you can impress upon him that this safety record is the wedge that will some day open a breach wide enough for him to step down off his platform into a better position where his virtues will win their just reward, you are using successful methods of safety.

Let your operator know that you believe there are scores of people in your city who owe their lives to his alertness and watchfulness; also picture to him the results of a moment of thoughtlessness—perhaps a child crushed under the wheels of his car—and I can testify that he will respond to both thoughts.

How often do you ride on your street cars? When you go back home make a tour of inspection; ask some operator at nine o'clock in the morning about the operating condition of his car; you will probably be informed that he has not tested it yet.

Step on the front end of another street car and study the countenance of the operator. Perhaps he has a haggard look, denoting a sleepless night by the bedside of a sick wife or child. You will rise up in your seat as he barely misses the automobile that drives on the track from a blind intersection. The operator's body is on the car platform, but his mind is in the sick room which he left a short time before.

Board another car, and you may find this operator has a sullen coun-

tenance. You gasp as an aged passenger fumbles and grabs for hand strap or seat back, almost thrown down by the rapid acceleration of the car. Watch this operator as he passes children playing on the sidewalks, with never a thought as to whether or not they will dash upon the tracks. Anger is an ally of accident. Of course, the types of operators I have referred to are exceptions, yet they can be found on any property.

The new employee is a fertile field in which to sow the seeds of safety. Upon him depends tomorrow's accident record. Every platform man employed is sent to our safety department and there receives instructions on safe operating practice.

In the beginning of our safety work, employees were selected from different departments and banded together as a safety committee. Heads of all departments became ex-officio members of this committee. The committee has continued to function down to the present time, with meetings held once a month. They last but an hour; they are snappy and business like and are never allowed to become tiresome. In addition to the regular committee meetings, the entire transportation department meets once a month for exchange of safety ideas and to receive new suggestions for further improvement in their work. When a particular group or department appears to be slipping or lacking in enthusiasm, special meetings are the order of the day.

Safety contests are held regularly to create added enthusiasm, in fact everything is done to arouse the interest of the individual. The willingness of every single worker to make an effort to prevent accidents and maintain eternal vigilance is first solicited and then demanded.

Applicants for Platform Jobs Pass Rigid Tests

Careful selection of men is given great attention. Applicants for platform jobs are subjected to rigid physical tests. We assume that all accidents can and should be prevented, but this ideal condition will never be reached, due to man's failure in a crisis. The man of jumpy nerves and similar weaknesses is no longer added to the payroll. In this manner accident hazard is diminished at the source.

The recent abolition of the folding step has proved to be another improvement in accident prevention. With closed vestibules came the folding step and with the folding step came more minor accidents in boarding and alighting. We soon returned to the rigid step and similar accidents have steadily decreased.

Nor have we stopped with our employees; we have not failed to enlist the interest of the public in safety work. Various methods have been employed for this purpose. We have found that simple and inexpensive advertising gets the desired results, provided the material is pertinent to the subject and directed in the right channels.

A series of poster cards was placed in the cars; these cards embodied cartoons depicting various hazards of the motorist, pedestrian, careless child, etc. The cards were a combination of good, sound advice with a touch of humor and human interest. They were changed at intervals

and subsequently superseded with a set carrying simple safety slogans, unillustrated but printed in a variety of colors. Dash signs with safety texts are also used. The latest move in this direction is a series of signs warning against the danger of swinging or riding outside the cars. Still other methods of impressing the public mind with the need of safety have been promulgated through instructions to school teachers, public addressees and the distribution of literature among school children.

It seems that everything possible is being done to promote safety on our property today, and yet we know that there is room for improvement. We still have "accidents" that can and should be prevented. Maybe some day every employee will be vitally interested in safety work, every motorist and pedestrian educated to the value of "Safety First." Then and then only will we truly be able to say that we are using successful methods of safety, because these methods have borne fruit.

Figures on the Cost of Safety Campaigns

VICE-CHAIRMAN EMERSON: Mr. Connors has proved himself to be a versatile young man. He has not only given us a very inspiring talk but he has injected a sales talk on membership at this Safety Congress. At this time I want to commend Mr. Connors as chairman of the Membership Committee, for the very competent work he did during the past year. Mr. Connors reported yesterday that he had taken 16 new applications for membership in the National Safety Council in the Electric Railway Section. That is an increase of over 10 per cent in the membership of last year. It is a very excellent showing and I hope we can do as well or better during the coming year.

A. D. BROWN (New York State Railways, Syracuse): I would like to know, Mr. Connors, what safety organizations you have on your property and how much it costs the company to conduct this campaign?

MR. CONNORS: We have a safety organization and safety committees. In order to answer your question as to the cost of conducting this campaign, I am sorry I haven't the figures with me. I want to say, though, that we spent \$171,000 on this property in 1920 for claims and safety work; in 1925 we spent \$46,000 for claims and safety and \$14,000 of the \$46,000 was for safety work. I hope that answers your questions.

VICTOR T. NOONAN (Chicago Surface Lines, Chicago): Mr. Connors spoke of successful methods of accident prevention. In addition to organizing, Mr. Connors, in addition to commendation talks to the trainmen, one must in these days do something more scientific. I would like to know the method you use in investigating accidents, the methods you use in making inspections of hazards, and the manner in which you bring to the attention of the human organization the causes of accidents.

MR. CONNORS: We have organized a class in safety education. We take and analyze the operation of the motorman's job. A motorman

stops to take on a passenger. We analyze the operation he has to perform to take on a passenger and we bring out a blackboard and illustrate the operation. On one side of the blackboard we bring out the hazards or the way a passenger may be injured in boarding a car. I want to say that there are eight operations that a motorman goes through in picking up one passenger, and there are nine ways a motorman can hurt a passenger.

MR. NOONAN: Don't think for a moment that I am trying to pick at your paper. We have come here to learn something about accident prevention and the more we can pin this discussion down specifically (getting down to the question asked by Mr. Brown, which is very important), the more we will get out of it. I didn't get clearly what you said in regard to safety organizations in your company to prevent accidents. Organization is one of the principles of success of a safety engineer, and I would appreciate your telling us just exactly what you are doing, whether you have safety committees, just how often they meet, and what they discuss.

MR. CONNORS: We have safety committees. These safety committees do not inspect. We have an entire organization divided up into committees and sub-committees. In addition to that we have these schools. We have 15 men in each group, but not more, because if you take over 15 men, a man in the group may have an important idea that he wants to bring out and may be afflicted with stage fright, so I believe that that is the best way I can answer that, Mr. Noonan.

We are using safety committees. In addition to that we have a school of safety education where the platform men go through a course, one hour each day of the week, for eight hours, and the hazards of the various operations of the street car are brought out on the blackboard. The operation is brought out first and then the men themselves bring out just how they may have an accident in performing the various operations which do constitute the operating of a street car.

Reasons Versus Emotion in Teaching Men Safety

DR. C. P. SEGARD (Third Avenue Railways, New York City): I'd like to make a comment or two with regard to the talk that was given. I took the place of a conductor or motorman here in this audience today, as I have done in a number of street railways, and to me this talk on safety divides itself into two very large groups. One is the emotional group which is very transient and temporary, and if we talk from the emotional side to the conductors and motormen you will find it will last just about as long as it is given.

The side of reason, a little bit colder perhaps, but one that will last considerably longer, is the better way. In the safety talks that I have listened to on various street railways, I find that when reason is presented to the men perhaps 90 to 95 per cent of the talk will last a good many times longer than when we assume the emotional side,

and lastly, may I say this: 'psychology has recently come into the realm of science and has passed out of the realm of philosophy. May not accident prevention do the same thing?

MR. CONNORS: I would like to answer that in a way. It depends altogether upon the audience. In Tennessee where the people are emotional, I find that the best way to get under the skin down there is to picture those things. We have a population of 99 per cent native born and that is a condition you don't have in New York. Our talk wouldn't suit at all before an audience of New York platform men.

A. L. HODGES (Brooklyn City Railroad Co., Brooklyn): What is your labor turnover, Mr. Connors?

MR. CONNORS: Sixty-five.

MR. HODGES: That is something we don't have in New York or Brooklyn.

Appeal to a Man's Heart When Talking Safety

MR. FUNK: I don't exactly want to ask Mr. Connors a question; I want to agree with him and disagree with the gentleman who was talking against appealing to a man's emotional side. I believe as my friend, Mr. Connors, does, that there are lots of things you can talk about from a scientific standpoint. I think that safety is a question after all of human engineering. I believe if we are going to put this thing over as we want to, we must talk to a man's heart rather than his head. I come from south of the Mason-Dixon line too; but I don't know that that has anything to do with it, at least I don't think so. Perhaps I am prejudiced like Mr. Connors, but I know that you can talk scientific things to the men in the ring and those are the things that don't last long, but picturing these tragedies as my friend, Mr. Connors, did this morning, I believe those are the things that stick in the men's hearts, and I don't care whether they live south or north of the Mason-Dixon line.

J. HARMON: What part do the heads of the various departments take in the safety work?

MR. CONNORS: They are all active. The general superintendent down to the platform men attend our safety meetings. In our organization the general superintendent is a man of pretty high station.

A. D. BROWN: (New York State Railways, Syracuse): I'd like to ask Mr. Connors if in holding a safety meeting the men are paid for their time and if their expense is considered part of the accident prevention campaign? Also, I'd like to ask about the zero day proposition, if the zero day is based on no reports sent in. We ask our men to send in reports of things which the men may or may not be responsible for. It may be an accident occurring near the street car line or it may be something when the car was standing still. It is merely a matter of chance in those cases and not a matter of judgment.

MR. CONNORS: We have a bonus system. This bonus is distributed at quarterly periods. At the end of every three months the bonus is

paid. A man that misses a safety meeting has one dollar deducted from his bonus amount, and this was brought about by a unanimous vote of all the employees. They used to say, "Bill Jones only attends a few meetings and he gets as much bonus as I do." So they decided to deduct a dollar from the man's bonus for every meeting he was absent from, this dollar to go into the pot and be divided among the men that attended the safety meetings. We get about 90 per cent attendance at our meetings.

In regard to the zero days; I came across a report before I came here where the trolley rope broke and the pole hit the main wire and a report was made out of this occurrence. That would eliminate a zero day.

Another report that came to my attention recently showed the operator of a car was waiting for a man to come down out of a flat and one of these signal lights had the man blocked. The man fell coming down the steps and a report was made on that. That would eliminate a zero day.

In regard to the question whether the men are paid for their time when attending a safety meeting, we do not pay them for attending these meetings. In fact, as I stated previously, there is a penalty for not attending. If a man misses a safety meeting and if the bonus during that period is \$18 he only gets \$17, and the extra dollar goes back into the pot and is divided between the entire group.

Points of the Bonus System Are Brought Out

R. M. READE (Quebec): I'd like to ask if medical expenses are included?

MR. CONNORS: That is separate.

E. K. MILES (New York State Railways, Syracuse): I'd like Mr. Connors to explain briefly what the bonus system is?

MR. CONNORS: I could not do it briefly. We put aside \$1,500 for each one of the three-months periods, and if our accidents run over what they did last year for the same period, \$10 is deducted for every accident over the corresponding period of last year; and if the accidents run less, \$10 is added to the \$1,500 for any accidents less than the same period of the preceding year.

S. W. HENNINGFELD (M. E. R. & L. Co., Milwaukee): I'd like to ask Mr. Connors whether there are any prize awards or contests in this safety work. I don't believe that just commending the men on the work they do, or calling them down for work they don't do, hits the average man on the platform or on the bus, and I want to ask Mr. Connors if there is anything else they do?

MR. CONNORS: There is quite a bit of competition among the bosses. We have a contest on among our five divisions and the division superintendent who leads during any one year with the greatest miles per accident gets a trip to the National Safety Congress. We happen to

have Mr. Bailey here as the man who won both the 1924 and 1925 contests between the divisions.

W. F. HANNA (United Railways, Baltimore): During their talks to the men, do they inform the men of the status of accidents?

MR. CONNORS: The first order of business of our meeting is to let the men know just how they are doing. In other words, we have these charts posted around where the men can see them. These charts are kept up from day to day. About 8:00 o'clock in the morning the entire personnel will know how many accidents we have had. We have got competition between the day and night men on each division, and it is especially keen on account of the bonus system.

W. J. ROUNTREE (Ga. Railway & Power Co., Atlanta): I want to ask Mr. Connors if there has been any increase in the blind claim reports after installing or beginning this bonus system?

Reports and Suggestions to Safety Committees

MR. CONNORS: Yes, but it is not alarming. The only way I have found to gag blind claims is on a percentage basis. In Nashville, six per cent of the report are blind claims. In Chattanooga, only one per cent. One out of every 100 is a blind claim and that is increased from about three per cent before the competition to six per cent at the present time. I don't feel that six per cent is a very alarming rate.

W. F. HANNA (United Railways, Baltimore): Do you have a system of reports and suggestions for the safety committee?

MR. CONNORS: We have suggestion boxes all over the property.

MR. HANNA: Are your meetings open for discussion?

MR. CONNORS: Yes, we try to get the platform men to talk. In a mass meeting I find that an inspiration meeting is the best thing, but you get some real suggestions on safety work in these groups of 15 men in the safety education schools. I have learned more about safety since I started that school than I thought I ever would know. That one plan, I believe, is the best thing we have to show results—the safety education school.

J. W. OLIVER (Chicago, North Shore & Mil. R. R. Co., Highwood): Who does the talking at your mass meetings?

MR. CONNORS: I do. I think it is mighty hard to get them to talk at a mass meeting. I find the best way to get those men to talk is in small groups of 15 each.

MR. OLIVER: Last year we tried out a plan on our property. We hold our meetings with all the employees. All employees are asked to attend, and last year in the Transportation Department we had 42 papers presented by the men on the job. One I recall was by one of the switchmen. He has been on that job for the last four or five years. We got him to get up on his feet and tell us about the hazards of coupling and uncoupling cars and we got more out of that than anything I know of, and after the meeting he came to me and he said, "This job of mine is more important than I realized. After I sat down last

night, before coming to this meeting, I tried to dope out what I was going to tell the fellows; and I learned more about my job last night than in the six or seven years I have been with the company."

We had 42 such papers, including a debate as to the operation of the day and night lines. I wondered if your men took any particular part at meetings?

MR. CONNORS: I just want to say this, when you start to analyze a man's job this is what happens: You tell a platform man that he has eight different jobs to perform in taking on one passenger and there are two things going to happen. He is going to say you are a liar or he is going to ask for a raise. Now, gentlemen, this is what happens. I get up there with a blackboard and go to analyzing a man's job and then he is going to find out that he has got a great big thing there and didn't know he was doing so many different things. I can't break this job into small parts and bring out the operation and get the details before the men. He sees it through his own eyes and he takes a pride in what is brought out. I feel it is one of the best methods in analyzing a man's job.

J. L. FAHEY (Scranton Railway Co., Scranton): Is there any penalty for the failure of the men to make the reports in the case of blind accidents?

MR. CONNORS: Yes, if a blind claim does come in that report counts as two accidents against this man's record. In other words, he cuts his bonus to two-thirds.

Methods of Disciplining Refractory Employees

MR. NOONAN: Talking about the reports, there is a difference of opinion here in the room as to these reports. I would like to know what you would call a report in your company? If a person loses a dozen eggs or sits down on a case of eggs in a car, does that come in an accident report?

MR. CONNORS: Everything is considered an accident with us. Even in the case of where the rope breaks, a conductor makes a report of that.

MR. NOONAN: I see; you call everything an accident.

J. M. LOFTIS (Pittsburgh Railways Co., Pittsburgh): What are the methods of disciplining on your property?

MR. CONNORS: We suspend the men. That is the best and most successful method of safety. If a man strikes an automobile and there isn't any doubt about negligence on his part, he is suspended.

MR. LOFTIS: Going on the theory you advanced in your talk what you tell the man about the good things he does, don't you believe that you can get away from suspending a man on that same theory?

MR. CONNORS: I do, but the superintendent of transportation doesn't.

MR. LOFTIS: No employee of the Pittsburgh Railways Company has been suspended since December 31, 1925, and our results are very gratifying. Our accidents have been cut down, our unreported accidents have been cut down, and on the whole we think it is the best system

that we ever tried out. Of course it is young yet, but we have got great confidence in it and that confidence comes through the confidence of the men, and we believe it is one of the best ways to prevent accidents.

VICE CHAIRMAN EMERSON: We will now have election of officers for the ensuing year and I will call on Mr. Reid for his report.

S. H. REID: In making up this report, the committee recognized the fact that we have three various, separate, and distinct problems confronting this part of the industry, or this Section. One is the bus transportation which is comparatively new, another is the urban or city transportation, and still another is the interurban transportation. All three of these have their separate and distinct problems, so we are recommending at this time the election of three vice-presidents, in keeping with the other Sections which have found it necessary to do that; one to have charge of the motor bus problems, another the urban problems, and another the problems confronting those who operate interurban systems.

REPORT OF THE NOMINATING COMMITTEE

For chairman your committee recommends Mr. R. W. Emerson, vice-president and general manager of the Cleveland Railway Company, Cleveland, Ohio.

First vice-president in charge of Bus Operation, Mr. A. W. Koehler, superintendent of accident prevention, The Milwaukee Railway and Light Company, Milwaukee, Wisconsin.

Second vice-president in charge of Interurban Transportation Problems, Mr. H. K. Bennett, safety manager, United Electric Railways, Providence, Rhode Island.

Third vice-president in charge of Urban Transportation Problems, Mr. E. K. Eastham, safety director, United Railways of St. Louis, St. Louis, Missouri.

For secretary, Mr. J. J. Connors, safety director, Tennessee Power & Light Company, Chattanooga, Tenn.

VICE CHAIRMAN EMERSON: You have heard the recommendations of your committee, what is your pleasure?

J. H. Cox (Cleveland Railway Company, Cleveland): I move the nominations presented by the committee be accepted and they be declared elected.

(The motion was duly seconded and carried.)

VICE CHAIRMAN EMERSON: The chairman will assume his duties tomorrow. Today he is the vice-chairman substituting for Mr. Hellmuth. I am very sorry that Mr. Hellmuth can not be here to see the wonderful results of his year's work as chairman of this Section. He has been untiring in his efforts and has done wonderful work. I have had a good deal of correspondence with Mr. Hellmuth. I know of the correspondence he has had with others, and it is regrettable that he can

not be here today to see the culmination of his efforts in behalf of this Section.

R. M. READE (Quebec): May I ask Mr. Connors if the men have given the bonus system their full and hearty cooperation?

MR. CONNORS: I would say about 90 per cent have. Of course you will have this condition sometimes where a man feels like he is unjustly charged with an accident, and of course he is going to be puffed about it, but I feel it is well worth the money spent on it.

MR. READE: For the information of all here I would like to say that the company which I represent joined the National Safety Council in 1913, so we have been members now a considerable number of years. We started the bonus system and all our men are organized 100 per cent. They asked to discontinue it and we have done so, and any reduction that they may have in accidents we have given back in free uniforms. We have got the cooperation of all our men and we gave them all free uniforms after 15 months of service. Further than that, if they made a greater reduction in accidents we gave it back to all of them in pay. We increased their rates. We have made a very great success.

In 1913 our accidents cost seven per cent of our gross earnings and our gross earnings were about \$450,000. Today we are running over a million and our accident claims, including mechanical expenses and legal expenses, are about .75 of one per cent, and I call that magnificent cooperation from organized men.

VICE CHAIRMAN EMERSON: We will now go on with the next paper, prepared by Mr. T. G. Hamilton, assistant general manager, Chicago South Shore and South Bend Railroad, Michigan City, Indiana; he is not able to be present with us today and Mr. Reid will present his paper.

HARMONIOUS RELATIONS BETWEEN EMPLOYEES AND MANAGEMENT AND THEIR EFFECT UPON ACCIDENT PREVENTION

T. G. Hamilton, Assistant General Manager, Chicago, South Shore & South Bend Railroad, Michigan City, Ind.

The unique prosperity of the United States has assumed such widespread interest, if not outright envy, in a world greatly impoverished by war that in recent years this country has been the objective point of scores of foreign commissions, groups of distinguished industrialists, economists and labor leaders.

With their fellow countrymen no doubt wondering from where their next meal is to come, let alone how they can manage to amortize their war debts, our visitors find it extremely difficult to reconcile this prosperity with the present financial plight of the rest of the world. They are at a loss to explain our exalted living standards, widely diffused happiness and industrial harmony.

They are conducted through our great steel mills, taken down into our coal mines, whisked about on our fast railroad trains and formally initiated into the complexities of our industrial structure. They are permitted to mingle freely with the workers in the front line in order to learn their attitude toward their employers.

The visitors are shown silent, efficient machines performing in a twinkling and with no perceptible effort the enormous tasks which once required the joint and arduous labor of hundreds of men. Instead of hosts of human toilers, crushed in spirit and health by long hours and back-breaking drudgery, they find a mere handful of skilled, healthy and contented workmen guiding and directing these giant, inanimate servants of mankind. They learn incidentally, too, that steam and electric power development has given every man, woman and child in our nation the equivalent of 50 ever-willing slaves.

Industry Is Organized to Give Men a Fuller Life

Their guides explain to them that the wholesale introduction of machine tools and power has not only caused our national output to soar to an unprecedented height, but has also increased the capacity of the individual worker employing them, many times over. They are shown that one of our largest automobile factories today produces 12 cars a year, per employee, as against two cars ten years ago, while a shoe worker turns out eight pairs of shoes each day, as compared with four pairs a day ten years ago. It is further impressed upon them, that volume production has materially reduced the unit cost of manufactured articles and that the greater profits, which naturally accrue, have inevitably drawn up the wages of labor after them, so that man today lives a fuller and richer life. His circumstances are immeasurably superior to those of a man of 100 or even 50 years ago. He has become a consumer. The more he gets, the more he wants. To supply his demands, the busy factories roar with industry and the utility companies are enriched by his opportunity to secure the conveniences and luxuries of life. That high wages have a very direct bearing on the nation's buying power with the result that comforts, leisure and luxuries are diffused among our people as they are among no other peoples of the earth, readily becomes apparent.

As these factors, which, at first, seemed to defy answer, are gradually unfolded to our foreign observers, it is probable that the most lasting impression of all is their discovery that the feeling of mutual responsibility and common interest on the part of American employers and employees is ever increasing in strength. They are quick to agree that in the recent strike, British coal miners were butting their heads against the stone wall of economics when they expected to squeeze higher wages from their employers by restricting the output of fuel. It is obvious to them that in America wages are not arbitrarily fixed by employers, but by the rate of production.

The invention of the steam engine and other early types of modern machinery and the advent of the factory system in the last few decades of the eighteenth century, decreed the end of the so-called "Cottage" industries, when virtually every man supplied, by his own efforts, the entire needs of his family. Industrialism required larger amounts of capital than a single individual could ordinarily provide.

Hence, a day soon arrived when industrial undertakings became a co-operative affair; each group contributing a certain part to the whole of productive effort. Some contributed savings, others inventive genius and executive brains, while still others entered the combine by giving of their time and physical efforts. The division of tasks multiplied as time went on and the former owner or manager, clad in apron or overalls, who once worked side by side with his men, inspiring them to better workmanship, found the increasing complexities of his business no longer permitted him actually to "work at the bench." Abstracted by other duties he began to lose touch with the personalities and problems of his men. The breach between employer and employee grew; the rift widened. The influx of new racial and national viewpoints due to immigration; the growth of the printed word with newspapers and periodicals flinging ideas into the uttermost reaches of a working population; changes in living conditions due to urban congestion and changed standards of living; the evolution of a highly complex social order out of one which had been relatively simple and homogenous—all of these subtle influences wove a curtain, not merely of misunderstanding, but of non-understanding, between employer and employee, each becoming an impersonal, unfeeling creature in the eyes of the other. As a consequence of these misunderstandings, pride of workmanship and efficiency slumped all along the line. The amount and quality of individual effort returned for every wage dollar expended was found to be in close mesh with individual attitudes, viewpoints, ideas and motives.

Recognition of the Importance of the Worker

More recently, however, this relationship has undergone a considerable change. Ownership no longer exercises the domination it once had over management, and the relative pressure of profit has somewhat relaxed. The best minds now are agreed that the door has been found in the plan, recognizing and admitting the importance of the worker to the whole scheme of things. He is recognized as the middleman between capital and machinery, for no matter to what stage of labor-saving efficiency we may bring machinery, it is short of what it was created for unless the man who operates it is possessed of equal efficiency. Thus, waste of materials, supplies, overhead, time, supervision and power has its primary source in human factors and the coordination of these factors lies in intelligent, informed and efficient management.

At the same time executives are beginning to realize what an indispensability to success is the loyal cooperation of their men. Labor is being taken more and more into their confidence. Employees are en-

couraged to buy stock and become partners in the business, thereby acquiring a more personal interest in its financial success. Through employee representation plans, labor is given a large voice in the management; more attention, in turn, being given to the welfare of the employee. Short-sighted is the management which does not realize that courteous and efficient employees offer the greatest assurance of success. In the public utility business the customer's impression of the company is received almost entirely by the treatment accorded him by the employee. In the customer's eyes, the employee is the company.

Without the loyal cooperation of trainmen and other employees in daily contact with the public, any permanent success in the electric railway business or any other public utility business is an impossibility. In spite of all the mechanical devices which may be employed to assure good service, the success of the company hinges primarily upon the good or ill will incurred by its emissaries to the public. Again it is the human factor—the tap root of which, among other things, means getting back to first causes in human beings. It is as important to know men as it is to know machinery. You can get little out of either unless you understand them, not only in their relations to each other, but to the operations they are to carry out.

Extreme Care Used in the Selection of Men

It is the policy of the company I have the pleasure to be connected with, to use extreme care in the selection of its men. It is our tenet that "As ye hire so shall ye reap." All applicants must not only furnish suitable reference, but they must satisfactorily establish their various connections for ten years previous. Hearing and vision tests are very rigid and medical examinations are given in an attempt to closely estimate the character of disabilities which would be apt to result in lost time. It is impressed upon him at the time that courteous, obedient service without accident is his duty, and that carelessness will not be tolerated. He is told that accidents do not happen haphazardly, but are caused, and that there is an underlying reason back of every accident. Often there are many factors not apparent at the time and place of the accident that have some bearing on the cause. But a study of accidents shows almost indisputable evidence that individual carelessness plays a prominent part.

In what way is this true? The best way to explain is to take an example. John Doe is a motorman. His superior has continually thwarted the men's demand for improved working conditions. John is disgruntled and discouraged. The management has been indifferent toward him and his needs. What more logical result of this policy than that he should be careless of the company and its interests? It is a consequence as inevitable as the appearance of the can opener among a household's culinary articles after the honeymoon is over. As a result John's frame of mind—his attitude—has grown bad for safety and favorable for acci-

dents, and, with his thoughts on his grievances instead of on his work, he bumps a car ahead of him or runs past a red block.

A myriad of similar illustrations might be given, but they would be merely cumulative—cumulative of the eternal truth that as men would be done by so must they do; not the gold plated policy of short-sighted capital and short-sighted labor, but the increasingly popular and always workable policy of justice born of love and begotten by the Golden Rule.

ADJOURNMENT

(NOTE: A full report of the Joint Luncheon meeting of the Electric Railway Section with the Public Utilities Section, Wednesday noon, October 27, will be found with the complete report of the Public Utilities Section, on Page 659, Volume II, of these Transactions.)

THURSDAY MORNING SESSION

October 26, 1926

The meeting convened at 10:00 o'clock, Chairman Emerson presiding.

CHAIRMAN EMERSON: The first thing this morning is a communication from the secretary. I will ask Mr. Eastham to read the resolution which he has.

SECRETARY EASTHAM: The resolution is as follows.

"WHEREAS the Chairman of this Section, Mr. G. T. Hellmuth, was called away on the first day of the Congress on urgent business and has not had the opportunity of seeing the culmination of his year's efforts in the splendid meetings of this Section, the most largely attended and enthusiastic the Section has ever held;

NOW BE IT RESOLVED that the Electric Railway Section expresses its deep appreciation of the untiring and well directed efforts of Mr. Hellmuth during the past year; that this resolution be made a part of the permanent record and that a copy of same be sent Mr. Hellmuth."

CHAIRMAN EMERSON: Gentlemen, I suggest that we adopt this resolution by a rising vote.

(The resolution was adopted by a rising vote.)

H. K. BENNETT (United Electric Railways Co., Providence): Mr. Chairman, may I offer the suggestion that instead of delaying the communication by letter it be sent as a day letter?

CHAIRMAN EMERSON: It is a good suggestion and we will follow it.

The first paper on this morning's program will be by Mr. J. A. Van Osdal of the American Electric Railway Claims Association, Indianapolis, Indiana.

CROSSING ACCIDENTS

**J. A. Van Osdol, American Electric Railway Claims Association
Indianapolis, Ind.**

In the problem suggested by this topic are three primary factors, the "way", the "vehicle" and the "individual", neither of which can be overlooked in any attempted solution.

Means of communication and transportation have always been influential in the development of any country. We think we are safe in saying that the most important physical factors in developing and unifying this nation are its means of communication and transportation.

In response to the demand for improved highways, stimulated by the rapidly developing use of the motor vehicle and encouraged by the lure of "Federal Aid", we find most of the states fairly launched upon a program of highway construction that was not dreamed of 20 years ago.

While the construction program has been and still is being rapidly prosecuted, it has not been able to keep pace with the increase in the number of vehicles which seek to use the way; with the result that the dangers incident to the use of the "way" have been many times multiplied.

The problem of the present is how to make our highways render the maximum of service consistent with public convenience and public necessity, and in these requirements is included the all important element of safety.

In considering the vehicle that is most often involved in these crossing accidents, we naturally turn to the motor vehicle. Probably no phase of accident prevention presents greater difficulties than the one that deals with the automobile. The diversity of interests encountered and the fact that practically every law or regulation looking to safety in this particular field impresses the individual upon whom it is intended to operate as an encroachment upon his personal liberty, serve to make progress in the direction of safety extremely difficult. This is especially true when the class to be restrained is composed so largely of persons of immature judgment, or of little or no responsibility. The question, however, is not the elimination of the automobile, but how to make its use as safe as possible.

Accidents have become so frequent that they cease to impress the general public. They mean but little to those not involved. It is only when we learn of some happening where a dozen or more lives have been snuffed out in a single accident that we are much impressed. Isolated happenings are not impressive.

In trying to evaluate the result of accidents we are mindful that there are certain factors entering into the value of a human life that are very real to those immediately concerned, but which are too intangible to be measured in terms of money; nevertheless, there are certain recognized standards by which the economic value of human life is estimated

at \$10,000. Accepting this figure as a fair average, we may approximate the economic loss which this country sustains annually in accidental deaths. Take 1924 for illustration. That year the deaths in the United States due to accidents were 85,000, representing an economic loss of \$850,000,000. Of these 17,500 were due to automobiles. This was at the rate of one every 30 minutes from this cause alone.

The rapid increase in the number of automobiles challenges the attention of any one who gives even passing attention to this question. The report of the committee on statistics made in February of this year, to the National Conference on "Street and Highway Safety" shows that the registered automobiles in the United States have (speaking in round numbers) come up from nine million in 1917, to practically twenty million in 1925.

From the report of the committee on Highway Safety made in March of this year, we quote the following:

"Nearly twenty million motor vehicles are upon our roads and highways. Our country was not laid out for this unexpected discovery. Our roads have to be rebuilt and our streets reconstructed. The whole of our traffic situation has to be reviewed and reorganized."

The committee on statistics in the report first referred to, said in reference to the showing made by certain tables set out in that report: "It is clear from the statistics given in the two preceeding tables that the advent of the motor car into the industrial and social life of the United States has added greatly to the complexity of traffic movement on our streets and highways. Unless its operations are properly controlled the toll of death and injury will continue to increase during the coming years."

Statistics Quoted from the Hoover Conference

The committee on statistics in its report made in February this year, to the Hoover Conference, shows that the fatalities on highways in 1924 were 23,291; at the recognized ratio existing between casualties and fatalities, this means over 600,000 casualties; and expressed in money, a loss of over two hundred thirty millions of dollars, to say nothing of the property loss entailed in these casualties.

This country was shocked and ready to respond generously with measures for relief for those who so recently suffered from the Florida tornado, but we venture the statement that if the facts were known, the actual loss in life and property from that storm would appear almost trifling compared with the loss resulting annually from highway casualties in this country.

It comes back to what we said a moment ago, it takes the cumulative force of the many fatalities which are involved in a single casualty, to impress us.

In 1924 and 1925, three times as many deaths resulted from the automobile as from diphtheria, and nine times as many as from typhoid.

The Hoover committee, in its February report says that during the eight years from 1917 to 1924 inclusive, there has been a constant increase in fatalities assigned to automobiles, and they have formed a constantly increasing proportion of the total number of accidental deaths.

Lest we despair at the enormity of the task presented, we should at this point, take note of some of the facts embraced in the report of the above-named committee, that are encouraging. Thus, taking the nine-year period ending with the close of 1925, the ratio of automobile fatalities to the number of registered automobiles has steadily declined, though the ratio appears to have remained stationary during the last two years.

While the totals of automobile fatalities have steadily mounted and still are mounting, due to the increasing number of those vehicles, we should note that in 1917, the automobile fatalities per 100,000 automobiles registered was 182, but, gradually declining to 100 in 1925.

Turning from the automobile for the time, let us see what there is on the other side of the account.

The number of fatalities caused by railway grade crossing accidents, by street car accidents, and by horse-drawn vehicles all declined.

That committee also found encouragement in the reduction in automobile accidents in some of the large cities and concludes its report with a recommendation which should give heart to those who have labored to increase the influence of the National Safety Council. I quote the final recommendation of that committee.

"On the whole, and considering the record from every possible angle, the committee feels justified in the conclusion that the safety movement and safety education generally are beginning to produce results in the traffic field, where progress has been much slower than in the field of industrial safety. The battle is not yet won, however. Merely to record a reduction in the rate of increase in automobile fatalities is not sufficient. Fatal accidents in other forms of traffic accidents are declining. They should decline still further. The number and rate of fatalities in automobile accidents should also be reduced. There must be no lessening of intensive effort until this needless loss of human life has not only been checked, but has been reduced to the smallest possible proportions."

Since the conclusion of the whole matter is how to remedy this situation, we shall take a few minutes to suggest certain of the conditions and certain measures for relief, that very naturally suggest themselves.

The Grade Crossing

While the grade crossing is not the scene of all of the accidents of this class it is the place where a great many of these tragedies are staged, and while they can not be entirely eliminated so long as we have the crossing at grade, their number can be greatly reduced.

Grade crossings can not be entirely eliminated until the general public

acquires a higher appreciation of the duty which rests on it in this matter, and is willing to bear a larger share of the expense which such an undertaking involves. Wherever a railroad is involved it seems exceedingly difficult for the public to see why the expense of grade separation should not be borne entirely by the railroad. The public is making a greater use of the highway today than ever before, with an ever increasing volume of traffic that moves over the highways in motor vehicles with a speed equal to that of a freight train, greatly increasing the hazard of highway travel and railroad operation.

Hence, the demand that the public should take its share of this increasing burden is a very reasonable one. Any plan which could possibly be adopted for grade elimination, or even their substantial reduction, would require years to carry out and involve a vast expenditure of money that must come from somewhere; but the establishment of new grade crossings where it is practicable to avoid them, and the clearing up of the view at existing crossings is receiving more consideration at the hands of railroads and public authorities than formerly and this is real improvement.

An enlightened and healthy public sentiment is quite essential.

Law Observance

Law enforcement and law observance go hand in hand in this country; you can't have one without the other.

Laws designed to regulate or abridge habits and customs which have become fixed with the people are apt to be looked upon as invasions of what we are pleased to call personal liberty and the difficulty of their enforcement is because of this popular, though erroneous opinion. This trait of human nature is probably most manifest when the law is designed to regulate the individual in pursuit of his own pleasure.

Laws which undertake to tell the individual how, when or where he shall drive his vehicle, how he shall travel on or across the highway, when to stop and when to go, what precaution he shall take for his own and the safety of others, are usually resented by those upon whom they are intended to operate; and that individual, in convincing himself that the law is wrong, entertains the same false notion of personal liberty that the one does who resists temperance laws, health laws, and other like police regulations. He resists the law because he sees in it an attempt to abridge his personal liberty, although in both cases the law is meant for his benefit, his safety and his well-being, as well as for the general welfare. He sees in it only an interference with his immediate comfort and pleasure and he seeks some means by which he can evade it. It is easy to get an exaggerated idea of personal liberty because we naturally think in terms of self. If we can impress the popular mind that personal liberty ends where the general welfare begins, law observance will be more common and law enforcement less difficult.

In all this, public opinion is a determining factor and legislation must not keep too far in advance of it, for if laws are enacted before there

exists a demand for them and before the people are prepared by education, to receive and support them, they become dead letters. Hence, an enlightened public opinion is of first importance. Let us repeat, respect for the law is the strength of the law, and respect begets obedience. Wise laws backed by public opinion command respect and are easy of enforcement.

But let us not at this juncture deceive ourselves with the idea that these accidents now under consideration can be wholly prevented by any sort of laws or rules which operate only to regulate the conduct of the individual. We can not absolutely regulate human inclination or human judgment by legislative enactment or judicial decree, but we can influence them by a course of wise and persistent education. To that end, systematic accident prevention should become a part of our national life.

A Campaign of Education Necessary

The influences which operate to educate the public will, at the same time, educate those who are charged with the immediate duty of enforcing the law. Courts and police officers will be found responsive to it.

The program adopted to carry on this work of general education must be sufficiently comprehensive to reach all classes, and sufficiently practical to arrest the attention of the man of affairs. This program must be applied constantly; we must not expect its accomplishment with a single effort. Knowledge is not attained with one lesson, rather it is "line upon line, precept upon precept, here a little and there a little." The methods by which the public can be sufficiently attracted to this program to insure real interest and a desire for its accomplishment are numerous and must be varied to suit conditions.

Thus far the effort to make safety popular has been exerted in the urban centers, but before we can bring all the people to the proper appreciation of this work, and before we can expect a healthy public sentiment so general as to insure law observance and law enforcement, the rural side of the problem must receive attention. That is a field practically untouched up to this time and while results must not be looked for as quickly as in some industry where instruction, inspection and supervision in safety work are matters of daily routine, rural life stands ready to respond with community effort whenever it can be made to see the need of it, and how to do it.

While the schools are a very efficient agency in carrying on any educational program, we must not lean too heavily upon that institution; we can overdo at this point. Hence a word of caution:

Don't Overload the Schools

Here let us say that by whatever method you endeavor to interest the schools care must be exercised not to add a new study to an already heavily loaded curriculum or you may fail entirely.

Commercial interests have long since sensed the value of the schools as an advertising medium, and teachers and school officials are constantly on guard to prevent certain interests from imposing upon the schools, and through them, upon the public, promotions purely commercial and in no sense essential to the cause of education.

The difference between the use of the schools for commercial purpose and their use in teaching safety is that the former is not essential in the education for which our schools are created, while teaching principles that protect human life is.

Never did society afford such facilities as now for popularizing any worth-while cause. Such civic organizations as Rotary, Kiwanis, Exchange, Lions, Chambers of Commerce, commercial clubs, and the many other organizations that stand pledged to useful service, easily supplement the work which the schools can do in putting this cause before the public. Such a program will undoubtedly have the support of the pulpit and the press.

CHAIRMAN EMERSON: Mr. Van Osdol, we are certainly indebted to you for this fine, enlightening paper. It is very encouraging to find that you can see a ray of sunshine on the horizon.

In asking for discussion on Mr. Van Osdol's paper, I'd like to call on Mr. H. A. Rowe, Chairman of the Grade Crossing Committee of the Electric Railway Association.

DISCUSSION OF MR. VAN OSDOL'S PAPER

**H. A. Rowe, Chairman, Grade Crossing Committee,
Electric Railway Association**

I don't know exactly what to say after listening attentively to Mr. Van Osdol's most illuminating paper upon this important grade crossing question. He has gone into it very intelligently, given a great deal of thought and study to it and presented it to you in a most admirable way. It seems almost a sacrilege upon my part to try to add anything to what he has said. But possibly because I have been interested in the grade crossing question for a number of years, it might not be amiss for me to say a few things.

Mr. Hellmuth, your chairman, asked me to say a few words to you because of my position as chairman of the Committee on the Prevention of Highway Crossing Accidents of the American Railway Association. Most of us are familiar with some of the work of this committee through our poster system, the booklets we have issued from time to time, the stickers we put upon our letters and the various other means we have used to attract public attention to the serious problem before them.

We recognized a number of years ago, back in 1921, that there was need for definite organized work upon the part of the railroads in the education of the public to their responsibilities for grade crossing acci-

dents. You know we are all self-preservationists to a certain extent and those of us who have been unfortunate enough to be attached to claim departments of our railroads, as well as to our safety departments, have sometimes felt pretty sore over the way the 12 good men and true have treated us, as far as grade crossing accidents are concerned. Possibly our self-interest actually does to a certain extent help in getting something organized and that same self-interest will affect you as well as it does us.

But apart from that, I can honestly say that it has been the purpose, the thought, and the desire of the American Railway Association to act principally from a humanitarian standpoint, to recognize the seriousness of the problem, try to do our duty as men, and having done what we can it is our duty not to rest exactly upon our laurels but still to press onward with the work, and that is what we are trying to do.

Railroad Men Must First "Clean House"

Mr. Van Osdol laid particular stress upon the obligations of the public, and of course it is far from my purpose to lessen that effect in any way whatever. But first it occurs to me that we must go at this problem with clean hands. We have no right as railroad men to go to the public and say to them "Men you must do this or you must do that or something else," if we haven't first done our full duty ourselves. We have got to be fair and decent in this matter and we have got to recognize our own short-comings openly and frankly and willingly, and we have to find ways by which we are going to improve our own short-comings, if we can.

The first thing you have to do on this grade crossing question is to clean house. We have here the statement made by Mr. Van Osdol and it is true, that the very highest percentage of all these accidents comes from the fault of the public; but there are occasions where our own men are at fault and we know it. It is our duty to train our men, to so impress our men that we are sincere and earnest in this question of life saving at crossings, that we must expect from them 100 per cent of their duty every minute of the time; and we must find ways and means by persuasion, education, by discipline, by any other means that come to our command to get our employees to do their full duty every time.

Now we can't stop at that. Our corporations have responsibilities and we must be open and frank about our responsibilities as corporations. If we have a situation which we know in our hearts can be improved from a business standpoint, from a construction standpoint, from a warning standpoint, or from any other standpoint that will give the traveler upon the highway a better opportunity to protect himself, then I say to you that is our primary duty, to so put our property in condition that we can and have a right to expect something from the other fellow.

Of course your problem is somewhat different from ours in many respects, but we on our steam railroads make annual inspections of our crossings to find out whether there has been an unusual growth along our right of way. For instance, we find out whether our crossing flanges have been maintained in good order, whether our crossing flanges are of sufficient width, whether the approaches to our crossings are fair and properly passable. In other words, we go through that situation and find out what we can do that will improve the local situation. When I say we do that, I don't mean to say that it is done on everyone of the 250,000 crossings in the country, but to a substantial extent on the more busily traveled crossings and to a real extent at the less traveled ones also.

I say to you that we also try to put up such signal systems as will give the public reasonable warning of their approach to a railroad crossing; and there are places where you gentlemen are confronted with the same situation, and with signal devices and various other means of protection you can afford some additional opportunity to the traveler on the highway to protect himself.

I think we ought to go into those things most thoroughly and with an open mind and not be afraid to spend those few dollars which are necessary to improve our situation. We have adopted a sign for highway marking so that we have a specific and distinct primary marking for steam railroads alone, which will show, and always have it so that the traveler will be able to see from what direction a train may come. Now that little scheme will be an additional aid. It may open a line of thought and suggestion to you as to something which you may be able to do to meet your specific problem. I am assuming, of course, that you have your interurban as well as your urban situation to look out for.

The Big Task Is to Educate the Public

After you have gone into that situation very thoroughly as far as your own properties are concerned and as far as cooperation with municipalities is concerned, you then have the problem of endeavoring to educate the public with whom you come in contact; and there, gentlemen, is the big task that is before you. When we started out five years ago to endeavor to educate the public on that line we commenced the work with a great deal of fear and trepidation. We were uncertain as to whether we were not going to get a boomerang, whether the thing wasn't going to come back upon us with such fearful force as to demand almost universal elimination of grade crossings, which you know are installed in all of our transportation systems.

But the very enormity of the problem was our strongest defense, and the public has recognized that it is a problem too vast to be set aside lightly, too vast to be overlooked by any corporation, or the corporations of the country, and one in which they have a definite co-interest

and responsibility. So that this very thing which we feared, has reacted to our advantage rather than to our disadvantage; and it may be that you will have some problem in your local situation that you fear will have a reaction undesired by your corporation. Look the matter squarely in the face, go at it with the intention of saving human life and put your human life element above the cost of the change that may be desired. You will find that you have taken the right attitude, as far as a human proposition is concerned, that your public will very shortly come along with you, and will not demand too much from you. It will demand that which we ought to give and that which you ought to be willing to give, but don't be afraid of the problem, gentlemen, simply because it looks too big in the beginning.

You can not go into a proposition of educating the public and expect them to produce results by the simple giving of a talk, by the simple publication of this, that, or the other thing. You have got to realize that the education of the public is a very slow, tedious, painstaking, discouraging proposition. You have got to recognize that you can't get results right away. You may not show results for a long while, but by consistent pounding of the same thoughts with certain modifications, and presenting them in a new way, but pounding and pounding, just as the little drop of water will gradually wear away the stone so will you overcome your difficulty in time.

Follow the Plan of the American Railway Association

I don't mean to say by overcoming this difficulty that you are going to eliminate all of your grade crossing accidents and your street highway accidents. But I do say that you are going to make a wonderful impression and in time you are going to bring them down to the minimum, which is after all what we might expect from such precaution.

I don't know just what you have done in the past, but it would seem to me that you have an opportunity to do much the same on the general principles as the American Railway Association has done. We have in our association a permanent committee on the prevention of highway crossing accidents. That committee functions year in and year out, and it is not for the purpose of making addresses, it is not for the purpose of making an oration, if you wish to call it, or a special report at any one of our conventions or to the National Safety Council. It is for the purpose of carrying on a daily work, a work of publicity throughout all of the years, and to have in mind that they have a continuous problem before them.

Each year we endeavor to interest the public by developing a different type of poster with a different slogan, always bearing in mind our slogan which a man from Canada can always pronounce—"Cross crossings cautiously." Several of our newspapers have said the thing can't be done, but it can be done and we can get people to think straight about a complex phrase like that; and the probabilities are that they

are going to think straight as to their actions when they come to our railroad crossings; at least it is upon that we are working.

I would recommend to you, if you have not already done so, that you establish a permanent committee; that you expect from your own permanent committee definite results; that you cooperate with that committee and give to it your full support, back it up by its publications, publish them everywhere. See that all the suggestions they make, whether you like them or not, if they are intended for the common good, are pushed out consistently to the public that you are trying to reach; and I believe that we can get enough publicity in this proposition that the time will come when we shall be satisfied with the labor that we have performed, or at least feel that we are accomplishing something in the wonderful work that has been done by this Council in endeavoring to save human life.

We believe that we have made our little impression upon the country, we believe that the attitude of the public today is different from what it was six years ago towards our railroads. You may not have exactly the same problem, though you have your local problem, which is hard enough to contend with, I appreciate; but by consistent pushing of a good work upon which you are honestly embarking and in which you are endeavoring to do your full duty, it will sooner or later have its effect. I commend to you then, gentlemen, that you establish such a committee if you have not one already.

I trust you will pardon me, Mr. Chairman, for time I have taken, but I want to leave with you one thing. I feel that this organization is going to be wonderfully helpful to the American Railway Association, if you do something on the line which we are doing; and together we can get the automobile to do something on somewhat similar lines, and with that we are going to reach the dawn of the day that we all hope for.

Automatic Lights and Bells Are New Dangers

CHAIRMAN EMERSON: Thank you very much, Mr. Rowe. We appreciate your coming here today and giving us such an inspiring talk.

MR. NOONAN: There has come with the grade crossing problem what I call a new danger in connection with the installation of automatic lights and bells at crossings. The danger is increased or decreased according to the number of tracks. If you have a one-track crossing, of course it is not so dangerous. I find that many roads are now putting automatic bells and lights at crossings, and they are making one of two mistakes. They may make the time from the moment a train approaches until it gets to the grade crossing so short that it isn't always possible for a truck or an automobile to get across, in my opinion, securely and safely.

The other extreme is to put the time of the connection between the approaching train and its arrival at the grade crossing so far back that the public have become aware of it and won't wait.

I am not talking theory, gentlemen. I have looked into it very thoroughly. I have got the figures and I find that trains are approaching grade crossings in congested places inside the territory limits of cities at 50, 55 and sometimes 60 miles an hour, and they seem to believe that a red light and a bell are sufficient. What happens to the automobile driver? He approaches the crossing, he has read all about the grade crossings in congested places inside the territory limits of cities become familiar with the bell and he says, "This is fine! I'm safe," and he proceeds to cross.

Now if it is a one-track crossing it is all right but if it is 10 or 12, as we have in some of our large cities, I am going to tell you that a train approaching at 55 to 60 miles an hour and striking the crossing 13 seconds after the bell rings, is too darn close a margin to save human life, in my opinion. I don't believe that any red light or any warning bell will ever accomplish its purpose unless we have a sensible reduction in the speed of trains, plus the bell and the light.

MR. ROWE: I think the gentlemen has a local problem in mind that ought to be handled properly by the local people, the municipalities and the railroads themselves. I think the principles of boulevard stops in some of our cities which control the stoppage by a red light should apply to our railroad crossings. We have in many of our major cities what is known as the "boulevard stop" and you need no police enforcement because the average driver is observant of the fact that he must stop at that certain street. Sooner or later, when that same individual sees the same light at a railroad crossing, he will not proceed unless he knows it is perfectly safe to do so.

You will recognize that in treating a matter from a nation-wide standpoint with 250,000 crossings to consider, that I am not in a position to speak of the merits of any individual crossing or whether the protection is simple or ample, but if you have a local situation I think it should be taken up locally and the necessary protection afforded at that crossing.

CHAIRMAN EMERSON: If there are no questions that any gentlemen would like to ask Mr. Van Osdol with reference to his paper we will proceed with Mr. Carrow's paper. Mr. Carrow is Supervisor of Safety, Pennsylvania Railroad System, Philadelphia, Pennsylvania.

EDUCATING THE PUBLIC AND EDUCATIONAL WORK IN THE SCHOOLS

**T. H. Carrow, Safety Supervisor, Pennsylvania Railroad System,
Philadelphia, Pa.**

It seems that somebody has to be a martyr in every cause and for some reason or other I know of no man that has ever been placed at the end of programs as much as I. I have no criticism of it, but I am willing to be the goat if anybody can follow such distinguished gentlemen as Mr. Van Osdol, Mr. Herbert Rowe, and Mr. Victor Noonan.

I am almost in the position of the German fellow I heard of a long time ago (and it hadn't occurred to me until this morning), who had a bakery business that was going on the blink, and he also had a dog. He was meditating about his troubles one day when he came upon the dog sitting by the fire perfectly happy.

"There you are," he said, "you don't have to worry about when you eat, you live contentedly and when you die that is the end of you. I am in an awful lot of trouble and when I die I've got to go to hell yet."

I should have liked to have given this question more thought. It isn't that I haven't given it thought, but it is my observation that it doesn't matter how much you know about a subject; if you are to present it intelligently to an audience of this type, it ought to receive a great deal of time and preparation before presentation. I have done the best I could with it, but I have had on my shoulders quite a lot of business. I had intended to look over a few issues of newspapers without regard to the date, and select a text from the daily items that appear before our breakfast every morning, but I slipped down here this morning and got a haircut that was very much overdelayed and I found exactly what I wanted.

Accidents Due to Lack of Appreciation of Danger

"Two men killed as automobile overturns, their wives die; driver loses control, car skids and is upset." That is my text. This case has been tried before all of the lower courts and up to the present time the verdict has been rendered at least partially against the plaintiff, the plaintiff being the railroads in this case. It seems to me we have got to take the proposition from an entirely different angle than what we have done heretofore. I was particularly impressed with Mr. Van Osdol's observations regarding the enactment of laws before people are educated enough to accept them, and how can we expect the public to obey with willingness laws they don't know or appreciate the reason for when they are enacted?

Nearly everybody thinks when he reads accidents like that which appeared in my paper, and which appear every day, that it is carelessness, criminal carelessness. Now I hesitate to say that it is not carelessness, because if I did somebody might make a beautiful newspaper story out of it, and it would go to the four winds of the earth, that highway crossing accidents are not due to carelessness. In my judgment, the fact that is as equally important as carelessness is failure of the pedestrian, the average automobile driver, the average person who is causing these accidents, to appreciate the dangers and the difficulties and the death-dealing qualities of vehicles on the highways.

If that is the case, it seems to me we ought to proceed on some definite line of attack. If it isn't due to carelessness, it is a reflection on any man's intelligence to say that criminal carelessness is wilful carelessness, as a preacher down in Maryland said. There is something more important to emphasize than mere carelessness. Your children don't

commit depredations because they recognize the fact that it is wrong; they are aware of it, but are not impressed with the thing that they are doing.

Now I want to illustrate that point. I was taking a trip from Pennsylvania on one occasion. My good friend, Dr. Housman, one of the brightest chemists in the United States, owns 14 automobiles and has been driving them ever since they have been made pretty nearly. He is a very clever driver, a man with very little physical strength but a very keen mind. He can drive his automobile in an expert way and has me beat a mile. He can drive almost as well as my wife can. We were going 35 or 40 miles an hour. His wife and mine were sort of flinging out death warnings every once in a while. He really was driving too fast for me to feel comfortable.

The Psychology of Contact With a Fatal Accident

He came to a crossroad and he saw a terrible wreck, a couple of people mutilated. What happened? He immediately slowed down and maintained a reasonable rate of speed for a long time. What is the psychology of that? What is the explanation of it? Was there something missing in Dr. Housman's mind that caused him to fail to realize at the time that he was driving at a dangerous speed?

How many of us here, for example, have had near accidents that have caused us to pause, that have caused us to hesitate, that have made us more careful? I was once driving down the road about 25 miles an hour and a lady who had no resources except three children that were too small to work, had stopped on the road to put up her rain curtains in a Ford car. A gentleman with a Dodge came along. His car was not under control and he went into us. We turned turtle with my wife and a friend inside, and by the grace of God we were saved. Since that day I never pass a man without more precaution than I did before that date.

Why was it necessary for me to have my life almost lost before I was impressed with the danger that I am constantly in when I am driving an automobile? Simply because I hadn't been instructed and because I hadn't been educated in the proper method of driving an automobile.

Knowledge is power, but knowledge isn't power until it is put into use. We don't need so much to be taught as to be reminded. All of us here have knowledge enough and intelligence enough to accomplish a great many things in our lives that we hadn't done, but we lack that particular thing that gives the impetus to carry on and do it; and that, gentlemen, is the thing that I am undertaking to emphasize here.

We want knowledge to be transformed into action so that the great bulk of these automobile drivers and pedestrians will realize what they are doing, and I can say this—God knows what would happen on the streets and highways of the United States if the automobile drivers were half as careless and negligent and stupid as the boneheaded pedestrians. We need to educate them on both sides. We want something put into effect that will make driving an automobile safer.

Take these obvious precautions that ought to be taken, such as slowing down. I hope before the convention is over that something may eventuate regarding this question, the question of slowing down. It seems almost incredible that a person with a bright light shining across a railroad track where the view is obtuse in both directions wouldn't slow down when he knows it. Looking in both directions—just the ordinary common sense of the situation—would suggest that any man would do that, and listen for the whistle, or the bell, or the locomotive.

It would seem to be even more obviously necessary, when one train is passing, to wait for another train to get out of the way if it happens to be coming in the opposite direction. Yet it is the disregard of those simple precautions, not anything that is obtuse, not anything that is covered up in mystery, not anything that we need to go to a technical college to learn, but it is just those simple precautions that people fail to exercise that are responsible for 80 or 90 per cent of the accidents on the streets and on the highways, and particularly at the railroad crossings, which are now amounting to nearly 23,000 fatal injuries and 600,000 non-fatal injuries a year.

Crossing Elimination Is Only a Fool's Dream

What is the remedy? My good friend spoke about a crossing elimination. I'll have to add that crossing elimination is a fool's dream. We are not going to stop eliminating crossings as long as we are in progressive America. But we can eliminate some, and if the people will get together and do their damndest we can eliminate more than a comparatively few crossings every year, and I think that people are waking up to that fact.

What is the other remedy? To teach 30 or 40 million drivers of automobiles to use ordinary common sense and the precautions that are suggested by common sense; and I am right here to tell you, friends, that when you consider what a terrible job the electric railways have in teaching Mr. Motorman to be safe, the magnitude of teaching 30 or 40 million drivers of automobiles safety is something stupendous. And for that very reason I think we ought to attack the problem in the most practical, common sense way that our intelligence will direct, and furthermore we ought to back it up by reasonable laws, not by this nonsensical idea that some seem to have—that you can legislate people into Heaven by enacting a law.

I don't believe in that so much. If we didn't have a single law enacted for 50 years the American people wouldn't be any worse off at the end of that time. I sometimes think that if through some magic we could wipe off every single law on the statute books we would be better off. Aside from some few isolated cases, it is my contention that we don't need many more laws; but we want something to start with that will back up a campaign of education and instruction that will tend to restrain people from doing the things that they are doing to cause these accidents that we are daily reading about. And in order to make my

point clear as far as railroad crossings are concerned, what we want is something to induce people to stop, look and listen, meaning to stop when it is necessary to stop.

What is the significance of all of these stoppages at crossings? I am a statistician, and you know that statisticians can lie, and liars can be statisticians, and it doesn't make any difference whether I am accurate or not. I have traveled as much as 600 or 700 miles in a tour in an automobile. It is my judgment if you start from Detroit today and go to San Francisco, then back to Baltimore and Washington and over here that the total time that you would lose at highway crossings by using common sense precautions would not exceed one hour. The time it would take you would be 130 days. That is an awful squandering of time, if you think of it. I don't believe people who are as intelligent as we are will resent being told that they don't waste time if they stop at crossings.

Now I am going very readily to my conclusion. How are we going to start about this thing? In the first place I want to draw an analogy here with which you are all familiar. I wonder if you realize that 10 to 15 or 20 years ago the matter of checking and educating, instructing, guiding, and directing locomotive engineers and motormen on the street cars was in a very embryonic stage. We had progressed very, very poorly in this direction. In 1910 the great Pennsylvania Railroad inaugurated a system of surprise checking, now called efficiency checking. The people who did this work were called gum-shoe artists and the men who undertook to carry it on for the railroads were looked upon with a degree of scorn by the men in the rank and file. What is the result? We have gotten to a point on all the railroads where we make check upon check on our 3S units. We have a man on every unit, in some units two or three, to be constantly doing nothing but checking.

We Can Not Always Be on Our Toes in Efficiency

Now why was that necessary? Why is there something in the character of the human mind that makes it impossible for everyone of us to be on our tiptoes to perform our duties right, unless someone is checking us, unless someone is prodding us, unless there is an urge to do it?

Now the same way that we have checked locomotive engineers and street car motormen, changed to suit the situation, has to be applied to the drivers on the highways and at grade crossings and everywhere else. Speaking about reckless drivers, for example, what is the difference between a man that goes into an alley at night and shoots you down and a fellow that recklessly drives you down with an automobile? Why, there is this difference: that the criminal who shoots you with his gun is congenitally wrong; there is something wrong with his ethical and his moral nature; but the man who runs you down with an automobile is frequently just as fine a character as any man in this room, and perchance the vast majority of them would restrain themselves if this method that I am going to come to right now were introduced.

Now the accident record is bad. It is woefully bad. I'll say to you if we are having 25,000 fatalities and 600,000 injuries on the streets and highways and at grade crossings, we would have 10 times that many if every time that every driver did a thing that was a potential cause of an accident, an accident actually followed.

Now, here is my proposition; it is a big job, it is a simple job, it is a job that I think you and the steam railroads, the National Safety Council and everyone else ought to undertake. We ought to start out with a proposition of making a universal check of the things that are done that result in accidents all over the United States. The state of Pennsylvania, from which I come, for example, ought to set aside a week, and every other state in the Union and every other city in the Union. My proposition is subject to elaboration or cutting down, or anything. All I want to do is to get away with the principle. A universal check, with 100 to 500 men on the streets and highways to check up reckless driving and tabulate the results. These articles that appear in the daily newspapers about people that are killed and injured would make not one-half the impression which would be made by a combination of the results of all the states in the Union setting aside one week or one day for a universal check.

Only Three Per Cent of People Wilfully Careless

That seems a rather incredible thing, and I will withdraw that proposition and submit to you definitely the details. All that I want done, all that I suggest here today, is to emphasize that people don't recognize the dangers with which they are confronted. They don't recognize what to do with respect to accident prevention and we must first,—like the railroad companies make checks on their engineers, like the trolley companies make checks on their conductors and on their motormen—make checks on the drivers; and after we have tabulated the information, broadcast it to the four winds. I believe if we can only start out in some simple way, it doesn't matter whether we get 48 states or six, if we can take some specific locality and combine the results of a check in that locality with others, and then proceed on the basis of the situation, I know it is going to help.

I made a check on the highway crossings and I found that only three per cent of the people were criminally careless or wilfully careless, at highway crossings. Now if the great majority of us are reasonably careful, another proportion a little more careful, then a very small proportion exemplify carelessness. It seems to me if we can fortify ourselves with that fact, there is no legislative body in the United States that wouldn't come across with that protective legislation which is necessary.

I trust that this intelligent audience will have the sympathy with me that ought to arise from undertaking to suggest and unravel so broad a proposition, and in conclusion I will say that as chairman of the Safety Section of the American Railway Association, if there is any way at all

that we can cooperate with you to put across this accident situation at grade crossings in a better light, and if we can help in any way by our cooperation, we will only be too glad to do it.

I will say for your chairman, as chairman of the Safety Section of the A. R. A., in being asked what my budget will be for next year, I have doubled the amount that we are going to spend for publicity on grade crossing accidents; and I haven't any doubt in my mind that the railroads and the trolley companies ought to spend five times as much for publicity and education in respect to highway crossing accidents.

Statistics Help to Visualize the Crossing Problem

CHAIRMAN EMERSON: I think it is very evident why Mr. Carrow is placed on the tail end of the program wherever he goes, because it is one way of holding the audience.

E. J. HARRINGTON (Cleveland Railway Co., Cleveland): What percentage of new crossings are being installed over the number of crossings that are actually eliminated?

MR. CARROW: That information is available from the Interstate Commerce Commission. I can only say that the number of new ones is greater than the number eliminated. I recently returned from a southern trip and there is absolutely a network of railroad crossings in those southern states, just as they are in this state, and there is no doubt that the question of railroad crossing elimination is merely child's play even to talk about.

MR. VAN OSDOL: I was very much interested in what Mr. Carrow suggested as one remedy. I don't know whether you are familiar with the report made by the committee on statistics at the Hoover Conference, but they have stressed very strongly, Mr. Carrow, the very proposition that you have presented to this meeting; and I want to supplement what you have said by recommending to the chairman of this Section that no more helpful measure can be adopted than to cooperate with the agencies that are gathering statistics along the very lines you have discussed. We have got to visualize this thing and you can't do it in one way. It won't do to say, "Oh, statistics are dry!" Statistics are facts, but whenever you can put the human element into statistics you will make them interesting, as you have done.

The point is this: I was very much surprised a short while ago in trying to get some statistics from the automobile association in my own state upon observations and checks that they had made with reference to operating automobiles on highways, and I found they had none. I had to go to other sources for the information that this association ought to have been especially interested in obtaining. They don't know a thing about it. They pay no attention to it. The whole purpose of that organization seems to be to make it as pleasant and as unobstructed for the driver of the automobile as possible. They don't think beyond the point of their own pleasure and look for no responsibility.

I would recommend along the lines of Mr. Carrow's suggestion, that this Section can't do a more effective thing in this year's program than to keep in touch with the Hoover Conference Committee that is going to undertake the checking for the purpose of obtaining the very information that you have recommended.

MR. NOONAN: I would like to go back a moment to the remarks that I made before Mr. Carrow spoke. We are here talking about prevention of accidents at grade crossings and I am not talking about generalities. I am talking about a specific danger—a specific danger which is not difficult to correct because some roads already have seen the light, and in addition to the automatic bell and the light they have reduced to a reasonable speed their trains. Now wherein comes the distinction in large cities? Mr. Rowe did not answer my question. As an officer of the American Electric Railway Claims Association he ought to be permitted to answer it. With that new hazard, that new cause, the railroads themselves ought to be interested in the elimination of that danger, because every time they strike a bus, or a street car, or an automobile they must face the cost.

Mr. Rowe made one very good suggestion which caught my fancy instantly. I don't recall in all the years that I have been attending these Electric Railway Section meetings—and I have been attending since 1913—that any officers from the American Electric Railway Claims Association have appeared on our program on grade crossing accidents.

A Committee Suggested on the Grade Crossing Problem

Mr. Rowe made a suggestion that we have a committee. Now out of this discussion, gentlemen, I want to see action, and I am going to move the chair that this group appoint a committee on the grade crossing problem to work with the committee of the American Electric Railway Association. I take it for granted that here in this room are operating men, division superintendents, and even trainmen who must take street cars across not only one track but 10 or 12 every day. Knowing from my own experience the great care used by the street railways, the constant cautions they are putting before their motormen and conductors, and knowing how faithfully they watch those crossings, I am not going to add any remarks that might be unpleasant; but knowing the check-ups that we make at the grade crossings in Chicago, we know the conditions that some of those crossings are in, and those conditions are similar to the conditions found in many small cities.

I want to say that I don't think it fair to put all the responsibility on the shoulders of the motormen and the conductors, on the heads of division superintendents or on the railroad managements, because I say here now, gentlemen, that a speed of 60 miles an hour, or 55, inside the city limits of any city is too dangerous and there is one remedy for it and that is that it should be reduced. I don't favor going after the steam railroads with clubs, because the steam railways have done a great work to conserve life on property and on their trains. I believe that we should

get more from the steam railroads through friendly contact, but I would predict for Mr. Carrow that if that particular system of safeguarding crossings with bells and lights, plus fast operation, is carried on at crossings where there are six, eight, or 10 tracks, wherever we meet next year some bus or street car is going to be caught in a death trap.

I wouldn't take this floor unless I thought this was very important. Two years ago I stood a lone figure in Cleveland in the Congress Hotel where I brought this same matter up before 300 or 400 steam railroad men. I pointed out to them the hazards of grade crossings in the city of Chicago, where we have had lives lost and where our property had been struck by a train—and you know what those wrecks are. Our trainmen had done everything possible, everything humanly possible to safeguard their passengers and crew.

Remove the Obstructions That Hide a View of Danger

My motion is that we have a committee to take this up with the American Railway Association; and I go further, gentlemen, and say that I think that our group here and the American Railway Association committee and the Steam Railroad Section, which is doing wonderful work, ought to sit in together for a day. One of the difficulties of safety work here is that you men do not come in contact with the safety engineers of the steam roads.

CHAIRMAN EMERSON: I am going to ask you just to defer that motion for the time being. Mr. Carrow has another meeting he wishes to attend. Are there any other questions anyone wishes to ask him?

MR. FUNK: I don't want to take any unnecessary time, but there is one thing about this grade crossing situation that sort of nauseates me. I agree with all these gentlemen have said, but here is the thing that I am talking about, that is, grade crossing campaigns. I have toured a good deal about the country and you can talk about safety devices, you can talk about lights, bells, and gates and all that. I am for them and we must have them. But it seems to me it is especially easy to tell a fellow, "All you have to do is stop and look." When he does stop to look he can't see on account of the obstruction.

I went to a sectional safety convention recently and they talked about grade crossing accidents. We inspected a railroad crossing of one of those railroads that is always talking about preventing grade crossing accidents, and there on both sides as far back as you could see was foliage of trees, shrubbery, fences, billboards, everything on earth to keep a man from using the best safety device he has—his eyes. I think as long as we are talking about cleaning up this thing, let's get our inter-urban people especially interested in making a survey of those crossings. What is the use of telling a man to stop and look and then shut off his vision? Let us go home and make a little, sensible common sense survey of what we are doing along those lines.

CHAIRMAN EMERSON: We have a telegram here from Samuel E. Johnson, district manager, Public Service Company of Northern Illinois, West

Chicago, who regrets very much not being able to be here. He has prepared a paper on "Mechanical Protection." In his absence, Mr. Eastham will present his paper.

MECHANICAL PROTECTION

Samuel E. Johnson, Secretary, Safety Committee, Chicago, Aurora & Elgin Railroad, Aurora, Ill.

It is necessary in presenting this subject to ask you to look back a few years to the origin of our country. I ask you to remember that on a day in July, 1776, this country of ours was founded on the expression of certain fundamental principals. The representatives started with a declaration of things that were to be objectives of the new government, and you will remember that these were Life, Liberty, Equality and Happiness.

Notice that among those ideals was Life. When your forefathers said, "We establish a man's right to Life" they meant his protection. They might also have meant his protection at grade crossings.

I read an article a short time ago which stated that, "As a matter of history railway grade crossings have been the subject of legislation co-incident with the opening of lines of railroads since the first. Massachusetts in 1835 passed a law reading as follows:

"And if the Select-men of any town wherein any turn-pike, highway or town-way so crossed by any railroad is situate shall be of opinion that the foregoing provision (crossing signs) is not a sufficient security to the public that gates should be erected across the railroad and that an agent should be stationed to open and close the said gates; the Select-men may request said railroad in writing to erect said gates."

I believe the first real form of mechanical crossing protection was when our ancestors built drawbridges over moats surrounding their castles. That, at least, made crossings safe, since they removed them when not in use.

About 35 years ago steam railroads conceived the idea that some sort of audible warning was necessary at their grade crossings to warn pedestrians and vehicles of the approach of trains. Electric railroads did not take up the idea until some time around 1900.

The first forms of crossing protection were indeed very crude and a great many consisted of nothing more than a bell mounted upon a cedar post at the side of the roadway. These crude affairs served their purpose and were perhaps the beginning of the education of the traveling public to depend on a warning device at grade crossings instead of relying upon their own senses and judgment to protect them.

Speed of trains has increased as the development in the art of loco-

motion has improved from time to time, with resultant improvement in the grade crossing protection equipment.

Higher standards of living have changed the mode of transportation, not only from the standpoint of railroad transportation but also has resulted in improved methods of individual transportation. The old one horse shay has been replaced with high-powered, high-speed motor cars which travel on our highways today at speed several times greater than that of the finest passenger trains when mechanical crossing protection was originated.

To the bell, originally used and which still remains as a warning, has been added many additional features. The next development was to place the bell upon the post which carried the cross-buck railroad crossing sign. This set-up was used for a number of years and constituted the first combination audible and visible signal. This combination, I believe, really came about as a matter of economy, as the mounting of the bell upon the post at the crossing sign eliminated one cedar post support for the bell. This brought about the first real connection between the warning gong and the railroad, and since it was placed on the railroad crossing sign it was thought apparent to the pedestrian that the bell indicated approach of railroad trains.

Protect the Pedestrian in Spite of Himself

Little or no improvement has been made in the audible signal for grade crossings or in gates or barriers; but other features have been devised from time to time in the form of additional railroad signs, advance notice signs, flashing lights, wig-wag banners, and finally the last word in automatic mechanical protection seems to be the installation of the protective equipment in the center of the highway and located on both sides of the railroad. Automatically operated barriers are now in use in a few locations.

It has only been in recent years that mechanical protection at grade crossings has been designed from the viewpoint of the pedestrian or vehicle driver. His protection in spite of himself seems to be the goal.

In the early days it was felt that the bell was all that was necessary to warn the public of the approach of trains, but as time went on and the characteristics, habits, standards of living and attitude of the public changed, the requirements to be met by the designer of mechanical protection have increased to a point where he must place himself in the automobile driver's position in order to develop really effective protective devices for grade crossings.

The first thought to be given the railroad with respect to crossing protection is the distance from the crossing to the starting contact of the signal operation, which is based upon a maximum speed of the trains operating over the particular crossings.

Today mechanical protection, to be effective and efficient, must be constructed so as to present an honest, well-proportioned endeavor to protect.

It must be attractive and have a setting that will produce the proper psychological reaction in the mind of the automobile driver as to the danger of the crossing.

Just a few years ago the wig-wag signal was developed and in many cases carelessly located at grade crossings, with the result that little or no protection was afforded the motorist or pedestrian. Still later the flashing light was developed and in a great many cases located improperly, so it seemed for a time that the expense of these improvements did not warrant their installation. At this point the engineers responsible for mechanical protection at crossings realized that greater study would have to be given the subject if the devices already developed were to be made effective.

Three results may be noted:

Results of the Study of Mechanical Protection

1. The old standby, the bell, was found ineffective in warning pedestrians and has only been retained in connection with other forms of protection.

2. The wig-wags, which were originally mounted from 16 to 20 feet above the highway crossing and at the side, and many times were carelessly placed behind trees where a view of the signal was obstructed from the motorist, have been lowered to a point where they are now very close to what might be termed the horizontal range of vision of the driver of an automobile.

3. The alternate flashing red light is also now placed at a level where it is readily within the range of vision of the automobile driver as he approaches the crossing. These devices are mounted on pipe poles and in a majority of cases are set on fairly large concrete foundations in the center of highways, where they cannot help but attract the attention of drivers of all vehicles.

From the standpoint of safety the whole atmosphere in connection with crossing protection therefore is greatly changed. In the old days if a pedestrian or the driver of a vehicle heard the bell and stopped, it was very good; but if he did not and was struck by a train, he of course should have heard the bell and waited until the train passed. Today in the majority of highway crossings, outside of territory where absolute barriers are provided, the whole thought given to the selection of the device and the location of the signal is from the point of view of absolute protection to the user of the highway. Individual study is given to each particular crossing, the topography, the trees ahead of the signal and those that form the background of the signal are all considered in the plan. Advance warning signs are located and study given to the height, the size and the color of paint employed in the warning sign.

Finally, inasmuch as the first and original requirement for crossing protection, as far back as 1835, was mechanical gates, and they have

been in continual use since, and also judging by my personal experience on our railroad, I honestly believe that the mechanical crossing gate is today still the safest means of providing warning and protection to those who use our grade crossings.

CHAIRMAN EMERSON: This concludes, gentlemen, the part of this session which has to do with grade crossing accidents, protection, and so forth.

Mr. Noonan, I will be glad to have you submit your motion now.

MR. NOONAN: The motion I made was to carry out the thoughts expressed by Mr. Rowe, that we have a committee to make a study of the grade crossing problem from the point of view of the electric railway, not from the point of view of the automobilist or the pedestrian.

It is contemplated that we be given an opportunity for a round table discussion with the steam railroad section. I find it very hard on my property in Chicago to get any contact with the steam railroads.

CHAIRMAN EMERSON: This committee you are proposing to have meet with similar committees of the steam railroads?

MR. NOONAN: They could meet in conference with them and keep in touch with them.

CHAIRMAN EMERSON: Your motion then is for the appointment of a committee on grade crossings as applied with steam railroads?

MR. NOONAN: Yes.

(The motion was seconded.)

Keeping the Grade Crossing Safe in Canada

MR. READE (Quebec): I would like to say a few words on this matter, Mr. Chairman. In Canada, we are under the jurisdiction of the Board of Railway Commissioners. In Quebec we have all interlocking at every grade crossing and where the street car crosses the steam railroad we have to bear the expense of putting in that interlocking plan with the railroad company that operates that crossing, and it is up to them to see that the crossing is always kept safe. We pay 50 per cent toward the upkeep of these crossings throughout the year. We have four in the city of Quebec and in my 33 years in Quebec I never heard of a railroad crossing accident and we have always had the interlocking plan.

CHAIRMAN EMERSON: We are discussing the motion Mr. Noonan made. Are there any other remarks?

A motion has been made and seconded that we appoint a committee on railway crossings as applied to the things which this particular section is interested in.

(The motion was regularly carried.)

CHAIRMAN EMERSON: The committee will be appointed later.

The next order of business is the discussion of Accident Classifica-

tion and Statistics, and it will be opened by Mr. H. K. Bennett, safety manager, United Electric Railways Company, Providence, R. I.

THE VALUE OF CLASSIFIED ACCIDENT STATISTICS

H. K. Bennett, Safety Manager, United Electric Railways Company,
Providence, R. I.

This is not a new subject. For more than 20 years it has cropped out here and there, only to be squelched with the fire of adverse opinion. It is true that local conditions do not always warrant an elaborate set of books to keep the various wheels going around. Yet I unhesitatingly say that if the department of my company of which I happen to be the head, did not keep an elaborate systematized accounting of the accident statistics, we would never know from one week to the other where we stand nor whether we were slipping backward or advancing in the right direction.

To the safety man these figures are as essential as costs are to the purchasing agent, or the number of passengers carried daily, in comparison with other periods, to the operating head of the company. It is true that one set of figures tells the latter story, whereas the safety man has demanded (and rightly, too) that accident statistics be vital and so arranged that they may be compared down to the nth degree if necessary; and wideawake, redblooded, modern executives are realizing this condition and gradually seeing the light of day.

Is it begging the question to know what types of cars are more prolific of accidents? Is it not essential to show the accident ratio between one-man operated and two-man operated cars? And the difference between the number of accidents of the various types as compared with open and closed cars, if you are so unfortunate as to run "bloomers," as they are intimately called? The trouble is that the usual claim department is so zealous in settling its claims that it gives little attention to the cause. The effect seems to be all that interests them. I have noticed, however, that these same claim departments point with pride to the decrease in accidents, the fewer claims presented and the reduced costs.

The question naturally arises, what is considered necessary in the way of keeping statistics?

Perhaps, if I outline briefly the system that is used in Providence, and make the modest assertion that with the ammunition furnished by these statistics we were able to get at the very foundation of accident causes, so that with the first full year of accident work on the property accidents were reduced 26 per cent and, notwithstanding a 20 per cent increase in automobile registrations, there was a decrease of 17 per cent in this classification of accidents, you may be at least interested, if not entirely sold, on the proposition.

In the first place, the safety manager's office is the clearing house for

figures that have to do with accidents on the property of the company, whether it be on the street, in the power station, pits or any other department.

Large maps of the principal cities in which we operate, enlarged to an approximate size of 8x10 feet, giving every street and lane, are used for the charting of the various classifications of street and highway accidents, by means of colored pins placed at the points where these accidents occur. Every day new pins are added and a glance will show where the automobile collisions, pedestrians injured, fatal accidents, derailments, car and car collisions, bus accidents and collisions with other vehicles occur. Thus, you have a birdseye view at all times as to where these various accidents are occurring.

Every accident report is gone over carefully and from each is taken the type of accident, place, date, time, type of bus or car, division, line, and years of service of employee involved. From this data, monthly, semi-annually and annually, reports are prepared for the operating vice-president.

On another chart we classify collisions with other vehicles, with other cars, falls upon boarding and leaving cars, as to the particular type of car. For instance, we have the one-man safety car, the one-man two-man safety car, and converted double trucks operated by one man, these latter having folding steps with automatic control of doors or stationary steps with manual control of doors. Hence the particular reason for this last chart.

For Too Many Accidents There Is Always a Reason

If we are having too many accidents (and of course any are too many) traced to boarding or leaving a certain car, there is a reason. It may be high heels, dragging skirts or plain carelessness; but, on the other hand, the platform may be defective, the edge of the step may be of the saw-tooth variety, there may be loose bolts or some obstruction on the platform, or floor boards or treads may be dangerously worn. The car is then inspected and if anything wrong is found, it is pulled off and taken care of.

Perhaps somebody will say here, "such a condition would not exist if there were proper inspections." My only reaction to this is that such a contention, of course, is perfectly true, but unfortunately there are those who still wait for the horse to be stolen before closing the barn door. Therefore, if anybody thinks we are keeping records unnecessarily, let them be considered simply as a check and the means of constructive criticism.

My good friend Noonan, of Chicago, goes so far as to classify automobile accidents as to the make of the car. Well, I am not going to say nay to that. He may have just as good or a better reason for doing this than I have to keep some records that perhaps may not appeal to you. So again local conditions must to a large degree govern the need for statis-

tics; but I repeat that every company, no matter how small, can well keep such figures as will show them whether they are slipping accident-wise or not.

If you are having a multiplicity of auto collisions at a certain point, there is a reason. Go out there and get a first-hand picture for yourself. It may be out on a suburban line, at a point where there is a density of traffic because some particular intersection is a popular way to reach a shore resort or pleasure park. Brush may obstruct the corner; it may be crossed at grade; or any of a half-dozen other physical conditions may have caused the accidents. Study the situation, put yourself in the place of your operator or motorman; then, if you are unfortunate enough to own an auto drive out and put yourself in the other fellow's shoes and see the accident from his viewpoint. Having done this, apply the cure that seems best to suit the case, remembering that the first application may not work and the patient may need a different kind of treatment. Do not give up for lack of remedies, however, for there are just as many remedies as there are diseases, and accidents are nothing more than a disease of a certain kind. There is a cure for every accident that ever occurred.

Statistics Help in Locating the Disease

But how can a disease be cured if you do not know what the disease is and the remedy to apply? How can accidents be stopped unless you know how, when and where they are occurring, and so have the facts in order to apply a remedy that will cure not only temporarily but permanently?

I have only alluded to accidents to the public but it is as important to know the kinds of accidents that are occurring to our employees as it is to know those affecting the general public.

If employees are being injured by defective tools, your safety department or somebody interested should know it. If any of your employees get a shock in connection with any machinery used in your shops, this fact should also be known. Where you have a safety man on your property, or someone to whom such facts would be valuable, I think an ideal way is to have the heads of your line, power, track, equipment and transportation departments keep separate records of employees' accidents; these should show the name of the injured person (for the purpose of seeing if this particular person is prone to have accidents), the particular classification of accident, where, when and under what circumstances the accident occurred and in connection with what appliance. A duplication of the cause, kind or person involved in a second accident naturally brings up the question of why, and this can be followed out to suit the individual desire.

These records, of course, should be kept in such a way that they may be looked over; and by this I do not mean a casual look over, but a systematic checking so that preventative measures may be applied as soon as possible.

Local conditions and the need for classification of accidents must be the predominant factors in determining just how far an individual company should go in this particular respect. It must be assumed, of course, that a company operating hundreds of cars requires much more information than the company operating a comparatively small number; but I do not wish to infer by this that it is not as essential for the small company, as for the large one, to use some classification.

It may be a new adventure for some companies to delve into this matter of accident statistics at all, but we must remember (and this is particularly pertinent for those of us who have been in the railway game for many years) that this is 1926 and not 1900, and that in this stage of existence there are many new angles to street railway work which could not have been appreciated 25 years ago. One would have been put down as a dreamer if he could have predicted, 25 years ago, some of these new things which are now engrossing the attention of our public service corporations.

So I strongly urge that each representative here give this matter serious consideration. When you get back to your respective properties look the matter squarely in the face, and with the knowledge that other companies have benefited by keeping these classifications, benefited in the reduction of accidents and in suffering, and also from the cold-blooded angle of dollars and cents, adopt some suitable plan meeting the personal needs of your organization and try it out for one year. If you will do this, I will venture to predict that the effort will not have been made in vain, and that at the end of the year you will say that you not only believe in keeping such records, but that you are adding to your classifications as the trend of the times demands.

CHAIRMAN EMERSON: In view of the fact that there are three gentlemen to discuss this same question of Accident Classification and Statistics. I am going to ask that we defer our discussion until we hear from the other two. I will call next on Mr. Victor T. Noonan.

DISCUSSION OF ACCIDENT CLASSIFICATION AND STATISTICS

Victor T. Noonan, Chicago Surface Lines, Chicago, Ill.

I am not going to weary you with any papers. I want to talk. This matter of the standardization of accident statistics is not new. It is as old as safety engineering is in this country. Proper statistical methods, scientific methods, are as necessary to accident prevention work as anything else you do because your accident statistics are the foundation of your work. You can't prevent crime, disease, or anything else unless you know causes and it is from these facts in black on white that the student of the accident problem gets his data. From that data he then proceeds to work out remedies.

I remember 12 years ago we had the same discussions, the same ignorance and the same indifference in the industries of this country in regard to accident statistics. Many of our largest industries made no distinction whatever between first-aid cases and lost-time cases and compensation cases. Everything was an accident and in the course of time I found myself as director of safety under the Industrial Commission and our statistical department was completely at sea because we were not able to compare the accidents of the various industries. I had to go into hundreds of large industries in Ohio and show them simple ways of keeping statistics for the purpose of getting everything on a standard basis, so that then we would know what was happening in the foundries between the various industries.

In education work I have consistently emphasized to every employer and to every safety engineer the utter necessity of having statistics that are right, that are scientific, and that are clear-cut. Now we come to the American Electric Railway. What do we find? We find, gentlemen, that we are in the same battle that the industries were in years ago, we can not compare our accidents from one city to another and if you did attempt to compare them they would be very inaccurate.

A Problem for the Safety Engineer

The American Railways have the same practice that the American industries had 10 or 12 years ago. They made the foolish mistake of calling everything an accident. Everything that happens on a street car is not an accident. With all due respect to our lawyers, as I said yesterday, if a woman sits down on an eggshell and crushes it on the seat of a street car, it is not an accident. If a man driving a Ford car has his fender bumped that, gentlemen, never in a million years can ever become an accident, because an accident can't happen to a piece of metal. Accidents happen only to human beings. Accidents don't even happen to dogs or horses and there is a clear psychology and a clear logic in this. Yet we find our railway brothers calling everything an accident.

Some of our claims men seem to be afraid to make a change. Why? They seem to think that with the coming of accident prevention work the amount of business they are going to do will be decreased. It won't be decreased. There will always be need for a claim department. We will always have accidents, no matter what you do. This problem, gentlemen, is not for the claim department so much. This problem is one for the safety engineer. It belongs in his department. If you can not make out the statistics themselves in an intelligent way then it should be done by the claim department and there should be close cooperation between the claim department and the accident prevention department, and the claim department should give the statistical information, if possible, in a way that it is desired in the safety department. If your accidents are not properly classified, what happens?

Here are some of the outstanding effects that I see, gentlemen. Please

note these two effects. First of all, I have observed that because accidents are not properly classified and put on a standard and intelligent basis, there is one department in every electric railway property that is crucified, loaded down everlastingly with the burden of the accident problem, and that is the transportation department or the operating department. Here is the claim department forever putting a load on them. 1,000 accidents a week, 200 litigations a week, and so forth.

Then the load is pushed down on the average executive so that he is afraid to look at his accident report. All he gets is that constant load of accidents and costs; and then the property itself in the eyes of the public is always being advertised in the press as being one of the worst causes of accidents in the city or town. A jaywalker crosses the street and collides with a street car and is killed. The street car is blamed for knocking down a pedestrian. A man makes a Dutch crossing with his automobile and collides with a street car and the street car company is blamed. A man is intoxicated and he forgets the track he is on; he is going west and strikes a street car going east and the newspapers have it, "Street car rams automobile and kills driver." That is all part of your system of reporting accidents and your system of keeping track of accidents.

Now, gentlemen, if the recommendation that I would like to see go through were adopted, it wouldn't mean a big change in the statistical methods in your claim department but it would mean a big relief and a big load lifted off your transportation department or your operating department and your trainmen, and it would mean more pleasant reports for your executive and vice-president.

Separate the Paper Reports from the Accidents

We should have the accidents brought out in the daylight and not submerged in a lot of camouflage so that you don't know what is going on from one year to another. I am very proud to say that the Chicago Surface Lines' claim department, headed by Mr. Treaty and his predecessor, Mr. Ginan, cooperated 100 per cent with our department. They gave us everything and worked out every new suggestion that was made with the result that today, in our property, we have daily reports and weekly reports and monthly reports which show a clear segregation of the major accidents, from which we are able to make charts and diagrams and put them in a magazine or put them on our bulletin boards, and from which I am able, myself, to put my nose on the track to locate some of the causes.

Now let us find out the simple basis that I would like to see adopted. First of all, instead of calling everything an accident, gentlemen, let us begin at the A. B. C. and separate paper reports from accidents. A paper report is not an accident unless someone has been injured. All things that happen, such as a woman tearing a dress, little arguments, fights between passengers and trainmen, all of those things are not

accidents and should be put in Class Number One paper reports. Not hard to do, gentlemen; it is very easy.

Secondly, going up the ladder, all property damages ought to be kept separate from paper reports. You see that, don't you? You operative men see what that would do, for you get that information every week. And thirdly, your injuries should be kept separate from your property damages. In Chicago we run anywhere from 800 to 1,000 accidents a week, calling them by old classification. It is very important for me, gentlemen, looking at it from the accident point of view every week, to watch that line and every day see how many paper reports are turned in, how many property damages. Why? Because the automobile is more and more becoming a costly problem for the operating railroads of this country. I want to watch that automobile line exactly and compare it with the previous month and with the previous year. Then your injury line—that is very simple. These three simple standards do not necessarily affect any changes in the system of accident statistics as originally adopted by the Claim Association ten years ago. It is a step more to clear the atmosphere.

Segregation of Fatal Accidents Necessary

Outside of your injuries you keep your fatality accidents. Here is one class of accidents that absolutely needs segregation. Many operating departments in this country are every month turning into the management fatal accident reports, and when you get them you find fatal accidents in there that no street car and no motorman ever caused. When a case came through where a girl was killed by a Ford car I use to pass it up. The train crew got out and took the license of the car and gave what first-aid they could, and properly. Yet that accident comes through on our fatal lists as one of our accidents. That is wrong! Fatal accidents other than the company's should be kept separate. That is not hard to see and we see no reason why any claim man should object to that. Yet they seem to object to it.

Then there ought to be a further sub-division along the line, divided into two main classes, injuries and deaths and property damages, calling them preventable and non-preventable; call them company accidents or non-company accidents; the accidents caused by our own trainmen; the accidents caused by the company's own fault; the accidents caused by failure of mechanical equipment, meaning bells and buzzers; and then the clear-cut accident caused by the other fellow, the truck driver who comes out of a side street and strikes the side of your car.

How can any accident prevention department prevent such an accident, and yet those types of accidents are happening. Those types of accidents caused by the other truck driver or the pedestrian should be absolutely kept separate in a classification of accidents because when they are kept separate the safety engineer as well as the general superintendent of operation and the division superintendent of the train

and the trainman can be supplied right along in their committee meetings and in their safety meetings, not with just general talk on the causes of accidents, but with illustrations of the types of accidents that are happening each day on the lines.

In the same way the costs ought to be split up. There should be more study of the causes of cost, and there should be more study as to where the cost lies and on what classes of accidents. We have 35 accidents per month out of 1,000 that are costing in the course of the year a quarter of a million dollars. Here is one bunch of accidents where our accident prevention work ought to center itself to see if they can cut down the number of those accidents and the cost of them.

Gentlemen, this is a problem for the safety engineer largely. Yet to everyone of you operating men here it is important because the proper standardization of accident statistics is going to be the greatest help to you, whether you have a safety department or not, in carrying on intelligently your accident prevention work, so that you will know exactly where to apply a remedy. It is unfortunate that some of our claim departments have taken what I may call an antiquated stand on this. They are behind the times, because this basis of accident statistics that I am urging is recognized by the best scientific experts on statistics in this country as the proper basis for keeping track of accidents. Therefore the claim men who will not cooperate with the accident prevention department or will not help their operative departments to secure this information and standardize it throughout the country, are simply holding back a good work; they are not cooperating in a great and important work in their own organization that has for its purpose the saving of human life and the prevention of suffering.

Cooperation Between Claim and Accident Prevention Men

I have been personally so discouraged about this—I have talked it at these meetings for years—that this past year I absolutely made up my mind that I would not discuss it here this year. I have said if I can't get cooperation through our National Association that I would go ahead on my own job and do the work as well as I can with the approval of my own management and with the cooperation and good will of my fellow associates. But I can look back and remember that Mr. Bennett, as a claim man, had the vision to see the value of this work, and he had the courage, gentlemen, to come here today and read this paper. He read it modestly but well, and when they asked me to back him up I could not stay in the background and refuse to say a few words here. I hope that these few words will give you something to think about, that they will impress upon each and every man here the necessity of watching your accident statistics and having a good standardized system to carry on your accident prevention work.

In conclusion I want to pay you all a compliment. I have attended these meetings ever since the beginning, and never before have I found such pleasure in attending an accident prevention meeting of our Electric

Railway Section and listening to such wonderful discussion from the floor as has come up at these sessions. I have been impressed by the questions that have been asked, and I think, Mr. Chairman, the officers of this Section deserve commendation, but the gentlemen who are present deserve the highest encouragement because I feel sure that each of you is sincerely trying to represent your own property and your own management in the way that men should do who have this great work at heart.

CHAIRMAN EMERSON: The concluding portion of this discussion is to be presented by Mr. G. B. Powell, superintendent of transportation, Louisville Railway Company, Louisville, Kentucky.

VALUE OF ACCIDENT CLASSIFICATION

G. B. Powell, Superintendent of Transportation, Louisville Railway Company, Louisville, Ky.

The subject could be made to produce a formidable array of comparative figures and pages of highly technical statistics but I am not a statistician and have no legitimate reason for attempting to punish those present. The value obtained from accident classification in the organization with which I am connected, The Louisville Railway Company, will constitute the message I have to deliver.

Two reasons for classification of accidents stand out with equal prominence. To determine the "Cause" and "Fix the Responsibility," both of which are fundamentally necessary if the attempt to prevent recurrence is to be successful.

All accidents are the result of the negligence of someone, so in public transportation of passengers it is necessary to classify in order to determine whether the responsibility rests on the employee, passenger or those on the streets. When it is found that the employee is responsible, the remedy can be quickly applied. If the passenger is to blame then by the slower method of additional safeguards and education the results may be obtained; but when it comes to dealing with those who share the streets with us, the careless jay walking pedestrian and the speed mad vehicle driver, the results to be obtained and hope for the future must come by the painfully slow process of legislation supplemented by public opinion produced through costly education.

We use more than 100 classifications of accidents incident to street railway operation. Automobile collisions constitute 80 per cent of the total, so, of course, head the list, and in seeking our goal, cause and responsibility in auto collision, the analysis leads to 20 or more classifications.

For instance, direction would seem very simple—right angle, same direction or opposite direction; but be not deceived if you expect our

good friend, classification, to produce results; open up its pages and search therein.

Right angle, yes; but at street crossings, between corners, from right or left, or at alleys; likewise, same direction or opposite direction is only meager information until classification discloses—struck rear, front, right side, left side, rear left corner, head-on, etc.

Persons injured classified as passengers, pedestrians and employees is only a start; each must be sub-classified under at least a dozen headings before the analysis will yield its value. Car collision, split switches, boarding and leaving, all down the line the process of proper classification must be pursued until each accident is properly tagged and hung up before us, with the reason therefor, as plain as if it had been purposely staged before an audience assembled to witness its production.

When this is done the value of classification manifests itself in the opportunity to present to the party responsible, those in authority over them, and the local safety council the true facts, which often results in cooperation in adopting means to prevent a recurrence of similar accidents.

Another classification we have found valuable is in relation to the location on the property where accidents occur. A map of the city showing all street car lines is posted and colored headed pins are stuck in the map at the exact location where an accident occurs; different colored pins represent the different kinds of accidents—white, auto accidents—red, car collisions—black, boarding and leaving, etc. This method of classification enables us to determine the location on the property where accidents most frequently occur and accordingly concentrates our efforts in the troublesome location.

Data Valuable in Analyzing the Accident

Another classification of great value is in relation to the time accidents occur; this is also kept with colored headed pins stuck in a chart which is divided into hourly divisions. As would be expected, the greater number occur during the peak hours of travel, but many important discoveries were brought to light by this method of classification; for instance, more automobile-street car collisions occur between 8:30 and 9:30 a.m. than during the peak rush hour, 7:30 to 8:30 a.m.

Analysis of this situation discloses that speed substituted for leaving home on time is the predominant cause of these collisions. The increase between 11:00 and 12:00 at night over the earlier evening hours deals with the homeward rush mixed with joy riders starting out, and includes many serious accidents in our line of business. The value of hourly classification is the information enabling concentration of efforts at the right time.

One more classification I desire to mention, one which we deem of vast importance, is fixing the responsibility in relation to our employees. All accidents are recorded on the employee's record card and are classified

"Blame," "No Blame," or "Non-committal." The non-committal are those accidents which the employee was not responsible for but which he might have prevented by the exercise of extreme care and good judgment. In other words, save the other persons in spite of their carelessness. This method enables us to keep constantly before us the efficiency of our force in accident prevention and has materially assisted in building up the splendid cooperation we enjoy in our organization.

Summarizing accident classification, as I see it, knowledge is conceded to be power. Analysis is recognized as the best method of obtaining the desired knowledge of any subject. Classification of accidents is an analysis which will reveal cause and responsibility, the necessary goal if prevention is to be secured. Therefore, classify the accidents which occur on your property: First, in general groups, then subject each group to an analysis which will spread them out before you until their legibility permits a clear vision of the cause and who is responsible, then and only then will you be in a position to apply the best possible remedial preventive measures.

Committee Study of the Various Classifications

CHAIRMAN EMERSON: This concludes the presentation of the subject and the meeting is now open for discussion.

MR. READE (Quebec): I have some interest in this last subject, especially on the point brought out by Mr. Noonan, and I would like to make a motion to the effect that the Council print the code followed by Mr. Noonan and send it out to all members of this section for their approval, and by doing that we can get some adopted plan to classify our accidents.

The motion was seconded.

CHAIRMAN EMERSON: Before asking for discussion on that, it occurs to me that the proper method to pursue would be for the committee to study the various methods of classification and then make a recommendation. The classification Mr. Noonan uses in Chicago wouldn't be the one that applies throughout the United States and Canada. I don't think a committee should be limited in its work to the study of any one particular system. I would like to hear remarks from the other gentlemen.

MR. NOONAN: I should explain that there was a committee in connection with this Section on standardization of statistics, but we got nowhere. My plan is not a classification which would conflict with the claim department because I have simply outlined a skeleton that any company could follow.

MR. VAN OSDOL: If Mr. Noonan's motion has prevailed it is certainly the motive of that committee, after a study, to make such standard recommendations as might seem proper and undoubtedly they will, by questionnaire or otherwise, get the reaction from the various interests; and it seems to me that that will cover the point made by the gentleman from Canada, and this committee will accomplish that very thing.

W. H. BOYCE (Pittsburgh Railways Co.): I would like to make a suggestion along the same lines. Inasmuch as there are about 150 company

members in this group railway Section, there are probably only 20 per cent of them represented by delegates here, and therefore this committee should send out a questionnaire to all the companies embodying the question Mr. Noonan outlined and all the details of Mr. Noonan's plan, and then let the committee study those replies and give that matter careful consideration before they make their report.

SECRETARY EASTHAM: As secretary of the Section during the past year and also chairman of the Committee on Recommendations, I think that the committee to which Mr. Noonan refers has already been under advisement, because the Committee on Recommendations thought that one of the main recommendations and investigations would be along this same line. In one of the news letters sent out during the past year a request was made that all the members send in what they were doing in the way of classifying accidents. I think about three answered out of the 150 members.

Assistance of Section Members Is Asked

Now for the new secretary or the new committee that may be appointed along that line, I would like to suggest that some means be had of seeing that the communications that go out from this Section reach the right party in the different organizations and then that the right party take the individual responsibility to reply to the request, whether it is in the form of a questionnaire or a request to have their classification of accidents or whatever it may be. It is only through the help of you members that this Section is going to be anything like a success.

I'd like to stress something that I think is in line with what is being suggested. I think it would be a splendid thing to get all the companies to send in to the committee just how they are classifying their accidents, whether from the claim department's standpoint or from the standpoint of those who have safety departments. With us, the claim department don't cover it as I want it, so I go over all the reports in my department and get figures for the safety department in addition. I am not going to take the time to discuss how that is done, but it is along the same general lines of classification, not quite as broad as Mr. Powell's, but broader than the average company.

CHAIRMAN EMERSON: I am going to ask you to defer that question until we finish this motion. We want to get an expression with regard to Mr. Reade's motion.

MR. POWELL: I don't believe in passing the buck. Now it seems to me that last year when they were working on this classification proposition, there had been a lot of literature sent out and questionnaires, and somehow or other I didn't know they had been sent out. Now this Section of the National Association should find some means of getting this information or these requests to the right party. Most companies have a safety department and I know they will answer and I know that every transportation department superintendent would respond too.

CHAIRMAN EMERSON: I presume it is the idea back of the motion that

this committee shall study ways and means of securing adequate data so that they can in turn make a recommendation.

MR. NOONAN: We had a committee on that proposition. May I make that clear again? I was on it and Mr. Powell was on it, too. The American Electric Railway Association had such a committee. I was on a previous committee some years ago in this very Section. Mr. Welch, the executive secretary of the American Electric Railway Association, down at his office in New York City has never been able to get information on questions from any companies throughout the country. It is my opinion that if you will draw up a model and send it out as something worked out and something constructive you will get far better results.

CHAIRMAN EMERSON: That is what Mr. Reade has in mind.

G. R. WHITMORE (Illinois Power & Light Co., Peoria, Ill.): I would like to know whether this classification applies to every department or merely the claim department. The transportation department may have a way of classifying accidents, the safety department may have a way of classifying accidents. Just what does this motion mean?

MR. NOONAN: This plan is simply to take the accident data as kept by the claim department which is the proper department to get it from. The claim department is the logical department to start with.

To Draw Up a Model Plan of Keeping Records

CHAIRMAN EMERSON: I understand that what Mr. Reade has in mind is the securing of the proper form of accident statistics which will be handled properly through the claim department, to be adopted by them and which will be adapted to any property. In other words, to draw up a model plan of keeping records and so forth which will throw more information into the different classifications and segregations of the accidents that occur. I think everyone here understands the motion. It has been seconded.

(The motion was put to a vote and carried.)

J. L. FAHEY (Scranton Railway Co.): I would like to ask Mr. Noonan whether he regards torn clothing, that is clothing damaged on the cars, of sufficient seriousness to be classified as property damage?

MR. NOONAN: Absolutely no. No material that is damaged is a property damage. There are a great many things that happen that don't come under either classification and then you put them under paper reports.

CHAIRMAN EMERSON: We will proceed to the last section of the program for this session, which is a round table discussion. The first section of that relates to "No Report Claims and What Is Being Done to Reduce Them." Mr. G. R. Whitmore, general claims attorney of the Illinois Power & Light Company, Peoria, Illinois, will present that subject to us.

NO REPORT CLAIMS AND WHAT IS BEING DONE TO REDUCE THEM

**G. R. Whitmore, General Claims Attorney,
Illinois Power & Light Corporation, Peoria**

Did any of you claim men ever receive a letter something like the following?

"I represent Sam Traicoff, who was seriously injured about two weeks ago, when he was thrown to the street while alighting from one of your cars at Main and Broadway. According to the witnesses, your motorman started the car with a jerk while my client was in the act of alighting from the car, and this is a straight liability case. My contract calls for 50% of whatever is paid either by way of settlement or suit.

If I do not hear from you within the next ten days, I will file suit for \$20,000.

Yours truly,
I. M. A. Chaser,
Attorney."

All of us have received such letters, and we immediately look through our files and records, and what do we find? Nothing. We then take up the matter with the operating department and both start an investigation.

There is no need to detail the grief, worry and absolute dissatisfaction that follow claims of this character. No one is satisfied or pleased, whatever may be the outcome of the case.

Typical "No Report" or "Blind" accidents fall into two classes, namely, those that are fake and fraudulent and those that are meritorious. This applies either to accidents to employees or to the public.

Accidents involving the public generally will be discussed first and then we shall take up the question of "No Report" employee accidents.

The main purpose of claimants in connection with fake or fraudulent "No Report" accidents is to capitalize them; the best way that we know of to reduce the number of such accidents is to keep them from being capitalized and thus discourage claimants. We can investigate the claimed accidents and the claimant himself, and, if not absolutely satisfied with every feature of the case, we can and should decline the claim. In an investigation of such a claim, something will always crop out indicating that the matter is not straight in every way, and intuition and experience will enable us to detect the crooked claimants.

We have adopted the policy of declining claims growing out of unreported accidents, unless we feel certain in each case that the accident did happen and that the claimant is telling a straight story. Our experience shows that we have very little trouble with claims of this nature, except in one large city where, it appears, there is a gang of negroes making a practice of pressing such claims. In the last three months we have had over a dozen such claims at this point but we have declined them all. Some suits have resulted but we intend to defend them. If we should concede anything in the way of settlement in any of these claims,

we feel that there would be no end to claims of this nature being pressed, especially by unscrupulous attorneys.

However, we believe that it is more important to consider here, how we can reduce or eliminate accidents that actually happen, but are unreported, and where the claims appear to have merit.

Most of the accidents of this class, in connection with electric railway operation, are of two kinds; one, vehicles or persons struck by other than the front end of cars; and two, passengers falling in cars, on platforms or in boarding or alighting.

Railway officials and operators or trainmen can not control the actions of vehicle drivers or pedestrians, who insist upon running into the side or rear end of cars, and such accidents, sometimes unreported if slight and a jar is not noticed by the car men, can not be prevented by the railway. We can and do prevent standing vehicles and persons being struck by the overhang of cars by careful operation, watchfulness and due regard for the rights of others by our car men. Safety lines help and so does proper parking, careful driving, thoughtfulness and alertness on the part of vehicle drivers and the public generally. Naturally, education of the public and vehicle drivers in particular regarding the danger of such accidents will tend to reduce them, but the first thing for us to do is to see that the company officials and employees appreciate the responsibility which they bear in this connection and do what is possible on their part to prevent such accidents.

The Human Element Important in All Claims

What are we doing and what can we do to prevent unreported accidents, where passengers fall in cars and from step and platform? Proper operation of cars in good condition over smooth track and with no outside interferences will tend to prevent them, but we do not always have such ideal conditions. All managers want their equipment and tracks well and economically maintained, but we know that sometimes economy alone in maintenance is the aim. This should be a point to strive for by every mechanical department but there should be no excuse for the operation of defective equipment. Sometimes a car in bad order will get out on the line, but it need not run for any considerable period, if motormen and conductors will report such cars at the first available opportunity to the proper company officials and such company officials do their duty.

It is our feeling that the human element is the main thing with which we have to contend. Our experience has been that one or two men out of a hundred have unreported accidents and these men cause most of the trouble. An old, experienced and loyal employee seldom has to be called on the carpet in connection with an unreported accident. It is the inexperienced, thoughtless, indifferent and careless employee that causes such accidents to happen; and, furthermore, if such an accident does happen he will either not know of it or, knowing about it, fail to report it unless the injuries are apparently quite severe.

The first duty is upon the superintendents, who hire the men, to use judgment in selecting men for operating our cars. Assuming that we have selected the right men as employees, there must then be constant supervision by competent officers to see that the employees are kept up to a high standard of conduct. All the rules and supervision in the world will not make a "bad" employee good and the quicker we weed out the shiftless, careless, thoughtless and incompetent employees, the sooner will this problem be solved. It has been our idea always that properly selected employees, well trained and supervised, will solve most of our accident problems, including the problem of the unreported accident.

The Unreported Accidents to Employees

Unreported accidents to employees are also a source of trouble and annoyance. I think it is the experience of most companies that practically all regular and steady employees report all accidents causing personal injuries to themselves. Occasionally, a very slight injury, such as a scratch or a splinter in the finger or the like, is unreported. Little attention is paid to an injury of this nature unless an infection sets in; then it often happens that the injured person can not recall the place, time and cause of the injury, thus making it very difficult to handle such an accident under the terms of the Workmen's Compensation Act.

Accidents causing strains and particularly ruptures are the most unsatisfactory of all unreported employee accidents. We have all had experience with hernia cases, but we are finding the remedy and a solution in the provisions of the Compensation Acts of the various States. For instance, in Illinois the situation as to hernias has been cleared up exceedingly by the enactment of paragraph D-1, Section 8, Workmen's Compensation Act, which provides as follows:

"An injured employee, to be entitled to compensation for hernia, must prove:

- (1) The hernia was of recent origin.
- (2) Its appearance was accompanied by pain.
- (3) That it was immediately preceded by trauma arising out of and in the course of the employment.
- (4) That the hernia did not exist prior to the injury."

This provision is also limited in that notice of an accident causing a hernia must be given the employer within 15 days after the accident.

Prior to the passage of this amendment to the Compensation Act in 1925, it was necessary that practically all hernia cases be handled in accordance with the terms of the Compensation Act. The time, no doubt, will come when each state, which has a Compensation Act, will provide for the handling of hernia cases somewhat in accordance with the provisions of the Illinois Law and then, in our opinion, substantial justice will be accorded both the employees and the employers in connection with such cases.

The remedy for unreported employee accidents, particularly those in which regular employees are involved, largely lies in constant supervision. By this, we mean that the managers and superintendents should see that the foremen, who are in direct charge of the employees, are instructed that regular form accident reports should be made out immediately upon the happening of an accident and that the foremen carry out their instructions. This is not so difficult where the industry is located in one or two central plants but the situation is complicated somewhat when, as in the case of a company like ours, we serve several hundred communities in a number of states and have various plants, small and large, at many points. However, it is just a question of having a good organization, specific instructions and constant supervision.

When it comes to the question of unreported accidents to casual employees, such as those engaged in track work in the summer, or construction work from time to time, we have a more difficult problem. Such employees are not particularly interested in the welfare of the company, are not imbued with the spirit of loyalty toward the company to see that everything is done in accordance with instructions and what is right and proper, and we often find that a large proportion of our unreported employee accidents come from this source. Casual employees are here today, gone tomorrow and can not be easily traced. With a regular employee, we have this original physical examination and other physical examinations from time to time, as well as a record of his past employment. Such is not the case with casual employees and when a claim is made by such an employee for an unreported accident, it is necessary to spend much time and energy to find out all the facts.

Unreported Claims Are Usually Found Unworthy

One remedy is that of discouragement, that is, an unwillingness to recognize any such claims, growing out of unreported accidents, until every source of information has been thoroughly investigated. We believe that in the vast majority of cases, such claims are found to be unjustified, if not fraudulent. We have just had two such cases, one, a construction employee, shortly after the work had been completed and he had been laid off, claimed that he hurt his leg, the injury resulting in an ulcer. Upon investigation, we found that some years previously this man had a claim under the Compensation Act against another employer and had received compensation. We located the doctor who had taken care of him and he stated that the injured man's leg was in exactly the same condition at the time of the hearing of his claim against our company as it was some years previously. We won this case. Again, another construction employee, shortly after his discharge, claimed permanent disability as a result of an unreported accident. Upon investigation of this case, we found that this man had had a claim against a previous employer and had been awarded compensation for permanent disability and had received a large lump sum settlement.

The attorney for this claimant dismissed his case after this evidence was introduced.

We believe that the safety department can do a great deal to eliminate unreported employee accidents. The safety engineers can educate the employees to report immediately all accidents, no matter how minor the injury may seem to be, can supervise and instruct foremen and can see that the instructions are followed.

Perhaps it is not within the purview of a paper of this kind that we should discuss the question of physical examinations of employees. We believe that practically all employers now follow the policy of having a thorough physical examination of employees at the time of their employment and further examinations periodically thereafter. We do not believe that many employers require physical examinations of casual employees. Our rule is that if a man, originally taken on as a casual employee, remains with the company for a period of thirty days, he must then submit to a physical examination. Solely from the standpoint of the claim department, and not considering anything else, we believe that every employee should have a physical examination prior to his employment. We find that reports of physical examinations are of value in checking up on injuries later claimed by employees, particularly in connection with unreported accidents, and more particularly, in connection with claimed hernias.

I have not attempted to set out how and in what manner all unreported accidents may happen but have discussed only those which are most common. Many otherwise unreported accidents become reported by reason of employees reporting every incident or occurrence in connection with company operations coming to their attention either while on duty or off; the employees should not judge of the importance or triviality of the matter but should report it to the company officials.

In my opinion, unreported accidents will be greatly decreased in number, if all company officials and employees do their full duty.

CHAIRMAN EMERSON: The second section of this discussion is "The Standing of the Safety Department in the Organization," by Mr. James Harmon, safety manager, Interstate Public Service Company, Indianapolis, Indiana.

THE STANDING OF THE SAFETY DEPARTMENT IN THE ORGANIZATION

James Harmon, Safety Manager, Interstate Public Service Company, Indianapolis, Ind.

In preparing a paper on this subject, I am doing so with the feeling that the safety engineer should do nothing except look after the safety work on his property, but I am taking into account also that some safety engineers, in addition to their safety work, take care of other duties of the utility such as claims, insurance, etc.

To find the standing of any department in an organization, it is necessary to study the workings of that department and learn whether or not it renders real service to its organization and the nature of such service.

In all organizations there is service which is productive and non-productive. The non-productive service is always more or less a source of worry to the management because it does not show a direct return in dollars and cents. Unfortunately, the returns from the service given by the safety department are indirect. This being the case we need not expect this department to rank as high in the organization as the productive departments, unless it furnishes an exceptional service, the value of which is not necessarily based on dollars and cents.

The safety department is created for the purpose of educating the employees in accident prevention work by enlisting their cooperation and affording them an opportunity to take a personal part in the program of this work, insofar as it applies to accidents to themselves, fellow employees and the public.

Employees Must Be Kept Posted on All Safety Rules

The employees as a whole must know that accident prevention work is very important and that in order to accomplish the results desired they must, at all times, be posted on the safety rules and instructions and their work must be governed by them. One of the problems of the safety engineer is to be able to make a check personally of his entire organization to see that all of the foremen are doing the things they should do by carrying out the safety rules, and frequently you will find they become careless and that is when the accident occurs.

Quoting Thomas A. Edison from Mr. Babson's book, "If success is the acquiring of money or power or fame, then the struggle is not worth while, because after you get these things you find them to be mere empty shells." The safety department is attempting to do something more worth while than merely to gain a success in money, power and fame. This is to make people happy and when you are able to do that you are a success and you are in a successful business. With that thought in mind, let us investigate the service that is rendered by any well organized safety department.

I have often been asked what is the nature of the work of the safety department. As the head of such a department, the only answer that I can give is that our work is to educate the employees and public in accident prevention work. Years ago before accident prevention work was as aggressive as it is today, it was often felt by the management of certain industries and utilities that in order to operate such properties it was necessary for a certain number of fatal and personal injury accidents to occur to those employed. But statistics show that since this work has been taken up nationally by many industries, and has been made a part of operation, there is a material decrease in the number of accidents on properties employing the same number of men doing prac-

tically the same kind of work; and for that reason the safety department standing in those industries is of the very highest.

One never knows how many people are made unhappy and sad on account of one serious accident. We all know, however, that in many instances it not only does cause unhappiness but also a great amount of suffering, especially if the one who is injured or killed is a father. The dependents will necessarily be deprived of the protection to which they are entitled.

Taking that one thought and comparing the number of accidents that occurred on your property ten years ago with the number that occurred in 1925, you can get one measure of the results of your work. That is the humanitarian side of the accident prevention problem. But there is another side that must be taken into consideration on well managed properties and industries, and that is the amount of money that necessarily must be spent on account of accidents.

When a safety department is able to show a reduction in the number of accidents, it not only preserves happiness to many but it makes a considerable saving in dollars and cents.

A peculiarity of the service given by the safety department is that all members of the company, both employees and employers, profit alike. They all need it and must have it if they are going to continue to be happy and successful.

Safety Work Must Be Done in a Businesslike Way

This department is not set off by itself as in some departments of other organizations. It is a department with which every official and employee should be closely affiliated. The safety director and his assistants only attempt to solicit and direct the support of each and every employee, but the work will not be successful if it is expected to be carried on by the safety department alone.

To conduct safety work successfully and maintain the high standing of your property, it must be done in a business-like way and be made a part of the operation the same as any other department; and it must not be allowed to be set aside in order that some other work of the organization can be taken care of. Every employee must understand that safety duties are as important as any other duties he has to perform.

If you are a successful safety engineer, in close touch with your organization, you are not only able to reduce the numbers of accidents but you are instrumental in bringing the management and employee closer together and so are enabled to establish better industrial relations. You have caused the management to become more interested in the employees and the employees to become more interested in each other. This naturally creates a friendlier attitude among all. Not only does it get the employer and employee closer together, but it develops unselfishness.

It also helps materially in creating a better feeling on the part of the public towards the company. For the public is prone to grasp such

a situation. We have two ways in which we are able to enlighten the public. One is through the employees and the other through the publicity department. All this naturally brings about much better feeling and creates better public relations. When you have reached this point you have accomplished a thing worth while. You have reached a higher efficiency, and this efficiency naturally will show up in the operating expenses of the company.

I have attempted to show that the safety department performs work of the highest class. In addition to the things I have mentioned, it is guarding the company against expenditure of money on which they get no return—that is, the expenditure of money made necessary by preventable accidents. Not only does it assist in reducing such expenditures but it helps materially in getting lower insurance rates.

Round Table Discussion Is Dispensed With

CHAIRMAN EMERSON: This part of the program was to be in the nature of a round table discussion. The two sections just read were to start the discussion. Due to the lateness of the hour I think it is inadvisable to start any sort of a round table discussion. I wish we could limit ourselves to this: that if any gentleman wishes to ask either of the gentlemen any questions with reference to their papers, or can throw any light on the ground which they have covered, we will be very glad to hear from them.

MR. READE (Quebec): I would like to ask Mr. Whitmore whether they ties have tried to pay the claim over there?
submitting these records to the other railroads to see if these same par-have a clearing house for these state claims. Do you have a way of

MR. WHITMORE: We compared notes with Mr. Harmon's company, but we do try to disseminate this information that we have regarding claims.

MR. READE: I think it wouldn't be a bad idea for either the National Safety Council or this Section to have a clearing house and submit all the claims, and then if a repetition came up we could easily isolate those cases.

MR. WHITMORE: I think that has been tried, Mr. Reade, several times. The question has been brought up at several conventions and it has always been found inadvisable to start a thing of that kind.

MR. BOYCE (Pittsburgh): When we get our statistics we don't clamp them up on the wall in the central office. For instance, in our company we get out a list of dangerous points where accidents have occurred and post them on the bulletin board for the benefit of the trainmen, showing them the number of accidents that have occurred within a three or six months period. We are constantly in touch with the inspector of traffic who has to do with all the traffic officers in Pittsburgh, and also the traffic engineer who finds it very helpful to have us turn those accident records over to him, and if we give him the benefit of the information we have he will probably be able to locate a beacon or a safety device that will save us accidents.

CHAIRMAN EMERSON: The following paper has been arranged in place of one upon bus operation which was scheduled for our Wednesday morning session. Mr. N. T. Brown, Vice-President, Philadelphia Rural Transit Company, Philadelphia, has very kindly consented to present his views upon the subject. I take pleasure in introducing Mr. Brown.

SAFE BUS OPERATION

**N. T. Brown, Vice-President, Philadelphia Rural Transit Company,
Philadelphia, Pa.**

Mitten Management has been operating in Philadelphia in coordination with the street car and sub-way-elevated lines of the city, a fleet of motorbuses to the number of about 400, in addition to which we operate an intercity bus service with Philadelphia as the hub, and reaching to New York City on the north, Washington on the south and Atlantic City on the east. All our buses are of the gas-electric type, which was developed by Mitten Management engineers in cooperation with the engineers of the General Electric Company and the Yellow Truck & Coach Manufacturing Company after several years of research. The gas-electric principle thus developed has been generally adopted by manufacturers and operators, and in our opinion is the feature which has made the motorbus entirely applicable to city transportation.

P-R-T motorbuses have had an enviable record of safety, and it is about this particular phase of operation that I wish to speak.

The gas-electric bus is superior, in our opinion, to the mechanical drive from the standpoint of safety. The smoothness of operation during the period of straight-line acceleration produces practically no jar as compared with the uneven advance of the mechanical drive. The significance of this feature is at once apparent when one considers the large number of stops per mile in city transportation service and that passengers are continually walking in the aisles toward vacant seats when the bus is accelerating.

The elimination of gear shifting enables the operator to keep both hands on the wheel and his entire attention on the traffic through which he is driving. The conservation of human energy because of the elimination of approximately 5,000 shift operations per day is helpful in preventing accidents, since the driver is more alert than he would be if he was compelled to shift gears, thereby more slowly reaching the point of physical exhaustion.

The gas-electric bus is provided with three separate and distinct brakes. The foot and hand brakes are common to the ordinary type of motor vehicle, and in addition there is a regenerative electric brake. In making a stop, the operator uses both the foot and hand brake at the same instant, doubling the safety factor. The electric brake is used in emergency, being especially valuable in controlling the bus on a down grade, its effectiveness being in direct ratio with the vehicular speed. That is, when the bus is moving slowly, the braking power is slight, and increases as the speed of the bus increases.

To protect against rear-end collisions because of frequent stopping, each bus is equipped with a rear stop-light. A tell-tale light is mounted on the dash in a position to be readily observed by the driver, so that he may tell at a glance whether or not the stop light is in operation, and govern himself accordingly.

The constant bane of every motorist is the brilliant headlight which blinds him at every hundred yards along our roads and our city streets, and many accidents are caused because of carelessness in the focusing of these lights. The headlights of P-R-T buses are kept properly focused in accordance with the state law, and recently we have installed safety lights which can be played on the edge of the road, allowing the upper headlights to be turned off entirely, and eliminating even the slightest glare in the eyes of the approaching driver, at the same time lighting up the side of the road so that there is no danger of ditching the bus.

We have installed in our central garage a brake testing machine, by means of which brakes are scientifically and equally adjusted, so that the pressure is the same on each wheel when the brakes are applied. The machine indicates the weight of the pull on each wheel, and instantly records any inequality of braking power, as well as whether power is being lost due to dragging brakes, when the brakes are in the off position. High points on the brake lining and drums, and similar brake failures are also indicated. Equal distribution of braking force on both rear wheels has eliminated the hazard of skidding on wet pavements.

Brakes Are Kept at Maximum Efficiency

It is thus possible for us, by regular test of every vehicle, to assure ourselves that brakes are at their maximum efficiency at all times. Since good brakes are a vital factor in the prevention of motorbus accidents, their mechanical perfection at all times is vital to successful operation.

Adequate inspection of a large fleet of motorbuses is a requisite, not only in order to make every vehicle safe at all times, but in order that maintenance may be kept at a high standard of efficiency. Inspection of buses is regular and frequent, and every mechanical detail is tested by expert mechanics.

Nor is the importance of trained personnel lost sight of. In fact, we recognize that the human factor is probably the greatest of all in the prevention of motorbus accidents. Drivers are employed only after passing rigid medical examinations, and after meeting equally rigid standards as to weight, height and age. These men are thoroughly trained in motorbus operation before they are allowed to operate in regular service. Because of this care in the selection and training of men, we have succeeded in building up a force within the past two years, which in appearance, in courtesy, in skill, in operation and in general efficiency has won the plaudits of the public of Philadelphia, and numerous comments from visitors to the Sesquicentennial this summer bear testimony to the esteem in which this operating organization is held because of the high standard of its personnel.

The bus is no longer an experiment. It has come to stay. It has a definite place in the coordinated transportation system of the great city. It finds a field of increasing usefulness in intercity and interurban service. It is encouraging to see that street railway and steam railroad managements are coming to a realization of the fallacy of attempting to thwart the progress of a facility which has so thoroughly met the popular taste by contributing a great share to the speed, comfort and safety of modern passenger transport.

In addition to these factors of safety as outlined, there is maintained in the central office a system map, the duty of one man being to place a pin on this map showing the location of each accident which may have happened. These locations are then analyzed, with the idea of determining whether or not any of the factors contributing to the accident hazard can be removed; for instance, possibly the moving of the traffic officer from one side of the street to the other, or the changing of traffic regulations at this location, or the removing of a billboard or shrubbery which may obstruct the view of the driver approaching an intersection. We have found that this has materially helped to reduce the number of accidents.

The News Letter Should Certainly Be Continued

CHAIRMAN EMERSON: Mr. Eastham spoke yesterday about the difficulty he had in getting responses to his news letters. I think that the news letter is a very good thing if it is followed up and if members respond properly to the information that is asked. Before we adjourn today, I would like to get an expression from those here as to whether they think the news letter should be continued. You are all familiar with it and all those who think it should be continued please raise their hands.

(About 15 raised their hands.)

These cards that have been filled out asking questions which we expected to discuss at the round table today—I know these gentlemen are anxious to have those questions answered. It is going to be impossible to do so this morning, so I am going to turn them over to Mr. Connors and if he sees fit he will use them in his news letters.

Gentlemen, we are about to bring this meeting to a close. Before we do so, I want to call on Mr. Reid who has an announcement to make.

MR. REID: Just a word or two as the chairman of the Program Committee. The program which we have had for the last three days would be absolutely impossible without the cooperation of the members of this Section. The papers which have been read and the speeches which have been made speak for themselves. I just want to express the thanks of the committee for the splendid way in which these speakers have responded. We first as a committee got together and decided upon the subjects which we thought would be helpful to the Electric Railway Section. We then decided upon the speakers that we thought could present the various subjects in a way that would bring some messages to this

Section, that would be helpful and worth while; and I am happy to say that not a single individual refused to write a paper or make a talk before this Section. I think that speaks very well for the interest of the men in the general accident prevention work and of the work of this Section in particular.

I didn't want to let this meeting close without this word of appreciation to those who have so splendidly responded to the preparation of these papers and these talks.

W. J. ROUNTREE (Ga. Railway & Power Co., Atlanta, Ga.): I have not been fortunate enough heretofore to attend a meeting of the Safety Congress so I have nothing to use as a basis of comparison, but in these three days that I have attended these meetings I, for one, feel that the Section owes Mr. Reid and his committee, as well as the speakers, thanks for the service they have rendered us, and I would like to express publicly that appreciation.

A Separate Pamphlet for the Section Minutes

CHAIRMAN EMERSON: Will you put that in the form of a motion?

MR. ROUNTREE: I make a motion that this Section extend to Mr. Reid and his committee a vote of thanks for the splendid work they have done during the past year.

(The motion was seconded.)

CHAIRMAN EMERSON: It is moved and seconded that the thanks of this Section be extended to Mr. Reid and his committee for the very admirable work they have done during the past year.

(The motion was carried and a rising vote of thanks was given Mr. Reid.)

MR. REID: Mr. Chairman, I would like to make a suggestion here and see what the reaction is to it. It will be quite a while before the National Safety Council publishes the proceedings. It is a tremendous job. This is one small section among the whole meeting in Detroit, and I am wondering if it wouldn't be helpful to the members of this Section if we were to ask the National Safety Council staff to print the proceedings of this Section and send it out to the members. I make a motion that the Council be requested to do that and not wait for the big, bound volume of the proceedings that will come out several months hence. I think it would be well to have this right away.

DR. SEGARD (Third Avenue Railways): I think there are 47 Sections in the National Safety Council and if each of these Sections made the same proposal it would simply mean duplicating the work of printing that tremendous volume which we each get free each year.

J. M. LOFTIS (Pittsburgh Railways Co.): I believe that the best results are to be obtained from getting this information to the member companies just as quickly as possible. While I do feel and agree with the brother here that it is a little bit selfish on the part of the members of this Section to ask for special consideration, yet I am thoroughly con-

vinced that the best results will be obtained if we get the information right away.

MR. BOYCE: It seems to me if we took the matter up with the reporting company who reports the convention perhaps we would get a typewritten copy which could in some manner be duplicated and sent to the members rather than impose the burden on the National Safety Council. I would like to hear from some of the members regarding this suggestion.

MR. REID: I would like to say just a word with reference to that. All of this material is set up in type for printing of the big volume that will come out some time and it would be a very small matter, if I understand it correctly, to print the proceedings of this particular Section and send it out in pamphlet form. It will not involve any very great amount of expense or trouble because the type is already set up, or will be, and it has to be printed anyhow. My idea was to get this stuff immediately rather than to wait for the big book that comes out.

MR. READE (Quebec): You can't expect something for nothing. We ought to pay a dollar or two dollars to get this in advance.

W. F. HANN (United Railways, Baltimore): I have attended all these sessions and I know what has been going on here, but there are several other Sections that were held at the same time that I would have liked to attend, and I would like to get a typewritten copy of those I was unable to attend.

CHAIRMAN EMERSON: That is beside the question now.

DR. SEGARD: I have never failed to get my volume of the proceedings of the National Safety Council in due time to use it in addition to my own personal notes.

CHAIRMAN EMERSON: Has the motion been seconded?

(The motion was seconded, put to a vote and carried.)

Many Platform Men Attended the Section Meetings

CHAIRMAN EMERSON: Gentlemen, just one word in closing. I want to thank you gentlemen for the honor that you conferred upon me yesterday. One year ago at this time the National Safety Congress met in Cleveland and that was the first Congress that I had ever attended. At that meeting the general manager of the Cleveland Railway Company gave a complimentary luncheon to the delegates and about 30 or 35 attended. Yesterday there were something over 80 tickets sold at one dollar and a quarter each. The same proportions, if not greater, has worked out in the attendance. The operating man can't help but feel the increasing influence of this safety movement. It is very evident that it furnishes a ground for the getting together of the various departments in the railways and also furnishes an opportunity to coordinate so that the best results may be obtained.

One of the things that gratified me particularly these last three days was to see the large number of platform men that have attended. I think this is a splendid showing. I think it is a splendid idea. I have been an

operating man all my life and I can look at things pertaining to a railway operation better probably from their standpoint than I can from any other. These men are the men that are going to get results in the end. They are the boys that are coming in contact with the public constantly. It is through them that we are going to get anywhere, if we do. I only hope in future meetings that the platform men will have a larger representation than they have had this time. I think it is a splendid start.

I wish to close in thanking you for all your kindness in attending these meetings. I shall be heartened by the interest you seem to have shown and in this coming year I pledge you my very best efforts to try and carry on the work which has been carried on so well up to the present time.

ADJOURNMENT

Employees' Benefit Associations Section

New Officers of the Section

CHAIRMAN: SIDNEY W. ASHE

General Electric Company, Pittsfield, Mass.

VICE-CHAIRMAN: W. FRANK PERSONS

The Milwaukee Electric Railway & Light Company, Milwaukee, Wis.

SECRETARY: JACK DEMPSTER

Canada Cement Co., Port Colborn, Ontario, Canada.

October 28, 1926

W. J. MacPHERSON, Chairman,

Manager of Industrial Relations, Public Service Company of Northern Illinois, Chicago, Ill.

THE first session of the Employees' Benefit Associations Section, National Safety Council, was called to order at 9:50 o'clock in the Small Banquet Room, Ball Room Floor, Statler Hotel, Detroit, Mich., Chairman W. J. MacPherson presiding.

CHAIRMAN MACPHERSON: The first order of business is the appointment of the Nominating Committee. The Executive Committee has informed me, however, that they have tentative plans for changing the scope of activities of this committee; we will therefore pass up the appointment of the Nominating Committee at this time.

We will take up the first paper, which is by Mr. Frank L. Rector, M. D., editor, *The Nation's Health*, Chicago, Ill.

HOW FAR SHOULD INDUSTRY GO IN A HEALTH PROGRAM?

F. L. Rector, M.D., Editor, The Nation's Health, Chicago, Ill.

How far should industry go in a health program? The answer to this question can be made short and to the point. We may say "the limit;" but as the limit varies in different localities and industries our terse definition needs some elaboration.

One of the qualifying elements to be considered in this question is the relation of the industry to hospital and other facilities. Obviously

in an organization such as a mining camp the management must provide a complete medical service, not only for employees but their families and dependents as well. An industry located near a community having adequate medical and hospital facilities might feel called upon to provide little except emergency treatment for its accidents arising directly out of the employment.

But further than this we may well consider just what should be expected from a preventive medical program among groups of industrial workers. Probably the humanitarian interest taken by managements in their workers is fostered largely by rigid legal requirements on the one hand and the desire to obtain increased production through increased efficiency on the other. This increased efficiency may be obtained in several ways, among which are lessened labor turnover, decreased absence due to ill health and accidents and a greater contentment of workers with their working and supervisory conditions.

Industry Has Obligations in Reference to Employee Health

By a strict legal interpretation of medical service we might say that industry as such is not responsible for any conditions affecting the employee's health or welfare except those associated with his employment; but the industry which places such a narrow interpretation upon its obligations comes far short not only of fulfilling its obligations to the workers but of getting from them in actual production the returns which they would have a right to expect if a more liberal policy of personal relationships prevailed.

A preventive health program comprehends the prevention of more serious stages of disabilities already contracted as well as the onset of any disability. First aid for illness is just as necessary as it is for accident. Headache, stomach aches, backaches, and other aches may be more disabling than some injuries, and may be the forerunners of more serious disabilities that threaten prolonged absence from work. While their immediate treatment may be for relief, the real object is prevention and as such has a proper place in a preventive health program in industry.

Further efforts than simple relief of the immediate disability should be made with these cases to determine the cause. Diagnostic means should be resorted to for the answer. Such types of illness are not regarded by the sufferer as of sufficient importance to consult a physician and if industry does not check them up they will go without consideration until another and perhaps more serious attack drives them to see a physician. Then it may be too late to remove the cause and the worker will be doomed to a chronic condition requiring extended and perhaps life long treatment.

Men who have had wide experience in this work are pretty well convinced that industry profits in all ways by furnishing adequate facilities for determining the physical condition of workers at any and all times. It is felt that industry should not be called upon to provide treatment for those conditions which have no relation to the employment but they

should provide such diagnostic facilities for the careful examination of employees who are below par physically as will enable them to know what is their actual physical condition. Such workers can then carry this information to the physician of their choice to guide him in the treatment of their cases.

Such a worker will not go to a physician of his own accord. He does not consider his ailment sufficiently serious to justify the expense. And the medical man would not be able to give a thorough examination and diagnosis, either out of regard for the expense to the patient or because of the lack of facilities for making the necessary tests. In such a case some superficial examination would be made and the patient dismissed with a prescription and some advice. In any case, no lasting good would have been accomplished.

Two aids to diagnosis are lacking in the average physician's office, the X-ray and laboratory facilities. Both are rather expensive to procure and both need special training to use, something which the average physician does not possess, especially if he has been in practice for several years. Moreover, his practice might not warrant the purchase of such equipment.

On the other hand industry can well afford to provide these two facilities as they will be in almost constant use. With the many cases to be looked over industry can afford to engage some physician skilled in the operation of such equipment to carry on this work, the expense again being unnoticeable.

Possibilities of the Health Campaign Very Extensive

If industry would make provision for such diagnosis, and then insist upon the periodic examination of workers and upon the proper attention by workers to any defective conditions which might be discovered, health improvement of such a group would become so marked as to return to the industry many times any expense which the provision of this equipment may have made necessary.

Instead of interfering with the practice of the local physicians the work as just outlined would be a great help to them. Diagnostic aids would be offered them in their own community that previously could be had only in some distant city. Defects and disabilities hitherto unknown or unsuspected would be brought to the workers' attention and he would be urged to have them corrected before they become incapacitating.

Industry should not undertake treatment of these conditions, but should urge and assist workers to have the work done. Tactful urging of the worker by the industrial physician and tactful cooperation with the family physician would bring about satisfactory results in the majority of cases.

Opposition to such work on the part of local practitioners is due to one of two causes; either the medical man in industry is too aggressive and undiplomatic in his approach to the problem, or the local physicians are satisfied in their smug complacency and resent the efforts of industry

or any other influence to wake them up to a true realization of their duty and opportunity.

We hear much these days of the increase of chronic diseases and the diseases of middle and later life, such as cancer, heart disease, apoplexy, and various forms of kidney disorders. One explanation of this increase is that in recent years much of the health work has been concentrated upon the infant and school child so that the death rate in this group has been markedly lowered. The child has been carried safely over the critical periods of early life, only to fall prey to the more insidious ailments in later years. The death rate from tuberculosis, a disease of adolescence and early adult life has also been cut in half. Typhoid fever, an early adult disease, has been practically wiped out. Diphtheria, scarlet fever and smallpox are on the way to extinction. The chronic diseases just mentioned usually have their beginning in early life although their onset is so insidious and so quiet that only a careful examination of the individual will detect them in their early stage. For this reason a periodic examination of workers should go carefully into any sign of abnormality which may appear and should be carried far enough to satisfy both the physician and the worker that the root of the trouble has been found.

Questions Regarding the Periodic Health Examination

Who should undergo this periodic examination, and how should he be selected? Every person actively connected with the organization from the president down should be included. Frequently the higher executives are most in need of such a physical inventory. Obviously this work takes time, and at first it might be well to take the oldest employees, or those exposed to possible poisons or other hazards, if there are such; another group will be found in those returning to work after a protracted absence following illness or accident. Still others will be found by the foremen who are falling down on their work or who give other evidence of declining vigor. Yet another group will voluntarily ask for such examinations, once they are available. A little quiet propaganda as to the value of these procedures in discovering to a few popular workers that they needed medical attention will do much to remove prejudices against it.

Thus far the financial and economic aspects of such a program have not been stressed although they are of as much, if not more, importance to the workman and his family as they are to industrial management. I would like to suggest to this group, interested as the most of you are in employees' benefit associations, a thought whereby your organization can render to your members a service of far greater value than that which now serves as the major reason for your existence. Benefit associations are for the benefit of their members. This idea of benefit has in the past been translated into personal financial relief in case of incapacity for work due to any one of several possible causes. I have not the latest figures before me but my most recent information was to the effect that the minority of such associations consider the physical

conditions of the applicant when he seeks admission to its ranks. Unless he is obviously disabled or diseased, and few such are found in industry, he is admitted without question.

To my mind, mutual benefit associations offer the finest possible opportunity for doing health work and a program something like the following could be undertaken with profit.

1. Require all applicants for membership to pass a careful physical examination at the hands of a physician designated by the association, who is familiar with the work the applicant does. The plant physician is admirably adapted to do this but in case he is not available a well qualified man should be placed in charge of this work. Those unable to qualify as first class risks may be given a deferred classification until their deficiencies can be remedied.

2. Provide facilities if they are not already available in the industry for determining what the worker needs to remove his deficiencies. If necessary, assist the workman with financial aid to have this work done. It will be much cheaper in the long run to spend a portion of the association's funds for remedial work with the provision that the amount so expended be returned by some regularly stipulated time, than to be compelled to pay for a varying length of time the benefit provided by the association's rules and regulations. Mutual benefit associations, if they so desire, could provide a complete remedial as well as diagnostic service for their members, together with nursing care. This complete service is seldom needed and is not to be recommended except in most unusual cases.

Inducements to Have Corrective Work Done

A higher rating with increased benefits could be made an incentive to have the needed corrective work done. If the organization so desired it could provide its own medical staff and nursing service to carry on this work. In doing this, however, certain matters should not be lost sight of and certain practices which have existed from time to time should not be indulged in. One of these is that of compelling a member to submit to treatment by the association physician, assuming that for some reason he did not wish that particular physician to do the work. The psychological effect of such an arrangement would do much more harm than good. To minimize the chances that such objections might arise the association should always have as its medical advisor a physician with qualifications second to none in the community. By his prestige his services will seldom be refused. Neither the physician nor the nurse should make investigations as to the cause of absences from work. A tactful layman is much better suited to make primary investigations and on the basis of his report the physician or nurse can take any action that is indicated. In that way their services are confined to those of helpfulness and they would be welcomed in their contacts with the workers and their families rather than shunned as so often happens when they are doing ordinary police duty, and that is what first investigations are. I know of nothing that will so quickly demoralize the

average industrial medical organization, both with the workers and with the medical personnel itself, as to require investigation work from the staff.

After nurses have gained entré to the home they will have many opportunities to drop a hint to wives and children regarding right habits of health. A suggestion upon some small but important domestic problems that will be helpful in the conduct of that home will always be appreciated. There are countless ways in which a nurse can render assistance. But she must be tactful at all times and never assume a superior attitude.

Keep each member's records securely away from public inspection. The physician alone should have full access to them. Association officials may be given sufficient information to serve their needs but confidence and cooperation can only be obtained by respecting confidences of others.

Let me recapitulate by saying that industry should go as far in a health program for workers as it can without pauperizing the employee or the private physician. Industry can do collectively for large numbers what few, if any, private practitioners can do in the way of adequate and accurate diagnosis. Such types of diagnosis as X-ray examinations and laboratory tests requiring special equipment and skill come well within the purview of industry to furnish.

The physician should emphasize periodic health examinations. He should give relief to temporary disabilities so that the workers can remain on the job. He should perform the indicated examinations and tests to determine the physical fitness of the worker, provided, of course, that very unusual tests are not needed. Whether or not he sees patients in their homes will depend on circumstances. In general, he should delegate home visiting to the family physician, although he should be in sufficiently close touch with the case to know if proper treatment is being given. He should seize every opportunity to impart some health information without being offensive or a bore.

The Nurse Should Assist in Health Education

The nurse should assist in health education while in contact with workers in the plant and when she visits in the homes it should be only on invitation from or consent of the worker or his family. Here her greatest opportunity will be found in teaching health. Needless to say, both the physician and nurse should be examples of healthy living. A lazy, indifferent and careless person, be he ever so bright mentally, will not be a good example for workers to copy. Physicians and nurses should radiate health as they will teach far more by example than by precept.

Neither physicians nor nurses should be used to make primary investigations of absence, due possibly to injury or accident. A tactful layman should be engaged to do this work and where a health program is tied up with a mutual benefit association the employment of such an investigator can well be a part of the association's program. This will leave the medical and nursing staff to carry on their professional work,

and will forestall any unpleasant criticisms of their duties by those they are serving.

A successful health program is a cooperative affair. Unless the sympathetic understanding of the workers is obtained and the active cooperation of the management is secured, the physician and nurse may blow their trumpets until the walls tumble down without making the slightest impression upon the situation.

Likewise where a mutual understanding is reached great good can be accomplished.

Nothing has been said about such health activities as dental work, eye examinations and furnishing glasses, day nurseries, children's clinics, and related problems. Most of these are of general community interest and should be undertaken by the community. If the industry wants to have a part in this work it can well do so by a contribution to the community chest or other fund which supports the work. Circumstances may make it advisable to undertake certain of these problems within the industry. When such a condition exists the general principles discussed earlier in this paper should prevail.

So we see that the limit which we placed upon this work at the beginning of this discussion is not a rigid one, but flexible and adaptable to varying groups. The greatest good to the greatest number should be the goal toward which all such work is directed.

Discussion Following Dr. Rector's Paper

CHAIRMAN MACPHERSON: We all appreciate Dr. Rector's comprehensive paper. I think that the wide scope of the paper makes the subject almost limitless, so there should be a lot of discussion. I am sure Dr. Rector will be glad to answer questions. The paper is now open for discussion.

H. C. LOGAN (Union Carbide Co., Niagara Falls, N. Y.): We have three doctors in our plant. One full time and the others part time. We have two nurses and two first aid men. We started primarily to take care of our employees but the scope is widening out. I would like to ask the doctor how far a person should go in dispensing medicine? In our winter and fall seasons when there are so many colds, our employees all want to take cough medicine and aspirin home with them. The amount of material going out of the plant seems to be unlimited.

CHAIRMAN MACPHERSON: I am going to ask Dr. Rector to make notes of the questions. There will probably be several of them and he could answer them all at one time.

HERMAN W. ALLEN (M. Wile & Co., Buffalo, N. Y.): We have a plant with about 1,200 employees and it struck me that Dr. Rector's paper referred mostly to plants with 20,000 or 25,000 employees. I don't think our firm would see very easily where they could absorb the expense of a staff physician and nurses. In fact, I think they would notice it so much that it would take a pretty good persuader to do it. Our benefit association keeps about \$1,500 ahead. We don't want to have any more than that because it amply takes care of our needs, and we like to have the

members feel that they are paying their way. The firm donates half the material for the association, and for any unusual occurrence there is always a check forthcoming to see that the fund is kept at this point. I would like to find some way out of it for us, because the doctor's recommendations are very fine.

L. J. PARRISH (A. O. Smith Corp., Milwaukee, Wis.): Referring to the gentleman's remarks on Dr. Rector's paper: he stated that he did not think the same principles could apply to a plant with 1,100 or 1,200 employees. Perhaps that objection could be met by several plants in the same locality going together. In our plant we have about 5,000 employees and we maintain quite a comprehensive preventive medicine clinic. We have a full time X-ray man. We have a full time doctor of internal medicine. We have a full time oral surgeon, dental hygienist and a bacteriologist. We have three technicians, stenographers and nurses. We have been in operation about two years and we are prepared to show that it pays.

Problem of the Company With Many Thousand Employees

HOMER W. BANG (Illinois Bell Telephone Co., Chicago, Ill.): I was not in to hear the first part of Dr. Rector's paper. We do not have periodic physical examinations, but we are very anxious to follow out a plan of that kind if it is feasible. What we are up against is this: we have about 25,000 to 28,000 employees in Chicago, and when you figure a year with 300 working days it will average about 100 physical examinations per day. We appreciate that, would take quite a medical staff, but we want to give them the kind of an examination they ought to have.

We now have health classes throughout the territory in Illinois for women employees. We experimented with that last fall and we are starting out full blast this year and that will bring about the desired periodical physical examination.

Now, as I say, we can not see our way clear to have a staff sufficient to give 100 physical examinations per day. We have about 150 at the present time just on health matters.

I would like to ask the doctor if it would not be a good proposition to offer this service to the employees for a certain amount? Some employees would not have to be examined over once every 10 years and that would make it possible to give these periodical examinations without making our staff almost a good sized clinic.

S. W. ASHE (General Electric Co., Pittsfield, Mass.): Judging by our experience, in order that a physical examination shall be of real value to the man, it has to be pretty thorough, and that means that it is a pretty expensive thing. If you have a head man of the department, for instance, a key man, it is going to cost you \$10 a man to get the kind of examination you want, and if you have 6,000 or 6,500 employees the thing becomes prohibitive; therefore while the periodical physical examination is a fine thing, I think that you have either got to be satisfied with a very nominal examination or you have to cast around for some other way of getting the examinations. One way is with your Benefit Association and

you can work to a certain extent with your local Board of Health, and you can work with the local physicians. Most of them will cooperate with you. You can get from the local Board of Health a list of all contagious diseases.

Now we are very much interested in that kind of work. We keep in touch with the local physician and the local Board of Health. If you see a person working whose record with the Board of Health indicates that he has a disease that needs attention, we see that he is relieved from his regular work and given proper treatment, and also the proper follow-up treatment in the home. In that way we can do it in a pretty thorough way, but if you try to detect all these things through the physical examinations, the cost will be prohibitive.

CHAIRMAN MACPHERSON: There is a challenge to the statement that the periodic examination pays and perhaps we will have some discussion as to how to measure whether or not it does pay.

J. W. RIDDLE (The Youngstown Sheet & Tube Co., Youngstown, Ohio): May I ask a question here? It seems that the discussion is all on the subject of expense. Does that mean the expense to the company or to the Employees' Benefit Association?

CHAIRMAN MACPHERSON: I would say that it depends upon the particular organization, because in some cases it might be a direct cost to the company and in others it might be a direct cost to the Benefit Association; or in some cases the cost might be to both when both contribute to the expense of paying the employees for lost time.

MR. RIDDLE: I brought up that question because it is apparent in our company, from the employees' standpoint, that our Association can not afford to make any sort of an examination outside of what the company might have to make when the man was employed.

The Confidential Relations of the Physician

DR. G. H. WOOD (Frederick Stearns & Co., Detroit, Mich.): Dr. Rector's paper is full of meat and good suggestions and is an excellent guide to certain industries. I would like to go over the whole paper, though that is impossible, but there are one or two points that I would like to bring out. The first is the confidential relations of the physician and his assistant. That is the thing which is violated a great deal in industries and Dr. Rector brought that out. Of course, slips occurs, but some industries want to compel the medical department to act as detectives and that is absolutely to be avoided.

In the course of 14 years' experience in medical and industrial medical work this question has come up to me rather forcibly a number of times. There were times when apparently I was in danger of losing my position if I refused to act as a doctor and then turn around and act as a detective. In other words, I do not go to the employee and get his confidence and then go and tell the employer the confidential things I have learned.

I protect the interest of the company by advising them as to the results to be accomplished if the man is unsafe in the industry. Or better yet, if the employee is in a condition where he should not work

and will not advise the company, I advise him to resign and do not allow him to be discharged. That is just an illustration to bring out what I mean.

In a few cases I have been asked definitely to go out and investigate a man who was believed to be faking or to have been drunk or something of that kind. Where I have done that I have not gone as a physician, I have gone out to his house and I haven't said, I am a company doctor; I have said that the management wants to find out the cause of your accident. I simply went there as a man so that there is no deception.

The point I want to bring out is this, the management should respect the physician's confidential relation with his patients and should not expect him, or a nurse working under his direction, to divulge those confidences. The doctor can protect the company without it. There is one thing in all these years that I have been unable to solve and that is the relation of the industrial physician to the family physician. Dr. Rector has brought up some points here on which I would like to have him give us a little clearer idea, if he can, where to draw the line.

Certain Ideals of Conduct for Every Physician

All physicians have certain ideals and in order to keep successful we must keep those ideals in mind. One of the things which the American Medical Association has written is this, "That no physician shall accept practice under such conditions that he will not be able to give the patient the benefit of his best efforts," and it is the one thing which we all try to follow out.

When a physician accepts a case he is responsible for the whole case until he is through with it, or until he is discharged by the patient. Under these conditions, how far can the plant physician go in treating a patient who is known to be a patient of the family physician? How far should a plant physician go in starting a case and then turning it over to the family physician? When should he turn it over? Dr. Rector says, if I understand him correctly, that when a plant physician undertakes a case he is to do it thoroughly, and later on he says that home patients should be delegated to the family physician.

Now I don't quite get the point as to whether the case is to be turned over to the family physician or whether the family physician is to be asked to work as assistant to the plant physician or what? I would like to see that cleared up.

One disadvantage of the plant physician starting a case and then turning it over to the family physician, is that the family physician does not know the beginning of the case, except maybe from the report.

The question of expense has been brought up here and that, to my mind is the one thing that makes it almost impossible for the plant physician to continue home treatment, because almost everybody tries to avoid the expense of the treatment. It is not merely because they do not like to spend money, it is because they do not have it to spend. The cost of living these days is so high that it is a serious proposition. That is a thing we need to solve and I hope that there are more speak-

ers here who can give us some light on the subject of how the question of expense can be met by either the Employee's Benefit Association or by the employer, or some other way.

H. JOHNSON (The Hoover Co., North Canton, Ohio): I think our subject is, "How far should a company go in a health promotion program," and I want to say that the Hoover Co., North Canton, Ohio, goes the limit. We have had a hospital with two nurses for two years. We have had a part time doctor for almost two years, and every one in our employ must take a physical examination and those physical examinations are charged to the company by the doctor. In fact, the doctor only charges \$2 for those physical examinations and he is assisted by nurses.

To our old employees who were with the company before the physical examinations were started, the physical examination was of course to be a voluntary proposition. I am sorry to say that only about two per cent of them have taken advantage of it. We are starting now to work out something that will give those fellows the incentive to take those physical examinations. We do not want to be making sport of it. Of course when there is sickness and those employees come to the hospital, that is the cue for the doctor to start the physical examination. We have put several physical examinations over in this way.

Our employees organized five years ago an Employees' Benefit Association of their own. They have about \$1,000 in the reserve fund now and the insurance is working out wonderfully without any of the company's help financially.

Advice to Go to the Family Physician

We find that most of our other employees have sickness. They are not injured, while the factory employees are so busy working that they get away from the psychology of having something wrong with them and they work it off, but we don't intend to have them take yearly examinations. We only give those to the employees who come in, and if the doctor finds anything wrong with them he will take another examination in six months of that particular thing that is wrong. He will advise all employees to go to their family physician. We don't ever want our doctor to get to the place where he is treating our own people. We want him to understand that we are throwing him business. We are paying the doctor for part time service and that is all we are asking him to give our employees.

In follow-up systems of that kind, our nurse will call up the family physician and get the data and reports on our employees who are sick. Every morning the foreman reports to the hospital all those who are absent on account of sickness. Where we have such a report, the nurse will automatically try to get in touch with them. Sometimes we find that the person who is sick has a relative working in the plant and the nurse follows up that medium to find out why he is absent. We are going to start the first of the year on a follow-up of the employees in the factory. We are only doing it now in the office, although the nurse secures the report of all factory employees reporting absent. If that

employee is absent three days the nurse will visit his home and find out what the trouble is.

Our Employees' Benefit Association will cover all that possibly in the next two months. They are printing a little returnable postal card and giving them to every employee who belongs to the insurance, and they will mail them in to the secretary when they are ill or are going to be ill for one or two days. The secretary in turn notifies the physical department. Ninety-nine per cent of the factory employees and 48 per cent of the office employees belong to the Employees' Relief Association.

G. M. KELLER (Colorado Fuel & Iron Co., Pueblo, Colorado): Our Health Department dates back about 40 years. We are the pioneer in industrial medicine, but we still have many of the same problems that have been discussed here. The first, I think, is a very delicate question. Just what is the relation of the medical department to the police duties of the employment department? I agree that the medical department must maintain the confidence of the employees or it loses its entire value, but it also has certain very definite responsibilities in maintaining the management standards of the physical welfare of the employees.

Our medical department was an established requirement for the new employees. With our medical department, no one would apply for employment with a venereal disease. We all probably agree that it is undesirable to have anyone with a venereal disease in your employ. The medical department would bar them upon the first examination.

Employees Invited to Go to the Hospital Freely

We want every man who has any disability to go to the hospital freely, and they do, but when a man goes to the hospital, say after some period of employment, for a broken leg or any injury, and while he is at the hospital or dispensary the doctor finds some condition existing as one of the diseases that would bar a man from new employment, what then is the hospital's responsibility? The hospital has set up the standard for new employees and here is a man discovered with a disease, which, if he was a new man, would make him ineligible. What is the doctor's responsibility?

I would like very much to hear the principal speaker's opinion on it, and perhaps some of the other people might express their point of view.

The other thing that was brought up is the matter of expense and I have a notion that possibly the Benefit Association may be a part answer to the problem of company expense. Our plan calls for a contribution of \$1.50 per month from every employee to the medical fund. This entitles a man to medical service for himself and medical service for his family at a reduced rate, but that doesn't cover the cost of our hospital and medical staff. There has been some talk of how it could be extended to give free service to the employee's family because, as has been said today, the question of doctor bills is a very serious proposition to the employee.

We are all getting the insurance habit and the mutual benefit habit and it may be the answer to our problems. We want the benefit fund to be such that it will entitle both the man and family to hospital facilities and medical attention. I know of one such association with the Standard Oil Company of Louisiana, at Baton Rouge, and I wonder if there is anybody here that can tell me just how that association operates?

MR. ASHE: I should like to reply to one question from the management's standpoint. Most companies say that the General Electric Company has set up certain standards for physical examinations on which they will determine whether they are going to hire the employee or not. If a venereal disease, or something of that sort, is found, for the protection of the other employees we will not hire that person.

Standards May Be as High or as Low as Desired

You can set your standards just as high or as low as you want in regard to taking the employee into your organization, but once you take the person into your organization he is a part of your big family, and if there is anything possible that the company or management can do to help him, it seems to me that in justice to the employee it should be done. Now that means when you have a Mutual Benefit Association functioning by the employees. Incidentally, we have a very successful one which we have run for about 15 years and it has cash assets of about \$20,000.

The Mutual Benefit Association has never said, "Well, here is an employee who does not look very well. We should not take that person into the association." If you will bring those things up and let the employees discuss them, you will find that they want everybody in, and the person who is not very well and the person who is likely to need help, they are the kind that they want in the association. You don't want to set standards that are going to keep this person and that person out because they are likely to be a bad risk. If you do that you are getting away from the fundamental idea of the Mutual Benefit Association. If you set certain fundamental principles of that sort back of your organization, all these other little things that come along and cause injustice will be taken care of automatically.

We do one little thing that might help you. We have the regular scheme of paying sickness and death benefits, but in addition to that, over a period of years, we have built up a separate fund, not from the weekly contributions to the association, but from profits of little carnivals and such things. We just let this fund keep on growing and only spend the interest on it each year. At the present time this fund is pretty close to \$10,000. The interest on it runs in the neighborhood of \$400 each year. If we have a case of a man who needs special hospital care or requires an X-ray examination, we have this \$400 each year for just such cases.

G. W. WILLOUGHBY (Michigan Bell Telephone Co., Detroit, Michigan): I am here not as an experienced man, but as a student to learn what

I may from your meetings. It seems to me that while all the points that have been brought up are very interesting, they do not all bear upon the subject as outlined in the program. Unless the time is limited to the discussion of that particular subject, we are not going to get the benefit out of the meetings that we anticipated.

Dr. G. H. Wood (Frederick Stearns & Company, Detroit, Michigan): I have been with my firm for eight or nine years. I have one of the most pleasant connections that could be asked for. My firm has been very liberal to their employees for 30 years, and they have done a great many things not generally done. Years before a compensation law was thought of they gave their injured men full time pay while they were off. That was 30 or 35 years ago, I believe, and they have done many things in a sort of personal way. They have not had an elaborate organization, but, of course, we are talking about organization and what has been done in various ways. When I went with this company eight or nine years ago the employment department wanted me to examine new employees and write out a report for them of what I found. I said to the management right away, "What I find is the basis for my conclusions and it seems to me that what you want is my conclusion, and not something about this man that can be talked about." The management agreed with me.

Men With Contagious Diseases Are Rejected

The management has certain standards that I am supposed to follow. When a man applies for employment, he comes to my office to be examined. I reject anyone who has a contagious condition that would be dangerous to the other employees, and write across his application "Not acceptable." If he is acceptable I write across his application "May be accepted." That is all the employment man knows about the details of the man's condition.

That, I think, will explain how we protect the company's interest and at the same time protect the confidence of the employee or the applicant.

CHAIRMAN MACPHERSON: I find that we are forcing Dr. Rector to write another paper, so I am going to ask him to answer some of the questions we have had thus far.

I want to comment on just two matters. The first is the question of police duty. The question was put up to the Employees' Committee, who have quite an interest in the Employees' Benefit Association, and their experience was that most nurses soon became spotters. We finally decided that if the figures indicated that we needed a spotter, we would get one for such work and not use a nurse. In that way we would not have to try to cover anything up. In fact, the Employees' Benefit Association was a little anxious to try out a spotter for a while. An analysis of cases showed, however, that checking of this kind was unnecessary.

The other thing is the cost of periodic examinations. Periodic examinations increase the lost time on account of illness, and the cost is very

great. The cost may be overcome by getting the people cured and back to work as more efficient employees. Without very elaborate statistics our records show that the periodic examinations have increased the days lost. It seems that "Go home and go to bed for a few days" is still one of our most popular medicines.

DR. RECTOR: The first question is about the dispensing of medicine. That has always been sort of a bugaboo in industries. As far as I know the lid should be clamped on very tight on that proposition. If a person comes in with a cold or headache and is going to stick on the job, you might give him a cathartic or give him a rhinitis tablet that will stop his sniffles and let him go back to work. Beyond that, they should get it outside. You can create the dope habit in a way by continually doping your employees; the first thing you know you will be running a pharmacy instead of an industrial dispensary. My advice would be to not dispense any drugs whatever except one or two minor things. Giving out aspirin tablets which can be bought at any drug store is poor business.

In Some Cases Small Plants May Combine Their Efforts

Now, the question of the small plant which may have a Mutual Benefit Association. The small plant has an opportunity to carry on some of the things that were suggested in the paper. One of the subsequent speakers said that the small plants in a certain locality could combine. I think the small plants should have their Employees' Benefit Association and a hospital. If the small plant can not do it itself, it might get two or three other industries of fairly good size to go in with it.

One of the best opportunities for real medical work is in the small plant. There is an answer to the small plant problem. It is a community or cooperative dispensary in which they could afford to have a full time set-up, both of personnel and equipment, and those full time workers, the physician, the nurses, the attendants and so on, would divide their time as needed among the industries in that community. It has been tried quite successfully in a few cases and I don't know why it has not been carried out to a greater extent than it has. I think that is the possible answer to the question of providing the facilities, which we discussed, for the small plant.

Regarding the cost of re-examining employees, I indicated some of those possibilities in my paper. One was, that when a man is away from work for any length of time on account of injury by an accident, he has to go through the medical department so that we can see what shape he is in. The question of the cost of re-examination in that they increase lost time is possibly so, but if you could check up the condition of your employees, you might find that you have saved a great deal more lost time in the long run, that has been the experience of people all along the line. The physician may send the man away from the job for a short time and thereby help to save a great deal of lost time that would have resulted if he had kept on going in the condition he was in.

Mr. Ashe's experience over in Pittsfield has not been so very good if it costs his company \$10 to have an examination done. I don't think it should cost that much except in very unusual cases where it would take an hour to give a man a physical examination. I think the executives of a company should go the limit in having their employees re-examined. They should have their employees' health looked after and see if there is anything wrong with them. They have a great deal of responsibility. If any of the employees show symptoms of illness, the doctor is justified in going to great lengths in giving those people thorough examinations.

In the case of the average employee, if you have a physical examination record, when he comes in you have a pretty good basis to go on. It should not take so long to make the examination, and it is not going to be a very expensive proposition.

Cost of Conducting Medical Department Is Low

It was found recently that the cost of conducting medical departments in the plants, good, bad and indifferent, all thrown in together, was only 36 cents per \$100 of the payroll. The cost of the work is nothing when we come down to the figures that show the value of the goods produced. I think that any industry can afford to absorb that without very much complaint.

The question of minor illness was brought up by one of the speakers here. I think every industry is justified in taking care of their employees as long as they stay on the job; if the employee is so ill that he must go home, then he should call his own physician. It is the duty of the company to take care of him while he is on the job.

Regarding the question of how far the plant physician should go in the treatment of employees, I think the plant physician should treat emergency cases, but when an employee is able to go home he should have his family physician. Of course, he may want to retain the plant physician as his family physician, which is all right, but the plant physician is justified and authorized to treat emergency cases only. After that it is a question of how far he wants to go.

I don't think I like Mr. Johnson's plan about giving the employee an examination when he comes into the dispensary for something or other. That won't go very long. It is one thing that you must keep away from. Don't try to put something over on the employees for you will find that procedure will not become popular with them. Be open and above board. Don't make the employees think that there is a nigger in the woodpile somewhere. Put your cards face up on the table.

Several years ago I was with the United States Public Health Service and we were doing some examining in northern New York. We went into a plant there and told the men what we wanted to do. We laid our cards face up on the table and got their cooperation, and almost to a man they came up to be examined, but there were a few who said that there was no government doctor going to examine them. We paid no

attention to them, ignored them entirely, and went ahead with our work. Usually the day before we got through we let it be known through the plant that we were going to get out the next day, and I think, almost without exception, all the men who protested against being examined came up and said, "All the other boys have taken the examination so we will take it too." There is always some way you can get at those things if you do not try to force them. If you use judgment and diplomacy, you can get by on practically all of these problems.

MR. JOHNSON: I wonder if we should insist upon the foremen of departments, office managers and assistants, taking the physical examination?

DR. RECTOR: It seems to me that if anybody is to be forced to take the physical examination, it should be the heads of the departments. I don't believe in force. I believe in persuasion, and that brings up a very interesting point. Unless you do get the management behind you in anything that you are doing in this line, you are not going to succeed. The employees will not come up to be examined if the heads of their departments have not taken advantage of the physical department's facilities. So the big problem of the physical department in the industries is to sell the management, from the executive officers on down the line. If all the heads of the different departments have taken advantage of the facilities offered by the physical department, it will not be much trouble to get the employees to fall in line.

A Peculiar Situation in a Boston Plant

I was in Cambridge, Massachusetts, once where the plant physician was on a part time basis and the work was in charge of a nurse. I noticed employees coming in and getting some sort of treatment or medicine and the nurse made no record of it. I told her that she must have a good memory to remember all the people that come in. I asked her why she did not make a record while the employees were there. She said to me, "You know, there is a peculiar situation here. The cost of the medical department is charged against each operating department on a monthly basis, and based on the number of employees who use the hospital facilities, and a number of the foremen will not permit their employees to come down here for treatment if we make a record of it so that it will be charged against them at the end of the month." That was very interesting and you can see what was happening. You must get the cooperation of the supervisors if you are going to put over anything of this kind.

CHAIRMAN MACPHERSON: I think we will have to close the discussion on this paper. I am sure we could go on all the rest of the morning.

The next paper on the program is by Dr. Eugene Lyman Fisk, of the Life Extension Institute, New York City. Dr. Fisk has been unable to get here, and he has asked Mr. Leo D. Woedtke, of the Fred T. Ley & Co., of Springfield, Mass., to read his paper for him.

PERIODIC HEALTH EXAMINATIONS IN INDUSTRY

Eugene Lyman Fisk, M. D., Medical Director, Life Extension Institute,
New York City.

The ways in which periodic health examinations may be linked to the activities of the mutual benefit organizations in the plant, have been well worked out by Mr. Harold A. Ley* and presented in a previous discussion before this body.

That the theory of periodic health examinations in industry is absolutely sound is, I think, admitted by all who have given this subject any attention. There are people, however, who accept the theory and principle but have their doubts as to its practical working in an industrial group. Surely no one familiar with industrial conditions can question the enormous influence of health on industrial productivity, on turnover, on the accident rate, and on perhaps the most important condition that we have to deal with in industry—fatigue.

In considering the problem of industrial fatigue, these questions should always be asked: "Is the worker tired because he is ill, or ill because he is tired?"

Also, industrial experts, experienced in dealing with human beings, realize how difficult it is to influence the personal actions of men. It is an entirely normal and healthy characteristic for men to have confidence in themselves and their health and power to work as long as they feel well. The difficulty of securing the cooperation of men whose impairments are not causing pain or actual physical disability, is well recognized; but most worth-while things we are trying to do in industry are difficult, and no important measure is to be disregarded merely because it is a difficult one to carry through.

In this brief paper I shall present certain evidence bearing upon the practical workings of the periodic health examination system in industry, and its actual results in so far as the service has influenced the lives of those examined. The statistics derived from life insurance sources have already been presented to this Section by Mr. Ley.

I may remind you that in nine years' experience of the Metropolitan Life Insurance Company, a reduction of 18 per cent was effected in the death rate among those examined; and among those found more or less seriously impaired, a reduction of 53 per cent was attained. In the Guardian Life Insurance Company of America, a study covering ten years' experience showed a reduction of 23 per cent in the mortality of those examined; of 26 per cent when the extreme old ages were excluded. These are business figures of tremendous significance. Many have been skeptical as to the degree to which policyholders in life insurance com-

**How to Interest Employees in Improving Their Health*, by Harold A. Ley. Address Before the Fourteenth Annual Safety Congress Held Under the Auspices of the National Safety Council in Cleveland, October 1, 1925.

Prevention of Waste from Ill Health in Industry, by, Harold A. Ley. *Safety Engineering* June, 1926.

panies would respond to the message of a Life Extension examination; but the answer is found in these figures.

Shifting our attention, however, to a different type of statistical proof, I call your attention to the accompanying table indicating the results attained in a group of about 600 industrial employees taking these examinations for three successive years.

TABLE A .

Improvement in Physical Condition of 596 Industrial Workers resulting from Periodic Physical Examination as revealed by the medical and surgical attention needed at 3 successive years of examination.

Class of Medical or Surgical Attention Needed	Number of Cases Needing Attention At 1st Exam.	New Cases Needing Attention At 2nd Exam..	Percentage of Cases Cured Within Year Following Discovery of Impairment
General Medicine	90	60	69
Eye	217	66	52
Ear	64	24	58
Nose and Throat..	144	79	50
Surgical	79	62	62

A study of this group shows why the death rate is so rapidly pulled down by a service of this kind. You will note in the various types of disabilities requiring medical attention, cures were effected ranging from 52 to 69 per cent; that is, within one year of the examination it was shown that the need for medical attention of various kinds had been reduced to that degree. This study covered a group of 596 employees selected at random simply on the basis of having had three successive examinations. In this way any possible special environmental influence is eliminated. These results would indicate the uncomplicated influence of the periodic health examination service and not of any special intensive work at any particular plant.

I think anyone familiar with industrial conditions will appreciate the enormous difficulty of attempting to trace the complete influence of such a service. The results on the death rate in these groups can only be ascertained after many years of exposure, and then it is often difficult to trace cases. The morbidity results may be affected by complicating factors, such as epidemics, special plant conditions and turnover, and other matters having nothing to do with the health examination service. But in this particular study we have evidence derived from individual consideration of the actual characteristics of the people examined and the extent to which these individuals have profited by the counsel given.

The type of examination I have been discussing is the standard one

employed by the Life Extension Institute in industry. This covers an examination of each region of the body, a chemical examination of the urine, and the delivery of a report by the examiner outlining conditions found and making recommendations as to the type of treatment to seek and the modification of personal hygiene that is necessary. This is the kind of an examination that is feasible and attainable for the average worker. I do not, however, think we should ignore the ultimate possibilities of these health examinations made on a broader scale for the higher class of executives. There is evidence available along these lines which is very illuminating and which is summarized in the following table:

TABLE B
Classification According to Degree of Impairment
100 Policyholders Examined Under the Vital Protective
Routine
(Average Age 43)

Class	Number
1. No physical defects or errors in hygiene.....	0
2. Very minor defects requiring attention or observation.....	0
3. Minor defects requiring hygienic correction, or minor medical, surgical or dental attention.....	12
4. Moderate defects requiring medical supervision as well as hygienic correction. Impairment influencing longevity.....	70
5. Advanced physical impairments requiring systematic medical or surgical attention.....	15
6. Serious physical condition requiring immediate medical or surgical attention	3

This group comprised 100 individuals carrying large life insurance policies who received very critical and thorough examinations at the Head Office of the Life Extension Institute, including X-rays of the teeth, of the chest, and of the heart; electrocardiographic study, blood chemistry, and practically every laboratory investigation and specialized study that is available. These men were all high-class executives, accustomed to the best of medical attendance, and carrying on important activities. Yet in this group, three serious cases of heart disease were uncovered, and 27 of the group showed important impairments which could not have been elicited by the more elementary forms of examination.

I am convinced that these broader examinations will in time become the vogue among important executives who require to know whether they are likely to have a fairly long look ahead in their chosen activities or whether they need to modify those activities or prepare in any way for their restriction.

The relationship of these physical impairments to industrial fatigue is very close indeed; in fact, it is my opinion, from a close study of the industrial situation, that the major factor in industrial fatigue is physical impairment and not the hours of work or the nature of the work.

A thoroughly sound and vital human organism can carry almost any load of work through a fairly long working day without accumulating any pathological fatigue. The fatigue that carries over to the following day and is more or less continuously carried day after day, almost invariably arises from some infection or poison or physical deficiency on the part of the individual, and not from the nature or quantity of the work performed. Of course, we meet conditions of mental ill health quite as definite as physical ill health, and these may be a factor in fatigue. These conditions, however, may be revealed by a critical medical survey and oftentimes corrected.

How much underlying unsuspected physical impairment exists in the population was shown by the results of a sickness survey made by the United States Public Health Service. Sickness is not always the real index of physical condition. The diseases that figure most largely in the death rate may show an almost negligible sickness rate—as sickness is ordinarily understood. It is only by the periodic health examination that this underlying physical state can be disclosed and pave the way for corrective work before it is too late.

I can not leave this subject without insisting that the most important measure that could possibly be adopted for the elimination of waste in industry and for the mitigation of fatigue in industry, is the periodic health examination, followed by proper counsel and direction as to the treatment of pathological conditions and the correction of any factors in the personal hygiene or environment that are contributing to physical failure.

In the report that I made to the Hoover Committee on the Elimination of Waste in Industry, it was set forth, on sufficient data, that failure to employ these methods generally throughout the country occasions an annual loss of some three billions of dollars, and that one billion, eight hundred millions are lost in industry. This loss is preventable, and the cost of prevention will leave a margin of profit of at least a billion dollars.

I see no reason to change these estimates which were derived from the intensive study of small but representative groups. This is a practical, constructive business measure in industry, adding not only to the productive lifetime of the worker, but increasing his capacity to work and to live and to enjoy life. That is the principle or theory upon which the work was started, and experience has justified it. There are many business measures universally applied which lack the proof as to their utility which is now available regarding the periodic health examination.

ADJOURNMENT

THURSDAY AFTERNOON SESSION

October 28, 1926

The second session of the Employees' Benefit Associations Section convened at 2:00 o'clock, Chairman W. J. MacPherson, presiding.

CHAIRMAN MACPHERSON: This afternoon's session is to be a "General Round Table," and a general round table means a group that gets together and has a sort of free for all discussion.

The Nominating Committee consists of Mr. Homer Neisz, of Chicago, and Mr. Willis MacLaughlin, of Toronto, Canada. Mr. Neisz could not be here and has asked me to present this slate for him.

They recommend for chairman of this Section, Sidney W. Ashe, of the General Electric Company, Pittsfield, Massachusetts; and for vice-chairman, W. Frank Persons, of the Milwaukee Electric Railway & Light Company; and they recommend that the secretary be chosen by Mr. Ashe because probably he will want to select someone close enough to him to be of considerable service in that position. If you want to grant that authority I will entertain a motion for the election of this slate.

C. G. PATTERSON (Alton Box Board & Paper Company, Alton, Illinois): I move you that the slate as recommended be adopted.

(The motion was regularly seconded and carried unanimously.)

CHAIRMAN MACPHERSON: This afternoon we have six subjects for round table discussion.

On the first subject, "How to Keep the Small Plant Association Out of the Hole," a good deal depends upon what is meant by "hole." In our case we have a very easy way of changing the dues and it is our aim to keep the dues fixed in such a way that the amount of money on hand will always take care of current liabilities. Fortunately, we haven't had to change very frequently.

We have no fear of going into the hole because simply by a vote of the board of directors elected by the employees we can change our dues effective the following month. So there is no such thing in our plant as going into the hole. I would like to hear how some of the other companies keep the small plant association out of the hole.

MR. H. JOHNSON: Our insurance has only been in operation since May, and those starting in January, February and March will possibly be the fat months of the year for benefits and we have contemplated that condition.

Is there any one here who can give approximately the increase of benefits likely to be necessary in what we call the sick months, that is the sickness over the summer months? We don't know just how we are going to get through the winter and we don't want to make an assessment. We all know that assessments are very hard and a very bad thing to start to do.

ARTHUR M. COON (Dunlap Tire & Rubber Company, Buffalo, New York):

Our Association pays a very small fee. The members are assessed 15 cents a week but whenever we vote a large amount of money like \$400 or \$500 to recreation like baseball or bowling or any similar case and we find it brings the reserve fund down further than we would like to have it, I simply notify the company that such is the case and they donate a check through the Association which pretty nearly covers the amount. It is never the same amount but that is how we keep out of the hole. The firm, of course, does this but the members still feel they are running and paying for the Association.

MR. JOHNSON: I want to meet and talk with any member here who has or knows about an association maintained by and for the employees and which is contributed to only by the employees. I think most of the companies represented here and having relief associations are contributed to by the firms also.

FRANK WHITE (American Multigraph Company, Cleveland, Ohio): Our Association is all by and for the employees and they are the only ones that make contributions to it. We have found, of course, that in the months of say November, December, January, February, March and possibly April, about six months out of the year, is when we pay out most of our benefits. I will go so far as to say 75 per cent of our benefits are paid in the six months I have mentioned.

The Association Is Insured Against Deficit

I don't know whether that answers the gentleman's question or not. The company does not contribute to the Association and the employees do not want them to give anything or make any donations.

G. F. CLOSE (Commonwealth Steel Company, Granite City, Illinois): We have had a Benefit Association for about five years, and while we don't have any profit during the year we have no fear of running into the hole because we reinsure the Association with an insurance company. We find that during the six winter months, from November to April, the benefits are about twice as high as they are during the other six months.

Of course when the Benefit Association finances itself, pays the benefits directly, they have a more difficult financing problem than if it is reinsured. We know what our rate is going to be all through the year and we may have to raise our dues at the beginning of a new year when we reinsure. We really haven't that privilege, of course, but during the year we have no trouble because the insurance company stands the gaff.

S. B. WILKES (Larkin Company, Inc., Buffalo, New York): I can't say anything that isn't corroborative. We have an association of 35 members. It is supported entirely by the employees and we have found that about 75 per cent of the benefits go out in the winter months.

NATHAN SHAW (Illinois Power & Light Company, Chicago, Illinois): I would like to ask the gentleman who just spoke what benefits they have that they reinsure?

MR. WILKES: Our Association is composed of two parts. We have

the life insurance which the company provides, and the men pay entirely for the sickness and accident insurance, but as a matter of fact we insure both. The part in which I am concerned covers sickness and accidents outside the shop. The inside accidents are covered by compensation. The Standard Accident Insurance Company of Detroit carries that risk.

JOHN D. SWITZER (Mathieson Alkali Works, Niagara Falls, New York): When our Association was organized about 28 years ago we had, I suppose, in the neighborhood of 400 employees. At that time the company donated 25 cents and the employees 25 cents each month and we paid benefits of \$5 a week. It went along on that schedule for about three years and then we went in the hole. One year we were forced to call upon the company for a loan of \$300 which we paid back later on and we went along for perhaps 15 years on that same basis. We had more members but we still paid the same benefits and received the same compensation.

Benefits Were Raised When Times Grew Better

In that way we swam through it, but about 1917, of course, wages went up all over the country and people were not quite so much disposed to get sick. If they did get sick they didn't lose much time. Five dollars a week was not much of an attraction to them. The result was that within five years we piled up a surplus on that basis of about \$1,500. Then we raised our benefits to seven dollars a week until such time as that fund would be pulled down to \$700, and that lasted for about two years.

I was secretary of the Association for about five years and the expenditures during that time were about 75 per cent higher during December, January, February, March, and sometimes April than they were during any other month or months during the year.

However, we have taken over the group insurance plan for employees at a premium of 50 cents per month. The company is not connected with the Benefit Association except in the way of helping them out, and we are now paying \$7 a week and we seem to be getting along very nicely.

EDWARD S. LIGHT (Empire Gas & Electric Company, Genoa, New York): Relative to keeping the association out of the hole, we are thinking of a plan now that we think will be quite successful and that is an investment for the surplus that we have in the Association. We are thinking of taking this surplus and allowing the employees to make loans on it, to borrow money out of it, and to pay six per cent interest unless the amount is to be used for sickness in their families or something of that sort, in which case they will be required to pay four per cent interest. If that plan goes through we think it will not only build up our surplus but will also make it quite convenient for employees who wish to borrow money in that way.

MR. SHAW: I want to repeat the question I asked when the meeting

first opened. Are there any members who have been connected with the Association who did go into the hole? We want to know what some of the pitfalls are that we might go into.

I don't believe it would be just right to discuss that question without referring to our own organization. About 62 per cent of our employees are now members of a hospital association which we have and which was organized in 1917.

At that time the company realized that in time of illness and death there was more or less distress among its employees and therefore they devised this plan. We are seriously considering revamping it and anything that I might contribute here is given with the idea that some of the others, with a more revised plan than ours, can help us. We have been in the hole and the company has very cheerfully and liberally contributed to the fund in order to keep it going.

During the life of the Association the company has probably contributed about \$90,000, and we graduate the dues or assessments to the fund on a salary basis. In the higher salaried classes they pay rather large amounts. In the lower graded salaries the contributions are very low, the smallest amount being 25 cents a month.

We have gone in the hole (although we don't feel we have provided excess benefits) and if there are other questions that will help us to bring this matter out and help someone else I should be glad to hear them.

Members Contribute According to Various Classes

CHAIRMAN MACPHERSON: Let me ask, when you have gone in the hole where is the burden placed, on the company or the members?

MR. SHAW: The company has always made up the deficit. There has not been any change in the assessment to the members. That is a fixed plan by which we assess them on a monthly basis and we don't change the amount they contribute.

MR. RIDDLE: May I ask what the cost is to the members and what they offer in benefits to the members?

MR. SHAW: The highest salaried employee contributes a maximum of \$4 per month and the lowest 25 cents per month. They are graduated in amounts of \$100 and down to as low as \$2.50, which run approximately 25 cents, 40 cents, 60 cents, 80 cents, \$1.20, \$1.60, \$2, \$3 and \$3.50, and as high as \$4 per month. On salaries less than \$200 a month it runs at one per cent per month and in excess of that amount it runs one and one-half per cent a month. The average cost per employee figures out about 22 cents per month.

It just happens that we have an Employees' Association with the cost all to the employees and where the company has never yet contributed, not because we couldn't secure that contribution but we have never found it necessary. Through 25 years the expense to the insured in the plant was 50 cents per month, with an average death benefit of \$250 and \$7 per week for accident and sick benefits. In the last 25

years with an average of 7,000 members, a surplus of \$100,000 has accumulated.

That is also being rather lenient with the claimant for benefits if it is found that at the end of the disability period (which in our case is 13 weeks) he or she is still in need of help, we may extend that to another 13 weeks in any one year or period. But since that time there has been so much cooperation propaganda about insurance schools with outside groups coming into industrial organizations (possibly you call it underwriting excess insurance), that we have formed a plan of our own where we know through our past experience and through the statistics offered by the various insurance representatives that we can't fail unless it is in the face of a catastrophe.

We have obtained all our figures from authoritative sources. They were accumulated from all the larger insurance companies who write industrial insurance in the United States. We took two months in which to investigate this and find out our cost. So we now have a \$1,000 death claim and \$7 or \$8 a week sick benefits with, of course, the death claim rated at the total disability rate, in compliance with various items in the By-Laws that call for a payment on loss of members and loss of time.

Nothing is Compulsory in the Association

In our Association nothing is compulsory. It may look as if pressure is brought to bear but there is none. We had one benefit where there was no examination necessary to enter the employment of the company, but we decided that in fairness to the other members it was necessary to go through this examination which meant the same thing as getting into the insurance plan. So these figures that I am giving you have really been compiled by the insurance actuaries who are specialists along that line.

CHAIRMAN MACPHERSON: I find the discussion is drifting toward the subject, "How can one determine the proper basis for membership dues?" and unless there is some other discussion on how to keep the small plant out of the hole, we will pass on to the next question.

I think also that the next subject is very much connected with number three and we might discuss them together. Number two is, "The Secret of Success of our Employees' Benefit Association." I think answers to that will be practically the same as the answers to number three, which is "What Is the Best Plan of Administration for an Employees' Benefit Association?" We might discuss those two together.

The secret of our success in the Benefit Association is the fact that it is operated entirely by the employees. They do their own checking up on malingering, make recommendations on cases that are entitled or not entitled to benefits and also the dues are based on our current expense, and, therefore, the employee is interested in keeping our expense favorable. In cases where the company pays the difference in expense, the incentive is probably taken away.

C. G. PATTERSON (Alton Box Board and Paper Company, Alton, Illinois): I am inclined to be like our chairman in his attitude of administration. We have only 175 men in our Association. Our Association attends directly to the employees and we have directors and sick committees who look after its members and in the last three years we have accumulated a surplus of \$3,000 upon 15 cents per week, per member.

The company put in 15 cents apiece for each member but above that we have saved more than the amount the company has given us in the last three years. Prior to that time we had 10 cents a week, a \$50 death benefit, \$25 childbirth benefit and we accumulated a surplus there. Then we cut out taking subscriptions from the men for over a year. But that eliminated the new men coming in, so we had to reform on this basis, with 15 cents a week and the company came in with their part of it.

Our office force is not in the Association at all. The directors are elected by the men. The secretary informed me the other day that the childbirth rate had drawn the fund down \$175 last month.

What Measures the Success of the Association?

HERBERT W. ALLEN: May I ask what you mean by the success of the Association?

CHAIRMAN MACPIERSON: Success might be measured in several ways and I suppose there would be as many opinions as there are people in the room. In my opinion one of the things that indicate the success of the organization is the percentage of members who belong to the Association. Another is the financial structure that guarantees the performance of what you say you will do.

In our particular case we have 92 per cent of the employees as members and have kept that number almost level for six years, and membership is not compulsory. Ninety-two per cent means almost 100 per cent because there are always a certain number of applications in the mail and our membership becomes effective following the first or fifteenth of the month. I would say it would run 98 per cent if we had the applications listed that are always in the mail.

The success of the Association might also be measured by your financial difficulties or the lack of them. In our particular case we have operated for six years without changing dues, and we started out with the intention of operating so that the dues would equal current cost. After six years we have a \$7,000 balance. We feel our rate was a pretty good guess.

Mr. ALLEN: We have been told in our Association that it would not be a success in any sense of the word if we had a 100 per cent membership. In other words, the life of your Association is to have a new knocker or a few people who do not see the benefit of the man at all. If every man is a member the interest sort of dies down and it is not as active and strong as it would be otherwise. For that reason we have never urged that our membership be 100 per cent. We have never made

any extraordinary effort. The ones who want it come and ask for it without being solicited. If they are ever solicited it is only through their work.

We feel that our Association is a success because of the 88 or 89 per cent membership under those circumstances and we take up any activity that any organized group of employees would take up or that they may wish to take up and that activity is paid for entirely through the funds of the Association. That covers everything from baseball and all sorts of sports to education and lectures, entertainment, everything imaginable.

We do what the group wishes to undertake and we feel that because they do take up so many of those activities (and they are usually a success) that our association is a success.

I might mention that we have an employees' representative council in our plant. The directors elected by each of the different departments constitute the representatives in this council and they act for their shop mates both in the Association and in this workmen's council and also in our safety council. The director is "some punkin" in the department.

CHAIRMAN MACPHERSON: We agree with the last speaker on the subject of lining up men. We set up a little resistance to joining by charging \$1 admission fee. That has nothing to do with the dues but we charge that \$1. We find that the fellow who decides not to join and happens to get sick and is sick for six or seven weeks without any benefits, becomes a very fine salesman for the organization in the future.

Each Man Should Be Sold on the Merits of the Association

G. A. DOELLER (Dayton Power & Light Company, Dayton, Ohio): When we employ a man, the employment office doesn't feel that it is really functioning in its fullest capacity if we haven't sold the man the merits of our Benefit Association.

It is rather pitiful when a man doesn't belong and is not in a position financially to take care of his obligations, and who shortly after he has been employed by your company is taken sick and is sick perhaps for six or eight weeks. We feel that we have not done our duty in the employment office if we have not sold him on membership in our benevolent association.

We do not have a compulsory method but in nearly all cases we put the matter up to the new man in such a way that we generally get his application.

MR. ALLEN: It seems to me if the employment department points out all the advantages to the new man he is going to do most anything to get the protection.

GEORGE E. BARLOW (Welfare—Olds Motor Works, Lansing, Michigan): May I ask what is your age limit for a member?

CHAIRMAN MACPHERSON: We have no age limit. Is there someone who wants to say something on that?

MR. RIDDLE: May I give you our experience? Our age limit is 55. Between the ages of 50 and 55 we have them pass this special rigid examination, and I feel that the success of our organization has been the keeping of the average age, the average age limit at 43. That is the insurable age, that doesn't mean the age of the man, that means the premium age. Thirty-five is the average age of the individual. When a man reaches his fiftieth birthday he has to pass a special physical examination.

N. F. STALEY (Goodyear Relief Association, Akron, Ohio): I would like to tell you a little about our relief association during the past 17 years. We have accumulated (if you want to call it a surplus) at the present time about \$123,000. We have been paying \$12 a week for Class A members which includes men whom we hire up to the age of 50. Men whom we hire over the age of 50 we rate as Class B and pay them \$8 a week. Class C are women and we pay them \$8 a week for ten weeks. The other two classes get benefits for 16 weeks.

Total Insurance Carried of Over Twenty-Six Millions

About two years ago we amended our rules and regulations to no pay for the first week and during the first 18 months of that time we ran a deficit of \$10,000. We pay where the state pays, regardless of whether the injury happens in our shop or outside the shop. We pay for it anyway and I think that is quite a drawback, because when a man is injured and gets paid by the company and the state too it has a tendency to foster malingering. The big thing that we are up against is our Class C, the women. We have run a deficit on those people ever since we took them over in 1917. This year I believe it is going to run something around \$2,000. Up to the present time we have been doing the best we could but we have made an amendment to our By-Laws whereby we are going to raise the dues on the women, making them pay the same as Class B, and we think that will wipe out our operating deficit.

We have enough money coming in on our securities to offset the deficit and I believe we are going to make a little net profit. Our investment must earn in order to cover the operating cost. The insurance is furnished by the Goodyear Tire & Rubber Company. That has nothing to do with the relief association any more than if you should join our association and we should make you a present of \$1,000 insurance and pay the premium.

At the present time we have what we call service insurance. That is where men have been with us for long periods of time. Our total insurance at the present time is over \$26,000,000.

Now that is not all paid by the Goodyear people. We have what we call personal insurance, or extra insurance, that the men can purchase at a very small rate, \$5.40 per thousand a year and quite a few have availed themselves of that opportunity. I think we have something like \$4,000,000 of personal insurance but the balance of it is paid by the Goodyear Rubber Company. The \$9 a year that the men are glad to pay, covers sick benefits for 16 weeks at \$12 a week.

We saw where we were going to run a deficit for paying the first week and we took it up with the men. We have, by the way, the industrial representation plan in our factory and you not only have the individual member to deal with but you have the industrial service to deal with. We took it up with some of those men and we finally did get it down where we didn't pay for the first four days, and that has saved us in the last year, approximately \$7,000.

We also have a clause that we must be notified within six days of a disability. That can be changed by the trustees. For instance, if a man is seriously ill he can not notify us at once but within a six-day period he usually can notify us, or some member of his family can do so. That rule, of course, is very flexible and I would like to hear from some of the rest of the Mutual Benefit Association men on notice of disability.

Our experience has been that some of the men will leave their work regardless of whether they are taken from the payroll, go away possibly the length of five or six states and come back at the end of three or four weeks and bring a doctor's certificate indicating illness during that time. We know we are getting stuck, but we can't help ourselves because we do pay on the doctor's certificate.

A Waiting Period of Thirty Days

Also we have a waiting period of 30 days. However, that does not affect the insurance; it is effective right away. We had one man who had only worked two hours and a block flew over and killed him, and of course, his family was paid \$1,000.

There was a time when we let them work three or four months before they were told about the insurance but that was a cumbersome way of getting men and it kept an extra solicitor on the work. So now we take them as they come through the labor bureau and we write them up right then and tell them the benefits will not be effective for 30 days. We charge \$1 initial fee. Every man is examined by a physician when he comes in and his physical condition determined at that time. But the thing I am interested in hearing is what is your experience with your women employees.

MR. CLOSE: The last speaker has raised the question which has bothered us more than any other one thing in our Benefit Association experience and that is the employees being sick and failing to give proper notice. We have a rule that a man must give notice within 10 days if he wishes to draw insurance, but as a matter of fact we can't enforce it. If a man is really sick and we know he is sick, even if he didn't give notice, we sometimes threaten him and tell him we can't pay him. We tell him the insurance company may turn him down. But as a matter of fact we have always paid those claims on delayed notice if they are bonafide sick claims and I don't believe there is any way of getting out of it.

The only way to do is to emphasize it in any way you can in your plant publication and through the board of directors, having them empha-

size it with the men in their departments; but after all if a man is really sick you are going to have a heart and you are going to pay him. It is a very serious problem and one that causes a lot of inconvenience and trouble.

If anyone here has found a way to solve the problem to really secure prompt notice in every case, I want to hear from him.

CHAIRMAN MACPHERSON: You will find that question is listed here on our program as number five, "How we check up on our disability cases," and I hope your question will be answered then.

I would like to move on to number four, "How can one determine the proper basis for membership dues?"

Now let's get that question in mind. I don't think the question means how much do you charge in your Benefit Association, but how to determine the proper basis upon which to make the charge.

Study of Other Associations Valuable

You will find when you have studied and discussed Benefit Association work, that one charges one price, say 50 cents a month or 50 cents a week, and somebody else charges some other amount; there are so many ways, we would have to get out our note books and take notes to remember them all. It all depends, of course, whether or not life insurance is included in your plan. It depends on whether or not you start paying benefits after the first week or after the first day or after the fourth day or some other period. It depends also upon whether or not the workmen's compensation cases are included. I think the money charged should not be included in this question. How can one determine the proper basis? I suppose the answer to that by a good many people would be, tell the actuary the kind of association you want to set up and then let them tell you the rate to charge.

In our case we went to three companies that had Benefit Associations; they had had them a long time. We found out what the amount of lost time was on account of sickness. In those companies we found sickness beyond the first week (which was what we wanted) amounted to 1.03 of the total working time. In other cases it was 1.06 and in another case it was 1.01.

We made a guess that our employees were just a little bit healthier than that. We guessed that we could charge dues based on one per cent of the benefits to be received. Then we distributed that cost to the men and to the company. The employees paid two-thirds of the benefits and the company paid one-third. When the rates change, that proportion still holds good. In six years we have not had to make a change.

Our scheme was to find out the amount of lost time and then base the dues on that estimate.

Now perhaps somebody has a better method or a more scientific scheme for determining the proper basis for dues. We would like to hear from you.

MR. JOHNSON: We guessed at it in this way. We tried to figure what

the lowest paid worker in our plant would consider. We guessed it 15 cents and it has always stayed there.

CHAIRMAN MACPHERSON: When you say 15 cents that has to be related in terms of what you pay, of course. For instance we pay from 75 per cent to 100 per cent of full pay for a period of 52 weeks. Most of our advisors told us that that method would cause malingering, but our experience has been quite the contrary.

MR. JOHNSON: Isn't it a fact the cost to the member is based entirely on the amount of money you pay back to him? An insurance plan as given to us by outsiders was based on the amount of money we had to pay outsiders and was paid on the amount of money we had to pay back to our group plan plus their overhead as mutual companies.

We took our record for 25 years and took their records on group insurance over an average insurable age about which I spoke a minute ago. In addition to that we figured we should have a certain backup to offset. Most of the smaller organizations' plants are in one place and the risk is all in one place. That meant that in the case of a catastrophe, a whole group would be wiped out and we figured that the success of our larger organization would be still greater if we combined the various works in the various states under this insurance, thereby spreading the risk; so I can say again that our cost to the member is based entirely on what we have to pay to the member or to those who have become sick or who have died in the meantime. And also by the figures of the actuary writing group insurance.

How to Check Up on the Disability Cases

CHAIRMAN MACPHERSON: On this next question, "How we check up on our disability cases," I think there will be a lot of discussion and questions.

DR. H. E. ROBERTSON (Norton Company, Chippawa, Ontario, Canada): We have about 225 men in Ontario under this plan. We find that it is very profitable to employ a trained nurse. Our By-Laws stipulate that a man must notify us within 40 days when he is sick. But our employment department makes up a list every morning showing the men who are absent. The first day the nurse will not look a man up but when he does not appear on the second day, the record will show that there has been a second day off and if she finds that he is sick she will render whatever service she can. By the time it gets to the fifth day, if he is not able to make out a disability slip she will make the slip and turn it in to the secretary.

Every now and then a man neglects to turn one in and it has been our custom when we find a man that has neglected to turn it in through some cause or other, to try to read the "Riot Act" to him.

We have our directors' meeting every Thursday night and we make it a point to bring him in and find out just why he failed to turn in his slip. In that way we throw a scare into the man and we find it is mighty good advertising. We get him up there, get his story and then,

of course, our By-Laws leave it up to the board of directors whether or not we can give him benefits. We put it up to the board of directors.

Then again in our annual meetings or semi-annual meetings we continually drum upon that subject of disability. It is really a process of education because while 75 per cent of your men may be steady you still have the new men that are coming in all the time, who do not know anything about the rules of your association and it takes time to educate them along those lines.

I will say in connection with the nurse's services, we have found it very beneficial. We have eight directors in the association spread out in the shops among the employees. We find that if we cooperate with the foreman who is vitally interested in the man being on the job, we get somewhere with the training. We have 30 or 40 men really tracing or training the new men all the time and in that way we keep down the malingering to a very great extent and find it very easy to operate.

Notice of Illness Must Be Given Promptly

We have a clause in the by-laws, "No benefits paid unless notice has been given within six days." Our organization is now on its second year. Since the day of organization we had over 30 per cent of the men and have had continually, for the past year 95 per cent and have also been a financial success.

One thing we have had since the first day of our organization: the fellow who don't report his disability until he is ready to collect his benefits does not get the benefits. We check up in this way. We made every foreman a member of the board of directors in the different departments and had them report all of their men that were off and the cause for the absence.

To show you how far some of them will go, we had one man who had been off 14 months and he wrote in for benefits. We had never had anything like that before. This fellow had gone six or seven states away and then made his claim. We have prided ourselves on the fact that we have always paid the benefits the second week after the man has been disabled and made all the further payments until he returned to work. We make the payments every two weeks and all of those fellows who did not report within the first six days, had to wait until after a regular period, until after the meeting of the board of directors, unless the men were in bad financial circumstances.

MR. JOHNSON: We haven't had a case of that kind in five months. I think it is due to the fact that we have a clause in the by-laws which states that if we are notified within three days they will receive compensation but otherwise the disability will not begin. It begins only on the date on which it is received by the secretary of our association.

Of course we do not pay for the first seven days' sickness or accident. If he is off seven days and we get the notice on the seventh day he would draw benefits on the eighth day but if he doesn't get his notice in until the tenth day he has lost three days.

Another clause we have is that no employee or member of the association dare leave the city in case of accident or sickness without first notifying the secretary, and that case will be brought up at the next regular board of directors' meeting. He may secure permission to go if he leaves the address to which he is going and keeps the secretary informed that he is away. Unless he does that religiously he will not be eligible for any benefits. We have had very good success with this plan.

We had a case of one of our girls going away to a resort in order to rest up. She had had a nervous breakdown. She reported to the secretary she was going to be away for six weeks. The secretary reported it to our company doctor who also called her in and talked to her. It was brought up before the board of directors when she came back at the end of 10 weeks and she reported back to the secretary and the secretary reported to the doctor who talked to her again, and the benefits were passed upon and approved.

I think enforcing those measures has done more to get our employees to report their sickness and accidents than any other one thing.

CHAIRMAN MACPHERSON: The point of view seems to be to make the Benefit Association an insurance company and puts the burden on the members. I wonder if we should not consider it as a service department of the company and that it might take the initiative and go out and try to serve the employee who is sick.

A Membership Committee Visits the Sick

If the employee is sick we go out to see him. The membership committee selects a man to go or maybe several will go and they will help him fill out his form of proof of claim, and see that it does get through properly and promptly. Do not misunderstand me, this isn't a professional visitor or a nurse, it is a member of the committee selected by the employees for that purpose.

C. H. WHITEMAN (The Mathieson Alkali Works, Saltville, Virginia): There is one point that makes a different condition at different plants. One of our troubles is we have several hundred foreigners. We have several hundred colored men employed. The ordinary American white man will understand the rules and will be very glad to comply with them, but it is a tremendous job to get the foreigners and colored men to take any responsibility on the thing at all. We do all we can in every possible way to help the fellow fill out his notice when he is sick but we have some 38,000 or 40,000 men and we can't get reports every day, not oftener than every week or every two weeks through our employment department to know when men are off.

We have a nurse we send around but, of course, if we don't know the case we can't send the nurse around to investigate it. That is the particular problem with us, these groups of people who are not educated in American ways of doing business and who don't seem to care to learn.

CHAIRMAN MACPHERSON: One scheme that sometimes helps a little is

to have the reports go to the office and a copy of them sent to the Benefit Association and someone there goes through them every day to make sure that none who are off duty on account of sickness are overlooked.

MR. PATTERSON: We have a bonus system in our plant that requires each man when he is off to notify us the same day or his bonus for the month does not stand. That bonus averages 17½ per cent of the man's monthly wage and it is quite an item. If a man does not report the first day he is off, his bonus is delinquent, so that helps us to keep in touch with all our men.

MR. STALEY: It is all well and good to have these rules and say that we won't pay if they do not notify us, but if a man is down and out and you know he is sick and he brings you the credentials that he is sick, I think that fellow should be paid absolutely whether he notifies you or not.

A Little Trouble Will Develop Once in a While .

Of course, we have a little trouble once in a while with a fellow that is beating you and he even boasts about it, that is hard to handle. We had a case of a girl who went out of the state and had a doctor from the Goodyear people to take care of her on the side and when she made that claim we had to pay her the money. Those are the cases I would like to know how to handle.

CHAIRMAN MACPHERSON: We have that problem to some extent in our association, but they know we will pay the benefits. We have heard of companies that wouldn't pay benefits unless they were notified by a certain date, but there aren't many who enforce such a rule and consequently we do not have such a statement in our rules.

On the question of malingering, whether or not some outside doctor states it is a bona fide case, our rules provide that when there is any question, or the membership committee refuses for some reason to sign the proof of claim or when any officer of the association refuses to approve it, that case is referred to the committee of employees who have final decision.

Our experience has been that the employees who are interested in running this association are very hard boiled on the subject and we haven't found a malingerer they let get by. Since this plan was instituted we have had only five cases where the employees' committee has recommended "no benefits" and a case like that now and then has a very wholesome effect.

MR. WHITE: I think the chairman has hit the keynote when he says that we should look upon the association as a part of the service division. Also the gentleman from Canada in the plan he outlined said practically the same thing.

At the multigraph company we know that sometimes we are being beaten by a malingerer. It can't be helped at times, yet if it is going to be a mutual organization in fact as well as in name we have got to consider in our estimation that it be part of the service division work to see that these men and women are taken care of.

We have our board of governors, composed entirely of employees out in the plant. We tell them if we can be of service to call upon us, but they prefer to run it themselves.

CHAIRMAN MACPHERSON: I have heard frequently that we are being beaten by malingerers and I have never had any statistics. In our company we picked out one division with 1,000 employees, appointed a committee consisting of both management and employee representatives, and had that committee analyze every single case of sickness for one year in that group of 1,000 for the purpose of finding repeaters or finding cases that could possibly be classed as malingerers.

That committee could not find a single case where they would even suspect malingering. Every case was checked up by someone close to the employee or by going to the family or the doctor, and they were not able to find a single case. We have had several cases where the employees have recommended discharge and no benefits. We have three cases within the last two years where the employees' committee has suspected malingering and where the company had to take a stand and prove the employee was entitled to benefits.

The Follow-Up System Prevents Malingering

MR. ROBERTSON: I believe if you have a Mutual Benefit Association you have to make it a part of your organization. You have got to follow up the production and where you have a large number of men or in plants where you can not have a trained nurse I think the followup system is certainly a wonderful thing and it can be handled through these committees. I have seen it worked out in other plants. I know how it worked in our plant. We have never had a case of malingering, due to the fact that we have had this followup system.

You should have a large number of men on these committees and if they discover any malingering it is up to the board of directors to disallow such claims.

DR. WOOD: When these employees make these investigations do they do it on company time and if so is there any special arrangement made for replacing them while they are away, or how do you manage that part of it?

MR. ROBERTSON: As this other gentleman stated, we work through committees. Each department has a committee according to the number of employees. They have a committee of one, representing about 15 employees and if that person can not call on the sick person the first night or the second night we have to send someone else because we must have a report not later than the second night. Of course, we look up all we can but it is simply a check, and they go on their own time.

We figure they are interested in the association to the extent of going to see this sick person and we have a rule that they may spend any amount of money up to \$3 for flowers, food or something of that sort, providing they have reasonable belief that that person is sick when they start out.

There is one little thing I would like to ask. How many accept a doctor's certificate as final proof of the sickness? We put that thing up to our board of directors. We believe there are some doctors who are not absolutely honest and ethical, just the same as other people in business, and we put it all in our board of directors' hands in case there is any suspicion of the doctor's veracity. We have an investigation made and sometimes we find it a good thing to do so.

LEONARD KING (Brooklyn, New York): You seem to have answered some of these questions in the same way we deal with them. We have a division in the company of about 25 bureaus. It is a gas manufacturing concern and these heads of departments have been sold on the association idea, so that they have to inform the members of the sick committee within that certain section by the second or at most the third day of sickness, and in case there is no such information given we hold the sick committee's representative in that section responsible.

The Doctor's Statement Is Not Always Final

I don't think we have under discussion the question as to whether the employee is cheating you or not. That does not seem to be very important to me. I guess all these gentlemen will admit that that is only a very small loss at least. It does not pay to take it into consideration.

CHAIRMAN MACPHERSON: Answering Mr. Robertson's question as to whether or not the doctor's statement is final: In our company it is not. The committee determines whether or not the individual is entitled to benefits. We had a case where the committee doubted the sickness and the employees questioned his rights to benefits. Then he brought a statement from the doctor, that so-and-so was absent from work on account of sickness. Then the committee called on the doctor and finally he admitted that the employee was absent on account of sickness but that it was on account of sickness of someone else.

MR. LIGHT: Our company supplies power and light and gas for the territory covering 18 or 20 towns and cities. In the cities we have perhaps two and perhaps three men that act on the board of directors, in towns or villages there will be perhaps only one.

These men are elected by the members of the association of their town or city and they have complete charge of visiting the sick, complete charge of collecting dues for their particular territory, and we find it works out very successfully. The word of those men is taken for the truth. Anything they think should be done, is done. They also send in requests for flowers and food or anything of that nature to be sent to the sick person and we find it works out very nicely.

CHAIRMAN MACPHERSON: We were asked a little earlier in the meeting to ask Mr. Williams for his observations and whether or not the so-called employees association is regarded by the employees as a company association or whether they think it is something the employees are actually running?

MR. WILLIAMS: I think the answer to that question depends on what the actual experience is in each case and how it works out for employees under a given condition.

I have been asked a great many times what the ordinary worker thinks about the plant doctor and whether they resist plant examination by the doctor. That was a question very much in people's minds several years ago and I kept my eyes and ears open and I found it all depends upon the way the people were actually being handled by that doctor. If they were handled well by the doctor they continued to believe in the system and if they were not handled well they thought it was a bad proposition; I was really shocked to find how badly handled the average worker was when he went for a physical examination.

The answer, therefore, to any of those questions is, that the worker is getting his attitude toward these things always by means of his personal experience. If he has a bad experience he is against the whole proposition and it is an idea that is worth keeping in mind.

Unemployment the Cause of All Unhappiness

The temptation of every convention is to leave out that factor of the actual closeness of relationship between those who are working out a given situation and those perhaps who have had a favorable experience, and we tend to overstress the value of that or this particular mechanical detail; so that we are inclined to say we will do it this way or that way because such and such reports a good experience from this plan, and then are surprised to find it doesn't work so well for us.

It seems to me that if you can make sure of keeping in close touch with the workers and see that time after time they are well handled, you can be perfectly sure you don't have to be bothered about any unreasonable attitude in the situation. It does seem to me in general the Mutual Benefit Association gives a tremendous service.

Of course we all know that unemployment is the cause of all unhappiness in the industrial world today. That is either the fault of the management or the industry or of the public or the ill health of the employee or by accident to the individual. And when I think of all the troubles I have heard told, told to me by workers in this country and abroad, I believe that practically 90 per cent of them are the troubles which come from the loss of jobs, either from causes over which they have no control or resulting from sickness or accident. The ordinary man who has a job and who is able to work is likely to be a fairly contented employee.

I think, Mr. Chairman, the better step along this whole line of the Mutual Benefit Association is to give more individual attention to health, to prevention of accidents and the happiness of the employees. Of course, more and more caution is being taken to prevent accidents and yet the matter of the prevention of ill health is being given no attention at all as compared to the attention given the prevention of accidents; and that is in the face of the doctor's statement that a great deal of

ill health is preventable; so I should like some suggestion that next year more attention be given at meetings like this to the possibility of the prevention of ill health as a legitimate part of the ordinary Mutual Benefit Association.

CHAIRMAN MACPHERSON: Our last topic is, "How far should the Company go in Contributing to the Up-keep of the Association?"

There are quite a number of ways of doing that. Some of the companies feel that the company should contribute to these losses and in that way make up the loss. That, I think, takes away a certain amount of incentive. There is an advantage, perhaps, in the company paying none of the Benefit Association costs and still most companies, before there was a Benefit Association, did pay certain people when they were sick and perhaps the company would be embarrassed to turn over to the association the results of their experience and make it look as if the company were trying to unload a certain obligation or expense; that is probably why some of the companies contribute to the association.

In our case, the company pays for the first week's sickness, half time for hourly employees and full time for monthly employees the first seven days. That has nothing to do with the association. After the first week the employee receives 75 to 100 per cent of his salary for 52 weeks.

The Company Here Shares in Payment of Dues

Dues are arranged so that the company pays one-third and the employees pay two-thirds. The company pays all the administration expense. So in the net result the company pays a little more than half the total expense for sickness but still when talking to the employees we talk about the fact that the employees pay two-thirds and the company one-third. We think it is a good thing for the employee to feel that he is carrying more than one-half the load.

I would like to hear a lot of opinions on how far a company should go in contributing to the upkeep of the association.

MR. ROBERTSON: Our association has, as I have stated, 225 men. We have two classes. Class A covers the employees who are earning less than \$90 a month. There are, of course, very few in that class. They pay fifty cents a month. All the others pay \$1 a month.

Our Mutual Benefit Association went into the group insurance plan and the company agreed to pay half of the insurance premium, which, at that time with about 95 per cent of the employees in the Benefit Association, amounted to \$1,600 a year, so that the company is paying really about \$800. Our dues from the association run at an average of about \$200 a month, which gives us a figure of \$2,400 per year, plus the \$800, which the company gives. You can readily figure out that the men are paying the major part of the money and the total of the claims run about \$1,000.

By that method any death benefits are taken care of by the insurance company and the Mutual Benefit Association is only paying the accident benefits which amount to \$6 a week, that is \$1 a day for industrial accidents, and \$12 per week on sickness. We find with that arrange-

ment we are above water and running along smoothly and giving service to the men which is the primary object of the Mutual Benefit Association.

From our experience it has a tendency to keep your employees satisfied and also lowers your labor turnover, which is quite an item in these days and always will be for that matter.

P. J. KORTSCH (Milwaukee Coke and Gas Company, Milwaukee, Wisconsin): Our company contributes 25 per cent of what the employees put into the fund, providing it is kept up to 65 per cent. We have clocks that the employees punch. As a matter of discipline we dock them for coming late or for missing the clock, and we never felt that that money belonged to the company, so we returned it by putting it into the Mutual Benefit Association fund at both our plants.

MR. WHITE: Our boys seem to feel that they are more on their own feet if they do not receive any cash contribution from the company. In other words they feel better about financing and operating their own project on the cash they put into it themselves and for that reason our company does not make any regular contribution. They would, however, make a contribution if we asked for it, any time. They have so stated that fact.

Employees Are Well Satisfied With the Association

Insofar as our employees are concerned they are perfectly satisfied with the way it is run.

In the group insurance, the company, of course pays all the premiums and that provides for \$500 insurance after 30 days in the service, increasing up to \$2,000 after 10 years of service. We have, in addition, the plan whereby the employees may elect to take an additional \$1,000 at a very low cost.

The fact that the company does not make contributions and that this Mutual Benefit Association is carried on by the employees has tended to create a better feeling in our company and in the plant. I would like to ask the chairman at this point whether or not we are going to have an exchange of opinion here this afternoon on the weekly or the monthly rates or dues and the weekly benefits?

The last gentleman said his dues amounted to from 50 cents to \$1 a week, or month, and that they paid \$6 a week benefits. It seems to me that there are some complications, and to get an exchange of opinion on all cases, such as death benefits and many cases that are unique within themselves, it would almost require the sending out of a questionnaire on the subject. However, if the members here feel that such information would be desirable do you think, Mr. Chairman, we could have that arrangement made?

CHAIRMAN MACPHERSON: Yes, that could be done but there has been information published on this subject and I assure you it is very complicated. It is a big subject and should be given time and thought.

MR. LICHT: It might be a good plan to exchange our constitutions

and by-laws. Then each member could be furnished a list and it could be mailed to them regularly after the information is collected.

(A motion was made that the chairman appoint a committee to go into the question and communicate with the members present at this congress, how far they would be willing to go and how much they wanted to contribute in the way of financing the project).

MR. ROBERTSON: I second the motion.

MR. H. JOHNSON: I want to offer an amendment to that resolution. I like the idea of the exchange of constitution and by-laws. That would give us just exactly what we want in the way of dues and benefits, but it might help all of us possibly to help our own association if we could get some of the good things out of our constitutional by-laws that we don't have time to note as we talk about them here in this meeting. If such an amendment is in order I would like to make it.

(The amendment was accepted.)

CHAIRMAN MACPHERSON: Any further discussion. I would just accept a modification if I may. There are 6,000 delegates at this convention and I do not feel we could ask the various companies to send us 6,000 booklets. I am going to ask the people here who desire such an exchange of information to notify me after the meeting and we will put them on the exchange list and try to get this information for them from all of the Benefit Associations of the companies.

(The motion was passed unanimously.)

CHAIRMAN MACPHERSON: We have gone through with the list of subjects that were scheduled for discussion today. Has anyone any general question or statement to make on this subject?

Problem of Incorporation in the Small Association

MR. LICHT: I would like to ask if any of these smaller associations have found it necessary or advisable to incorporate? Our association is studying out that problem now and we haven't quite decided but we feel as though we must do something before long because if any of those funds were misappropriated the directors would be held responsible.

CHAIRMAN MACPHERSON: We contemplated that very question and took the matter up with our attorneys who recommended that while the association should operate independently, still the recognition of it by the company and by the board of directors should make the Benefit Association a department of the company and that covers our incorporation. The Benefit Association legally is a department of the company.

MR. COON: This is not in strict accord with the discussion right now but the question has been asked as to whether it is a general practice with the companies to set aside time for the directors' meetings.

In our plant the Benefit Association has been in effect a very short time and no provision has been made for that proposition.

MR. SLOAN: We have an association controlled entirely by the employees, while we have the undivided support of the company along

with it. We employ, when we are in full operation, about 1,800 to 2,000 men. We have about 50 per cent of them in membership. Our dues are \$1 per month. We have accumulated about \$1,100, possibly \$1,200 in a period of four years. We pay \$12 a week for sick benefits, \$12 a week for accident, and the accident benefits start after the third day and the sick benefits after the first week off.

Our relief association is incorporated under the state law of Ohio. Our board of directors is elected at our annual meeting for the election of officers. We have a president, a secretary and the board of directors, consisting of nine members.

The board of directors passed a resolution on a motion that any director failing to attend is fined and each director is paid for those meetings by the relief association out of their funds. Each director is paid \$3 a meeting for attending. Of course we are a rolling mill, and rolling mills never operate after 11:00 o'clock Saturday morning. That is the way our association is run and we have been very successful in four years.

CHAIRMAN MACPHERSON: It would be very presumptuous for me to try to interpret the attorney's decision but I think the company would back up any controversy by a member suing the association or for any other situation that might come up.

MR. STALEY: Our relief association was incorporated as a separate association for the relief of sickness and accident and it has been operating very successfully. The company has nothing whatever to do with the management of it. The directors are all elected from the membership and we really try to keep executives from being elected on account of the effect it might have on the membership at large.

Does the Association Pay An Income Tax?

I would like to ask what some of the associations have been doing in the way of income tax, whether they have been paying any or not? That is a question that we have been up against for several years. We haven't paid any yet but we didn't know whether we should set aside a fund for it or not.

MR. RIDDLE: We have been organized for 16 years and have paid no income tax. We are not incorporated. We feel that we are a relief association whereby all money paid in by the members is payable back to the insured. Therefore, we do not come under the state commission of the state or the other association. If we incorporated we would have to lay down certain specific rules that we would have to live up to.

Previous to the war we had paid no income tax and after the war the Government sent on some men and notified us that there had been a special tax placed on relief associations, that this law had been put on the statute books of the United States Government and that we were compelled to pay a certain tax per member for a period, I believe, of three or four years. We went back and pleaded our case and we have

been notified that anything we do so long as it is not for profit is not taxable.

C. W. ALBRIGHT (Morgan and Wright Company, Detroit, Michigan): I will say that in Michigan the general incorporation law passed by the legislature in 1921 provides specifically for the incorporation of non-profit Mutual Benefit Associations. This gives the advantage of naming the association legally to handle all money and to own property and to sell it. That is necessary to carry on the business and does not involve any elaborate, technical organization or responsibility which would be embarrassing.

ADJOURNMENT

Food Section

New Officers of the Section

CHAIRMAN: VERN D. SUTTON

Postum Cereal Co., Inc., Battle Creek, Mich.

VICE-CHAIRMAN: F. A. HASSE

October 26, 1926

VERN D. SUTTON, Chairman

Safety Supervisor, Postum Cereal Company, Battle Creek, Mich.

THE Food Section of the National Safety Council convened in Parlor "D" of the Book Cadillac Hotel, Detroit, Michigan at 9:30 o'clock, Mr. Vern D. Sutton, safety supervisor, Postum Cereal Company, Battle Creek, Michigan presiding.

CHAIRMAN SUTTON: Well, gentlemen, the first session of the Food Section of the National Safety Council will come to order.

We are very glad to see so much interest manifest in the new Section.

PURPOSE AND SCOPE OF THE FOOD SECTION

Vern D. Sutton, Safety Supervisor, Postum Cereal Company,
Battle Creek, Mich.

Ellis Parker Butler, in his very amusing story, "The Great American Pie Company," tells of a couple of old codgers following the occupation of delivering pies baked by their respective wives. Meeting one day with their baskets of wares, they fell into heated argument over the competition each was creating for the other, but finally decided that more profitable than fighting would be to combine their interests and control the market for home-made pies in their village. With control of the market they could raise their prices, and with the extra profit buy up the fruit in season which came into their town, and thus eliminate competition of the commercial bakers.

Following this they might corner the entire fruit market and prevent the manufacture of goods to be shipped in by outside bakers. To prevent overbidding by bakers, canners, and fruit and produce men, they would buy up the orchards and farms and hire the farmers to run them. This would give them control of the wheat as well, and they would have to buy up the mills for grinding the wheat, the lumber and cotton industries for making boxes, barrels, and bags, the railroads for transporting their goods, the steel mills for nails and railroad iron, and ultimately the state legislatures and Federal Congress.

In organizing a Section of the National Safety Council for manufacturers and distributors of foods, we found ourselves with almost as limitless prospects before us as the pie merchants of Mud Creek, Indisourl. All Sections of the Council are closely affiliated with the subject of "Food," because this is vital to life itself and the major part of life's activities center about it.

Take food out of transportation and that industry would find its business greatly curtailed. The Steam Railway and Marine Sections, therefore, are eligible to the Food Section.

Much food distribution is by automobile, and because of this and that customers must be brought to points of distribution, we also welcome the Taxicab and Fleet Owners Section, and the Electric Railway Section.

To provide vehicles for delivery we gladly include the Automotive; and to provide tires and gasoline, also the Rubber and Petroleum.

Our foods must be prepared by heat and we open our doors to the Public Utilities and Mining.

We must have buildings to house our distribution points, and therefore Construction, Cement, Quarrying, and Woodworking are joyfully embraced.

And so we might go on, including Health and possibly, for obvious reasons, Rehabilitation, and all other sections. At any rate, friends, members of all Sections are royally welcome to the Section of Food Manufacturers, Distributors, and, to be more comprehensive, Consumers.

But if our interests are so interwoven with the other Sections, why separate ourselves from them? Because, while our topics are of interest

to them and their topics of interest to us, we may have topics not applicable to them and they have had topics not applicable to the manufacture and distribution of foods. During past Congresses of the National Safety Council, your speaker has found it necessary to try to spread over so many Sections that he ultimately was too thin even for pancake batter.

I would visit the Automotive Section, for instance, to hear a discussion of "The Value of Statistics," and at its termination the next speaker started to talk on "The Hazards of Spraying Bodies." Now we are dealing with the inner portions of bodies, and Duco finish and like subjects are of greater interest to us when we are seeking our new chariot and flirting with the temptation to lay safety aside and step on it out on the highway.

In the Mining Section "The Display of Posters" enticed me into the meeting, but the succeeding topic, "Blasting" frightened me out. If we were brides instead of representing experts in food preparation, we might care to know something about blasting.

In the Metal Section, "Shop Committees" was decidedly appropos, but "Foundry Hazards" did not aptly apply, as our moulding is more likely to be done on a moulding board.

It Is Now Possible to Be Mutually Helpful

So it is readily perceived what agility was required in order that a delegate might hear two or three papers of interest during a session. By having a Section devoted to the Food Industry it should be possible to have all topics on our program of more or less direct interest to all delegates from food manufacturing and distributing concerns.

It will be possible also to be mutually helpful throughout the year by pooling our problems and exchanging ideas. One of the ways in which this can be done is the news-letter. Now, a news-letter is not a book written by the president or secretary, or one versed in letters; it is the views of all members who are sufficiently interested to take part in the discussion, and unless there are contributions from a large number it will be worthless.

We have issued four news-letters, inviting responses in each, and have received just three letters contributing matter to be incorporated, one of which arrived just as I was leaving for the Convention. I'm sure others had something to say, but why didn't you say it? During the coming year I hope you'll say a plenty.

How about the posters of the National Safety Council? A lot of them are not good for the food industry; isn't that right? They will be glad to publish some that are good. What are your ideas for a poster? The Section ought to be able to help the Council get out some fine food posters.

There are many things in which we can help each other. If organization has made possible the great safety movement in industry, in public and in the home, why will not organization of those whose interests are more specifically the same, make possible great achievement in safety among those engaged in the manufacture and distribution of food?

I am going to ask Mr. Wiedenmann to speak along the same lines on "The Purpose and Scope of the Food Section."

DISCUSSION OF THE PURPOSE AND SCOPE OF THE FOOD SECTION

A. H. Wiedenmann, Casualty Reciprocal Exchange, Kansas City, Mo.

Having been associated several years with an insurance institution specializing in only a few industries, all of which with the exception of two, might be classified under the "Food Industry," I have felt the need of a Food Section in the National Safety Council to stimulate the industry's interest in accident prevention.

It may seem strange to those present associated with the food industry, but there are still an enormous number of food manufacturers, large and small, who have an alarming number of accidents, but consider them inevitable or not preventable and take no action to eliminate them. They feel that insurance will make amends for their neglect to preserve life, limb and property. Incidentally these concerns are working hardships on others in their industry as well as themselves.

Wherever our engineers can tactfully do so they recommend membership in the National Safety Council. In the past when the benefits of the Council were outlined a large percentage of our policyholders have felt little good could be gotten out of it because there was no Section to fit their particular needs.

Now comes the establishment of the Food Section, and I feel confident that as soon as we can get the news of the Section broadcasted among the industry generally we shall have one of the largest and most active Sections in the Council. I have some ideas for advertising the Section and feel that if everyone present puts forth his best efforts toward this end, our ambitions will be realized.

I feel statistics can be gotten for the different industries which will bring to light many safeguarding methods not heretofore used. In my experience I have seen hazards which were believed beyond correction for lack of methods. I have even made some suggestions which, perhaps, were not at all practical and have had the engineer explain to me how impossible it was to guard the hazard. And then I have seen this same engineer get a vague idea out of my impractical suggestions and eventually work it into an effective safeguard.

Experience of this kind means only one thing, and that is that each of us may be the means of bringing to these Congresses ideas and suggestions that can help in the solution of problems for somebody.

CHAIRMAN SUTTON: There may be some little discouragement because of the limited representation we have, but it is pleasing to know that we have a larger representation than the National Safety Council anticipated. That is evidenced by the fact that we are over-crowding our room.

In order that we may be well acquainted, I want to say that Mr.

Wiedenmann, who has just spoken, represents the Engineering Department, Casualty Reciprocal Exchange, Kansas City, Missouri; he has been one of the members of the Steering Committee and has rendered very splendid service in organizing this Section.

Another member of the Steering Committee is Mr. Strobhar, Wagner, Tayler Company, Philadelphia, Pennsylvania. I am going to ask Mr. Strobhar to express his ideas along this same line.

THOMAS F. STROBHAR (Wagner, Tayler Company, Philadelphia, Pennsylvania): I did not hear all of Mr. Sutton's first remarks, but I listened to enough to find out he was describing this as the National Safety Council meeting and that all the other sections are subsidiary to ours.

We were presented with a long list of members of the National Safety Council who possibly might be interested in the Food Section. We had expressions from a number of them apparently not being in favor of organizing a separate section. Those letters I believe came mostly from the packers and tanners. They seemed to think that we were trying to take food from them.

We have received one letter, however, from a Mr. Snyder who is with the Griggs Cooper Company of St. Paul. I am going to read a letter that he wrote in, because, I think that letter amplifies some of Mr. Sutton's remarks on the subject. The Griggs Cooper Company are manufacturers and wholesale grocers.

Letter From An Interested Food Manufacturer

"Your letter in reference to the organization of the Food Section of the National Safety Council received, and in answer will state that this movement has my hearty cooperation. In regard to the problem of accident prevention in my plant, I would say that we are in rather a unique position owing to the peculiar condition of our factory.

"In the first place we operate a 60-oven cracker bakery, making all kinds of crackers and cookies, from the cheaper grades to the highest in the market. The plant is extensive and very complete. Next we have a large candy factory which is also complete in every detail, making a general line of candy of every description. Then we have a complete roasting establishment, spice grinding machinery and extract department and other departments where we manufacture and pack baking powder, soda, and starch. In another department we prepare and bottle pickles and olives. In connection with this we also have a vinegar department where vinegars are reduced and put up in barrels. Then we have an extensive preserve and syrup department where we make a complete line of jellies and jams and put up all kinds of syrups and molasses.

"In conjunction with these factory units we have just constructed another building to take care of our large jobbing business which heretofore has been located down in the center of St. Paul. We have our own refrigerating plant with large coolers where we store tons and tons of raw material of every kind. We have just constructed a large garage

because we cover both St. Paul and Minneapolis with our truck service.

"You will see, therefore, from this brief resume that our hook-up, if you will pardon the term, is rather unique. We have a great deal of machinery in these various units of our factory that would possibly not be found in another establishment of a somewhat similar character. We have them all safeguarded and in our past experience have had a very low percentage of lost time accidents." (You see, that, perhaps, is why he is not here today. They are perfectly satisfied with what they are doing, but we will show them up later in the things we want to bring out.)

"In thinking over what part of our institution would probably interest manufacturers of food as safety problems"—you see, this is a news letter item he is bringing right here—"the thought comes to me that we have one thing that no doubt every manufacturer of food some way or another uses—the steam jacketed kettle, which is used throughout our plant and they are very hazardous. We have had a number of blow-ups in times past and one just recently where the bottom of a large kettle blew. Fortunately we have had no serious accidents result from the blow-ups, but if some course could be taken whereby all steam jackets could be made uniform with all popular safety facilities I believe this one proposition would be very effective in national safety work."

Now, I took the trouble to salvage that letter from among the number that we received in our steering committee work, thinking that it would open up avenues of thought and use in this Food Section from other members, and also to get those who are members and who are affiliating with the Section to go after the other manufacturers that we would like to have reap the benefit from the Section work that we are going to put out.

The Food Industry Shows Need of a Food Section

One of the other particular reasons for having a Food Section, aside from all the things Mr. Sutton brought out, is its use, its universal use. As you go over statistics, for instance, in the state of Pennsylvania, the manufacturing state, for the first six months of 1926, we found that the building and construction program showed an increase of 44 per cent in accident frequency. Food section, plus 66 per cent, the outstanding one of the entire list. Textiles, three per cent; publicity minus 41 per cent. Hotels and restaurants, plus two per cent. Metal workers, plus 10 per cent. Now, if that applies in Pennsylvania, (and no doubt it applies in other states, as well), if those interested in food show an increase in accident frequency of lost time accidents of 66 per cent, that industry needs help.

At this Congress, I believe, the Construction Section is going to ask the National Safety Council to provide a paid secretary. They are claiming that they are the largest industry; that is, that the Construction Section represents throughout the country the largest wealth and that they had the highest accident record. No doubt they do have a

great many accidents and they do need help, but when we take frequency of accidents—lost time—plus 66 per cent in one state, I know that by cooperating together in a body, exchanging ideals, helping each other, that we can not help but show something like the public utilities here show in a minus 41 per cent.

CHAIRMAN SUTTON: In order to perpetuate this organization it will be necessary that we have officers and at this time I am going to appoint a Nominating Committee who will report at our session tomorrow morning. I will appoint on that committee Mr. F. A. Hasse, of the Corn Products Refining Company, Mr. H. T. Eggert, of the National Biscuit Company, and Mr. S. H. Kershaw of the National Safety Council. These gentlemen will report their nominations at our meeting tomorrow morning.

The matter of steam jacketed kettles has been very splendidly introduced already into this meeting and we are now to know something about this subject. Mr. J. T. Morrison, chief inspector, Hartford Steam Boiler Inspection and Insurance Company, Chicago, Illinois, will speak on that subject.

STEAM JACKETED KETTLES

J. P. Morrison, Chief Inspector, Hartford Steam Boiler Inspection & Insurance Company, Chicago, Ill.

(Accompanied by lantern slide projections.)

One identified with the Hartford Steam Boiler Inspection and Insurance Company derives great pleasure from attending the National Safety Congress for we have been engaged in "Safety First" work for something over 60 years. In fact, I am confident in saying we were the pioneers in that field. Our first policy of insurance, issued about 60 years ago, and subsequent policies, carry the provision that our inspectors have reasonable access to the boiler, steam jacketed kettle, or other insured object, for the purpose of making inspection to prevent loss of life, injury to persons, and damage to property.

When the inspection work was inaugurated, the steam boiler was looked upon as the source of energy most likely to get beyond control and wreck the surrounding property, but as industries developed and changing living conditions resulted in the establishment of immense food preparing plants, in which the old-fashioned preserving kettle, which the housewife had used on the kitchen range, was replaced by vessels of much greater capacity, using steam instead of the direct action of the fire as the heating element, the safety of such equipment naturally became one which concerned not only the owner of the establishment but the public in general, as the explosion of a jacketed kettle or rendering tank was quite likely to be disastrous.

Those things having a direct influence on the safety of steam jacketed kettles, retorts, rendering tanks, and pressure vessels of most every description, may be grouped under the classification of material, design, construction, installation and operation.

The material should be suitable for the purpose intended. Many of the acids and gases which result from food preparing processes, have a rapidly corrosive effect upon iron and iron alloys, while they may affect to a less extent such materials as copper and aluminum. On the other hand, the vessel of copper and aluminum may not safely withstand the pressure which could be carried upon a similar vessel constructed of steel.

Assuming the material and design of the vessel is all that it should be, the methods of construction employed by the manufacturer may be such that the vessel is irreparably damaged, and does not possess a sufficient margin of safety when it reaches the purchaser. Such imperfections may be so concealed by other parts of the structure that they can not be detected until failure takes place. A means of avoiding methods of that kind is to provide in the specifications for rigid shop inspection by an expert representing the purchaser. We frequently encounter the excuse, "That's good enough," when material or workmanship is criticised by the shop inspector. I know of nothing which will undermine and destroy the workman's judgment more rapidly. The man who is continuously being satisfied with inferior goods because it is "good enough," soon loses the power to judge and appreciate perfect work.

A Copper Hemispherical Jacketed Kettle

You will recognize the accompanying slide as representing a copper hemispherical jacketed kettle, such as is used in the majority of food preserving plants. The outside shell of the jacketed section is exposed to stresses tending to pull the copper sheet apart, while the inside shell is subjected to collapsing stresses, which copper, as a material, is poorly equipped to resist. The small cross section illustrated, gives an idea of the manner in which the material was stretched during the process of manufacture. This reduction in thickness could not be detected after the parts were assembled, so the vessel continued in operation without its weakness being suspected, until it failed quite violently, causing the death of two men. The manufacturer of such equipment should know if his finished product possesses but one-third the thickness, and one-third the strength the material had before fabrication was commenced.

We encounter a great variety of methods of connecting up food cooking equipment. In some cases there is a safety valve on one steam line leading to the kettle, although there may be two or more such steam lines without any pressure regulating device. Again, the safety valve intended to protect the vessel from an over-pressure may be located directly on the vessel, which, in the case of rendering tanks and objects used in kindred service, is prohibited, as the contents of the tank are quite likely to obstruct the safety valve if it has occasion to operate, so future operations will be seriously interfered with, if not absolutely prevented.

The food preparing plant should be equipped with a sufficient number of steam headers, that each vessel of a certain pressure classification may

be connected to the header carrying that pressure, and the steam header should be provided with a stop valve, pressure regulating valve, safety valve and pressure gauge, of sufficient capacity to meet the requirements of all the vessels connected to it. A jacketed kettle intended for but 20 pounds pressure should not be connected to a steam line carrying 80 or 100 pounds pressure, with the thought that the attendant will regulate the steam flowing to the jacketed kettle with such precision that the 20 pounds pressure will not be exceeded, unless the branch line leading from the higher pressure header to the lower pressure object, is equipped with proper safety devices, consisting of a stop valve, pressure regulating valve, safety valve and steam gauge.

- E-edge of flange $\frac{1}{16}$ " "

Kettle -

Copper - 500 Gallons
54" diameter x 27" deep

Drawing of a copper hemispherical jacketed kettle.

In our inspection work we are frequently confronted with the statement that a certain condition, which has been criticised, has existed for weeks or months or years, and an accident has not occurred. If such reasoning is carried to its logical conclusion, we might be just as sure that we shall never die, because we never have. I was impressed with a news item from Washington, D. C., which appeared in the daily press recently. A blacksmith is said to have had 25 years of experience at his trade, and during that time is estimated to have put on 100,000 horseshoes, which would correspond to an average day's work of shoeing three horses. He had been quite fortunate, and had never suffered injury. However, a few days preceding the date of the news item, the horse-shoer entered his chicken yard. His Plymouth Rock rooster jumped up and kicked him. The spur entered the knee between the joint and the kneecap. The blacksmith is on crutches, with the probability of being a cripple for life. So do not let anyone tell you that because an undesirable condition has existed for a number of years, it should not be remedied.

There seems to be abroad in the land the idea that steam at 80 pounds pressure contains twice as much heat, and will do twice as much work in one-half the time, as will steam at 40 pounds pressure. So the plant superintendent, anxious to increase production, and reduce production costs, is inclined to carry a higher pressure on the jacketed kettle than that for which it was intended. I have in mind the chef of a large kitchen which was equipped with a large variety of food cooking vessels, upon which 100 pounds pressure was carried, although the margin of safety required by good practice would limit the pressure to 40 pounds. In fact, one of the kettles was tested to disruption, and failed when the hydrostatic pressure exceeded 100 pounds but slightly.

The chef would not agree to a reduction in pressure, but when a pressure gauge was so adjusted that it traveled from zero to 100 pounds, while the pressure actually was increasing from zero to 40 pounds, and the regulating devices were set to control the pressure at 40 pounds, the chef was entirely satisfied. He could not tell the difference between 40 pounds and 100 pounds by results, but depended entirely upon the pressure gauge, which in this case had been purposely calibrated to deceive him.

The Incident of the Michigan Cheese Factory

Before considering seriously any plan to exceed the safe pressure on a jacketed kettle, tank or retort, try setting the pressure gauge a few pounds ahead, and see if the results are just as satisfactory. The increase in pressure from 50 pounds to 100 pounds, increases the stress in the material 100 per cent, and reduces the margin of safety by 50 per cent; while the heat contents of the steam at 100 pounds pressure is but approximately one per cent greater than in steam at 50 pounds pressure.

Just by way of emphasizing the little thought given to even primary safety requirements by some people operating pressure vessels, I would mention a recent experience of one of our Michigan inspectors. He visited a food preparing plant. As a matter of fact, it was a cheese factory. He was to make the preliminary inspection of a boiler which had previously been uninspected and uninsured. Aside from a number of defects resulting from operating conditions, the boiler appeared to be an average risk. But the inspector could not locate the safety valve. Upon inquiring of the engineer he learned that the factory inspector had visited the premises but a short time before, and that during the visit the safety valve of the boiler operated automatically. When it did so, a considerable cloud of soot was discharged from the boiler-room into the cheese making department. Quite naturally the factory inspector objected to the preparation of food in just that way. Those in charge interpreted his objection as being directed at the safety valve, and proceeded to remove the offending member just as soon as the boiler could be taken from service. They explained to our inspector that the factory inspection laws of Michigan do not permit the use of a safety valve on a boiler in a cheese factory. It had apparently not occurred

to them that the safety valve could be adjusted to discharge in some other direction.

"Familiarity breeds contempt." The truth of this old saying appears to us quite frequently. The man who has observed a certain pressure on a certain vessel daily for a number of years, soon becomes of the opinion that everything is safe and serene, and that there is no cause for uneasiness. Forty or 50 pounds pressure is quite low when compared to the 1,200 or 1,300 pounds pressure now being carried in some of the central stations, but those boilers and turbine casings subjected to that pressure possess a relatively larger margin of safety than does the ordinary jacketed kettle or rendering tank carrying 40 pounds.

After an explosion in a rendering tank at St. Louis.

The accompanying slide pictures the results of the explosion of a rendering tank when carrying 40 pounds pressure. The failure resulted in damaging a considerable part of the plant, as well as in the death of one man, who was decapitated, and the serious injury of another. The investigation which followed developed the fact that the rendering tanks in the establishment had been examined thoroughly during the month of June. Several of them were found to be so badly corroded they were considered unserviceable, and accordingly were disconnected from the steam header. The tank which exploded, and the one adjoining it, were criticised, but it was estimated they could be continued in service until the first of the year, possibly a term of five or six months. The inspector understood those tanks which were immediately removed from service would be replaced with new ones, but such was

not the case. The balance of the tanks were continued in service approximately 24 hours a day, so the deterioration was twice as rapid as the inspector estimated it would be. The explosion occurred on November 13.

A vertical rendering tank showing corrosion.

It is logical that some means be devised to detect the deterioration which takes place in cooking vessels, so plans can be perfected for replacing the old ones with new before the point of failure is reached.

The third side is intended to represent a vertical rendering tank, with which our packing houses are equipped by the thousand. In the sectional view you will note the manner in which the internal surface has been corroded until the tell-tale holes have been reached, resulting

in slight leakage, to be taken as a warning of the decrease in thickness which has taken place. Under ordinary operating conditions, the tell-tale hole may be closed by a wooden plug until the "cook" is completed, and after the tank has been emptied, may be permanently closed by the use of a one-quarter inch rivet driven cold.

These tell-tale holes are one-quarter inch in diameter, and drilled one-quarter inch deep from the outer surface of the shell of the average size vessel, say 72 inches in diameter, and are located opposite the region of greatest wear, which occurs on the inside surface of the tank. This plan, with certain modifications, can be applied to pressure vessels of all descriptions, where the operation is likely to cause a reduction in thickness, and weaken the vessel.

The operation of a pressure vessel, such as a jacketed kettle, rendering tank, retort or compressed air tank, may not in every case present a hazard equal to that encountered with the operation of a steam boiler, for the steam boiler has temperature stresses, and is subjected to the changes which result from the use of impure feed water; but the cooking vessel is subjected to some temperature stresses, may be affected by acids and gases, and, in general, is operated by men having little or no mechanical training, undependable in an emergency, and properly enthusiastic in catering to the needs of the inner man. So I would urge that some competent authority be consulted when new equipment is purchased, and that you have a survey made of that now in use, to determine if life and property are being needlessly exposed to danger.

Discussion Following Mr. Morrison's Paper

CHAIRMAN SUTTON: Would anyone like to ask Mr. Morrison any questions or make any comments on this paper?

MR. STROBEAR: I should like to ask regarding the location of the relief valves on the cooking utensils. You spoke as though they were to relieve right at the utensil; is that customary?

MR. MORRISON: The relief valve and all the safety devices should be on the steam line furnishing the steam to the cooking utensil.

MR. STROBEAR: I get that all right, but perhaps the relief should blow off in the room. You were talking about the cheese factory and the boiler blowing off in the cheese room in making Roquefort cheese, which they had not anticipated. Now, the question comes from the picture you were showing and the description you indicated on that slide.

MR. MORRISON: That is one point I did not go into. I did not go that far with it. This should not discharge in any place that would be likely to injure a workman. Ordinarily those pipes are piped to six or eight feet and discharged upwards. They do not need to be located in the room. They can be located at any place. You have brought up a thought of something that occurred in Detroit not so very long ago in a large automobile plant. The safety valve on a boiler discharged right toward the man-hole of another boiler and when that safety valve blew, two men working in that other boiler were killed. Those safety valves

should discharge so that it would not likely injure anyone by escaping steam which is quite hot, but I did not go quite that far.

MR. STROBBER: I had that in mind when I asked the question. The other was the possibility of taking some legal action against the manufacturer of that kettle. Were you able to recover on account of any negligence on the part of the manufacturer when he made a copper jacketed kettle such as you described, as being one thickness in one place and another thickness in another place—one thickness at a joint or bend? I inferred that it was extreme negligence on the part of the manufacturer to make an apparatus of that kind.

MR. MORRISON: That was not done and I would say that after that had been in service a year, it would be hard to establish the manufacturer's responsibility.

CHAIRMAN SUTTON: Safety is practically synonymous with far-sightedness and in making safeguards and corrections of hazards it is always necessary, as has been brought out in this discussion, to be very certain your safety provisions do not create another hazard. We have found that very frequently.

We have another interesting talk, in fact, two more which I believe will apply more or less directly to all of our industries. The first is by Mr. G. C. Agry of the Lanson Company, Syracuse, New York.

HANDLING OF BAGGED AND CRATED MATERIALS

G. C. Agry, Special Representative, The Lanson Company,
Syracuse, New York

While I am admittedly new to this particular group meeting and its intents and purposes, I have endeavored to read, behind the actual subject assigned, the intent which caused the assignment. I have given careful thought to what form of message would prove of greatest interest to this important branch of the National Safety Council. With a desire, therefore, to give you as constructive a message as possible, I am taking the liberty of broadening the subject assigned to me and have given it my own interpretation, which is perhaps best summarized in the following rewording: "Safety in Handling Package Loads." My discussion, while particularly applicable to food plants, has many factors which have equal application in most other forms of industry. I hope the very broadness of its scope, therefore, will have a particular appeal.

Some ingenious person for convenience of memory, has divided the common forms of package loads into what he popularly terms "the six B's." They are: Bags, Boxes, Barrels, Bundles, Bales and Baskets. Of course, as particularly applied to the Food Industry, there are many subdivisions of these, and there are forms of containers in common use which are not adequately described by any of the six "B" terms, such as Cans and Bottles. But for purpose of having in mind what is meant by pack-

age loads, the six "B's" will serve excellently, and further description of packages will be given as we have occasion to make mention of them.

It will be well appreciated that the advantages of mechanical movement and handling of materials have been largely viewed from other aspects than that of safety. In the use of automatic conveying machines, emphasis has been largely laid on such important factors as, speeding production, saving in handling labor, reduction in floor space requirements, reductions in cost of manufacture and similar production and cost minimizing considerations.

Let us, however, take these four items and see how many safety factors are automatically incorporated in them. Let us do this by comparison methods.

Speeding Production

Picture a plant not equipped with modern conveyORIZED methods in which the necessity of increased speed of production has become essential. It is difficult to describe adequately all factors. Probably, however, it will be necessary largely to increase the force of laborers devoted to handling and trucking materials, raw, in process, finished product. Can any such increased handling force be used with full efficiency? It is doubtful.

If unloading platforms and storage space for incoming material have been adequate under former conditions, necessity of increasing volume of production by increased handling labor is almost certain to result in increased congestion and confusion throughout the incoming materials division. The same is true, probably in even greater measure, as concerns the handling of work in process. Aisleways are likely to become overcrowded. The injury hazard is not only increased by larger numbers of people passing to and fro for the carrying of materials, tending towards accidents due to collision and dropping of materials, but overcrowded aisleways tremendously increase the danger that not only handling labor but machine operators will be jostled or bumped in a manner so that clothing and parts of the body become caught and entangled in machinery.

Finished products in the increased volume brought about by greater speed of production must be handled into storage and out to shipment—but how? If handled by increased labor, the hazard of collision accidents along loading platforms oftentimes adjacent to railway sidings is increased; strains and over exertion casualties in finished stock warehousing operations are subject to increase, not only because of larger number of workers, but because of the haste and necessity of work under tension.

Suppose in contrast we substitute for attempts to speed production with larger man power facilities, conveyORIZED movement of material, incoming along receiving platforms and into storage; through the processes of manufacture, to and from the various machinery operations within the plant; and out to freight car or auto truck loading of finished product and into finished product storage.

Taking these in order, we shall then have for incoming material a system of conveyors arranged in logical manner along unloading platforms and into storage. The man-handling of materials will in general consist merely of placing the materials on the conveyors at the loading point and removing them at the opposite end. Peaks of handling and necessity of providing speed in movement of incoming materials can readily be taken care of by a properly controlled conveyor flow, for mechanical conveyors can be made to run at a speed in excess of the maximum rate at which materials can be placed on and removed from the conveyors. Under such conditions there will be no increased congestion or confusion in handling incoming materials under necessity of speeding production.

Similarly, conveyors for handling material in process can be arranged to give a logical flow between operations. Many times even the removing of loads from conveyors can be taken care of by automatic deflectors. Speed in production with conveyORIZED movement of materials eliminates necessity of otherwise traffic crowded aiseways. Some conditions will permit of placing conveyors on ceilings and in all events, since there will no longer be necessity of people moving about aiseways carrying or wheeling articles in process, collision, dropping of loads, jostling of operators near machinery and similar hazards will be entirely done away with.

The use of elevating conveyors for raising loads between floors, and of chutes and spirals for downward passage of material, eliminates the hazards incident to the operation of elevators for materials handling movement. Involved in this are all the well known dangers of elevator operation, the getting of loaded vehicles or hand carried loads on and off of elevator platforms and similar considerations.

Conveyors for the loading out of finished product into railway cars, auto trucks and into warehouse storage will be, for the most part, non-reciprocating. A movement of finished product by conveyors does not nominally require a return of an empty container for reloading. If such is required, returning loads are arranged to flow over a uniform, well designed and adequate pathway. The condition is in contrast to outward passing loaded trucks with returning empties and the hazards of confusion, collision and excessive strain under pressure of speed. Conveyors can properly meet any necessity of speed in handling, and warehousing operations are simplified by conveniently arranged conveyORIZED movement to and out of storage.

Saving in Handling Labor

The safety factors involved in this production item are obviously allied with those previously brought out.

There are many operations in industries which can be done only by human hands and human intelligence—plenty of such operations go around. The more we can relieve labor from performing as a truckhorse or beast of burden, the more we reduce the hazard of strain, flat feet and

casualties resulting from overtired physical condition. Reduction in numbers of material handling laborers of course reduces hazards in proportion to numbers.

Reduction in Floor Space Requirements

From the standpoint of production it is very evident that factory floor space should be devoted to machinery and manufacturing operations and not to storage of materials in process. Much emphasis in connection with the consideration of the use of conveyors is therefore rightly laid upon reduction in floor space requirements through making as large a percentage of actual factory floors available for manufacturing operations as possible. Let us consider for a moment then, what is the effect on safety factors of this improvement in use of floor space.

A plant operated without modern handling methods and utilizing a considerable portion of floor space for storage of materials in process evidences considerable accident hazard, due to materials standing about machines and piles of unfinished merchandise stored in various places around operating floors. Trays, boxes and containers of one sort or another; standing trucks, platforms and similar paraphernalia promiscuously standing about machines and aiseways increase the hazards of stumbling falls. In many plants where the movement of materials from operation to operation is dependent upon the intermittent arrival of labor, it is necessary that goods in process shall be placed in temporary storage in an unavoidably haphazard arrangement about machines and other forms of manufacturing operations, awaiting the arrival of the laborer who is to move these goods.

Such standing merchandise, especially with unavoidable lack of uniformity of location at all times, is unquestionably a fall and bruise hazard. We are all creatures of habit. Witness how successfully we move about a darkened room at night when all pieces of furniture are in their usual place, but how quickly we stumble and bruise ourselves on articles out of their accustomed location, even though we ourselves may have placed them in their new position but a few moments before. In similar manner, operators, with minds intent upon production, find difficulty in moving about floors with promiscuously placed merchandise.

Then, too, standing merchandise has an important effect upon proper lighting at machines and other operations.

Standing merchandise creates an extremely dangerous hazard when it prevents accessibility to machines in case of accident either to machine or operator.

The extent of hazard resulting from fire with piles of unfinished merchandise standing about manufacturing floors is obvious.

Again, standing materials in process are often a detriment to efficient supervision and departments operated with imperfect superintendency obviously offer greater accident hazards than do departments which, because of fully supervised orderly methods, function with standardized efficiency.

There are many other angles from which this interesting consideration can be viewed, but time permits me to stress only a few of the reasons why a consideration of methods of reduction in floor space requirements, through the employment of mechanical carrying devices, automatically improve the casualty hazards. In general, conveying machinery can be arranged to give uniformity in flow of material from operation to operation, can be placed in a manner largely to eliminate idly standing merchandise, and where storage between operations is necessary, such can be provided for in uniform manner, at definite locations where all hazards of light, accessibility to machines, fire precaution requirements, and proper supervision have been definitely considered. Very frequently, too, the utilization of conveyors suspended from the ceiling will provide a large amount of "conveying storage." I mean that goods are in storage while they rest on the conveyors; and since in the latter instance the conveyors are suspended from the ceiling, adequate storage space is provided with the merchandise entirely removed from the manufacturing floors.

Reduction in Cost of Manufacture

This is the last of the four commonly stressed production factors which I have suggested. It is obviously so wide a subject that lengthy discussions could be given to it alone. Let us briefly consider only a few of these.

Oftentimes excessive costs are brought about through a lack of uniformity in the timing of flow of material. Intermittent man-handling of goods in process brings about time almost of idleness about machines and other operations, during periods when operators are awaiting the arrival of new work; while in marked contrast there are peak periods when congestion of work is so much in evidence that operations must be performed with extreme haste under pressure. Such peak conditions may become extremely tiring to operators. Haste of itself, when operators realize that an abnormal amount of work must be performed in a brief space of time, brings about a psychological condition in the manner in which materials are handled and work performed, which is not conducive to safety.

Perhaps one of the outstanding performances of conveying machinery in general is to bring about uniformity in flow of material. The pace is set for proper performance of work and goods pass forward continuously and uniformly, according to standardized methods carefully determined upon. There are no periods of breathless haste supplemented by periods of comparative idleness. Proper relaxation is taken care of by definite rest periods, and expertness during working hours is brought about by uniformity in volume of work to be worked upon.

Another important item in the reduction of cost of manufacturing often revolves around the consideration of reducing the interval of time of manufacture. It is frequent that the time necessary for the complete manufacture, inspection, packing and shipping of products can be re-

duced as much as two-thirds through the installation of systematic uniform methods of handling materials through all processes. While the chief factors of such accomplishment involve large financial savings in goods in process and permit that manufactured articles be turned into profitable sales much more speedily than would otherwise be possible, it is evident that from the safety side, such accomplishment in reduction of interval of time of manufacture can only be brought about through simplified, uniform, systematic methods of handling throughout. All reductions in handling decrease accident hazards in proportion, and especially is this true if handling methods are scientifically studied and worked out.

CHAIRMAN SUTTON: His talk has been so complete and lucid I think there is very little we could misunderstand about it.

A recent no-accident campaign on the part of neighbors of my own company, the Kellogg Company, enlisted my interest so heartily that I found myself participating in spirit almost to the same extent I would have, had the contest been in our own plant. When finally a lost time accident occurred, you can imagine the feeling I experienced, and we have with us Doctor Arthur C. Selmon of the Kellogg Company of Battle Creek, who is going to talk to you, I hope, on the no-accident campaign to which I refer.

"NO-ACCIDENT CAMPAIGNS"

Dr. A. C. Selmon, Kellogg Company, Battle Creek, Mich.

This paper will be based on the "No Accident Program" which we are following in the Kellogg Company factory. While we were proud of our past low accident record, yet the very much lower accident rates reported by certain other industries assured us that we could do more than we were doing to decrease the sum total of mutilation and suffering resulting from injuries sustained in our plant.

Beginning with July of this year, we started on a program that is producing very gratifying results. In the recent past our plant averaged a lost-time accident for every 70,000 man-hours. July and August have always been our worst months for accidents because during these months we have a large number of new and untrained workmen. But in spite of this handicap, under our new program we put in 700,000 man-hours without a lost-time accident instead of 70,000, which had been our average previously. For the 71 days, from the first of July until the ninth of September, our Safety banner was not lowered once, a record many fold better than any previous one in our plant.

The main objective in a "No Accident Program," as I conceive it, is to take men and women who are already well stocked with old, careless habits and root out these, planting new and better ones in their stead. We started out by attempting to get every employee thinking and talking about Safety First. It is surprising that even in the best regulated factories workmen get into the habit of doing many thoughtless and

careless things. To break these habits requires at the outset something in the nature of a decided jolt or shake-up.

We put up bulletins offering a reward for the arrest of the cause of accidents, and asked for slogans, suggestions, posters, etc., bearing on accident prevention in the plant. The price paid for the usable ones was large enough to make it worth striving for. Slogans and suggestions poured in by the score. They came from men and women in every department, from janitors to foremen.

A sub-committee from our large Safety First Committee met daily for the first few weeks, and later two or three times a week, to go over these contributions and select the best ones. The usable ones were posted throughout the factory, together with the names of the authors.

Thought was given to methods which would be most effective in making use of the "eye-gate." A large safety banner was made and hung in such a location that one could not pass the time clock without seeing the banner. When there is a lost time accident, the banner comes down for a whole day and its absence is so conspicuous that it strikes you with almost as much force as though the floor had been taken up.

A Gold Banner at End of a No-Accident Month

We started with a green banner and when the month of July was passed without a lost-time accident, we replaced it with a gold banner. When the demon of carelessness finds his devilish way to our factory and we have an accident, the gold banner comes down and the green banner goes up again, but it carries a gold star for each month passed without an accident, in order to keep prominent the record of past achievements. The gold banner replaces the green one at the completion of a full month without a lost time accident.

In the use of slogans, bulletins, posters, etc., staleness must be avoided. A single fresh slogan or poster every day or every couple of days, is noticed and read, whereas if the board is posted over with a number of bulletins, the men, seeming appalled with the effort required to do so much reading, only give a passing glance and do not stop to read. Fresh posters or bulletins every day or two lead the men to form the habit of stopping at the bulletin boards daily—whereas material left on the boards for several days gets stale and destroys this very valuable habit. Even such a minor thing as changing from day to day the location on the bulletin board of the bulletins and posters is well worth while.

We make use of a large, three-sided pedestal-like bulletin board for extraordinary announcements. When in use this is placed in the lobby in such a position that one or the other side directly faces every person passing in or out of the plant. When an accident happens and the safety banner is taken down, a bulletin is posted immediately on this board, giving name of the injured, nature of injury, how it happened, department where he was working, etc.

In checking up on the adequacy of guards and the presence of hazards, a safety first man of wide experience was invited to spend some time

working with our own safety inspectors. At the time of instituting our present program the whole plant, from cellar to garret, was given a thorough going over. This is very essential because even a very good safety first man who has continually inspected the plant may fail to note things that need attention. So it is worth while occasionally to get in a man who is not familiar with the plant, just for the sake of a check-up on things that may have been overlooked.

When making safety first inspections, examining guards, looking for hazards, etc., there is an educational value to the workmen in doing this ostentatiously. By making a certain amount of show of the work the men will be impressed with the importance of everything that has to do with accident prevention. The men should be encouraged to point out to the safety inspector anything they think is a hazard and he should get their suggestions. In this way he will often pick up something of value. Whatever he does, he should not give out the name of the man who reports these things, if by so doing there is any possibility of getting him in bad with his foreman or fellow workmen.

A Small Safety Committee a Mobile Unit

Accident prevention work covers every phase of a plant's activities and we have found it essential in our factory to have a small safety sub-committee of four or five men who form a mobile unit, giving prompt attention to everything connected with safety work. They promptly investigate every accident and as far as possible assess responsibility, considering such factors as whether the accident was due to lack of proper guards, neglect of foreman to instruct the man, carelessness on the part of fellow employees, or whether it was due to carelessness or disregard of safety rules on the part of the injured man himself. The result of their investigations is put in writing together with any suggestions as to measures to be used in avoiding a recurrence of such an accident.

Many of the near-accidents, that is, minor accidents which come near to being serious ones, should be looked into by this committee. The hospital staff and the foremen must cooperate in this accident prevention work. It rests with them to get the data on how and where these near-accidents occurred. This information must reach the small safety committee without delay.

Upon investigation it will often be found that the stage was all set for a crippling accident but an overruling Providence in some way mercifully intervened. It may have been due to a piece of gross carelessness or to disregard of safety rules, and should this be the case, if the party responsible is given a few days layoff, the lesson to him and to his associates will be driven home and clinched.

Activities of this nature have great educational value and therefore are well worth the effort. It is a case where a "stitch in time saves nine." The men are brought to realize that accident prevention is as much a part of their job as is the oiling of their machines. They find out that accidents, near-accidents, and disregard of safety rules are really serious affairs.

CHAIRMAN SUTTON: Are there any questions you would like to ask Dr. Selmon?

MR. STROBHEAR: You brought up a very interesting subject when you talked of near accidents. So few of the companies keep a record of the near accidents. I would like to know if you have the relationship of near accidents to accidents. Do you keep a sufficient record to chart and show how they bear to lost time accidents? If you know what an accident costs, you can readily see the value of the safety work.

DOCTOR SELMON: You understand, I am a novice in the whole safety work. Medical work was my line, but it struck me this is the finest piece of preventive medicine that can be done any place or by anybody. That is what interested me in this work. If we went along at the old rate we would have 19 people with eye or other accidents, whereas we only had three; so I can visualize that bunch of 16 people with fingers on their hands and eyes in their heads that can see. That appealed to me and as a result we had a check up on those near accidents. That is where the nurses and doctors in the medical work must cooperate by carefully and diplomatically inquiring into how this thing happened and finding all about the people concerned and all the factors concerned. But we haven't been going long enough to get this proportion that you mentioned here. We will have that in time, but to give you figures now would be of no value at all because the time is too brief.

Green Favored as Color for Safety Signs

MR. WIEDENMANN: I am not criticizing Dr. Selmon's signs at all; I think they are very fine; but there is one thing that I noticed and that is red. We have quit using red almost entirely on any sort of safety signs and are using green. I think it is more restful to the eyes, draws more attention, and is certainly a positive color for safety.

DOCTOR SELMON: I accept that criticism. It is well taken.

MR. MORRISON: I would like to inquire about the plan of positively fixing responsibility for the accident, or at least, broadcasting the responsibility. That is something of an innovation. I would like to know how it is received in general by the employees. Now, that is one of the British methods in case of a boiler accident. They classify them, minor and major. In case of a major boiler accident resulting in considerable injury or death they hold an investigation and not only fix and publish the responsibilities but frequently in a measure fine the responsible workmen, the money so paid being turned over to the injured party or the defendant, as the case may be. In a sense, making the party responsible for the accident contributes toward compensation payments.

DOCTOR SELMON: This is the only instance of the kind that we have had, but after carefully investigating the case in question and consulting also with the man's fellow workmen, there was no question at all about his negligence. So far as we can see it had a very wholesome effect, and as far as the man himself is concerned, I think he rather accepted it that he had been careless and something was coming to him.

We were very discreet about it and considered it from the stand-point of his fellow employees, whether we were doing him an injustice; that is one of the things we must not do, treat them unjustly.

MR. AGRY: I would like to ask Mr. Wiedenmann concerning his comment on the use of red. I am new to safety councils of this sort, but I visit a great many plants and I venture to say that 80 per cent of the plants I visit do have red signs. I notice that whenever I go into a plant I always read the red signs. I wonder what the experience of the council has been? Has the experience of the council been such that they feel that green or red is the best color?

MR. WIEDENMANN: I think the red signs are good for fire apparatus and things like that. Red is all right for a single danger sign or something like that, but for safety instruction I think green is far better. I have made some tests with that in a few plants and it has met with their hearty approval.

More Posters for Food Section Next Year

MR. AGRY: There is a little feeling that the use of too much red is bad.

MR. WIEDENMANN: Yes. We consider green a positive color.

MR. EGGERT: I think it is wise practice to change your colors every week or two, or every month. If you leave the same color they think it is the same sign and it doesn't create the interest necessary to accomplish what you are after.

CHAIRMAN SUTTON: At the beginning of the meeting we spoke of the possibility of getting some posters for food members, I think we have found that there is a talent in the Food Section and we should make an effort during the coming year to get out some food posters or to assist the National Safety Council in getting out some.

This banner to which these slogans and posters are attached, covers one which the Council put in here. Now, these bulletins, which you can not now see, are all usable in our industry, but do they carry the forceful message that something especially applicable to our business would? This emphasizes, I believe, the need of endeavoring to get out some Food Section posters.

MR. STROBBER: I don't want to make any comparison. I think we might get ourselves in a little bad here if you are trying to compare the posters as issued by the National Safety Council against one issued by one of our members. We are selling the National Safety Council service and along with that goes the use of posters which our members may procure. I think we might, as a Section, appoint a committee on posters, and either ask our members or others to contribute posters, material and experiences which may be turned over to the National Safety Council for use among our members. If you wish to stimulate that income of posters I am perfectly willing to offer a personal prize for the best one that the committee might select or something of that kind. The committee has at its own disposal the selection of them. I

won't mention what the prize will be but the committee can make the selection as to the one which deserves the prize.

CHAIRMAN SUTTON: That is the spirit. I think we have demonstrated here a fine spirit. I am glad Mr. Strobhar spoke as he did. I don't want to be misunderstood. The National Safety Council has entreated us to send them our home made posters and suggestions for posters that they might serve us better, and I am not criticizing the service they have rendered because they have done splendidly in getting out the posters that we do use, without our assistance. They have offered prizes to the workmen who would suggest a poster, and those workmen, of course, would suggest something applicable to their line of work. What I am trying to emphasize is that this Section should at once take up the work, as you suggest, of contributing our part and our ideas on safety posters so that the National Safety Council can serve us better, as they so earnestly desire to do. I am sure we will be benefited by it. I think the suggestion of appointing a Poster Committee is one thing we should do and I believe you are all agreed upon that.

ADJOURNMENT

WEDNESDAY MORNING SESSION

October 27, 1926

The Food Section of the National Safety Council convened in Parlor "D" of the Book Cadillac Hotel, Detroit, Michigan at 9:30 o'clock, Mr. Vern D. Sutton presiding.

CHAIRMAN SUTTON: The first thing on our program will be the report of the Nominating Committee. Mr. Hasse will give us that report.

MR. HASSE: Gentlemen, the Nominating Committee selected the following officers for your approval, to serve you the following year: Vern D. Sutton, chairman; F. A. Hasse, vice-chairman; A. H. Wiedenmann, of the Casualty Reciprocal Exchange, secretary. On the Executive Committee we have H. P. Eggert, of the National Biscuit Company; T. F. Strobhar, of the Wagner, Taylor Company, Alexander Dienst, National Sugar Refining Co., and S. H. Kershaw, of the National Safety Council.

MR. STROBHAR: Mr. Chairman, to save time, I move that the secretary be instructed to cast a ballot making the election of these men as proposed unanimous.

(The motion was regularly seconded and carried.)

CHAIRMAN SUTTON: The first talk we are to have this morning is by Mr. John S. Spicer, chief of Accident Investigation Section, Pennsylvania Department of Labor and Industry, Harrisburg, Pennsylvania.

SPECIAL SAFETY PROBLEMS IN THE FOOD INDUSTRY

John S. Spicer, Chief, Accident Investigation Section, Pennsylvania Department of Labor and Industry, Harrisburg, Pa.

When this subject was assigned to me, I thought it might be interesting to give you the actual experience in our state, and accordingly I asked our statistical division to give us a statistical report of accidents in the food industry for the year 1925 and the first six months of 1926.

I am not quite sure whether it covers the scope of this Section. In fact, it may overlap some of the other sections that have been formed. But during 1925 in the state of Pennsylvania, 31 fatal accidents were reported to the Department, and 4,133 non-fatals; as compared with the first six months of 1926, when 16 fatals were reported and 2,460 non-fatals.

I have my own ideas, of course, of the specific problems in the food industry because all the accidents occurring in Pennsylvania pass over my desk every day and sometimes they average from 200 to 900 a day.

Naturally, you get a little bird's eye view of what is occurring throughout the state.

Now, the food industry is not peculiar in itself. It has a few individual problems, but as far as accidents are concerned the food industry is the same as any other section of industry in the kind and variety of accidents occurring.

I thought it might be interesting to analyze the fatal accidents that were reported and so I gathered together those 31 reports that were sent in to the department during the year 1925. I thought we would analyze them and see whether there are any particular outstanding features of those reported accidents.

In the first place, I found that five of the reports covered accidents which occurred in previous years. For some reason they had not been reported in the year in which they occurred, so that leaves us a net total of 26 fatalities occurring in 1925 and in the second six months three additions were reported, so as far as the record of our department in Pennsylvania, we absolutely know there were 29 fatal accidents occurring in 1925.

Details of the Fatalities During 1925

Now, consider for a moment how these were classified. Two fatalities were automobile collisions; one being a grade crossing, and the other the night foreman of the mill was killed by being crushed between two railroad cars in the mill yard. Two fatalities occurred to painters who were up on a scaffold painting a building. The rope was a very stiff new rope, and in some unaccountable way it came off of the F hook which holds the scaffold and those men were dropped to the ground. Three were elevator accidents. One of them a man was going up in the elevator and stuck his head out and got crushed between the elevator floor and the floor of the building. Another fellow was on the floor and he raised the gate and looked in and got crushed, and the third man opened the elevator door and stepped into the open hatch-way. One was kicked by a horse. Two were killed by means of fire arms. One was a district manager, held up and shot, and one was a guard who dropped his gun out of his pocket; and incidentally we have had almost a half dozen of those accidents where a guard leaned over or something, and the gun dropped out and he was killed. I think I can recall three within the last few years, showing the absolute need of guards wearing holsters at all times when they are carrying firearms.

We get now down to the accidents which are peculiar to the food industry.

We had two men killed with, or, in connection with kettles handling hot material. One man was making cheese and it boiled up in some unaccountable way and the stock ran over him and scalded him and he died a few days later. Another, in a candy factory, had had steam on a kettle and he turned the steam on, but instead of waiting for a

little while until the steam condensed and the pressure was relieved, he opened the top and it came out and scalded him and he died. Then in handling material, the same old story, you know, occurs in all industries. We have five killed from that cause. One fellow hoisting sugar bags in a sling. A couple of them rolled out and knocked him off of the pile of sugar bags and he was killed. Another one, a repair man was hit by a falling pipe. Another fellow had a strain from lifting; peritonitis developed and he died. We had two blood poisoning cases. One fellow was pulling back a bolt on a door and lacerated his finger; blood poisoning set in. And another one was handling crates of material and he crushed his finger and blood poisoning set in.

So as we analyze these various accidents we find that very few of them are hazards peculiar to the food industry. They are found in all these various industries.

Accidents in Machinery Peculiar to Food Industry

Our machine accidents, however, show some things which are interesting peculiarly to the food industry. We had one fatal in the bread mixer. We had one fellow get up in a conveyor to adjust it and he fell off and was killed. Another man removed the belt, or a guard from a belt, on a shaft and was trying to make some adjustment. He was caught in the shaft and whirled to his death. Another fellow was working alongside of a large fly wheel, which was guarded with standard rails, and the supposition is that he fainted, and when he came to in a dazed condition he wanted to crawl away, but instead of crawling away from it he fell over the board in the fly wheel and was mashed up considerably.

Another was crushed by a big truck backing up against him. Another man was helping an electrician trace out short circuits and he caught hold of the brass electric light fixture and the floor was wet and he was covered with perspiration and he was electrocuted. Another one occurred in a sugar crusher, which was a horrible accident. It seems that it was the end of a turn and the man when he came on was supposed to go up and look at the crushers and see that they were all right before he started them in motion. He came on the job, went up and looked into one crusher, but failed to look in the other one where a man was employed making repairs. He went down and turned on the juice and as a result that fellow was mashed up.

Now, there is an analysis of the 29 fatal accidents occurring in one year. You will see that a very small proportion of them were the result of hazards peculiar only to the food industry.

I did the same thing with 1926 accidents which were reported for the first six months to our department. We had 16 reported as you will see in the table. Five of those were for previous years. So that left a net total of 11 occurring in the first six months of 1926. If we consider that with the 29 reported as occurring during 1925, we will find that we have had a 24 per cent reduction in fatal accidents in the food industry. Assuming, of course, that our experience during the

last six months of this year will be as good as it was during the first six months. But on the other hand, our non-fatal accidents have shown, as you will note, considerable increase. About 4,900 this year, as compared with 4,100 last year. Assuming, of course, that the rate for the last six months of the year is the same as for the first six months.

An analysis of those accidents shows as follows. Five were falls of persons. One gored by a bull—a dairy man, with a dairy company. A machine accident—another bread mixer. Now, during these two years we have had reports of three fatal accidents in bread mixers and they were horrible things. One occurred, I think, in Philadelphia, where the man was attempting to clean the bread mixer. Of course, he tried to do it while it was in motion, as they alway do, and was drawn into the mixer. It took them a half hour, I think, to try to get him out by running the machine backwards, and, of course, he was smothered to death besides being mashed all to pieces. A street car collision. Another hold up. Another strain while lifting a lot of meat. Another fellow was up tightening the gasket on an ammonia line while it was under pressure and the ammonia blew out and suffocated him.

So as far as fatal accidents are concerned we find that the food industry has the same problem, in so far as the general trend of accidents is concerned, as any other section of industry. You can take experience in any particular industry and you will find that the outstanding classifications under which accidents are occurring are those old familiar ones of persons falling, falling objects, and handling objects. Machines are generally in the minority.

In Pennsylvania Machine Accidents Being Reduced

I think you will find it very interesting also to note that as far as experience of Pennsylvania is concerned the number of machine accidents is being reduced.

Now, what are these machines that are being reported as causing these accidents? Well, this matter of bread mixers sort of got on my nerves. I took over this work about two years ago and as you sit at your desk and observe a flow of accidents coming over, from 200 to 900 a day, you, of course, can't pick out many details, but there are certain things that are outstanding and that impress themselves on your mind. What we try to do is pick out the serious ones—the ones we thought there was some possibility of doing something to prevent and then studying them; sending them out for investigation by our inspectors and then taking another procedure which I want to talk to you about and which has brought wonderful results, I think.

In the matter of bread mixers we decided, of course, that these accidents only represent the most serious. There were a bunch of other cases where bread mixers were involved, where a man maybe got his arm broken or a less serious injury, because it was possible to shut that

machine down; somebody happened to be there before the man was drawn in, and possibly it was not a high speed mixer where if it once gets hold of you I guess it is almost impossible to get away.

We started in reporting these accidents back to the manufacturer of the machines. We would send a man out and investigate them and then we would report back to the manufacturer of the machine. That has had wonderful results. I think chiefly on that account one of the firms manufacturing these machines has developed an electrical control whereby this type of accidents will be eliminated.

I believe today if you will go in any bakery, factory or industry you will find the men cleaning the machines while they are in motion. There are signs on the machines that you are not to do it, but the men will do it. When the machine is thrown—turned over on its side to throw out the dough—after the dough has gone out, then they will take their paddles and get in there. Of course, they are careful and many times they get away with it, but sometimes on these high speed machines, if they get caught, then, of course, it draws them right in as it did in the three cases I cited.

An Electrical Control Was Developed

The company I mentioned has developed an electrical control. As that machine is tilted to a certain angle it stops and as it gets over further the only way in which you can make it revolve is by pushing a button, and then they can clean it out with the one hand on the button. If that hand is released from that button the machine stops, so the possibility of getting caught, I think, has been reduced to a minimum, because if a man gets caught he is not going to keep his hand on that button. It will come off immediately. They at first, I believe, developed a system of foot control that you had to keep your foot on a bar, but you can imagine if a man was caught with one or both hands he would try to push down with his feet and the chances are would keep the power on the mixer and the danger would not be eliminated. But with this system of one hand being necessary on this electric control button while he might use the other cleaning, I think those accidents have been reduced to a minimum.

Another class of machines on which there are very many accidents is the meat grinders. I venture to say that in a year's time I have had 50 cases. They got so numerous I could not help but notice them and I started to follow the same plan of procedure. There were about four, five, or six companies in the country who were manufacturing these grinders and I began shooting out these accidents to them, showing these employees in hotels and plants who were sticking their fingers in the hopper instead of using the plunger which is always provided. They stick their finger in and get the end of the finger chopped off; and in fact in one case in a packing house, it took a man's arm off to the shoulder. These manufacturers said, "We never

heard of all these accidents occurring. We are surprised. We can hardly think it is possible."

Well, why haven't they heard of them before? For this reason, I think. Here is a man who purchased a machine from a manufacturer. It is in perfect condition and he turns it over to his employee and says, "You shouldn't do this or that with the machine," but the man does. He does take chances. He doesn't use the precautions which he should and he is injured. The employer doesn't think it is the fault of the machine, and as a matter of fact it isn't. The employee has taken chances which he should not have taken, and naturally there is no report made to that manufacturer.

Results of Reporting Accidents to Makers

Well, we take the other position; we believe that the manufacturers, if they know that accidents are occurring on their machines, will take some particular pains to see if they can't make that machine so that accidents will be eliminated. One company manufacturing meat grinders, and selling a large proportion of the ones that are in use, began getting these accidents and they began to sit up and take notice. I notified them all. I would tell them we had an accident on a certain type of machine at a certain place at a certain time. They all get that same information. Naturally they are not interested to see so many accidents occurring on their particular class of meat grinder, for you can fully imagine that their competitors will say, "Our machine is safer than that fellow's. They are having a lot of accidents."

Well, they began sitting up and taking notice, and the company has developed now a machine which I had the pleasure of looking at last week, where they have changed the hopper arrangement and have an auxiliary feed to take the meat from the hopper into the worm that does the cutting, and which generally cuts fingers at the same time, so that the chance of accidents has been almost eliminated. There is one possibility. If a man reaches his hand way up in under he might have the tip of his finger cut off. What has happened to that particular machine? They are now able to advertise, "We can cut meat with speed and safety," and not only is the machine more safe, but it has increased the capacity almost three times.

One of our largest companies which uses enormous numbers of those machines and in whose branch plant occurred that case where the man's arm was taken off, is seriously considering, I understand, putting in all these new machines. We believe that this system of going back to the manufacturer of the machine and telling of these accidents is going to have more weight and we are getting more accomplished than by any other system we have adopted.

In the food industry, I think about 78 per cent of these machine accidents occurring particularly in bakery products—occur at the point of operation, and we find that particularly the case with respect to rolls of all kinds. We had an interesting experience along that line by re-

ferring these things back to the manufacturer of machines. It was where they were making pans, which, of course, is a part of the food industry in a way, but they were corrugating rollers where the sheet metal was run through the roll to make a little corrugation. The fellow got his fingers in there—I don't think he was very seriously hurt, as I recall, but we sent that accident out to the manufacturer of that roll and we said, "Have you devised any way in which that point of operating can be guarded?" It developed that the owner of that machine was running it backwards and of course the manufacturer was only too glad to set him right. He was tickled to death that we had called the matter to his attention; and the owner of the machine, of course, was satisfied, and we were helping everybody. Naturally, the chance of accident in that machine was eliminated.

I don't think I can stress that matter too strongly. If the owners of these machines will shoot back their experiences to the manufacturer we are going to get improved machinery and we are going to eliminate to a large extent these machine accidents. I think the reduction in machine accidents as shown by our experience there is an indication of this kind of work, particularly on safeguarding, because at the present time if there is a serious accident occurring our inspector is on the job usually within a week, as soon as we can get the information out to him and he finds time to go around.

An Enormous Number of Accidents in Automatic Machines

In the development of automatic machinery, like packaging machinery and wrapping machines, we have an enormous number of trivial accidents and still they are reportable accidents from these causes. Little gears and sprockets and chains sometimes have not been guarded. Now I remember not so long ago, I found a fellow that got his fingers caught in a pie making machine. I never knew there was such an animal and I wrote out to the company; I found there was a machine that makes something like 100 or so pies an hour, but there are little gears and sprockets on those things which are not protected. We called the matter to their attention, and I think the new machines that they send out are going to be safeguarded in those particular places.

We have had the same thing occur on conveyors. Conveyors are going to cut down our handling accidents considerably, but on portable conveyors we have found little gears or sprockets or belts that have not been guarded and the men invariably get caught in them. As the accidents occur we refer them back to the manufacturer of the machine and they are developing little aprons or little guards to cover up those things. On dough breaks we have had a bunch of accidents. If you recall, I think, there are two sets of rolls there. The men shove the dough in at the bottom and it comes out at the top roll. They put their hands under there and invariably if they are not careful they will stick their hand in with the dough underneath. Within the last six weeks I had a man come to my office from across

the river. His hand was in terrible shape. It was a question of whether they wouldn't have to amputate it. On one of the dough breaks a little apron is now being developed that is put on those machines so that it will protect and keep the hand out from under that roll where for some reason they will stick them in.

So that all this automatic machinery with the small gears, cogs and belts, if you people have them in your own establishments, I think it is well worth while considering having those moving parts covered up, because sooner or later these men get hurt on these things.

Then the question of infection is one which I suppose has been considered. It seems prevalent, more prevalent in the food industry, especially in meats and packing houses and things like that. A small cut generally results in infection if it is not given careful consideration. It is peculiar that where meat is handled the chances of infection seem to be greater than in many other branches of our industry and we have a large number of accidents. This is particularly so in places like restaurants and hotels where meat is cut and sliced. Then the slicing machine is another source—bread slicers and meat slicers. We have been having the same experience on those machines as the grinding machines, and we are keeping back the accidents.

Manufacturers Getting Tired of Hearing About Accidents

I know from the tone of the letters that some of these manufacturers are getting sick and tired of hearing about accidents occurring on their particular machines; but we shoot them back just the same and I see it reflected in some of the talk of the salesmen. I was down at the Sesquicentennial at Philadelphia where a lot of machines are on exhibition and I questioned them and some of them are making claims on their various machines that they are more safe than others and so on. But we feel that you can't give a man a machine and say, "you must use the plunger." You have got to make that machine so the use of the plunger is a necessity, and if that is done I think we are going to eliminate a lot of machine accidents. Just how it can be worked out is going to take a little time. The thing can't be determined in a minute. But I think the problems can be worked out, and who is better fitted to do that than the manufacturer of the machine?

We have had 100 to 200 accidents on bread slicing machines and meat slicing machines in a year's time and usually it is the tip of the finger or even one or two fingers that have been taken off. They will take a small piece of bread or small piece of meat and instead of putting the block back of it and shoving it up against the knives they stick their fingers in there and the first thing you know it is off. As a matter of fact, down at the Sesquicentennial exhibition there are two meat slicing machine exhibits side by side. Of course I went in and looked them all over and did not tell them who I was. Afterwards I was telling why I was interested in one particular machine and he said his rival demonstrator was giving a demonstration of cutting

meat and, be-gad, he got his finger cut off right there in the demonstration. So when the demonstrators of the manufacturers cut their fingers off I think it is high time for the manufacturers to sit up and take notice.

In talking about these matters I am not covering all these hazards. I realize that very seriously, but I am giving you our experience on what is actually taking place. There may be more dangerous machines. There may be greater hazards, but if there are they are not being reflected in the accident reports which are turned into our department from day to day.

The main things are rollers, slicers, dough mixing machines, all kinds of packing machinery, wrapping machinery, meat grinders, sausage stuffers, ice making machines. They are the types of machines which are causing the trouble. Particularly where you have to put something in the hopper and the man will follow up and stick his hand under or in after the material. For instance, in a grinding machine there is an orifice at the bottom usually where the ground material comes out. Now, there seems to be a peculiar fascination for a man to stick his fingers up in there to see what is in there, just like they stick their fingers in the cigar cutter. They put them in there to see how the end of the cigar is cut off and they find that the man gets his finger cut off. Now, they have done that on the grinders. They stick their fingers up there. One of the manufacturers has made a series of rods that are up in the orifice there so that the material can come out, but the person can not get his fingers up in the mechanism. I think that is a very good development.

This Man Showed Just How the Accident Happened

I remember a case in a lumber mill—a wood working plant, of course—but a fellow had been injured on a saw and his fellow employee took another man down to show him how this fellow was injured and he stuck his fingers up there and had the same accident occur to him.

We don't believe that you can stop accidents until two or three things are done. First, is the machine. It has to be made fool-safe. Second, the foreman has to be on the job everyday, insisting that the men perform their work in a safe and sane manner and be held strictly accountable for the accidents occurring in his own particular department. And third, we believe that it is absolutely necessary that the man at the top be sold on safety.

I don't care how much safety engineers work or how hard they work or what they do, if the boss at the top isn't sold on safety, his efforts are practically of no avail. These safety meetings that are held when the boss is conspicuous by his absence are, to my mind, simply a waste of time. If a man isn't willing to put his time against the time of his employees at a safety meeting, I think you might just as well not hold them. I have reached the point in my experience that I would not go out and talk at a safety meeting if it wasn't held on company time. The plant that wants to hold a safety meeting at noon while the men

are eating is just making a gesture in safety and really is not sold.

In the last analysis I think you will find that up at the top is the main factor in not holding that meeting on company time.

In conclusion I would like to say that the food industry is, to our mind, no more hazardous than any other. It has a few particular problems, yet a majority of them are almost the same as other plants; and my plea to you, as owners of machines, particularly if you get these accidents, is that you shoot them back to the manufacturers. We are going to get somewhere, we believe, if you do that. We have had evidence of it. I could cite you 50 cases, I think, similar to the ones I have given you, and in so far as machines are concerned, I think we are going to get an awful lot in reduction of accidents if we work along those lines.

Discussion Following Mr. Spicer's Paper

CHAIRMAN SUTTON: Are there any questions anyone would like to ask Mr. Spicer?

MR. STROBIAR: I think Mr. Spicer brought out a very important point. So many of the machines used in the food industry are made by the manufacturers themselves. It is right, and I am thoroughly in accord with the idea of communicating with the manufacturer and seeking his cooperation and support. I think the same thing should be done with every manufacturer of food machinery. The food industry has people who make other similar machines and I don't think there is any necessity of keeping those things a secret any more than the Department of Labor and Industry.

Perhaps if the department in Pennsylvania found that the National Biscuit Company was manufacturing a machine for its own use that was discovered to be dangerous and could seek their cooperation and support in improving it, which I am sure they would do, it would be a fine thing. There are other manufacturers of similar products that ought to be advised of that dangerous condition. I don't know whether they are communicated with. For instance, in many of the various kinds of equipment that are submitted to the Underwriter's Laboratory for approval and bear the label of the Underwriter's Laboratory in Chicago, that in itself is an indication of the efficiency of that particular type of machine and it is so published and listed in the selling of it; and people will say, "Has it been approved by the Underwriter's Laboratory?" Food machinery is never submitted to the Underwriter's Laboratory for a label—that is machinery made by a manufacturer for his own use. I have never heard of any. I was wondering if we might not in some way become a clearing house for communications with our members if we learn of a dangerous proposition or if we learn of a good means of protecting the dangerous equipment; why couldn't we broadcast that information to our members who, I am sure, are interested in the subject?

CHAIRMAN SUTTON: That is a very splendid suggestion. Anyone else?

F. J. MALLOBY (Representing the Province of Ontario Health and Labor Department): I notice that there were several fatal accidents, and other accidents on elevators. I do not know whether the state of Pennsylvania has adopted inter-locking systems which we have in Ontario, but in the last two years we have not had a single fatal accident and very, very few minor accidents. I am just wondering whether they adopted that or not?

MR. SPICER: We certainly have, but inter-locks won't prevent a man from sticking his head out as the elevator is going up or down. In that connection I want to make this point on elevators: within a space of two years, notwithstanding our inter-lock, a large number of accidents occurring in cities of first importance, like Philadelphia and Pittsburgh, have come to our attention. Of course, these larger cities have their own elevator inspection departments and are not under state control. In our monthly bulletin some months ago I made a list of about 25 accidents, many of which were fatal, where men had walked into open shafts. The door had not been closed or there had been some reason for that inter-lock not operating.

Elevators as a Rule Are Not Properly Lighted

I think that has been due to a large extent that elevators as a rule are not properly lighted. In several places lights have been on the elevators and the man has reached in to turn on the light before he steps in, thinking the elevator is there and then he goes to the bottom. We had a case of a nurse in a hospital; it was a hydraulic elevator, I believe; and she got into the elevator and got off at a certain floor, leaving the door open, and the elevator crept up a little bit. It was a little dark, you know, and she came back and walked into the open hatch-way without looking. We had another case in a factory where the elevator was not to be used for passenger service. It was contrary to the rules, of course, but it seemed to be the custom that about 5:00 o'clock when the factory closed, they would jump on the elevator and ride down four or five stories. In order to do away with this practice, they shut down the power and when they got down half way between the floors the power went off and one of the women got excited and pulled up the gate, tried to jump off and rolled under the gate and down the shaft way under the elevator floor.

Now, possibly inter-locks would have stopped lots of those accidents if they were in proper condition, but I think in some way they had gotten out of order and of course, had not been discovered up until the time the accident occurred. Notwithstanding the strict enforcement we are trying to do, these elevator accidents are continuing. Of course, we have quite a number of elevators in the state, but I would like to emphasize that many accidents could be prevented if our elevators had sufficient illumination and if the people would get out of the habit of going into a dark hole.

CHAIRMAN SUTTON: We have another very interesting topic to be handled by Mr. David J. Price, engineer in charge of development work, Bureau of Chemistry, United States Department of Agriculture, Washington. I have been very anxious to know what Mr. Price is going to tell us.

THE OTHER SIDE OF DUST EXPLOSION PREVENTION

David J. Price, Engineer in Charge of Development Work, Bureau of Chemistry, U. S. Department of Agriculture, Washington, D. C.

A National Safety Congress is evidence of the fact that safety to life is of nation-wide importance. It can no longer be considered a local matter, in which interest in a catastrophe or a disaster is limited to the section of the country where it occurs. Matters that concern the protection of human life are of nation-wide interest. We have learned by costly experience that the disaster of the East or West today may become the catastrophe of the North or South tomorrow.

It is, therefore, a splendid arrangement which makes possible a national meeting where safety to life is the principal object and where plans for the application of safety measures can be given thorough consideration. The creation in the National Safety Council of a section designed to give direct attention to safety in the manufacture of our food products also makes possible the consideration of any special industrial hazards.

Attention in the United States and Canada has been directed in recent years to a peculiar industrial problem involving extensive losses in life and property. The possibility of dust explosions in the manufacture of our essential food products is now generally recognized, with the result that research has made very helpful contributions to the knowledge available on this subject.

The purpose of this address, however, is not to refer primarily to what would be termed the technical phase of the problem. It is rather my intention to refer to an aspect of this industrial plant study not heretofore presented, an aspect that has impressed me as peculiarly significant, which may be termed the "other side of the story," or the humane aspect of the work.

It is sometimes difficult to measure the accomplishments of safety work and really to see that encouraging results are being obtained. This address, therefore, resolves itself into "a message of encouragement" to the safety men in the industries, with the thought that it may stimulate them to greater achievements if possible in the noble work in which they are engaged. No one can engage in a nobler undertaking than to devote his time and effort to the development of preventive methods that will result in the protection of the life of his fellowman.

In recent years dust explosions have occurred in lines of industry where they had not previously taken place. The number of industrial plants in which the dust explosion hazard exists appears to be constantly increasing. Explosions of wood dust, powdered rubber, sugar, sulphur, zinc

dust, magnesium powder, aluminum dust, cork dust, powdered milk dust, paper dust, dye material, pitch dust, leather dust and starch dust have occurred. In fact, it appears that any type of dust which will burn will readily explode and result in a dust explosion under favorable conditions.

This development in recent years, which indicates definitely that dust explosions can occur in practically all lines of industries where combustible dusts are created during manufacturing operations, is of particular significance. We readily recall that in view of the fact that the earliest dust explosions occurred in flour mills and grain handling plants, it was the general opinion for some time that such explosions were necessarily confined to the grain handling industries. The disastrous losses experienced, however, in a large number of recent dust explosions indicate the wide range of the problem. This emphasizes the importance of careful study to determine the relation between certain types of processes and the dust explosion hazard.

Extent of Losses

The Bureau of Chemistry has a record of 280 dust explosions in industrial plants. In 70 of these explosions 459 persons were killed, and in 92 of them 760 were injured. The property loss in 144 explosions amounted to \$33,500,000, an average of approximately \$240,000 for each explosion.

The importance of this can be more fully appreciated when we realize that a recent census of manufacturers shows that approximately 28,000 industrial establishments in the United States alone are subject to this hazard. These factories employ approximately 1,324,000 persons and manufacture products of an annual value in excess of \$10,000,000,000.

Research work has shown that dust explosions and gas explosions are somewhat similar in behavior. The causes which ignite combustible gases will readily ignite combustible dust. The various dusts have fixed ignition temperatures, as have the combustible gases, and require certain limits of concentration to make an explosive mixture. The control of the problem, therefore, must be approached in much the same manner as the control and prevention of gas explosions.

Progress Made in Control

Although the matter of dust explosion prevention has been given direct attention in the United States and Canada only in recent years, significant progress has been made in the fields in which this special endeavor has been undertaken. Marked progress has been made in connection with the losses from dust explosions and resulting fires in grain threshing machines in the Pacific northwest. These explosions and fires cause extensive losses to both threshing machinery and grain and very little relief was afforded until the matter was taken up by the United States Department of Agriculture and the state experiment stations in that territory.

The investigations resulted in the development of effective control measures which have been instrumental in the reduction of losses and the prevention of these explosions during the threshing of the grain crop in

the northwest. This is a definite example of service which the Department of Agriculture has rendered the farmer. The value of this work has been recognized by the insurance companies, with the result that special rates are now given to the machines equipped with the devices developed by the engineers of the Department of Agriculture.

Marked progress has also been made in the control of dust explosions in certain lines of industry. This is particularly true in flour mills, in which the first disastrous dust explosion on record occurred. This resulted in the design and installation of mechanical methods for effective dust control. The explosion in the Washburn Flour Mills in Minneapolis in 1878 resulted in the loss of 18 lives. The records indicate that only four lives have been lost in dust explosions in flour mills since that explosion.

This must not be taken to mean, however, that dust explosions do not occur in flour mills any more. There have been a number of explosions in recent years. Because of the effective control and preventive methods adopted, however, they have been localized in effect and confined to very limited areas.

Similar progress has been made in other lines of industry, particularly in those industries in which large losses of life and property damage have been experienced.

New Contributing Causes

The question as to why so many dust explosions are occurring in our industries in recent years in comparison with the earlier periods of operation is raised. This ought not to be difficult to understand.

There are several principal contributory causes of the frequency of dust explosions in our modern industries. The expansion to large-scale operation, accompanied by new processes for the utilization of by-products, naturally increases the hazard. Large-quantity production results in the creation of finely-divided dust clouds, which make the ignition more readily possible. New lines of operating processes and new types of machinery and appliances have also contributed to the hazard. In dealing with this matter it must be understood that many of our dust explosions at the present time occur in what may be termed our modern up-to-date and improved industrial plants.

The "Other Side" of the Story

I do not propose to discuss the technical aspects of dust explosion prevention. I am dealing today with "the other side" of the story. The research work is directed primarily to the determination of the causes of these explosions and the development of control and preventive methods. It is gratifying to observe that, as a general rule, these measures are applied by the industries as rapidly as they are developed by the engineers of the Bureau of Chemistry, and that very close cooperation exists between the manufacturing companies and the Bureau in this research work.

There is a certain stimulation, however, to the safety worker in the manufacturing plant, that should make a special appeal for renewed interest and activity in this industrial problem. In dealing with a subject of this kind one naturally becomes impressed with the importance of the protection of the lives of the workmen involved.

In the investigation of industrial plant dust explosions it is necessary to proceed very promptly to the scene of the explosion and to remain long enough to obtain at least some definite idea as to the circumstances under which the explosion occurred and the methods that might be adopted for the prevention of a similar occurrence in other lines of industry.

This close contact with the "human aspect" of the problem gives the investigator an impression which can not be obtained under any other circumstances. In many instances when the explosions have occurred in extremely cold weather the recovery work has been very difficult. Sometimes from ten days to two weeks have elapsed before all of the bodies have been recovered. Often identification is impossible, which adds to the complicated situation.

One can not deal with a problem of this kind in which human life is involved without being tremendously impressed with its seriousness. An explosion resulting in the loss of lives of 50 workmen means a large number of dependent wives and children. The pathetic instances surrounding tragedies of this character leave an impression upon investigators that can never be entirely taken away. It affords a stimulation for greater incentive and for wider exertion of effort to bring about a full realization of the importance of this entire matter and the development of additional precautionary measures.

Value of Safety Work

During the recent observance of fire prevention week our attention was called to the importance of the reduction of our fire losses. The estimates indicate that the annual fire loss of the United States for 1925 was about \$570,000,000, making an approximate loss of \$1,084 per minute. Although this fire loss is increasing at a rapid rate, the tragedy of it all is that reports indicate that upwards of 16,000 lives were lost last year in these fires. President Coolidge in a special proclamation referred to "the thousands of lives sacrificed each year through fires" and stated that "the conservation of man power and material wealth from such destruction is a challenge to the progress of our civilization."

It appears that approximately \$150,000,000 of the loss was caused by fires on farms. These losses have been advancing at a very rapid rate. Secretary of Agriculture Jardine in a statement on fire prevention week, called attention to the losses from fires on farms and referred to the estimated loss of 3,500 lives each year as a result of fires in farming communities. Up until this time very little has been done in a national way to make a thorough study of farm fires and to render assistance to the farmer in the prevention of these fires and the protection of life and property.

When we consider that 16,000 lives are lost annually in explosions and fires in the United States—approximately two lives every hour—the larger proportion, of course, being in the industries, we can not help but be inspired to greater effort and endeavor.

Safety work in the food industries is a noble undertaking. Although the results in many cases can not be definitely measured, this work should carry with it a sense of satisfaction that could not be enjoyed in any other line of effort. The desire on the part of the safety man to acquire all knowledge available on the subject of dust explosion prevention is deserving of the greatest encouragement.

The application of this knowledge in the installation of control measures will eventually result in the reduction of our losses from dust explosion and fires and in the saving of life and property. The human appeal that accompanies work of this character should in itself be an incentive for greater effort on the part of the men in the industries to protect the lives of the workmen engaged in the operation of our factories.

The Food Section of the National Safety Council can render a ~~distinct~~ service in this matter and it is hoped that this address will direct attention to the "other or humane side" of the problem. A service of this kind rendered to one's fellowman, although difficult to measure, will eventually result in those accomplishments which under no circumstances could be otherwise obtained.

The U. S. Department of Agriculture is willing and anxious to make available all information it has that will in any way assist the industries of the country in the reduction of the losses of life and property as a result of dust explosions and fires.

Practical Experiments at a Plant in Louisville

CHAIRMAN SUTTON: We are certainly very grateful to Mr. Price for coming here, and we feel that he has given us some very valuable information. Are there any questions you would like to ask Mr. Price?

W. P. PENTY (Kellog Company, Battle Creek): At Louisville, two years ago, I was greatly interested in the subject of dust explosion, and was disappointed because the gentleman who was supposed to speak did not appear. But through the information I received there I sent to the Bureau of Chemistry at Washington and they very kindly sent a miniature grain elevator to our plant. I collected dust—possibly 10 or 15 different kinds—and we had a demonstration to about 1,500 employees, and in every instance the dust exploded, more particularly the dust that comes from the unloading of corn. That seemed to be more powerful really than powder. We have been very careful since to keep the dust cleaned off and in a safe manner.

MR. WARREN (Minute Tapioca Company, Orange Mass.): We had a question in our mind as to whether our raw material, being a tapioca flower, had any dust hazard; and so our chemist took the matter up with Mr. Price's department and we sent samples of various dusts of the product in various parts of the processes. The report came back—a very

complete report—showing just wherein there were no hazards and wherein we should take a particular safeguard. We have used the vapor-proof lamp in our raw material department where the flower comes in, feeling that there was a possible danger. The report was of particular benefit to the men. Probably you also have workmen who have been with you for a number of years, who have said, "Oh, there is no danger here. We haven't had any trouble—probably won't have any trouble."

But we got the different foremen together and went over very carefully with them the report and it was a very liberal education; they were surprised and since that time it is quite often that they come to us and say, "Now, do you think this particular thing that I am doing is going to have any possible effect upon any hazard?" The effect we have gotten with the men looking out for any trouble has been a wonderful help to us to get that thought of a possible hazard across.

The Department Actively Cooperating With Industries

MR. PRICE: Mr. Chairman, I certainly appreciate those kind words. I would like to make clear this one thing. We enjoy at this time in this work pleasant relations with everybody concerned. I mean by that, the companies and insurance people and underwriters and everybody in the game. I am chairman of two committees of National Fire Protection and the insurance men are all close friends of mine, but we appreciate at Washington what might occur as far as that particular aspect is concerned. If an industry finds there might be a dust explosion hazard present and that there might be an unpleasant relation resulting from the insurance aspect, they may take the matter up confidentially with the Bureau of Chemistry. We have had a policy from the very first that if any company sends in a sample of dust and wants that confidential relationship it will be maintained. If, for instance, an insurance inspector goes out and collects samples from this factory and sends them to the Bureau, we have refrained from making a test of that dust until we are assured that the company which operates that plant is a party to the agreement. We will not send the report unless a copy is sent to the company, and it has worked out very nicely and there is no embarrassment. The big thing, I think, on both sides is to try to get somewhere in the way of control. We had a case last week where we were in conference with a company in the east that is grinding a product that is shipped in a bale from Japan. It is used in the manufacture of insecticide—very explosive. In that conference we tried to convey this thought: the morning after an explosion takes place and the New York executives call you in they get an awful lot of satisfaction out of the fact that they were doing all they could to stop it. The executives are quite remorseful when they haven't done just as much as they ought to have done, and that is the important thought—a fellow gets an awful lot of satisfaction out of knowing he has done all he can do.

MR. EGGERT: Is that reel available?

MR. PRICE: Yes, we have quite a number of the reels. During fire prevention week we had several copies in use and we will be glad if you

will write in for one and we will send one to you. We also have lantern slides we can send out. Anyone needing that material may write to us at Washington and we will be glad to supply you either with the films or lantern slides. If at any time our engineers are in your vicinity when you are having a meeting we will be glad to have them arrange to stop off with you. We can't always send them to meetings on special occasions. But if they were in your territory and an explosion occurred, they might stop over and see you on the way back.

CHAIRMAN SUTTON: The Postum Cereal Company also borrowed these films and the miniature elevator from Mr. Price's department. We put on an exhibition and we took one precaution, purposely, in giving our demonstration. We gathered the dusts, as did the Kellogg company, but before blowing them into the miniature elevator we put them in a mass on the table and touched a flame to them and none of them would ignite in that way, but blowing them into the elevator, suspending them in the air, mixing them with the oxygen, they exploded, every one of them.

Hazards from Dusts in the Event of a Fire.

MR. PRICE: This afternoon at the request of the Detroit Fire Department, I am going to show this same film. Some of our greatest disasters have been as a result of dust explosions. For instance, firemen have attempted to draw the contents of a bin after they thought the fire was out. We had one case in Milwaukee, a furniture factory where there was no evidence of any fire remaining. The sprinkler heads had worked and the firemen could not see a fire but they did not want to go back without making sure the fire was out, so the chief kept one company of 12 men and they pulled the contents of a bin. It was about 30 feet deep. It was fine wood dust, and when they were doing that an explosion occurred and six of the men were killed—the captain and five others—and that same thing has occurred in many instances. That is one type of hazard. The contents of such bins should never be drawn during a fire or after a fire, but they should be wetted down and the contents left in. You can appreciate the reason for that, because if you are pulling the contents out into a room and get the right mixture of dust in the room you are going to get an explosion.

Now, another hazard has been in the firemen approaching these plants during a fire. There was a case of this character in a cinnamon factory, where 18 men were caught and who were right over the bins when the bottoms dropped out and the cinnamon dust exploded. The other point the chairman referred to brought this to my mind. This pile of dust will not explode unless you diffuse it with the air. In some cases we have had explosions where the firemen could not understand what happened. They approached the building and it blew up. We had a case in a cork factory where they were manufacturing oil cloth. It seems a heavy stream of water struck the dust and blew it into the air. If it gets into the air you are going to have an explosion. That is a very interesting development. The firemen should not have approached it with a very heavy stream of water, because the shooting of the heavy stream

into the pile of dust will blow the dust into the atmosphere and if there is fire an explosion will follow. We have had several cases in the last year where men have been killed.

MR. SMOKE: Doesn't that same thing occur where you have static electricity in a mill?

MR. PRICE: There is a possibility of that if you are using air for removing dust from machines. Of course static sparks will ignite dust, but I don't think it would be safe to blow dust if you were near a fire or source of ignition.

MR. SMOKE: I was getting back to Postum's idea of the short circuit and the charred wood and dust.

MR. PRICE: The static as a rule would have to come from some operating machinery.

MR. SMOKE: Belts and things.

MR. PRICE: It is a very interesting thing. We have gone out where they are threshing grain, between the Cascades and Rockies, where there were as many as 400 explosions in six weeks in threshing machinery, right out in the open fields. It is a very low humidity and a high temperature and the wheat entering the machines, the friction of the straw on the metal surfaces, gives the same effect as if you stroke a cat's back. You build up a static charge and the static sparks ignite the grain dust. The first thing we did was to ground the machines like a lightning rod system on a house. Of course it was difficult because the ground was dry and it had to be moistened. They burned up so many machines insurance companies would not carry the risk and it was a very pretty problem to deal with. I think it has been controled to this extent: we have placed fans on the decks of the machines and have used the grounding method; but it indicated beyond a shadow of a doubt that the static sparks were sufficient to ignite the dust. Some engineers said it was too cold a spark to ignite the gas. We have had many cases recently in industry to contradict that. It appears as if certain of these dusts will electrify themselves by friction.

CHAIRMAN SUTTON: The present problem is to dispose of the dust?

MR. PRICE: I think so, yes.

CHAIRMAN SUTTON: I am sure we have many good things today, and we have a very interesting talk coming next by Mr. Thomas S. Strobhar.

DANGERS FROM FOREIGN OBJECTS IN FOOD PRODUCTS

Thomas S. Strobhar, Wagner, Taylor Company, Philadelphia, Pa.

Some of you are manufacturers of food, some dispensers; we are all consumers, for we must eat to live. My particular plea is to safeguard the public from foreign objects in the food they eat, and at the same time protect the manufacturer and the dispenser from a comeback on the part of the injured public with unreasonable and exaggerated claims.

The numerous claims brought by consumers of food on account of the presence of foreign objects has resulted in practically all casualty insur-

ance companies looking askance at insuring manufacturers or dispensers of food, especially the chain restaurants and chain stores.

I have in mind a certain chain restaurant and retail store, the insurance of which has been offered to every large insurance company, either to be declined or cancelled. In order to find out why this was so, I made a study of all claims brought against this concern, analyzing them as to cause and effect, and learned certain facts which may be of interest.

Six Months Summary

Number of Houses in Operation.....	28
Cause:	
Glass	29
Stone	11
Nails	7
Tacks	5
Wood	4
Miscellaneous	4
Live Stock	3
Wire	3
Bones	3
Shot	3
Tin and/or Solder.....	2
Pits	2
Total	76
Effect:	
Nervous Indigestion	3
Broken Teeth	19
Lacerations and/or Infections of mouth and/or throat.....	51
Miscellaneous	3
Total	76

A study of this table shows that the larger numbers of injuries were found to be due to the presence of glass, stones, nails, tacks, wood; whereas livestock was a comparatively small cause, showing at a glance general cleanliness.

The presence of foreign objects in food naturally causes alarm, resulting in some cases in nausea; and a large number have resulted in lacerations of the mouth or throat, with consequent infection; also broken teeth, and usually a loss of time from business. It is against all this that a defense must be developed.

There is very little law on this subject, but the cost of investigation and of building a defense against shyster lawyers, especially in this particular kind of claim due to negligence or implied warranty, is very expensive. A lawyer who pursues a nuisance claim or who seeks an amicable settlement out of court should not be encouraged but should be faced in court and no claims paid until the court so decides.

To return to the analysis, after a six months' drive, the number of claims was reduced from 25 to 13 a month.

How has this been done? By organizing for safety. It may seem a coincidence that the ratio of the number of accidents to the public is in direct proportion to the number of accidents to the employee; but it simply means that if the employee is deeply interested in the idea of safety for himself and others there will be fewer accidents to the public and vice versa. Safety committees, safety sections, plant inspections, analysis of the principal causes of accidents, all play their part in the campaign to eliminate foreign objects in food.

Safety activity should begin at the time the applicant applies for a position. Safety should be stamped indelibly upon his mind and he should be made to realize the importance the management gives to safety, and by keeping everlastingly at it the entire personnel of any organization may become imbued with the safety movement and, naturally, result in greater efficiency and safety to the public and the employee.

A Concrete Example Is Stones in Beans

Let us consider as a concrete example of our problem, the presence of stones in beans—the ubiquitous bean—for there are perhaps more orders of the homely bean served from coast to coast than any other cooked food. The stone which is usually found in beans closely resembles the bean in appearance and perhaps goes undetected until someone's tooth is broken. The same problem was faced by coffee roasters years ago, and eliminated by a device which all bean packers would do well to adopt. An apparatus was devised whereby coffee is placed in a hopper on the floor, is passed through metal chutes through the floor and lifted up by air into storage bins; all but the stones or nails which are not lifted but sifted out at the bottom of the chute.

Or take, as an example, nails which are sometimes found in cereals. This foreign object is removed by having the grain spread on a jiggling table, enclosed on the sides but open at the ends, with a trough leading into a metal chute. Underneath the table are long bar magnets. As the table moves back and forth the grain is jiggled to the ends and as it passes over to the edge of the chute, any nails or pieces of metal adhere to the magnet.

Glass, which I found to be the cause of the largest number of injuries, is frequently accounted for by broken electric bulbs having fallen into uncovered containers, or by broken containers themselves. Glass is found in sugar because the lid is often screwed on carelessly or too tightly, or because when a tray holding a number of bowls is jarred and the edge of a bowl cracked, a piece of glass may fall into the sugar.

The department for assembling food is often too crowded and too poorly lighted. These conditions, if present, can be changed. There should also be a separate room where boxes and containers can be opened and thus remove from the assembling department the hazards attendant on unpacking, such as nails, nail heads, splinters, etc.

Constant supervision must be made by a foreman to see that the employees are using due care in handling food so as to avoid the presence of foreign objects. Too much emphasis can not be placed on the need

of daily inspection of the employee as to neatness and cleanliness. During the last six months we have only had one single claim for the presence of pins in the food. Prior to this, it was customary to have as many as five in one week. The pins were worn by the serving and waiter girls and those in the bakery and kitchen. Pins worn by factory girls should be prohibited and their need replaced through garments that may be tied on.

In this brief space I have only touched on a few of the foreign objects in food, how they can be removed and the eating public protected. Each one of you will have his own special problem to work out but we can all get together in taking every precaution for safety in the preparation of food or, if accidents will happen, by fighting nuisance settlements of unjustifiable claims through cooperation.

Foreign Particles in the Food a Serious Problem

MR. EGGERT: I am absolutely in accord with Mr. Strobhar's idea of fighting shyster lawyers. We come in contact with them ourselves and we know our own experience.

CHAIRMAN SUTTON: I think we all agree with that. You may save some money in one case by conceding to the lawyer and settling your claim, but you are opening the gate for all the rest of the shyster lawyers in the country.

MR. EGGERT: They are worse in New York City than in any other place.

CHAIRMAN SUTTON: I said, jocosely, in opening the session yesterday, that I thought we might include not only food manufacturers and food dispensers, but food consumers. We learned from Dr. Jackson Monday afternoon, and from Mr. Strobhar this morning, that there is great possibility of applying safety to food consumption, and it might be well either to adopt that phase in this Section or organize a Section in the National Safety Council to teach the people how to eat.

It may be that food manufacturers can find some way to prevent foreign particles getting into food some day, but they haven't found it yet, and when you fight it one way you find it popping up in another. I know in our plant we did as Mr. Strobhar has suggested. We provided aprons that tied on and the girls were not allowed to wear pins. We also ruled against their having pockets so that they could carry anything to the machines in their pockets. But there are certain articles that girls must have, and when we did that they would carry these little articles in the front of their dress; when they leaned over the food those things would sometimes drop in, and we had a veritable avalanche of shine eradicators. So now we don't know where we are.

MR. SMOKE: There could be a long discussion had between Postum and Kellogg on that subject.

MR. WIEDENMANN: I think in the food industry welfare work is very important because I have known of cases where there has been malice on the part of the employee toward the employer and they would see

that some foreign substance would get in the food before it went out. We have had cases like that.

MR. EGGERT: That happened more frequently during the war.

CHAIRMAN SUTTON: We had a case just like that. The girl got angry at her forelady so she took some of these little rubber bands and she cut them in about half inch pieces and threw a handful of them into a package, and we got a report from the customer that the grape-nuts was full of worms. I am glad you suggested that, Mr. Wiedenmann. That is another application of welfare—how it reflects to the employer by protecting against just such things as that.

We are now going to have the pleasure of hearing about the "Specific Hazards in the Sugar Industry," by Mr. Dienst.

HAZARDS AND THEIR PREVENTION IN THE SUGAR INDUSTRY

Alexander Dienst, Safety Supervisor, National Sugar Refining Co. of New Jersey, Long Island City, N. Y.

In days gone by sugar refineries were referred to as slaughter houses with respect to accidents, but today they are as safe to work in as any other well guarded industry. This is due to continual striving for safety on the part of the management and its staff.

A sugar refinery consists of much high speed and heavy machinery, such as centrifugal machines, conveyors, elevators, minglers, high pressure pumps, etc.; also hot water and liquor tanks which are of a most hazardous nature. No expense has been spared in properly guarding all these hazards. This is a most essential step. The next is to educate your workers to think safety, and continually keep this thought in their minds by having an occasional rally with a safety talk by some expert safety engineer who can put the idea over, and by displaying safety bulletins all over your plant. This counts for much, as the pictures bring the safety thought home to the men when other methods sometimes fail. A most pathetic picture was published recently under the caption, "Why Doesn't Father Come Home?" These words were uttered by a little girl standing at the gate of a small cottage awaiting the return of her father from his day's work. Instead, notice came that he was lying in a hospital—a victim of carelessness. Articles of this nature have a powerful influence upon the minds of workers.

Team work produces results; train your men's minds upon one thought, "Safety," and have them pull together and you will meet with success.

Promote the fullest cooperation in your plant. This can be done through the foremen only, by bringing them together at an occasional meeting. We find the best time to do this is immediately after working hours in your cafeteria (if you have one) and serve them with a dinner and a smoke. They then become warmed up and express their ideas of safety freely and point out the weak spots in their various departments, if there are any. Encourage them to talk, don't throttle them.

Walter P. Chrysler says: "If you know how to do your job better, don't hesitate to tell your boss about it. Men who advance far do not refuse to listen to suggestions from men they employ, but welcome practical suggestions for improvement.

Bring the men on the firing line into the picture and fix their responsibility. Show them the main objective toward which your organization is directed. Keep this objective continually before them in visual form if possible. Show them the obstacles which confront them and the challenge which is laid down before them. Express your confidence in them, and make them feel that success rests upon their shoulders.

The problem of accident prevention may be briefly stated as follows:

Make it some person's business to discover unsafe conditions and practices and then do everything possible to eliminate them through active cooperation between this person and those responsible for the performance of the work.

Education is obviously required, but discipline to enforce the results of education is equally essential.

If you do not get cooperation voluntarily—force it.

We had a case where our mechanics deliberately removed the glass guards on the emery wheels before using them. We immediately placed a sign on each wheel reading: "Don't use this wheel without the guard in place or wearing goggles, otherwise you will be discharged." This produced results.

The Birth of the Safety Organization

Now let me tell you about the birth of our safety organization.

Some five years ago a safety rally was held in Long Island City by the Metropolitan Safety Council, then a local branch of the National Safety Council (of which I was a member). We attended this meeting, fourteen strong, and afterward adjourned to a dining room nearby where one of the party suggested that we start a safety organization in our plant and we then and there organized and elected our officers.

One week later we called a meeting in our main office after work and invited our plant manager to attend.

He met with us and commended our action, told us we had his hearty approval, that we could count on his support, and assured us that the management would back us up to the full limit.

We enlarged the organization to include all first class foremen in the plant.

The following object was unanimously adopted:

"The object of this organization is to promote safety throughout the refinery and to lend encouragement to public safety, to the end that accidents may be prevented and better industrial conditions and civic life may be promoted."

After holding several meetings we found that matters were getting complex. As important questions came up, there were too many conflicting opinions and we got nowhere (a case of too many cooks spoil the pie).

We then organized an executive committee of six, consisting of the assistant superintendent, assistant consulting engineer, master mechanic, production manager, personnel manager and safety supervisor, who meet bi-weekly during business hours and discuss and pass on all matters of importance and report back to the general committee who meet monthly around the table. This works out very satisfactorily as it gives everyone a chance to talk for himself.

We have three factory inspection committees, each consisting of three first class foremen who serve four months during the year. They, with the secretary, make a complete tour of inspection through the plant monthly and note any possible hazard they may find.

We also have a safety inspector who makes an independent inspection weekly and bends every effort to find hazards the committee may have overlooked. The moral effect keeps the committee alive.

Details of the Practical Safety Plan

These reports are discussed by the executive committee at their meetings and orders are given to make the necessary changes to eliminate the hazards reported.

Giving the executive committee power to act on these questions saves much lost time.

A complete report of all matters transacted by the executive committee is made to the general committee at their monthly meeting for discussion.

The officers of the safety organization are safety supervisor, safety engineer, safety inspector and secretary (who keeps all records and attends all meetings).

Our dispensary, or first aid room, maintains a medical department consisting of a full time graduate nurse and a part time physician who visits the plant one hour each day and is on call at all time for emergencies.

All cases that receive first aid treatment by the nurse are ordered back the following morning for examination by the doctor who passes on the merits of each case and a complete record of same is filed.

The personnel of this department is such that the workers feel entirely free to come for treatment or advice for the most trivial accident, as they are always treated with courtesy and kindness.

We are running a safety contest and distributing cash prizes to each foreman and sub-foreman of the five departments having the best safety records for each six months, and those winning first prize also have their names inscribed on a banner displayed in a conspicuous place in our cafeteria. This contest is based on hours lost and the results are obtained from past experiences and a suitable allowance for the hazard in each department.

All our men are examined for hernia before employment.

We have a fast rule that each mechanic before starting to repair any machinery must remove the fuse from the fuse box and carry it with him, so that no other person can possibly start the machine while

he is working on it. There is also a sign placed on fuse box reading: "Hands Off—Repairs Being Made."

When instructions are given to clean or repair a bucket elevator the foreman locks the fuse box (which automatically lights a red light on top and at the elevator boot), and keeps the key in his possession, giving the man a key to unlock the boot, which he is not supposed to do unless the red light is on. After the work is finished the man locks the door in the boot and returns the key to the foreman in person and he in turn opens the fuse box with his key and starts the elevator. We place the entire responsibility on the foreman.

I will quote our accident record since 1922 which shows a marked improvement.

ACCIDENTS CLASSIFIED

Year	No. of Accidents		Percentage Based on Full Time Workers		
	Total	Monthly Average	No Lost Time	Lost Time	Total %
1922	471	39.25	2.12%	1.47%	3.59%
1923	226	18.83	0.71%	1.22%	1.93%
1924	227	18.92	0.89%	0.83%	1.72%
1925	140	11.67	0.33%	0.74%	1.07%
6 Mos.—1926	67	11.17	0.23%	0.73%	0.96%

As a result of the workings of the safety organization every piece of machinery is guarded as far as practicable and various safe practices have been inaugurated.

Among the material effects of this work are the following which in most cases are characteristic of the sugar industry:

- 1:—All new installations are inspected thoroughly by the safety engineer and are not allowed to be put into operation unless O. K. from a safety standpoint.
- 2:—Centrifugal Machines: Individual vertical motor drives have replaced the horizontal line shafting.
- 3:—Char House: a ventilating system has been installed to drive out the intense heat, making working conditions more favorable.
- 4:—Boiler House: a ventilating system has been installed to expel the gas fumes, thus lessening the liability of men being overcome.
- 5:—Belt Conveyors have been placed as near the ceiling as is practical and in other cases railings have been placed around them.
- 6:—Live Steam Lines: at each live steam outlet a bottle of carron oil and some cloths are placed, in order to give a sufferer from burns some relief before going to the first aid room. All foremen are trained how to use it.
- 7:—Ash Cellar: water has been run in with the ashes to lessen the amount of flying dust and so lessen the chance of eye injuries.
- 8:—Dust Collector: a dust collector has been installed in the powdered sugar department, which makes working conditions better. This collector deposits the dust in water, thus decreasing the fire hazard.
- 9:—Notice: we hand each new employee a memorandum reading as follows:

NOTICE—Read Carefully

It is the policy of this company to cooperate with its employees to prevent accidents.

Should you meet with an accident, no matter how slight (if only a scratch) report to your foreman at once, and go to the First Aid Room for treatment.

This may prevent infection, loss of time and much suffering.

This notice is printed in four languages, English, Polish, Italian and Spanish.

We also have a Safety Boosters Club consisting of all employees. Each member is presented with a Safety Boosters button.

CLASSIFIED PERCENT OF ALL ACCIDENTS

Year	Hand Labor	Infections	Burns	Eyes	Falls	Machinery	Miscellaneous	Total
1922	49%	4%	4%	13%	14%	9%	7%	100%
1923	63%	3%	2%	9%	8%	3%	12%	100%
1924	64%	7%	3%	10%	10%	3%	3%	100%
1925	70%	2%	4%	7%	8%	4%	5%	100%
6 Mos.—1926	64%	3%	4%	14%	6%		9%	100%

Actual results which are accomplished by saving man from pain and suffering have a tendency to promote good will among workers. Workers' good will has definite value as a factor in increased productivity; yet, important as productive efficiency may be, unquestionably the conservation of human life, health and happiness is a much more important consideration.

MR. SMOKE: May I ask the number of employees you have?

MR. DIENST: Twelve hundred. This is just one plant that I look after.

CHAIRMAN SUTTON: I want to say that I think next year at least, so far as my influence will be effective, we shall have a less number on each program, and have a larger number of sessions and opportunities for further discussion—more discussion than we have had. Moreover, I am going to endeavor to convince the rest of the committee that we ought to have a luncheon and get-together and get acquainted with each other as some of us did at breakfast one morning. It is very helpful.

Now, we are going to hear something of specific hazards in bakeries by Mr. Allan H. Wiedenmann, manager, engineering department, Casualty Reciprocal Exchange, Kansas City, Missouri.

SPECIAL HAZARDS IN THE BAKING INDUSTRY

Allan H. Wiedenmann, Manager, Engineering Department, Casualty Reciprocal Exchange, Kansas City, Mo.

It will be my endeavor to cover my subject by a review of the causes of accidents in 100 bakeries for a period of one year.

While this experience may not be indicative of the entire industry, observation and experience show that there will be but few causes that

escaped listing. I am sure that if there are any such causes, the frequency thereof will be of no consequence.

The plants analyzed have been taken at random from the subscribers at Casualty Reciprocal Exchange having annual payrolls varying from \$3,000 to \$200,000. Thus, we get what may be referred to as average plants, going from the smallest to those with a comparatively high payroll exposure for a bread bakery.

The year 1924 has been used in this survey, because it is the latest year in which complete information can be had on the time lost and labor costs.

In analyzing the 100 bakeries producing the 384 accidents, we made some interesting preliminary disclosures. For instance, there were 58 of the 384 claims not tabulated because there was no time lost, no medical expense, and no compensation expense; 144 medical cases had no lost time; 117 medical cases involved lost time, with a total number of 704 days out, and 65 compensation cases with 1959 days lost time. The severity of these 65 cases can be judged by the fact that there were only four costing more than \$300 in combined medical and compensation cost, three of which were from \$300 to \$500, and one cost approximately \$1600. There are no dismemberment cases other than the loss of fingers.

While the 100 plants reported 384 accidents, there were 36 that did not report a single case, 21 reported only one accident, and 21 reported more than five accidents; only nine of the total number had more than 10 accidents.

Excluding the plants reporting no accidents and the 58 claims without loss of time, medical, or compensation expense, we have a remainder of 326 cases, which have been divided into the following 25 causes:

Number Proximate Causes	Medical Only		Compensable			
	No.	Time Lost	Non-Serious	Serious	No.	Time Lost
44 Falls of Persons.....	40	121	4	132	—	—
35 Handling Objects.....	33	71	2	14	—	—
31 Striking Against Objects.....	23	49	8	140	—	—
23 Operating Machines.....	10	7	12	321	1	186
23 Pushing or Pulling Objects.....	17	50	6	209	—	—
21 Gases, Acids, Hot or Corrosive Substances.....	18	20	3	63	—	—
18 Falling Objects.....	17	47	1	8	—	—
17 Machine Exposed Moving Parts.....	16	32	1	90	—	—
15 Lifting.....	11	37	4	142	—	—
15 Cleaning Machines in Motion.....	8	15	7	254	—	—
12 Hand Tools.....	11	24	1	13	—	—
10 Falling Objects Handled by Inj.....	8	29	2	37	—	—
10 Caught Between Objects.....	9	69	1	46	—	—

326 Totals.....	261	704	64	1773	1	186

FALLS OF PERSONS:

Ladders, pushing objects, stairs, wet and greasy floors, tripping, slipping on level and an elevator shaft contribute to this cause, and with the

exception of one case, accidents were not due to defective equipment or the absence of safeguards. In my opinion, the elimination of this cause will require carefully prepared educational campaigns:

HANDLING OBJECTS:

A total of 35 accidents come under this cause, 14 from handling defective or rusty bread pans, eight hot bread pans, two defective dough troughs and 11 miscellaneous objects. The prevention of this cause requires careful inspection and maintenance of bread pans and dough troughs. Also that employees be instructed to use pads or gloves, with ample protection of the fore arm in handling hot pans.

STRIKING AGAINST OBJECTS:

This cause is purely a case of carelessness or clumsiness on the part of the injured and can be remedied only by instilling the safety habits.

OPERATING MACHINES:

These accidents are due to the point of operation hazard of the machine which frequently becomes jammed or the dough sticks and without thinking the employee attempts to get the dough feeding properly again by pushing it with his hand while the machine is in motion. The machines on which the majority of these accidents have occurred are the dough mixer, divider dough brake and moulding machine. Safety rules on this cause should be posted instructing employees to stop machine before relieving jam. Enforcement is imperative.

Other Classes of Minor Accidents**PUSHING OR PULLING OBJECTS:**

Seventeen of these were bread racks, four dough troughs and one box. The employee jammed the bread rack against another one, wedging his finger between or, in pushing dough trough through a door, would strike the side of the door jam with his hand. There were also two hernias and four strains caused by attempting to push or pull a rack or trough too heavily laden. Prevention of this cause can be accomplished through proper instructions on handling objects and careful physical examinations.

FALLING OBJECTS:

Most cases occurred where the employee was struck while passing by or coming in contact with improperly piled stock and material, such as bread pans, rolls of paper, sacks of flour, etc. The prevention of this cause will require the careful inspection of stocks and seeing that they are safely piled.

MOVING PARTS: ARE DIVIDED AS FOLLOWS:

Eight gears, five belts and pulleys, two chains and sprockets, one set screw and one shaft end. Accidents of this nature can be prevented by efficient safeguarding.

LIFTING:

These accidents in most cases are caused by the employee not properly lifting or attempting to lift too heavy a load, in each case resulting in a hernia or a strain. The elimination requires instruction in lifting properly and careful physical examination.

CLEANING MACHINES IN MOTION:

Machines entering into this cause are moulder rolls, dividers, dough mixers, rounders, and bread wrappers. Machines must not be cleaned while in motion.

HANDLING TOOLS:

The majority of these were caused by the careless handling of the (dough) scraper commonly used in bakeries in cleaning machines and other equipment.

FALLING OBJECTS HANDLED BY THE INJURED:

In most cases this was purely carelessness or too much speed. Prevention can only be accomplished by instilling the safety habit in the employees.

You can readily see that the majority, in fact nearly all, of these accidents have occurred through thoughtlessness and violation of safe practices on the part of the injured. This is true also of the remaining causes whose occurrence has not been so frequent.

There is no doubt that these causes can be eliminated only through educational measures such as frequent instruction, oral and written, in the proper operation of machines, accident prevention contests, safe practices, and safety bulletins characterizing the most prolific causes.

Experience Favorable from an Insurance Standpoint

The point desired to be emphasized is that all of these plants have had periodical inspection for the removing of dangerous conditions evident to competent safety engineers. They have also had the bulletin service, which, while general in character, continually reminded the employees of the possibilities of accidents and their basic causes.

With these considerations taken into the analysis of the claims, we believe the experience for this period may be considered favorable from an insurance standpoint. However, much yet remains to be done in the prevention of accidents, through perfecting more "fool-proof" bakery machinery, and through the careful planning of educational campaigns. Our own observation of other plants where the same type of safety engineering and accident prevention service has not been in effect would indicate that the baking industry outside of the plants served at Casualty Reciprocal Exchange, has a far greater frequency and severity of accidents.

In the past, I believe the point of operation of the dough mixer has been the greatest hazard, causing death and permanent disabilities, all of a gruesome nature, and all resulting from the bakers attempting to remove dough, or clean the machinery while the power was on. There has been no practical way devised to guard the mixer so that the power could not be applied when the mixer is in a tilted position; however, companies are now manufacturing the tilting type mixer with an auxiliary motor, so that power is applied to the rotating of the mixing arm only so long as the operator keeps his finger on the safety button located in front of the dough mixer. This permits him to have one arm free for the removing of dough

or the cleaning of machinery, and likewise places the control of the machinery under his finger at all times.

It is hoped that this type of mixer will rapidly replace the old type, although the bakeries still demand the old type, and manufacturers, eager to satisfy this demand, and with no thought of safety, continue to make them. That same thing applies to a great many machines manufactured today without proper safety devices. There has been a noticeable improvement in the last several years in the manufacturing of bakery equipment, and you will seldom see modern equipment now which does not have the moving parts completely guarded before leaving the factory. As a whole, we believe the manufacturers of baking equipment should be commended for the improvement they have made from a safety standpoint.

There is much to be done for the elimination of accidents in the baking industry. I am not only expressing my personal opinion, but the opinion of my principals, when I say that the Food Section of the National Safety Council is invaluable in promoting safety among bakeries, as this section will concentrate its activities on the methods of preventing accidents in the foods industry.

NOTE

Volume III of these Transactions, containing the Public Safety and Education Sessions of the Congress, is being sent automatically to certain members of the National Safety Council who are believed to be interested in this subject. Any other member of the Council may also receive a copy of this Volume III without charge by requesting it.

Marine Section

New Officers of the Section

CHAIRMAN: CAPT. WM. P. KAIN

American Steamship Owners' Mutual P. & I. Assn., New York City.

1ST VICE-CHAIRMAN: C. H. POTTER

Potter Transportation Company, New York City.

2ND VICE-CHAIRMAN: ROBERT F. HAND

Standard Oil Company, (N. J.), New York City.

3RD VICE-CHAIRMAN: CAPT. R. C. BRENNAN

Pacific Steamship Company, Seattle, Wash.

4TH VICE-CHAIRMAN: F. P. FOISIE

Waterfront Employers' Association, South Seattle, Wash.

SECRETARY: A. R. BUSH

The Barber Asphalt Company, Maurer, N. J.

Committees

POSTER: CAPT. G. BARTLETT, Chairman

Cosmopolitan Shipping Co., Hoboken, N. J.

PROGRAM: R. E. PROUTY, Chairman

Aetna Life Insurance Co., New York City.

MEMBERSHIP: ARTHUR M. TODE, Chairman

The Texas Company, New York City.

STEVEDORING: F. H. WEEKS, Chairman

Weeks Stevedoring Co., New York City.

RESEARCH: CAPT. IRVING L. EVANS, Chairman

United States P. & I. Agency, Inc., New York City.

PUBLICITY: ARTHUR M. TODE, Chairman

The Texas Co., New York City.

INFORMATION AND SERVICE: MILTON D. MCINTYRE, Chairman

Pickands, Mather & Co., Cleveland, Ohio.

ENGINEERING REPRESENTATIVE: W. E. WELCH

The Travelers Ins. Co., New York City.

October 26, 1926

W. E. WELCH, Chairman

Safety Engineer, The Travelers Insurance Co., New York City

THE first session of the Marine Section of the National Safety Council Congress convened at 9:30 o'clock, Tuesday morning, October 26, 1926, in the Statler Hotel, Detroit, Michigan. Mr. W. E. Welch, chairman, presided.

Fifteenth Safety Congress

CHAIRMAN WELCH: We of the Executive Committee desire to thank you for your presence here. There are not so many in quantity but the quality is good. We extend a welcome to you all and also the membership of the Marine Section.

The first thing on the program is a report from your chairman for the year. I haven't much to report. We have increased our membership slightly and it is in good shape. In addition to this good membership, some of the steamship lines are placing safety aboard their ships along the lines of the activities we have suggested through the Marine Section and the Executive Committee. I have in mind the Texas Company, the Garland Steamship Company, the Standard Oil Company, and so on.

We started our news letter about the first of the year and we have as good and instructive a news letter as any Section in the Council; and that has all been done through the hard work of our news editor, Mr. Bush.

In addition, we have held a meeting, every month, of the Executive Committee, conferring together, giving assistance to those who were at the meetings in connection with safety aboard ships. We have placed bulletin boards aboard ships, and so on.

We will hear from Mr. A. R. Bush, chairman of the Program Committee.

Reports of Two Committees

A. R. BUSH (The Barber Asphalt Company, Sewaren, N. J.): The activities of the Program Committee during the past year may be summarized chiefly in the items of this program which we are about to present to the Section, in all of which we are confident you will be greatly interested.

In addition to the program planning, the committee, upon request of the Section Chairman, inaugurated in February a News Letter which has been issued at regular intervals up to the present time. It is hoped this feature has been a real service to the membership for this is its sole purpose and justification for continuance.

CHAIRMAN WELCH: Now from Mr. Edwards, Statistics Committee.

R. F. EDWARDS (Prudential Insurance Company, Newark, N. J.): My committee can report progress. The work has been principally an effort to gather statistics. Probably the most valuable work is on the way now, which is an analysis of the P. and I records, of which Captain Evans will give you more information in his paper. That promises to be a very valuable contribution when it is finished. I know we will have a very good line on health hazards in the direction of disabilities and fatalities in the marine industry.

An effort has also been made to get real statistics from a number of oil companies, and many matters are still in the air. It has not been definitely settled as to just what we can do in that line.

CHAIRMAN WELCH: The next in order is appointment of the Nominating Committee and I will name the following for this committee:

Robert F. Hand, Standard Oil Company.

Arthur M. Tode, The Texas Company.

Captain W. P. Kain, American Steamship Owners' Mutual Protection & Indemnity Association, Incorporated.

These gentlemen will please report at tomorrow's session the designated officers and chairmen of committees for the coming year.

We will now listen to a paper by Mr. D. N. Hoover, Supervising Inspector General, U. S. Steamboat Inspection Service, Department of Commerce, Washington, D. C.

ESSENTIALS OF MARITIME SAFETY

D. N. Hoover, Supervising Inspector General, Steamboat Inspection Service, Department of Commerce, Washington, D. C.

Safety of human life, the thing for which the National Safety Council exists, safety at work, on the street and in the home, is something that has developed increasingly in modern times. It has become the purpose of many associations to conserve human life, and as we travel upon railroad and steamship, as we undertake to cross busy thoroughfares, we may see at every hand the effort that is made by man to prevent accidents and possible loss of life.

So far as the service of which I am the head is concerned, you are interested in knowing the policy that is followed in the Steamboat Inspection Service with a view to carrying out the constructive principles for which you gentlemen are working; and it may be stated that our first thought is to make the thing itself safe from a constructive point of view. To illustrate, a man may have a sore upon his body and a lotion or salve may help him; but it should be remembered that if his blood were pure there would be no sore; hence the intelligent physician, while he may undertake to give local relief, will also seek to find the causes back of the condition with which the man is suffering.

Applying that principle to the inspection of ships, we first endeavor to see whether the hull of a vessel is in proper condition. The Statute, in brief, requires that the local inspectors shall, at least, once in every year, carefully inspect the hull of each steam vessel, within their respective districts, and shall satisfy themselves that it is of a structure suitable for the service in which she is to be employed, has suitable accommodations for passengers and crew, and is in a condition to warrant belief that she may be used in navigation with safety to life, and that all requirements of law in regard to fires, boats, pumps, hose, life-preservers, floats, anchors, cables, and other things are faithfully complied with. The local inspectors shall also, at least once, in every year, carefully inspect the hull of each sail vessel of over 700 tons carrying passengers for hire and all other vessels and barges over 100 tons burden carrying passengers for hire within their respective districts, and shall satisfy themselves that each is of a structure suitable for the service in which she is to be employed, has suitable accommodations for the crew, and is in condition to warrant the belief that she may be used in navigation with safety to life.

Whenever any inspector or assistant inspector shall find on board any

vessel subject to the provisions of this title, any equipment, machinery, apparatus, or appliances not conforming to the requirements of law, he shall require the same to be placed in proper condition by the owner or master of the said vessel, if possible; and if he shall find on board any such vessel any life-preserver or fire hose so defective as to be incapable of repair he shall require that the same be destroyed in his presence. Local inspectors have power to enforce these requirements by revoking the certificate of the vessel, and by refusing to issue a new certificate until the requirements shall have been fully complied with.

In the inspection of the hull, the inspectors are called upon to see that the vessel is properly constructed, whether she possesses proper strength, whether her bulkheads are properly placed and constructed and, since the Eastland disaster, the inspectors have given increased attention to the matter of the stability of ships. In a word, we seek to do with a ship what a municipality seeks to do with a building, for in the building it matters not how excellent the walls may appear or what kind of a roof may be required, we must be certain what kind of a foundation the building has. Hence, in the case of a ship, regardless of what may be placed in her in the matter of boilers and machinery and on her in the way of life saving equipment, the important thing to determine first is that the ship, herself, is good.

No Ship Is Better Than Her Boilers

If one speaks to an engineer, he will hear him say that no ship is better than her boilers. The law contemplates the importance of this feature, and in the Revised Statutes states that "The local inspectors shall also inspect the boilers and their appurtenances in all steam vessels before the same shall be used, and once at least in every year thereafter, and shall subject all boilers to the hydrostatic pressure. All such vessels shall comply with the following requirements: That the boilers are well made, of good and suitable material; that the openings for passage of water and steam, respectively, and all pipes and tubes exposed to heat, are of proper dimensions and free from obstructions; that the spaces between and around the flues are sufficient; that flues, boilers, furnaces, safety valves, fusible plugs, low-water indicators, feed-water apparatus, gauge cocks, steam gauges, water and steam pipes connecting boilers, means of prevention of sparks and flames from fire doors, low-water gauges, means of removing mud and sediment from boilers, and all other such machinery and appurtenances thereof, are of such construction, shape, condition, arrangement, and material that the same may be safely employed in the service proposed without peril to life; and the local inspectors shall satisfy themselves by thorough examination that said requirements of law and regulations in regard thereto have been fully complied with. All boilers used on steam vessels and constructed of iron or steel plates, inspected under the provisions of section 4430, shall be subjected to a hydrostatic test, in the ratio of 150 pounds to the square inch to 100 pounds to the square inch of the working steam power

allowed. No boiler or flue pipe, nor any of the connections therewith, shall be approved, which is made, in whole or in part, of bad material, or is unsafe in its form, or dangerous from defective workmanship, age, use, or other cause."

In proceeding in this matter of boiler inspection, the law and the rules require that the plans of Scotch and similar boilers shall be approved by the respective boards of local inspectors having original jurisdiction and, in the case of water tube and similar boilers, the plans are required to first be approved by the Board of Supervising Inspectors. But we do not stop with the mere approval of plans, and require that all material subject to tensile strain shall be tested by an inspector of this Service. That material is tested and stamped with the tensile strength, the initials of the inspector, the stamp of the United States Government, and the number of the plate, and we have in the office of the Supervising Inspector General at Washington a record that is not complete until each plate in every boiler subject to inspection is checked by the record of tensile test reports in the office at Washington.

Equipment of a Life Saving Character

It is also required by the law that at least once a year hydrostatic pressure shall be applied in the ratio of 150 pounds hydrostatic pressure to 100 pounds of steam pressure. Furthermore, at annual inspection, the inspector is required to enter the boiler, if possible, and by actual visual examination and the use of the hammer, determine whether the boiler is in good condition. This matter of annual inspection takes place also with reference to hulls and the hull inspector is required to go through the water bottoms and, in fact, every part of the ship, and determine whether the ship is safe to be certified for another year.

We may now have a vessel excellently constructed, according to plans laid down by the best and most expert naval architects, boilers composed of the finest steel and fabricated by the best workmen and, yet, there is another factor to be considered in the matter of inspection and that is the equipment of a life-saving nature, such as life boats, life rafts, life preservers, davits, hose, etc. Life boats are built according to plans and specifications approved by the inspectors and this is also true of life rafts and life preservers and all of this apparatus is carefully examined at the annual inspection and, in the case of excursion and ferry steamers, at least three times a year in addition. The davits for ships are carefully tested and anyone who has ever seen davits tested, either at the foundry or place of manufacture, must be impressed with the gruelling tests imposed by the Government upon the manufacture of such apparatus. In order to get water to a fire, it is necessary to have hose, but hose is of no avail if it be not strong enough to carry the stream, and hence the inspectors are particularly careful in their inspection to see that it will stand a certain pressure.

Ships, however, are built not for pleasure or for the purpose of giving employees of the Government an opportunity of inspecting them. They are built for use in transporting people and cargo, they are built as a

business investment and hence we have to bear in mind the discipline that must prevail and the regulations that must exist with reference to the transportation of certain kinds of commodities. The law is very particular in laying down certain things that shall not be carried and in stating the conditions under which certain things may be carried as, for example, "No loose hay, loose cotton, or loose hemp, camphene, nitroglycerin, naphtha, benzine, benzole, coal oil, crude or refined petroleum, or other like explosive burning fluids, or like dangerous articles, shall be carried as freight or used as stores on any steamer carrying passengers; nor shall baled cotton or hemp be carried on such steamers unless the bales are compactly pressed and thoroughly covered and secured in such manner as shall be prescribed by the regulations established by the board of supervising inspectors with the approval of the Secretary of Commerce; nor shall gunpowder be carried on any such vessel except under special license; nor shall oil of vitriol, nitric or other chemical acids be carried on such steamers except on the decks or guards thereof or in such other safe part of the vessel as shall be prescribed by the inspectors.

Precautions Against the Hazards of Fire

"Refined petroleum, which will not ignite at a temperature less than 110 degrees Fahrenheit, may be carried on board such steamers upon routes where there is no other practicable mode of transporting it, and under such regulations as shall be prescribed by the board of supervising inspectors with the approval of the Secretary of Commerce; and oil or spirits of turpentine may be carried on such steamers when put up in good metallic vessels or casks or barrels well and securely bound with iron and stowed in a secure part of the vessel; and friction matches may be carried on such steamers when securely packed in strong, tight chests or boxes, the covers of which shall be well secured by locks, screws, or other reliable fastenings, and stowed in a safe part of the vessel at a secure distance from any fire or heat. All such other provisions shall be made on every steamer carrying passengers or freight, to guard against and extinguish fire, as shall be prescribed by the board of supervising inspectors and approved by the Secretary of Commerce. Nothing in the foregoing or following sections of this Act shall prohibit the transportation by steam vessels of gasoline or any of the products of petroleum when carried by motor vehicles (commonly known as automobiles) using the same as a source of motive power: Provided, however, that all fire, if any, in such vehicles or automobiles be extinguished immediately after entering the said vessel, and that the same be not relighted until immediately before said vehicle shall leave the vessel: Provided further, that any owner, master, agent, or other person having charge of passenger steam vessels shall have the right to refuse to transport automobile vehicles the tanks of which contain gasoline, naphtha, or other dangerous burning fluids.

"Provided, however, that nothing in the provision of this Title shall prohibit the transportation by vessels not carrying passengers for hire,

of gasoline or any of the products of petroleum for use as a source of motive power for the motor boats or launches of such vessels: Provided further, that nothing in the foregoing or following sections of this Act shall prohibit the use, by steam vessels carrying passengers for hire, of lifeboats equipped with gasoline motors, and tanks containing gasoline for the operation of said motor-driven lifeboats: Provided, however, that no gasoline shall be carried other than that in the tanks of the lifeboats: Provided further, that the use of such lifeboats equipped with gasoline motors shall be under such regulations as shall be prescribed by the board of supervising inspectors with the approval of the Secretary of Commerce: Provided, however, that nothing in the foregoing or following sections of this Act shall prohibit the transportation and use by vessels carrying passengers or freight for hire of gasoline or any of the products of petroleum for the operation of engines to supply an auxiliary lighting and wireless system independent of the vessel's main power plant: Provided further, that the transportation or use of such gasoline or any of the products of petroleum shall be under such regulations as shall be prescribed by the board of supervising inspectors, with the approval of the Secretary of Commerce. Provided, however, that kerosene and lubricating oils made from refined products of petroleum which will stand a fire test of not less than 300 degrees Fahrenheit may be used as stores on board steamers carrying passengers, under such regulations as shall be prescribed by the Board of Supervising Inspectors with the approval of the Secretary. Provided, that the owner of any automobile in which all fire has not been extinguished and the motor stopped immediately after the automobile has taken its position on any vessel found on navigable waters of the United States and in which such fires do not remain extinguished and the motors remain idle until the vessel is made fast to the wharf or ferry bridge at which she lands, shall incur a penalty of not more than \$500, for which the automobile shall be liable."

You Can Not Get Away From the Human Equation

While this Statute goes into considerable detail, it had to be changed as it contemplated conditions as they existed on western river steamers, and hence we are confronted with the problem of applying a law that is more applicable to a western river steamer than to an Atlantic liner. The law has been amended and the Interstate Commerce Commission has given authority to formulate regulations with reference to the transportation of dangerous articles on board ships, and, eventually we shall have a good constructive code to follow with reference to this subject.

You may have a good ship, well constructed, of the best material, boilers composed of the finest steel, fabricated by the most expert workmen; you may have a sufficient number of life boats and life rafts, life preservers, pumps, hose, davits and, yet you can not get away from the human equation. The Steamboat Inspection Service does not operate ships, although whenever a great disaster occurs, the public seems

to think so. But we do recognize the existence of this human equation and here we come to another arm of our Service which has to do with the licensing of the officers who command these ships, such as masters, mates, pilots and engineers and the licensing and certificating of able seamen and lifeboat men. Licensed officers are required to be examined in the principles of first aid, and deck officers have also to pass an examination in color sense and visual acuteness. Licenses are issued for five years unless suspended or revoked and, in the case of deck officers, at every renewal of the license, the man is examined for color sense. The reason is because, as you know, there is a green light on the star-board side and a red light on the port side of vessels; also, you know that buoys are of different colors and these colors mean something, and, hence, it is absolutely necessary that a deck officer shall have correct color sense so as to avoid possible disaster as the result of collision. Furthermore, all licensed officers have had actual, practical experience on board vessels.

Conduct Investigations of Law Violations

In carrying out this work, we not only license men and take their licenses from them, if necessary, but we also conduct investigations of violations of law by licensed officers, so that you have, in the case of the Steamboat Inspection Service, an organization that is unique in the Federal Government. We have certain administrative functions to perform when we inspect hulls and boilers and certificate vessels and license men. We have certain quasi-judicial functions to perform when we investigate the conduct of licensed officers and in so proceeding the boards of local inspectors have original jurisdiction. From the decision of such boards, an appeal lies to the supervising inspector of the district and from the decision of the supervising inspector an appeal lies to the Supervising Inspector General in Washington. We have legislative functions to perform when the Board of Supervising Inspectors, consisting of the Supervising Inspector General, as president, and the respective supervising inspectors of the districts, formulate rules and regulations and these rules and regulations, when approved by the Secretary of Commerce, have the force of statute law.

Despite the care taken, however, disasters occur, and it will always be so, because we are human and not perfect, and, because, no matter how perfect a thing may be, there will yet be found some flaw in it, and, because, despite regulations, there is always present the human equation.

Yet, this is true—that the inspection work done by this Service has been effective and it may easily be said with reference to the Service that "by its fruits you shall know it," for during the year ended June 30, 1926, 350,370,065 passengers were carried on steam vessels that are required by law to report the number of passengers carried. Dividing this number by 103, the total number of passengers lost, shows that 3,401,651 passengers were carried for each passenger lost; also during the last fiscal year, there were 752 lives saved through apparatus furnished

for that purpose. At the same time, however, it is to be remembered that if it were possible to make perfect rules and regulations, if it were possible to make perfect ships, if it were possible to make men with perfect minds who never erred in judgment, there would be no need for an inspection service and there would be no need for a National Safety Council. But, it is because we recognize our human shortcomings, that we organize ourselves into Associations for the purpose of conserving human life and we have our representatives in Congress passing laws making men be careful whether they will or not.

We would be dead men however, if we only look backward and quote statistics, or if we only look at that which exists and say this is good enough. We are only live men in proportion as we have vision and look toward the future, and there are some things necessary to be done in the matter of laws in order to improve safety conditions on board ship.

For example, we need a new law for boiler pressures that will, instead of writing the matter into a statute and taking all discretion away, give the Board of Supervising Inspectors the discretion of making such rules and regulations as may be necessary covering boiler pressures. I have referred to the necessity for a change in regard to the transportation of dangerous articles. You will recall that we had certain disastrous fires not long ago on the Atlantic coast and this brings up the question of proper fire control, a matter that has been receiving the attention of this Service; and we hope, within the not distant future, to be able to formulate rules and regulations in this respect that will be abreast of the best modern practice, in accord with the best authorities in this country and abroad. In the formulation of such regulations, our spirit is not necessarily to say to a man you *must* do a certain thing or you *cannot* do a certain thing, because, after all, people do not like to be talked to that way; but to take into our confidence, if you please, the various interests which we touch, consisting, upon the one side, of vested interests in many millions of property in the shape of ships, and, on the other side, of men who go down to sea in ships, such as licensed officers, able seamen and lifeboat men; and, last but not least, and, in fact, most important, is what I may term the "third estate," the people, the public, who pay taxes for all of the service and who have a right to obtain efficient service.

Discussion Following Mr. Hoover's Paper

CHAIRMAN WELCH: We all desire to thank you, Mr. Hoover, for that very fine exposition of safety which will make a very good hand book on safety when printed.

R. F. EDWARDS: I would like to ask Mr. Hoover, if you have any details of accidents and what they are?

MR. HOOVER: When accidents occur the licensed officers are required to report them to the local inspectors of the district that has jurisdiction. The local inspectors of the district are required to investigate those accidents and make a report to Washington. Those reports are not made

at the end of a month or a fiscal year, but as they occur, so we have a complete index covering as many details as we can get.

MR. EDWARDS: Does that cover accidents that occur on ships?

MR. HOOVER: Yes, accidents that occur on inspected vessels.

F. P. FOISIE (South Seattle, Wash.): In connection with a proposed longshore compensation act now before Congress, suggestion has been advanced that the authority and jurisdiction of the Steamboat Inspection Service be extended to the ship's gear for cargo handled. Do you care to contend that that is feasible?

MR. HOOVER: I might say in regard to that that during the past years we have gradually been extending our inspection in some directions over things over which we have not had express jurisdiction—ship's gears in particular.

Up at the Great Lakes particular attention has been given to inspection because I have discussed inspection service with supervising heads at Detroit and Cleveland on safety devices.

Answering your question squarely, it ought to be extended, and our service could handle it.

CHAIRMAN WELCH: Having had considerable to do with stevedoring work I believe your activities in our direction would be a great movement.

GEORGE A. MARR (Lake Carriers' Association, Cleveland, Ohio): We feel we are so well acquainted with the Steamboat Inspection Service we do not have to ask questions. They answer them without query. We do find that the Steamboat Inspection Service is ready at all times to cooperate with the vessel interests and that the vessel interests receive a great service from the Steamboat Inspection Service and that inspection protects us from ourselves.

I think Mr. Hoover has brought out the point very distinctly that the human equation is the one most serious question that has to be considered in matters of safety and we always find and always will find that men are not only liable to err, they are willing to err if they can save a little money or save themselves some trouble and effort. The Steamboat Inspection Service is the safeguard we have against committing errors intentionally or unintentionally and our cooperation with them is always to our own benefit.

CHAIRMAN WELCH: We will now hear from Lieut. Commander H. H. J. Benson, U. S. N., Naval Hydrographic Office, Washington, D. C.

THE NAVY'S CONTRIBUTION TO SAFETY AT SEA

Lieutenant-Commander H. H. J. Benson, United States Navy,
Washington, D. C.

The navy's contributions to safety at sea have been of two kinds: Those relating to safety on individual ships such as interest every ship owner and ship master, and safety as it affects the navigation of ships in general. The mission of the Hydrographic Office, where I am on duty, is to assist mariners to travel with safety on the sea. I will, therefore, dwell chiefly on that phase.

Since its earliest days, the Navy has stood for safety at sea, although before 1840 perhaps its chief contribution was in fighting to protect merchant shipping from interference by the Barbary pirates and even by the civilized nations whose ships stopped ours and impressed our seamen into their own service.

The Hydrographic Office was established under the Navy in 1830. To carry out its mission, charts, light lists, sailing directions, and navigational books are issued. Due to changing conditions, earthquakes, erosion, new discoveries and new construction, the charts, light lists, and sailing directions must be continually revised. For this correction, daily and weekly notices are distributed, containing all new information and when urgent, messages are broadcast by radio. To obtain the necessary data, the office is in communication with its surveying ships, other Naval and over 3,000 merchant ships all over the world. In addition, official notices and new charts are received from foreign governments.

The work of the Hydrographic Office has been a steady development from the start. The development during the time of Commander M. F. Maury was particularly marked. This was from 1842 to 1861. Commander Maury during this period, after consulting the log books of thousands of voyages, obtained data from which he was able to determine with considerable accuracy the prevailing winds in the various parts of the sea, and the general flow and strength of the currents. This information was laid down on charts in such a way as to be of practical use to mariners. Until his wind and current charts were issued, little information was at hand regarding the effect, for instance, of the Gulf Stream on trans-Atlantic ships.

An Old Chart Produced by Benjamin Franklin

One of the first current charts indicating the effect of the Gulf Stream was produced by Benjamin Franklin from a drawing made for him by a Nantucket ship captain. This drawing was used to explain why vessels of the Colonists were able to make better time to America than the British mail packets, which were larger and faster ships. The Colonial vessels knew of the Gulf Stream, and utilized it going to the eastward, and avoided it returning, while the British packet ships, not having this information, bucked the current on the trip to the westward.

Since Maury's time, repeated effort and investigation have been made to determine with accuracy as much information as possible regarding the Gulf Stream. These investigations have been carried on principally by Naval officers, and among those who have been specially connected with this work are the late Rear Admiral Pillsbury and Rear Admiral Sigsbee.

The courses that could be followed with best results in taking advantage of the prevailing winds and currents from our ports to other ports of the world, were laid down on the wind and current charts for sailing vessels. In those days, practically all of our commerce was carried on by sailing vessels.

Captain Jackson, commanding the "H. D. C. Wright" of Baltimore, was the first to follow the new track from the United States to Rio de Janeiro.

He made the voyage out and back in the time frequently consumed by the outward voyage alone. The work of planning new sailing routes was continued in all of the oceans as rapidly as data could be collected and utilized. The time saved on voyages from New York to San Francisco, in consequence of these well studied and laid out routes, was 44 days.

When the steamship *San Francisco* was wrecked with hundreds of U. S. troops on board, Maury showed the Secretary of the Navy on the chart just where the wreckage would drift, and where to send relief. The survivors were picked up in the place indicated.

Up to 1850 no soundings of great depths had been made, it being impossible to heave up the weights from great depths. About this time, Midshipman Brooke proposed a contrivance by which the weight would detach itself upon striking the bottom and the line was reeled up with a sample of the bottom in a cup on its end. This device together with the use of fine piano wire working on a metal reel operated by steam, made it possible to take soundings of any depth. This enabled the sounding of large areas of the Atlantic and led to Maury's recommending the route for the laying of the first trans-Atlantic cable, between Newfoundland and Ireland.

Charts Are Important in Life Saving at Sea

Charts are highly important articles in safe navigation at sea. Mariners' charts may be compared to road maps for the automobilists, but as the ocean is not so well marked with sign posts as most of the roads, charts are very much more necessary than road maps. The safe channels, aids to navigation and the dangers to be avoided are plainly marked on the charts. A poor chart is probably worse than none. Their importance is fully recognized by Naval officers and a great many of the charts of the world are made from surveys undertaken by our ships.

Thus, while on cruises, to show our flag or to protect our interests in far corners of the earth, Naval officers have taken advantage of the opportunity to add to existing or frequently non-existing information. Among the early editions of charts are several made by the expedition under the command of Commodore Perry when he opened up Japan to trade with the United States. These charts are very interesting, showing many historical details, such as the house where the treaty was made and positions where the ships anchored. Our ships still continue such work and recently the ships of the squadron stationed in Central American water, where revolutions are not altogether uncommon, have surveyed several harbors while at the same time protecting United States interests. Three Naval vessels are maintained for and employed in surveying duty alone. They are now surveying the coasts of Cuba and Venezuela.

In addition to the charts for navigational purposes, charts are published monthly which show the conditions of wind, weather, and ocean currents which may be expected during the month. These charts are called "Pilot charts" and are further developments of Maury's original charts. On them we advise what tracks are desirable to follow in going from one port to another.

In 1855 Maury published a chart with two lanes laid down, each 25 miles broad, for the use of steamers in going and returning across the Atlantic. By following these lanes, vessels avoided the danger of frequent collisions with other steamers, sailing vessels, and icebergs, particularly during the dense fogs which hang perpetually over the banks of Newfoundland. This was the beginning of the elaborate system of tracks at present followed by the principal steamship companies across the Atlantic. They are changed with the seasons and are so laid down as to reduce the dangers from ice and fog to a minimum.

If we consult a winter pilot chart of the north Atlantic ocean, we see that vessels going from ports on the English Channel to New York will probably encounter many gales and adverse currents along the northern routes. The large, high powered vessels are not seriously affected, but for the smaller, low powered vessels, heavy winds cause great delay. Therefore, we find that the route for such ships is laid down far south where the percentage of gales is much less. Such vessels following these courses as laid down actually make better time for the voyage and arrive in port having sustained little or no damage from heavy weather; whereas vessels in trying the high powered route suffered heavy damage during the same time of the year. Vessels following the northern routes to European ports have the benefit of favorable currents and winds. The winds in the strong gales are generally astern and tend to help them along.

Stories of the Strange Drifts of Bottle Messages

Knowledge of how the currents flow has been and still is greatly augmented by the use of bottles containing papers giving date and place where set adrift. The stories of these, in many instances, are quite interesting. One of the most remarkable drifts of bottles which has been reported is one which was dropped overboard in Latitude $50^{\circ} 30' S.$, Longitude $50^{\circ} E.$, far south of Madagascar. This bottle drifted about two-thirds of the way around the world and was picked up on the coast of Chile three years later.

Recently a paper was returned by a man in Australia who apologized for not sending it sooner, explaining that his pocket had been picked and as the paper was in the wallet with his money, it was some few weeks before he could recover it. Another paper has been sent in by a woman who walked 18 miles to have it forwarded to our office.

One of the sources of danger to ships at sea is caused by derelicts, waterlogged vessels, frequently loaded with lumber, which float very little, if any, above the surface of the sea. These would be very dangerous to any vessel which collided with them. Derelicts have been known to drift around the ocean for years and travel thousands of miles. Whenever their positions are reported by vessels, this information is sent out by radio and is printed in our publications.

An interesting drift of a derelict is that of the "Fannie E. Wolston," a three-masted schooner, abandoned October 15, 1891, off the North Carolina coast, northeast of Cape Hatteras. Reports from ships which sighted this derelict show that it made a complete circle around Bermuda, going as far east as Longitude 40, over halfway across the ocean. It then drifted

almost to the Bahamas, then northeastward to a position about 700 miles east-north-eastward of the position where abandoned. It was last sighted October 21, 1894, having drifted approximately 9,000 miles in six days more than three years. During that time it was reported 46 times. It drifted backwards and forwards in a very irregular course.

Between October 1923 and October 1924, the derelict schooner "Governor Parr" drifted over 4,000 miles in a very circuitous route from the place she was abandoned south of Newfoundland. When last reported it was near the Canary Islands. During the year it crossed the steamer lanes several times, drifting in unusual directions.

In 1885 the Hydrographic Office started collecting data on the use of oil to prevent damage by heavy sea. Such use is encouraged and accounts of success are published in the Weekly Bulletin. These reports are numerous. During the last year, the most outstanding example of the use of oil to calm seas was when the crew of the Antinoe was rescued by the President Roosevelt in such a brilliant manner. This rescue also brings to mind the successful use of the radio direction finder or radio compass.

The radio is a very important aid to the Hydrographic Office in circulating information regarding navigational dangers. The Navy was the first regular customer for radio telegraph apparatus in this country. Companies were formed and the Navy cooperated closely with them. In the early days there was practically no other field for the sale of radio and competition was keen. The Navy assumed a large part of the development charges of these pioneer companies and practically supported the growing industry.

The Battle Fleet Carried Radio-phones in 1907

It is an interesting fact to those who think that the radio telephone is very new, to know that in 1907, when President Roosevelt sent the battle-ship fleet around the world, each one of the ships was fitted with a radio-phone.

In 1912 experiments were begun with various schemes for obtaining directions of radio signals. An elaborate shore compass system was established during the war. Since then they have been used both for military and navigational purposes. Over 19,000 bearings were given during the month of June for navigational purposes.

Recently a vessel with her magnetic compass damaged so as to be useless, was navigated into port by the use of radio bearings from a shore station and the master was most profuse in his praise of the service. Another case was that of a vessel noted by the radio compass observer on shore to be standing into danger. He told the captain of the vessel he had better back out. The captain stopped his engines but did not back and in seven minutes an S O S went out saying the ship was aground.

This instrument, developed primarily as a war device, is of the great est value for peace time activities. As it has been so successful in locating ships from shore stations and in assisting one ship to locate another whose position is unknown or doubtful, the next step may well be as an adjunct to the whistle to avoid collision in a fog, particularly on the high seas where such additional warning would greatly reduce the danger.

Many lives are now saved each year by the prompt answer of assistance to S O S calls. Whenever an S O S is heard, the radio compass stations attempt to ascertain the position of the vessel sending it. If successful, the position can be broadcasted even though the vessel may have been unable to include the position in its message.

If, some night, you are listening to a good radio concert and the station has to shut down for an S O S, don't object. Remember the compass operators are straining to get a bearing of what may be a very weak signal, perhaps the last dying squeak from some vessel.

In addition to using the radio for broadcasting messages notifying vessels of navigational dangers, the weather forecasts and time signals are also sent out by radio. By use of the weather forecasts and reports obtained from the weather bureau and broadcasted, mariners can make up their own weather maps and shape their courses so as to avoid dangerous storms. To encourage the practical use of these reports, articles on the subject are frequently published on the pilot charts.

In 1821 a ship was given the wrong chronometer rate and in a voyage to the Cape Verde Islands of 25 to 30 days got about 60 miles out in her reckoning. Due to this, she might easily have been lost with all on board. Such errors need not occur today as vessels can receive the time signal from the more important Naval radio stations twice a day and so be sure of the correct time which is so important in navigation.

Naval officers frequently assist mariners in correcting their chronometers. Recently the captain of a schooner signaled the captain of one of our destroyers to ask him to assist in finding the error of the schooner's chronometer. The answer was "certainly, bring it aboard." He was surprised to have the skipper come aboard with a big alarm clock which he used for a chronometer and with which he had navigated a quarter of the way around the world.

Patrolling the Area of Dangerous Icebergs

In 1913, after the Titanic was sunk by collision with an iceberg, the Navy started patrolling the area of dangerous ice during the season when bergs might be expected to menace the steamer lanes. The positions of bergs were broadcast by radio and vessels kept informed of safe courses. The next year, there were no Naval vessels available for this patrol and the coast guard service sent ships. They have continued it each year. This work is known as the international ice patrol and is supported by contributions from all the leading nations. The cutter on patrol locates the ice, informs vessels in the vicinity, broadcasts it and reports to the Hydrographic Office. The information is then circulated to mariners in the chief ports of the United States and to ships at sea by radio.

In experimenting with devices for detecting sounds under water, for the location of submarines, the sonic depth finder has been developed. This has been very successful in sounding the depths of the oceans. Types have been developed for use as sounding machines. These will be a great protection for vessels approaching shallow water in fog, or when, for any reason, their position is not definitely known.

The Navy publishes nautical almanacs and navigation books to enable the mariner to fix his position at sea. New methods are being constantly developed. Those which are considered most useful are published. Only recently two volumes have been issued which simplify navigation immensely.

Much of the development of safety of operation of marine engines has been due to the Navy. Practically all forms of motive power in the United States have been developed first by Naval ships. The steam reciprocating engine, the turbine, the Diesel engine, and the electric drive are certainly steps for safety because each enables more power to be used with safety.

A Naval medical officer, in collaboration with officers expert in diving, a few years ago carried on an extended series of experiments which made it possible for divers to work more efficiently and with more safety at great depths.

Great progress in the development of water-tight compartments has been made in the constant improvement of war vessels, as in these water tightness is a vital consideration in war time. The results were apparent in the last war when many of the merchant ships which were torpedoed were brought into port without sinking.

In general, the Navy has been interested in any device which would increase safety at sea.

Fatalities at Sea Through Careless Motor Boats

J. F. H. WYSE (Canadian National Safety League, Toronto, Canada): This paper is of especial interest to me because Commander Benson is one of my nephews of whom I am very proud. He has had a wonderful record as cadet at the Naval Academy and as officer of the Navy, and this paper has a special interest as it gives us a great deal of information.

His mention of the wreck off San Francisco Harbor is also of special interest as this ship went out from New York carrying a regiment of 500 soldiers to San Francisco to look after the Indians who were kicking up a disturbance. My father was in command and my mother was on board that ship with her first baby. They were wrecked and my mother was put in the first life boat. My father and some of the other survivors were found, probably due to the information furnished by Commander Morey as to the drifts or currents carrying the wreckage from where it was first wrecked by the storm.

One matter of special interest that my mother told me was that Colonel Washington, then in higher rank than my father, came on board the ship late, at New York. Through some mistake my father and mother had taken staterooms on board the main deck which was the top deck, and when Colonel and Mrs. Washington came aboard they put father and mother down below deck (as I suppose was perfectly proper). The result was that when the storm first broke over the vessel these staterooms aboard the main deck were carried away with Colonel and Mrs. Washington, and my father and mother were safe below deck.

MR. WYSE: I would like, Mr. Chairman, to ask this meeting or any one personally, if they know anything about licensing gasoline motor

boats? We have had, in Ontario, several fatalities on account of the careless handling of motor boats. They bulldoze the smaller craft and act as though they were the only boats on the water, and we have had two instances where they have run down people through careless handling.

I only know of one place where there has been any attempt to license boats and that is in the harbor of Toronto. There is a life saving service and police patrol handled in connection with the city and harbor, and they require all boats, including canoes, to take out license.

I haven't been able to get any action from the Dominion Government, although I have taken it up. What I want to ask of the committee is, does any one know of any place where the matter of licensing smaller craft on the water, especially motor boats, has been taken up with the local authorities in control?

MR. HOOVER: I think I can answer that. The inspection and control of smaller motor boats in this country, from my own point of view, is not at all satisfactory. We have what is known as a motor boat act—the act of June 9th, 1910, which endeavored, theoretically, to get safer conditions. That law is thoroughly absurd and inadequate. For example, it is possible in the United States to have a steam vessel of not over 65 feet in length, carrying passengers for hire (examined only if she be between 40 and 65 feet as to approval of the design of machinery) in charge of a licensed operator who need not be 21 years of age and who passes no examination. We are forbidden to examine them. This young fellow has in his hand a piece of paper as beautiful to hand down to posterity as the licensed steamship master. He may be a minor or he may be an alien. That is what the law has done for us.

Peculiarities of the Maritime Regulations

By that same law a steam tug boat, no matter what her length, must be in charge of licensed officers; so you have the startling picture of a steam tug boat being given greater care than a steam passenger boat of the same size. I am working along the line of increasing inspection; thus far I have not been able to get accord between the different minds.

What ought to be done is this: they ought to give us a law that will permit us to inspect, and when I say inspect I mean to examine, as we do a steamer by rules applicable to a motor boat. Of course not such as you give to an ocean liner, but a sufficient inspection, especially on that type of boat that is carrying passengers; and beyond that, certain inspection of every boat of that kind that would insure that it was in good condition.

I would be in favor of a law that would enable us to examine these operators at least in regard to "rules of the road" and visual accuracy as well as color sense. I don't wish to infer that we should give the same examination to an operator of a small craft as that given a master of an ocean steamer. The difficulty is that so many people take license and liberty to mean the same thing. They feel that the slightest interference with their pleasure (an inspection of their motor boat for in-

stance) is interference with their liberty. It is as Mr. Marr so aptly stated, saving them from themselves.

MR. WYSE: Yes, to a certain extent, but the main question I intended to put is, is there any place in the United States licensing small craft, privately owned and not operated for hire or gain or remuneration?

MR. HOOVER: I think that is covered by what is known as the Bureau of Navigation, to a certain extent. It gives numbers to these motor boats. If your question has to do with the exercise of police jurisdiction, that is something, of course, not exercised by the Federal Government. It might be by certain municipalities; certain harbors may have local authorities to do something.

In my opinion the control of motor boats is not effective and it ought to be extended to what I consider an intelligent inspection and control of the personnel in charge, no matter how small.

MR. WYSE: There is necessity for licensing privately owned pleasure boats the same as the licensing of an automobile.

MR. HOOVER: I quite agree with you, but we have not been able to get any satisfaction simply because it has often been held to interfere with the individual liberty of the person.

MR. WYSE: We ought to safeguard people in lesser craft that are at the mercy of these small motor boats: I mean the row boats and the canoes.

I have in mind my own experience. I was out from port in Lake Erie; I was anchored and fishing and a motor boat carrying passengers drove right at me. If I had not pulled up anchor and gotten away they would have run me down. It was a sort of joke with them but not with me. A fatality I have in mind was on the St. Lawrence River where a school teacher was swimming across a bay and a motor boat ran her down and killed her. That boat drove right into her. There was no check on those boats and they had no license; they were just operated by careless operators. Every year we have had that kind of thing to contend with in Canada.

CHAIRMAN WELCH: Mr. R. F. Edwards will now read a paper on the "Hazards of the Maritime Industry from the Life Insurance Point of View," by Mr. A. D. Reiley.

MARINE RISKS FROM THE LIFE INSURANCE STANDPOINT

A. D. Reiley, Mutual Life Insurance Company, New York City

I should say that the life insurance standpoint is the dollars-and-cents standpoint on a purely life and death basis. We, of course, judge our risks in their relation to the average mortality of healthy lives, which is, after all, what is meant by a mortality table.

There has been adopted recently by the actuaries, underwriters and statisticians of a number of companies, a new occupational classification for statistical purposes, and in this the classification of marine risks is as follows:

OCEAN STEAMERS:

3,000 or more gross tonnage.

Tropical ports.

Other ports.

Less than 3,000 gross tonnage.

Tropical ports.

Other ports.

GREAT LAKES STEAMERS:

2,000 or more gross tonnage.

Less than 2,000 gross tonnage.

Sailing vessels—ocean and Great Lakes.

RIVER AND HARBOR CRAFT.

ALL OTHERS.

This is not quite as diffuse as the classification for rating purposes used by most life insurance companies. The classification for this purpose which is used by the company with which I am connected is as follows:

STEAM AND POWER VESSELS:

Ocean.

Temperate zone and to Cuba and Porto Rico.

First class vessels, regular routes, 2,500 tons and over.

Vessels less than 2,500 tons, and tramp steamers.

Torrid zone except Cuba and Porto Rico.

First class vessels, regular routes, 2,500 tons and over.

Vessels less than 2,500 ton, and tramp steamers.

Great Lakes.

Vessels 2,000 tons and over.

Vessels less than 2,000 tons.

Inland—river, harbor, and lake, excluding Great Lakes.

SAILING VESSELS:

Sea and Great Lakes.

Vessels 150 tons and over.

Vessels under 150 tons.

Coastwise.

Vessels 60 tons and over.

Vessels under 60 tons.

Inland.

POWERLESS VESSELS (barges, lighters, etc.):

Sea and Great Lakes.

Inland.

This last classification is not as diffuse as that proposed by Captain Evans before last year's Congress.

From these classifications it will be seen that distinction is drawn along several lines:

1st—Size of vessel.

2nd—Deep sea, coast or inland.

3rd—Whether she plies in temperate or tropical waters.

The distinction between sail and steam is, of course, decreasing in importance. The reasons for the first two classifications are obvious. The last contains a strong health reason.

There is also a distinction drawn between officers, engineers, radio operators, pursers and chief stewards and seamen, firemen, etc.

In general, most companies make no extra charge for straight life insurance to officers and engineers on ocean steamers of 2,500 to 3,000 tons and over, traveling on regular lines in the temperate zone, and for officers, engineers, pursers, etc., on inland steamers. For other classes, smaller steamers, tramps, sailing vessels, vessels going to the tropics, etc., and for seamen an extra charge varying from a rate covering a mortality of from 125 per cent to 200 per cent is made. That these rates have rather favored the industry is shown by the experience of all life insurance companies. This was brought out in the joint investigation of occupational hazards by Life Insurance Companies; the Medico-Actuarial Investigation published in 1913. Of course this experience is familiar to everyone, but I quote it merely for continuity.

Officers and Engineers on Steamers on the Great Lakes

Actual Deaths	Expected Deaths	Ratio of Actual to Exp. Deaths
95	80.80	118%

Officers and Engineers in Coastwise Trade, excluding those traveling to the Tropics.

Actual Deaths	Expected Deaths	Ratio of Actual to Exp. Deaths
34	24.69	138%

Officers on Steamers on Rivers, Lakes, Sounds and Harbors, excluding Great Lakes.

Actual Deaths	Expected Deaths	Ratio of Actual to Exp. Deaths
75	70.41	107%

Officers and Engineers on Ocean Steamers.

Actual Deaths	Expected Deaths	Ratio of Actual to Exp. Deaths
103	66.07	156%

The death rate from accident among those whose duties keep them on rivers, lakes, sounds and harbors was three times the normal; among those on the Great Lakes, four times; among those engaged in the coastwise trade, and on ocean steamers, five times the normal.

Practically all the data included in this study date back 20 years or more. On the other hand, the classes are the most favorable in the straight marine part of the industry, as they include only officers and engineers.

A limited life insurance experience to which I have had access shows but little change in the mortality on the same classes for the last 18 or 20-years up to the present time. In fact, where there is any difference the mortality is a few points higher. The accidental death rate also swings in much the same scale although this may be due in part to claims during the late war. This is by no means conclusive that there has been no improvement in the industry from the standpoint of mortality during this period. The experience is not large and is subject to considerable accidental fluctuation. I am of the opinion that, could the

joint experience of all life insurance companies be taken, it would show considerable improvement.

This view seems to be borne out in part by the latest Combined Group Mortality Investigation, 1913-1924. This shows among employees on vessels other than river, a mortality only 63 per cent of the expected by the A. M. table as compared with 84 per cent for the entire group experience. The actual deaths numbered 20 in an exposure of 3,388 years of life. This is also a very small experience and valuable only in connection with other data.

The English compensation figures (1920 to 1924, inclusive), show that fatal accident rates are higher in the shipping industry than in any other

Cause of Death	1	2	3	4	5	Total
Accidents	---	---	---	---	---	---
Drowning	---	3	7	7	16	33
War claims	---	---	1	---	12	13
Falls of all kinds	---	---	1	---	3	4
Murders	---	---	---	1	3	4
Explosions	---	---	---	2	1	3
Asphyxiations	---	---	---	1	2	3
Auto accidents—in car	---	---	1	1	---	2
Crushed by falling tree	---	---	---	1	---	1
Diseases	---	---	---	---	---	---
Influenza	---	1	2	6	5	14

Peritonitis	---	---	---	---	1	1
Syphilis	---	---	---	1	1	1
Embolism and thrombosis	---	---	---	1	---	1
Disease of arteries	---	---	---	1	---	1
Disease of bladder, prostate, etc.	---	1	---	---	---	1
Sudden death	---	---	---	1	---	1
Total	6	5	23	49	70	153

of the seven large groups of industries, not excluding even mines or quarries. The rates varied between 1.1 and 1.6 per 1,000 exposed during the five year period 1920 to 1924, as compared with an average rate of .4 for the entire experience. The English figures are given separately for steam and sailing vessels, and fatal accident rates calculated for the five year period 1920 to 1924 are 1.2 per 1,000 exposed for steam vessels as compared with 4.0 for sailing vessels. No further data on types of vessels or trade routes are given.

As these figures are not given sufficiently in detail to admit of close analysis, we can not tell whether the somewhat low accidental death rate is due to dilutions or not. By dilutions we mean the inclusion of numbers of risks not subject to the same hazards as the group that furnishes

the American mortality. The accidental death rate is noticeably lower than the American experience. As this was given by Mr. Edwards in his paper before this body in 1924 it need not be repeated here.

The accompanying table is an analysis of 153 life insurance death claims drawn from the following classes:

1. Steam and power vessels—Great Lakes, 2,000 tons and over.
2. Sailing vessels—Ocean and Great Lakes.
3. Steam and power vessels—Coastwise.
4. River, harbor and lake steamers, excluding Great Lakes.
5. Steam and power vessels—Temperate zone (including Cuba and Porto Rico) 2,500 tons and over.

These are all officers and engineers. No seamen are included.

Accidents caused about 40 per cent of the total number of deaths, 63 out of 153. Of these accidental deaths, more than half were the result of drowning. The tuberculosis mortality was about 50 per cent above normal. The mortality from influenza, pneumonia and suicide was about twice the average and the homicide rate was about five times the average.

It is interesting to compare this data with that given by Mr. Edwards in his paper in 1924 from which I beg leave to quote:

"Considering the mortality data at hand covering the experience of the British merchant marine during the period 1919-1921, it will be noted that pneumonia caused the largest number of deaths, or a rate of 6.2 per 10,000 men employed. Circulatory diseases were next in frequency with a rate of 3.9, followed by tuberculosis with 3.4, malaria with 2.0, typhoid fever with 1.4, and alcoholism with a rate of 2.1 per 10,000. The death rate from diseases varied with the class of vessel, or from 15.2 for sailing vessels to 36.0 per 10,000 for steam vessels. The corresponding suicide and homicide rates were 1.5 for sailing vessels and 3.1 for steam."

A Higher Mortality Expected of Common Seamen

None of the foregoing remarks have any relation to any class of marine risks other than officers and engineers. Seamen, firemen, etc., are not included. This is because I have no data, whatever, to offer, and I think few, if any, old line companies have. The sailor is not a provident soul and is scarcely the type that applies for old line life insurance. Again, it has been only of comparatively recent years that old line companies accepted deep sea sailors at all, and many, perhaps a majority, do not do so today. Those that do accept them charge heavy extra premiums.

In all probability the strictly industrial accidental death rate among deck hands, seamen, stokers, etc., is no higher than among officers, and may even be lower. In spite of this fact, life insurance companies expect a higher mortality from them than from the officers. This is due to the generally accepted opinion of the sailor's mode of life. I have had a little sea experience myself and know that, in the past at least, when confronted by the three great instruments of relaxation, wine, women and song, the sailor was never one to confine himself to song. Further, when confronted by the middle instrument, he did not greatly trouble himself with abstruse problems of race, creed or color, especially on ves-

sels touching at tropical or Asiatic ports; these penchants are scarcely the attributes of good life insurance risks.

With regard to special conditions in tropical ports, the United States Public Health Service reports that about one patient out of every three who report to the Manila station for treatment is afflicted with venereal disease. The majority of these infections have been acquired in Japanese and Chinese ports. However, the same condition may obtain elsewhere, for the Hamburg port medical officer reports that venereal diseases constitute one-third of all cases of disease among sailors in the port of Hamburg, Germany.

Careless life ashore has other effects, however. Malaria is of frequent occurrence on ships trading to the tropics. It is reported that between 1908 and 1914, on ships calling at Hamburg, 6,697 cases occurred in a total of medical casualties of 46,000. Figures for 1921-1924 show a smaller proportion, 2,000 malaria cases out of 21,315 patients. Also 124 cases of dengue were reported, almost exclusively in ships from India, 14 per cent of whose crews were affected. In the last three years there were 165 cases of dysentery and 65 cases of typhoid.

I have heard that higher wages and better living conditions are gradually producing a change in personnel and deportment among sailors as they undoubtedly are among ship's officers, but I doubt if the day has arrived when seamen will show anything but a mortality considerably above average.

In summarizing the subject, I think it clear that the old line companies, as a whole, have treated the marine industry up to the present time with perfect fairness. Such extra premiums as have been charged are amply justified by the mortality, as we have been able to ascertain it, and whatever divergence there has been, is on the side of liberality toward the industry rather than the opposite. I believe that conditions are steadily improving and that the mortality rate is gradually receding toward the normal. Certainly no one wishes it to reach that goal more sincerely than the life insurance underwriter.

CHAIRMAN WELCH: Our good friend, Mr. Prouty, of the Aetna Life Insurance Company, New York City, will read a paper by Mr. S. F. C. Sweeny, Safety Engineer, Shipping Federation of British Columbia.

GENEROUS COOPERATION A NECESSITY FOR PROGRESS OF THE SAFETY MOVEMENT IN THE STEVEDORING INDUSTRY

S. F. C. Sweeny, Safety Engineer, Shipping Federation of British
Columbia, Vancouver, B. C.

Cargo handling is a peculiarly hazardous occupation for many reasons, from among which might be selected the following five as being perhaps the most outstanding:

(1) World need for economy, which drives ship owners to supply poor and inadequate gear with which to work their ships.

(2) Competition among stevedores causing cutting of prices and the consequent avoidance of all actions causing delay; in other words, creating *rush*.

(3) Lack of final authority to insist on improvement of working conditions, or the taking of prompt action when unsound conditions present themselves.

(4) Working hours are irregular and employment is full of peak loads and depressions. Night work under bad lighting conditions is prevalent.

(5) The type of work is continually changing.

For these reasons, through cooperation of a very generous nature only, can the hazards of cargo handling be materially reduced.

Poorly found ships, poorly maintained, make for carelessness on the part of every individual having anything to do with them. Bad working conditions are a depressant.

Competition must acknowledge the clear boundaries of safety.

Safety must have authority.

Continuity of work must be striven for.

Adaptability must be attained.

From a responsibility classification of injuries received over a period of nearly two years we are in a position to say:

Statistics Based Upon Experience of Two Years

(a) That from the frequency point of view 80 per cent of our longshore accidents could have been avoided by carefulness on the part of the injured or their partners, and 20 per cent might have been avoided by better methods, more consideration or better gear as provided by the stevedore or ship owner.

(b) That from the severity point of view these figures must be altered to 60 per cent and 40 per cent respectively.

What need for cooperation here? Obviously some need, and when we consider that both costs and personal suffering are more nearly proportional to severity than to frequency we feel inclined to accept the severity rating of responsibility for injuries as being the measure we should adopt.

In all our large ports we have, besides a general port authority, (a) a General Port Federation or Association of Shipping Interests, and (b) a General Port Federation or Association of Labor.

Now the recipients of practically all the injuries are the longshoremen. They are protected usually by some compensation law insuring them 60 per cent to 65 per cent of their wages for time lost through injuries received while at work. As a class they are not thrifty, they spend just what they earn and, if not seriously injured, rather enjoy their better than half pay holiday. There is of course a percentage who strive hard to avoid injuries but the bulk are of rather fatalistic tendencies.

This being the case, definite stimulation from some outside source is necessary to accomplish any reduction in this 80 per cent frequency and 60 per cent severity. Obviously the first essential is to present the case clearly to the longshoremen and to continually keep them posted as to

their responsibility for individual accidents as they happen. They must then be impressed with every phase of the necessity for making an effort to improve their safety record, through encouragement to avoid the misery caused to themselves and through the enforcement of regulations to avoid the expenses caused to the industry. Here then is where a "Safety Department" operated by the employers is necessary; the first act of cooperation on the part of the employers.

This safety department must analyze the hazards existing, determine the relation of employer and employee responsibility, where injuries are received, and frame regulations or standards of practice to prevent recurrence.

Having this part of the safety department's work accomplished will take us, however, only part of the way to a substantial reduction in this 80 per cent of injuries received. Effort is necessary, and more than the effort that can be instilled by the most rigorously enforced regulations. An effort of good will is required from the longshoremen. The desire to make a sustained effort to reduce injuries received must be instilled into the men and their associations. If the men can be induced to encourage carefulness and censure carelessness within their own associations, to hold Courts of Inquiry where they have been held to blame, and to run safety competitions among themselves, injuries can be reduced to a minimum. It means selling the idea to the men's associations and this selling is one of the most important functions of the safety department.

The idea is "Goodwill" and the price is "Cooperation." The employer can have cooperation of the employee if he will give of his good will to the extent of acknowledging his responsibility for injuries, and by taking definite action to improve the conditions which have placed this responsibility upon him.

The Employer's Responsibility for Injuries

This brings us to the employer's responsibility for injuries received, which we have set at 20 per cent frequency and 40 per cent severity. What further need for cooperation here?

Better working conditions are required, and they are not so easy to obtain, because the working places and a great part of the machinery used are supplied by owners, often represented only by agents in the employer's association concerned. In simple language, stevedores can only supply good working conditions insofar as they can supply good tools and good supervision. Unless ship owners maintain good machinery and good equipment bad working conditions will prevail. Cooperation between stevedores, shipping companies, ship owners and ship agents is necessary to obtain sound working conditions.

"Good will is the birthplace of good work and of good working conditions." . . . This is an axiom that might well be adopted wherever industry is carried on. As an example, it is necessary that steamship agents should be ready when so required to support the association by going to owners they represent and asking for improvements in equip-

ment and machinery, to eliminate unsafe working conditions and maintain the good will existing. That such action is necessary is realized by every stevedore who has loaded ships. Working conditions such as are found in almost a majority of deep sea ships would never be allowed in factories on land.

Among the prevalent hazards might be mentioned: (1) hatchbeams that can not be securely fixed in their sockets; (2) winches lacking guards over moving parts; (3) winches with insecure clutches; (4) insufficient lights for night work; (5) bad ladders into holds; (6) ill fitting and poorly conditioned hatchboards; (7) lack of holdfasts for snatchblocks or other means of mechanically stowing heavy, bulky cargo such as logs; (8) poor and insufficient holdfasts for guys and preventer guys on derricks.

Good will is the foundation of accident prevention and to maintain this foundation it is necessary for shipping interests generally to get together and improve working conditions.

I maintain that the shipping organization should operate a safety committee to investigate all important accidents, the prevention of which lies outside the power of the injured individual to prevent (I estimate these at 20 per cent of the accidents happening) and should take action to minimize the causes.

I maintain that the men's organization or associations should operate safety committees to investigate all important accidents, the prevention of which lies within the power of the injured individual to prevent, and should take action to minimize the causes.

I maintain that if any benefit is to be derived from these committees, their respective associations must support them by taking action with respect to their recommendations or findings.

I maintain that unless the employer tackles the question of "Improvement in working conditions" and makes progress in his attack, it is useless for him to expect the worker to give up his careless habits.

I maintain that without standardization of safe practices the employer can not eliminate many hazards now existing, because of the necessity of avoiding loss of time.

I maintain that with progress in the attack on "Unsafe working conditions," enthusiasm will prevail, the safety committees will flourish, safety competitions will be possible, and "No Accident" campaigns will be carried to successful conclusion.

I maintain, lastly, that with standardization of practices an undesirable phase of employer competition will vanish.

Such is my idea of the cooperation necessary to insure progress of the safety movement in the stevedoring industry.

ADJOURNMENT

WEDNESDAY MORNING SESSION

October 27, 1926

The meeting was called to order at 9:30 o'clock by Mr. W. E. Welch, chairman, who presided.

CHAIRMAN WELCH: We will listen to the report of the Nominating Committee for the officers and chairmen of committees for the coming year, whose date of office will take effect after the adjournment of this congress.

A. R. BUSH (The Barber Asphalt Company, Sewaren, N. J.): In the absence of Mr. Hand, chairman, I have been asked to render report by the Nominating Committee.

Chairman, Captain William P. Kain, manager, American Steamship Owners' Mutual P. & I. Association, New York City.

First Vice Chairman, C. H. Potter, president, Potter Transportation Co., New York City.

Second Vice Chairman, Robert F. Hand, assistant manager, Marine Department, Standard Oil Company (N. J.), New York City.

Third Vice Chairman, Captain R. C. Brennan, operating manager, Pacific Steamship Co., Seattle, Wash.

Fourth Vice Chairman, F. P. Foisie, industrial relations manager, Waterfront Employers' Association, Seattle, Wash.

Secretary, A. R. Bush, safety supervisor, The Barber Asphalt Company, Maurer, N. J.

A motion to accept the nominations was regularly made and carried.

CHAIRMAN WELCH: The next paper will be by Mr. Arthur M. Tode, superintendent, Technical Division, Marine Department, The Texas Company, New York City.

ACCIDENT PREVENTION ON TANK STEAMSHIPS

Arthur M. Tode, Superintendent, Technical Division, Marine Department, The Texas Company, New York City.

Virtually every accident on board ship is preventable. On this fact hinges the success or failure of an accident prevention campaign, which consists primarily of bringing home this message to every one connected with the shipping industry.

A careful study of the accidents which occurred on board the vessels of the Texas Company's fleet during the years 1923 to 1925 inclusive, and an analysis of the injuries which resulted, made it apparent that relatively few of the accidents could be classed as unavoidable. In fact, the majority of them could have been prevented by greater carefulness and watchfulness on the part of the men injured, and by co-workers, who in

some instances were partly and in others entirely responsible for the accidents.

The problem of promoting safety on board ship resolves itself into one of education and proper supervision. The first part, that of education, consists in a mental training of all the personnel to think of safety and follow out the principles which promote safety in their daily tasks. Recognizing that mechanical appliances play but a comparatively small part in accident prevention, and that the greater proportion of accidents are attributable to the human factor, an effort must be made to arouse the interest of the worker in the safety of himself and his fellow employees. The individual man on board ship must be taught that his safety depends largely upon himself, just as does the safety of others. The second part of the problem, that of proper supervision, requires the cooperation and assistance of every member of the Marine Department from the highest executives down to the ordinary seamen, wipers, and messmen.

Proper Supervision of Men and Machinery

Proper supervision must include men and machinery. The licensed personnel on the ships, who frequently complain of the inexperience of the men in their charge, must be taught to realize their own responsibility for this condition and make serious efforts to train and instruct the men under them.

The marine department management in turn, must find the ways and means to arouse an interest among the officers on the ships so that the principles of safety, through them, will be indelibly impressed upon the men. This is important because the turnover of the unlicensed personnel on board the vessels is large in proportion to the officer personnel replacement.

The executives of a steamship company, especially one engaged in the oil tanker trade, when attempting to inaugurate or follow out an accident prevention campaign have not the same facilities or opportunities to pursue this work which are available in general factory or plant management on shore.

Chief among the advantages offered the factory employer who is interested in reducing his list of accidents is the opportunity which his safety representative has of talking collectively and individually to the superintendents, foremen and other employees of the various departments; the holding of safety first meetings and rallies at suitable times and places; the inspection of possible hazardous appliances, places or conditions in the plant when reported; and the ability to investigate fully the causes of accidents as soon as they take place and to analyze them with the view of preventing a recurrence.

In contrast, let us consider what the marine department of a large oil company must contend with. Here there are a large number of ships carrying cargoes of crude and refined oils to ports on the several continents. In the tanker trade a quick turn-about is of the greatest importance. Before reaching the loading port the crew of a tank vessel are

busily engaged making all preparations to take on board the oil cargo immediately upon arrival. Not infrequently an oil tanker will reach her loading port in the morning, and before the sun has set will have started on her return voyage. In the interim a cargo of some 60,000 or more barrels of oil has been pumped into her tanks, several hundreds of tons of package freight securely stowed in the 'tween decks and holds, and bunker fuel, boiler feed-water and commissary stores loaded. At the same time such repairs and adjustments have been made to the machinery as may have been required, and the many miscellaneous duties, both on deck and in the engine room, which must be attended to have received the proper attention.

Upon the vessel arriving at her discharging port a similar picture is presented. The safety representative of the oil company would receive but little encouragement from the master or chief engineer of the ship, should he attempt under such conditions to talk to their crews on accident prevention. The safety representative of a general passenger or cargo steamship company whose vessels are in port from one to several weeks at a time may, perhaps, have the opportunity of personally talking to and impressing upon the men the company's ideas of safety.

Voyages Are Governed by Supply and Demand

In the oil tanker trade the voyages of the respective ships are largely governed by the law of supply and demand—both domestic and foreign trade. With loading terminals on the southern and western coasts of the United States, in Mexico and in South America, and with many discharging ports at home and abroad, it is difficult and in many cases impossible to determine the itineraries of the vessels for any considerable future period. Under these conditions the safety representative may not have the opportunity, much as he may desire, of visiting some of the ships excepting at very low intervals.

The Texas Company, upon serious consideration of the best means to reduce the accidents on board its ships, found itself confronted with the difficulties which have been mentioned. It appeared that a good start toward reducing the number of accidents could be made by stimulating "safety thinking" among the sea-going personnel, by attempting to create good-will for accident prevention work among the men, and by reminding them of the care to be exercised in performing their duties with the highest degree of safety for themselves and their fellow workers. It therefore was decided to display safety posters on all vessels of the ocean-going fleet, the barges, the tugs, and at the several marine warehouses.

As the preparation of a large number of original safety articles and posters would entail considerable time, the poster catalogue of the National Safety Council was consulted. Of the many hundreds of splendid posters available from this source only a comparatively few are applicable to marine work. About seventy posters finally were selected with which to start an accident prevention campaign. Various types of bulletin boards for displaying the safety posters were considered and two sizes of boards chosen. The boards are of a neat appearance, one

size being 18 inches by 24 inches overall, for the large vessels, the other being 18 inches by 12 inches, for the small fleet. A metal sign "SAFETY FIRST" is attached at the top of each board. On the large ships two bulletin boards have been placed (each displaying two safety posters), the latter being changed weekly by the master of the vessel. On the barges and tugs only one bulletin board has been installed, displaying one poster which is changed weekly. Lack of space on the latter craft made it necessary to furnish them with the smaller size boards.

Considerable thought was given to selecting the most desirable locations for installing the boards on every ship, that is, to select places where the majority of the crews would be brought in contact with the departments' ideas of safety. In the majority of cases the safety posters are being displayed simultaneously in the officers' mess room and in the crews' mess room, although in some instances, other locations were selected.

All the bulletin boards and the complete sets of safety posters were assembled at one office and, together with complete instructions for their installation and display, were sent to the marine superintendents at the several terminals of the company for delivery to the vessels upon their next arrival in port. In addition, letters outlining the marine department's plans for lowering the accident record were sent to all masters and chief engineers.

Consultations on safety work are being held with the officers of our ships as the opportunity offers. Their interest and cooperative spirit are gratifying and should be the contributing factor toward a successful accident prevention campaign. Material is being gathered in order that original safety posters may be prepared by the Texas Company to be used when the present supply has been depleted. As these safety posters are finished from time to time copies will be submitted to the National Safety Council in Chicago so that other steamship companies and allied industries may use them. Such cooperation should assist in promoting safety at sea on board the ships of those companies which are members of the Marine Section of the National Safety Council.

Discussion Following Mr. Tode's Paper

MR. GEORGE A. MARR: I would like to ask if you trade between regular ports?

MR. TODE: Yes, we do trade between regular ports but we rarely can tell to what port the ship is to go. A vessel may leave Port Arthur bound for Boston; on the next trip it may go to Stockholm or Italy or some other place and a great many times the charters for these vessels are for one voyage only. Arriving at designated port she may immediately be chartered to another port—Port Arthur, or México, or another place. Sometimes we have charters that run over a six months' period or even a year.

MR. MARR: A vessel doesn't trade between Port Arthur and New York, and so forth?

MR. TODE: No. There are several vessels we do keep in a close trade

and some intercoastal trade, but that is all governed by the law of supply and demand. If we get a charter and must send a vessel to a port we must take it out of one trade and put it in another.

MR. MARR: Do you change your crews in trade?

MR. TODE: Among the licensed men we have stable crews but among the unlicensed men it is only fair.

MR. MARR: When do you pay off?

MR. TODE: We pay off at the end of every trip.

MR. MARR: Do you hire without the men leaving the vessel? Is it quite the usual thing for a large portion of the crew, outside of licensed officers, to remain on the vessel?

MR. TODE: I would say on the whole, yes. At times you will find a ship, and perhaps it is a happy ship, going on a far voyage and some of the men prefer to remain along the coast; in such instances we may lose five, six or eight members of the crew; but many times a ship comes in found for Europe and no one will leave.

Get the Men Engaged in Safety Actively Working

MR. MARR: In the discussion of this paper, Mr. Chairman, which is a very interesting paper and one which in theory confirms our theoretical ideas in regard to the safety work on board ships, I want to ask how much interest you would have in your safety council if your members gathered here today, again next year and the next and were only given a paper or pamphlet or circular to read and take away with them to their homes? I don't think you would have the meetings more than one or two years.

You are not going to get active interest in any movement you undertake unless you get the men engaged in that movement actively working. I don't think the poster on the wall is worth the paper it is written on unless it is followed up by a real active working interest by the men concerned.

You can go to a church and if there is nothing there but the minister and his sermon you go away without any particular interest in that church. But if you take part in the singing and in the prayers and all that sort of thing, a real active interest, you will come back again and you will go away feeling better and come back feeling better.

The Lake Carriers Association has been active, I think. One of the first things it did was perhaps before our safety movement got going. You will remember the first danger sign that was adopted, possibly by the National Safety Council, was a red disc. Every time that red disc was placed anywhere it was an indication of danger.

About that time Mr. Collins was chairman of our welfare committee and he devised a sign to put on board our boats consisting of a red disc on top of a piece of metal, and under that red disc was written "Safety First" in large letters. Below that were five or six general cautions such as "Be Careful," "Look Before You Leap," and such things.

I went to a great deal of expense on them. I had them made of red and blue enamel with white lettering. One of them was fastened on the

forward end of the after house and one on the after end of the forward house, so from any place on the deck those two signs were facing right down the deck. How much good those things did I don't know but I haven't any idea they were worth the price we paid for them; still we are turning them out and furnishing them to vessels today. I venture to say that a regular sailor will go aboard and work for a month and not be able to tell you whether those signs are there or not.

Now I really think the thing you have got to do is to get active work among these men and I don't believe that posters will do it. I think you have got to get those fellows thinking safety first, as you say, and that is the sum and substance of the whole thing; and that is what your conclusion was, Mr. Tode, that was the theme on which you have spoken.

MR. TODE: The points you have just brought out concur with mine fully. We also realize that putting up posters is not going to prevent accident to an appreciable degree. However, it is a start, and you have got to start somewhere; it brings the thing home to officers to whom we want to sell our idea, and also to the men, by having the safety posters before them and giving them the "Make It Safe" pamphlets.

We realize the turnover on crews is large compared with licensed men, and our company is trying to educate the unlicensed personnel. Our officers are loyal and, as a rule, have been with the company many years, especially captains, chief engineers and first assistant engineers. It is to those men we are trying to sell our message.

Safety Posters Are Urged Upon All Vessels

I visit the vessels four times a year. I go a considerable distance from New York to make an inspection of a ship and on that trip I talk to the captain and to the chief engineer about safety. I try to sell the idea to these two men and any other officers who happen to be present, because I feel we can only reach the unlicensed men through the officers who are in contact with them all the time. No one can take the time to talk to every steward and mess man aboard a ship.

Now there is another point. I should like to see a great deal of additional interest taken by our own Section and by men who are not members of the Marine Section at the present time. Supposing the Lake Carriers' Association, the Barber Asphalt Company, the Standard Oil Company and Texas Company were all trying to work up safety (and they are), that is perhaps five per cent of all the steamship companies operating. If a sailor or fireman sees a safety poster on one vessel and then goes to another and does not see a safety poster the effort of the one is wasted; but if we could only put the idea across to steamship companies the same as the railroads have done, we could get somewhere. No matter what railroad you cross you see a safety sign at every crossing. If we could visualize before them the idea of safety and the necessity for stimulating safety thinking, much could be done.

A. C. WARFEL (Supervising Safety Engineer, Hartford Accident & Indemnity Company, St. Louis, Mo.): Mr. Tode brought very vividly to my mind the first trip I made to sea on board the "Admiral Farragut," of the United Fruit Company. I went as an engineer cadet. I don't

know whether they use such a term now but I was what is now known as a wiper.

I was about 14 and going to grammar school. One morning as we came out of Port Antonio one of the oilers came down and was tinkering over his particular engine; it was a twin screw, and he was drunk. The first assistant engineer saw him and could have stopped him then and there, but this fellow went on feeling the eccentrics with his fingers and before he realized what he was doing he had cut them off.

It goes to show that had the first assistant engineer been approached and talked to on safety and had there been posters around and some word given about the danger of a man going on watch drunk, an accident could have been prevented.

CHAIRMAN WELCH: We will now hear from Mr. Ralph E. Prouty, engineer, Aetna Life Insurance Company, New York City.

SAFETY ENGINEERING AS APPLIED TO SHIPBUILDING

Ralph E. Prouty, Engineer, Special Risk Division, Aetna Life Insurance Company, New York City

A discussion of safety engineering as applied to shipbuilding may well be opened with brief definitions of the terms that will be employed. As used in this paper, "Safety Engineering" is the science of applying engineering principles to the prevention of accidents.

There are three main branches of safety engineering—the educational, mechanical safeguarding, and engineering revision. As we proceed, the importance of each in the solution of shipbuilding problems will be obvious. "Shipbuilding" will be used in its broadest sense, and should be understood to include yards devoted to steel production, yards equipped to turn out wooden vessels, and, in addition, what properly should be called repair yards, since no new work is done in them.

In order to determine the relative importance of the several branches of safety engineering in the shipbuilding industry, analyses have been made of a number of accident, lost time, and accident cost records. Some of the data were secured during the great activity in American yards the last year of the World War and the year following its close; others are of recent origin and refer to conditions which may be considered more nearly normal; all are thought to be indicative of the general hazards of the industry.

Chart No. 1 shows the accidents in a large eastern shipyard during the period of greatest activity. In this yard the steel was shaped, the plates cut, punched and bent, and extensive shop work of all kinds performed. In the preparation of this chart all accidents reported were included in the analysis, as it was thought that they would show the potential dangers of the industry better than would charts based upon analyses of tabulatable accidents only.

Chart No. II shows the percentage of lost time from different causes in one of the largest steel yards. This chart should be of considerable

interest, for after all the economic losses from accidents sustained by employers, employees and society vary with accident severity rather than accident frequency. It is striking to observe in this connection that in both forms of analysis the part played by machinery is practically negligible.

Turning now from the steel yards to those in which wooden vessels are built, a study of Chart No. III will show principal accident causes. In wooden shipyards there are machine hazards which can not be ignored, and this chart particularly illustrates their relative importance.

Chart I: Accident analysis based on accident frequency. Chart II: Accident analysis based on accident severity.

Chart No. IV is based upon an analysis of accident cost in the same yard covered by Chart III. Accident cost includes compensation payments and the amounts expended for medical treatments.

Two more charts conclude the series. They are designed to show the causes of accidents in yards that do shipwright work only. Chart V refers to shipwright work on wooden vessels such as barges, tugs and launches, while Chart VI portrays the accident frequency in a steel repair yard.

Having reviewed these analyses, one is impressed with the preponderance of accidents and the large percentages of time and monetary losses from the non-mechanical causes. Inasmuch as non-mechanical accidents are due in a large measure to shortcomings in human nature, and only in a small way to physical conditions, the educational branch of safety engineering assumes great importance.

Safety education in a shipyard should begin in the employment office. One looking for a job expects to be told at the time he is hired of the conditions under which he will work and the rules which he must agree to observe in order to obtain employment and hold down a job. His mind is very receptive at this time, and an employment manager fully in sympathy with the safety movement can invariably get a new man started

right by judicious reference to accident prevention during the interview and while waiting to turn him over to his foreman.

Foremen are, or should be, leaders of men. A good one will not only be able to keep his gang keyed up to the required productive pitch, but he will take each man in turn as he joins the force and instruct him in the safest way to do the particular job to which the man is to be assigned. Further, he will keep a constant check through his assistants and by means of personal observations on the manner in which the daily work is being done, and will correct immediately any practices likely to cause accidents before casualties occur.

Orig - M 33-aer. Stat.

Chart III: Accident analysis based on accident frequency.

Chart IV: Accident analysis based on accident cost.

The safety engineer of the yard should make daily inspections of the premises, or such parts of them as his time will permit. He should be vested with sufficient authority to enable him to have dangerous conditions corrected without having to go through a lot of red tape. His efforts and those of the foreman should dovetail, and his success will depend largely upon his ability to sell himself to the foreman as a "regular fellow." If he can do this, he can educate the foreman to his point of view and have the support of the ones whose help he needs most in putting over his program.

There should be periodical meetings of foremen for the consideration of accident prevention. The executives should attend these meetings, and by their presence put the stamp of approval on the efforts being made by the ones directly responsible for the safety work. Accident prevention should be discussed at these meetings not as one more thing to engage the foreman's attention, but as a part, and a very important part, of the productive program.

Safety rallies and meetings for the entire personnel may or may not produce desired results. If the meetings are made interesting and are addressed by men who can talk the language of the yard, much good can

be accomplished. On the other hand, a meeting that leaves the men talking about the white-collared guy who doesn't know his stuff may do a lot of harm.

Visual education often proves more effective than the spoken word. Carefully selected safety posters on well-placed bulletin boards constitute the most valuable single medium one can use in a shipyard. Motion pictures and stereopticon views are also invaluable. The safety man who can use a camera to take pictures in the yard for home-made bulletins will be well repaid for his trouble by the added interest aroused through giving the bulletins a bit of local color.

Safety men have discovered an important truth which is well known to all who are called upon to lead in movements requiring the cooperation of a large number of men. It is that you can best develop interest and, having developed it, keep it alive by giving as many as possible something to do. Churches, fraternal organizations and other bodies make use of this principle, and it has been employed to good advantage in shipyard safety work. In one yard which came under my observation, a committee of workmen was appointed and the membership of the committee changed at frequent intervals. During their service on the committee, each man was provided with an attractive safety committee button. After being relieved from active committee duty, the button was retained, and each man was given to understand that he was still considered a part of the safety organization. Within a comparatively short time there was a large number of men in the yard wearing safety buttons and boosting for safety.

Another method by which the interest of the men can be secured and their cooperation developed is through the use of safety suggestion boxes. These boxes are placed at strategic points throughout the yards, and all employees are asked to place in them suggestions for preventing accidents. Sometimes cash prizes have been awarded for the best suggestions, and it is interesting to observe that many suggestions have been received through this source that not only had a distinct bearing upon the accident prevention problems, but on production as well.

Mechanical Safeguarding

Mechanical safeguarding in a shipyard should be considered to include the proper protection of scaffolds, runways, hatches, approaches, and other physical equipment as well as machinery. Time will not permit the detailed consideration of the best and safest methods of constructing scaffolds and other equipment of a more or less temporary nature. During the war specifications for safe construction were prepared by the Emergency Fleet Corporation from extensive studies in yards throughout the country. One can do no better than to follow these specifications in so far as local conditions will permit.

Without attempting to go into detail, a few general principles of mechanical safeguarding might well be mentioned. The belts, dangerous moving parts, and points of operation of all machines should be guarded adequately. All scaffolds should be provided with toe boards to prevent

tools from falling, and guard-rails for the protection of the men working at elevated points. Hatches should be provided with guard-rails and toe boards, as well. All ladders used in hatches should extend at least three feet above the hatch level, and the rungs above the hatch level should be removed so that it will be possible to step through the side-rails instead of around one of them.

To prevent certain types of accidents, safeguards must be applied to the men themselves instead of to equipment. Riveters, caulkers, chip-pers, welders and others exposed to flying particles or harmful light rays should be provided with suitable goggles and required to use them. Men handling acids and corrosive substances, such as certain employees in galvanizing shops, should be furnished proper protective garments. The

Chart V: Accident analysis for shipwright work on wooden vessels.

Chart VI: Accident analysis for shipwright work on steel vessels.

constant use of these forms of protection, once they have been provided, can only be insured by a combination of good discipline and effective educational work which will bring home to the men the folly of taking chances.

Engineering revision is a most important factor in accident prevention work. It contemplates improved designs of machinery and equipment to the end that the tools of production may be made increasingly safe for use. Educational activities are carried on very extensively in American industry in connection with accident prevention work. Mechanical safeguarding has been perfected to a gratifying degree. The next big step in the prevention of human suffering and monetary losses arising from industrial accidents will be a more general acceptance of engineering revision as an aid in the good cause. To the question, "What can be done to make the machine more efficient?" the words, "and safer" will be added by the designer of the future.

A few examples of engineering revision in the shipbuilding industry may be cited. The heavy electric drills and reamers used in ship work

are built to overcome any resistance which might be encountered in drilling or reaming a hole. When a drill is cutting properly, the operator has no difficulty in holding against the torque or pulling force of the motor. Should it bind in the hole, or take an extra heavy bite in the work, the motor immediately responds with greater power. If the operator is unprepared to resist the sudden push on the handles, he may be forcibly thrown aside and seriously injured by falling or by being hit by the handles of the drill, which are then revolving with the drill housing.

Engineering revision eliminated this hazard. The tools were re-designed in such a manner that the removal of the operator's hands from the handle, either voluntarily or by the jerking of the handle from his hands, would cause the current to be shut off automatically and an electric brake applied.

The ordinary bucket which has been used to catch heated rivets from time immemorial was made the subject of engineering revision by a safety engineer in a shipyard on the Pacific coast. He designed funnel-shaped rivet catchers made of sheet metal and provided with outside handles so the hand of the one catching would be protected by the taper of the funnel. Under certain circumstances it is necessary to heat rivets on one deck level and use them on lower levels. Throwing rivets down ladders was common practice until an ingenious safety man hit upon the idea of using chutes to carry the heated rivets to points immediately adjacent to the place where they were to be used.

Summing up, safety engineering in shipbuilding requires the application of all of the branches of the science if accidents are to be controlled. Educational work alone will not suffice; mechanical safeguarding by itself will prevent but a small percentage of the accidents; engineering revision is only a part of a complete accident prevention program. A combination of all three elements, each given the degree of attention required by existing conditions, is bound to produce satisfactory results.

A Great Percentage of All Accidents Avoidable

MR. TODE: I believe that Mr. Prouty mentioned something about the number of avoidable accidents, and in my paper I also call attention to that. In fact in a great many addresses which are made on safety in any Section one hears of the large percentage of avoidable accidents.

I attended the conference at Washington a few months ago which was called by Secretary of Labor Davis, and in his opening address there Secretary Davis pointed out that figures on avoidable accidents in industry had been compiled by the Bureau and the statistics showed that 75 per cent were avoidable. I mention that because I have been looking over the accident records of the Texas Company for four years and for my own satisfaction have determined that exactly 75 per cent of our accidents have been avoidable accidents. It struck me as a coincidence that it was the exact figure that Secretary of Labor Davis brought out, where, in his case, several millions of accidents had been recorded.

In compiling our records we have sent letters to our captains and

chief engineers asking them for all possible information, but I believe you can do more by personal contact in talking to a captain and getting him to relate the history of his life and asking him where he has been sailing, and then gradually getting around to accidents. He will tell how many have been injured on the ship and you can get him to realize and feel sympathy for his men. In that way you can generally get him around to giving some good suggestions which might not have been thought of.

MR. PROUTY: Personally I don't believe in paying a man to do what is right. I don't think we need to provide bonuses to get a man to practice safety. It is true that in many cases the initial safety stimulus has been provided by giving to men who do something meritorious a little prize, not always in the form of cash, but perhaps a little emblem which will be a visible token to display to companions and fellow workers indicating that he has done something to protect them and protect himself. I like the idea of giving these little pins and buttons to men who come across.

There is an opportunity in the marine industry to stimulate the safety work in general by getting the men to make suggestions and to tell you of things they discover in their daily work which have nearly caused them to get hurt.

Statistics Show Conditions in Particular Yards

MR. EDWARDS: Mr. Prouty, I would like to ask if you have included in that paper the statistics as given on your charts? I raise the point for this reason. I think the information given there is not only valuable but should be brought to the attention of every one of us. I have found it rather difficult to get charts and data printed unless it is included in the article.

MR. PROUTY: I purposely omitted reference to the ship yards and I did not include the basic data on which the charts were prepared. I took all of the accidents and considered them 100 per cent and included the different causes. The actual work in making the charts was done in the home office from their data. I assume they still have those figures and I shall be very glad to look them up and let you have them.

I don't think it would be safe or fair to take such statistics as these and assume that they indicate anything beyond the particular yards to which they apply. There is not a sufficient exposure of accidents, not enough of them. This simply shows what happened in these particular yards.

CHAIRMAN WELCH: In connection with this paper I desire to state that the ship construction yards should belong to us; I don't think they are hooked up with any other Section now. During the next year I am going to try and get them in where they belong. A good many of the ship yards are members of the Council but they are possibly hooked up with some plants and they should go to the Marine Section.

Now we would like to hear from N. F. Titus, Chief, Division of Transportation, Bureau of Foreign & Domestic Commerce, Washington, D. C.

ORGANIZING FOR SAFETY ON THE PACIFIC COAST

N. F. Titus, Chief of Division of Transportation, Bureau of Foreign and Domestic Commerce, Washington, D. C.

A paper was scheduled for the Friday morning session of the Marine Section by Mr. J. J. Rosedale, safety engineer, in charge of the safety work in San Francisco, and I looked forward with a great deal of pleasure to hearing this paper. On account of the inability of Mr. Rosedale to appear, I suggested to Mr. Welch that it might be interesting to some of you to know what is being done out there.

I am taking the floor with considerable reluctance because what I have to say is entirely impromptu. I would have liked to have the advantage of weeks, if not months, of preparation; but I felt that it would really be unfortunate in a meeting of this kind, if the program were allowed to go through without something being said about the safety work being produced on the Pacific Coast relating to maritime affairs. What I am going to say is just a plain statement of what the work consists of, how it was started and really what is being accomplished.

In order that you may understand the situation I would like first to explain that San Francisco is the major headquarters on the Pacific Coast from a shipping standpoint. By that I don't mean the volume of business conducted, but I would say San Francisco is the headquarters of most of the operators, or rather operating companies. We have about 35 or 40 major shipping companies, and we have in San Francisco the headquarters of the American Steamship Association which really represents the offshore operating fleet. We then have a Ship Owners' Association which was organized because we have on the Pacific Coast a peculiar type of vessel known as the steam schooner which is a particular Pacific Coast development.

The problems affecting that business were so different from the offshore trade, it became necessary for steam schooner operators, owning 225 vessels, to form their own organization.

There is a third organization, known as the Waterfront Employers' Association, just a company of stevedores.

These three organizations work closely together; they occupy an office building exclusively their own. They each have their own secretary and their own directors. Every Monday morning at 11:00 o'clock they have a joint meeting of the directors of the three associations so there is the most intimate correlation of effort. They also have an employment bureau located on the ground floor, with a general manager supervising the employment service. So we have here a distinct organization for cooperative effort.

Now the background of this situation goes clear back to 1911. At that time one of the brokerage concerns in San Francisco introduced a Pacific Coast Protection and Indemnity Insurance, as we all knew it. This brokerage concern operated a market in England where, in that

year, 1911, practically all the Pacific Coast operators entered their fleets in one or other of the British clubs. They did not enter strictly as a member but took out the real P. and I. policy on a flat basis. A few of the companies have, from time to time, come into the American club which Captain Kain represents, but most of the insurance of P. and I. was taken out with the British clubs.

Of that business most of it went to the West of England Steamship Owners' Protection and Indemnity Association.

The plain statement of the case is this, that from 1911 until quite recently, within the last year or 15 months, the steamship owners have considered that the thing was off their hands, that having P. and I. insurance fully covering their vessels they were no longer concerned in accident prevention, it was the insurance company's business.

We all know the fallacy of that viewpoint, but the fact remains that these operators were so busy securing the handling of lumber, oil, ore and so forth, they were too busy to pay much attention to this thing, especially since they considered it the insurance company's business.

You can imagine the result of a situation of that kind when no one paid any attention to the business of accidents. Accidents multiplied and within the past two or three years they have nearly trebled. If I told you they went up 30 or 40 or 50 per cent you could understand that; but it is a fact they nearly trebled. We tried to compare experiences to find out how and what caused it and it seemed due to a general laxity on the part of the operators and owners.

Murmurings of Discontent in London

As a result we began to hear murmurings of discontent from London. Finally Holman & Sons who represented the operators in the West of England Steamship Owners' P. & I. Association relinquished some of the business. They gave us certain classes of business on the Pacific Coast so within the last two years we have found a new situation and that is that many of the owners not able to get the West of England P. & I. insurance through Holman & Sons have been obliged to get the brokers on the streets of London to get regular stock company insurance.

We found that as the P. and I. Associations developed this business and accumulated data through long experience, that the regular underwriters who write it as they would a P. and I. clause on the regular Hull policy, excluded whole blocks and sections of the trade from the P. and I. Clubs due to their accumulation of very bad experiences. The situation kept getting worse and worse and it was quite noticeable at the first of the year when a great many renewals came to be placed. There were indications of increase of rates and more stringent alignment of conditions on the policies, and those people who were at all thoughtful began to exchange experiences.

The situation came to a head in March. We then had a joint meeting in one of the clubs in San Francisco where the representative members of these three associations met and considered this matter. The condi-

tions of the problem were very simple. The owners recognized that rates and conditions were becoming more stringent and wanted to get together and find out what they could do about it. Very naturally when you talk over these things and you find your insurance rates and conditions getting more stringent, you find out the cause is frequent accidents, and the only way to correct that is to reduce it. So, by the very force of the onslaught on their pocketbooks they were obliged to take up some sort of consideration for a reduction of accidents, a consideration of safety methods, and through no bright analysis, but simply by the dollar and cents standpoint, they were forced to consider the suggestions of this Section.

A committee of seven was appointed; a general chairman and two members from each association, to look into this matter.

This, in brief, is the situation (and I am speaking from memory) that up to last year, for instance, the steel fleets were insured, in general, at five-eighths per cent with no deductibles. Along about the first of the year the rates began to creep up to 70 or 80 per hundred and instead of no deductibles we began to find a \$50 deductible. Then along about January, February and March, very rapidly as other members began to renew their policies, instead of a \$50 deductible we found \$200, \$250 and \$500 deductibles, and the last of March the rate ran up to one per cent and a great many are now paying one and one-quarter per cent.

More and More Difficult to Get Insurance

When you tell a man that his rate jumps from five-eighths to one and one-quarter, he can look at his premium and he can read; but when you speak to the average operator and tell him that his deductibles increased from \$50 to \$500, he does not know what it means. Of course he knows it means something serious. So at that meeting we analyzed that feature and through the very fine work being done through Mr. Foisie's organization, which is really the only organization which had made any analysis, we were able to find that a \$500 deductible meant, as I recall it, that if 88 per cent of the claims were for the owners account, with a \$500 deductible the P. and I. Association or underwriter would only assume 12 per cent of the number.

Then another remarkable situation came in. Some of the owners who had probably a little poorer experience than others could only get insurance at \$1,000 and some \$2,500 deductible. A man with \$2,500 deductible is getting paid for death. Some accidents come within the total loss insurance.

In other words, by not only doubling the premiums and greatly increasing the deductibles the result was that the British clubs found the risk too great and had to run out from under, leaving the Pacific Coast handling its own insurance. So, very naturally, what we did was to study the situation very rapidly. We did not have much time. Each new cable that came in gave more drastic quotations, so very quickly we secured a couple of safety engineers whom we hired, one to act as a

sort of consulting engineer. That is Mr. Rosedale who was to be here to speak to you on Friday; and another full time man who went up and down the waterfront.

On account of the peculiar nature of our organizations out there, we decided to let the safety work apply on shore and on board ships as well. So the thing I want to point out is that I think there is here the first cooperative effort ever started in America for a safety program that is comprehensive in its application among a large number of fleets, both ashore and afloat.

We had enough common sense to know that when we tackled this thing we would have to be tireless in our efforts, so we tried to find out what other people had done. We examined various situations and found very quickly the fine and able work done by the Lake Carriers' Association. We read some of the articles published by Mr. Marr that are what we might call, a specialty covering a peculiar type of carrier and only accomplished by a safety committee on shipboard. Due to the fact that most of their work is carried on by mechanical loaders and unloaders it did not offer much of value to us except as safety work on shipboard.

Reports of Safety Work Good in Seattle

We found practically nothing being done on the Atlantic Coast. Bad as we were, we felt conditions intensely worse on the Atlantic Coast. We found practically nothing on the Gulf Coast, so really we had to come back home with very little in the way of experience we could copy except what had been done in the northwest. We found there considerable comfort because we found Mr. Foisie's organization had done some very fine work. At that time they had been operating for nearly two years with safety engineers. We also found the shipping federation at Vancouver had done some fine work under Mr. Sweeney. We noted that as a result in some 18 months or two years Vancouver had reduced their accidents in the neighborhood of 40 per cent.

The reports in Seattle showed about 35 or 40 per cent reduction at that time. We noticed with a great deal of interest that in a six months' period in Seattle some of the most outstanding things had speedily been corrected. Their reports showed they had had 13,000 house losses through the giving of wrong orders. They speedily corrected that condition and in the next six months they had no house losses. They showed a way whereby we could greatly profit and apply it to our business.

The work in Seattle was very encouraging. In this connection we also looked into the situation at Portland. They had no safety engineer there but had a safety committee headed by a young and progressive stevedore operator, and some data obtained there showed 30 or 40 per cent reduction in accidents. And so we felt the only way to accomplish these things was to get right down and do it.

We put two engineers out and started a campaign. We issued a weekly bulletin and printed the things they discovered. These bulletins

were more for popular consumption and management of men and were not scientific. The engineers were charged with the responsibility of taking photographic records of good and bad practices and getting out specific data on the subjects.

The committee started right away to communicate with the British brokerage concerns, C. T. Bowring & Company, Sedgwick, Collins & Company, and Robert Gardiner Mountain & Company, telling just exactly what we were doing. In other words, we started a back fire to let them know we were not as bad as they thought us and that really, through the spur of necessity, we were doing some work. We got some very interesting responses.

The sum and substance of this thing was that it was high time we woke up. It had been a constant source of amazement to the Britishers that we had gone along these 14 or 15 years and had not thought about these things. It only started when the insurance companies raised their rates because until they raised their rates they let the insurance companies pack the load, and as long as they carried the load they let them.

American Losses Six Times Greater Than British

As chairman, I received one very interesting letter from Holman & Sons and I remember the figures very distinctly. In addition to the general comments upon the fact that they felt it was high time to get into the safety work, they commented on the fact that in their association, which is the largest association of its kind, they having had most of the Pacific Coast fleets, the British vessels entered showed a loss record for loss of life and personal injury claims of five-tenths per gross registered ton, and the American records showed two shillings and six pence. Their records showed that our losses were six times greater than the British and it certainly is no wonder they were filled with amazement at our criminal neglect in our business.

I left the coast about six weeks ago, and we had a meeting of the directors of the three associations to take stock of this safety program that had only been in operation in San Francisco for four months. At that time they had this first aid convention at San Francisco and they had a big time and all the safety engineers were out there and we had Mr. Markle come in and make a report. Our directors were very anxious to know, as business men, what was being accomplished. They liked the theory and wanted to know the actual results and Mr. Markle was able to show, as a result of the first 18 months' work in Seattle, a reduction of 61 per cent. We were certainly collecting some very obvious evidences of bad practices, and there were some operations that were almost criminal.

We very quickly discovered this: that through the peculiar nature of the shipping business we found the average executive—the president, the vice-president and the general manager, for instance—did not know a sailor or longshoreman by name. To them these men were merely beasts of burden and meant no more than automobiles or auto trucks

or horses mean to the ordinary business; they were merely adjuncts to the business.

The executives, far removed from the scenes of activity, knew very little of what was going on; so we found most of the bad practices were the result of this removal of the managing power. We set about making quite a conscious effort to bring the management in touch with shipping labor.

We found situations like this up in Seattle, that during a certain period three or four men in Seattle met death through defective hatch covers. I know the president of my company and I know him well, and I don't think any president, if he knew there was a defective hatch cover, would hesitate to say, "Have a new one put on," or "Why the devil don't you fix them?" I am sure he couldn't see any sense in his fleet being operated with defective hatch covers. But it seems the trouble comes in along the line—the passing and shifting of responsibility, and that is why the thing isn't taken care of. It may also be due to the superintendent or engineer holding down too closely on repairs, but some one along the line is responsible and the responsibility has to be traced to bad practice in management, and when we discover these things we must correct them.

Mr. Foisie found that one of the greatest troubles was caused by the fact that the general offices in San Francisco, conducting agencies in Seattle, did not give authority to these local agencies to go ahead and repair defective gears or hatch covers, and the management in San Francisco had not been thoroughly aroused to attend to these things.

Necessity Forced a Real Cooperative Plan

All that I am telling you here today is simply this: that through the force of necessity the main operators there have gotten together on a real cooperative plan and they are working with Seattle safety engineers and the San Francisco engineers and are exchanging experiences and are rapidly getting to a point of a united Pacific Coast program ashore and afloat.

It is the only place I know of where this is being done. San Francisco is charged for going into the Los Angeles harbor and we are considering a safety engineer for Los Angeles. I think the results of Seattle and Vancouver speak for themselves. Sixty-one per cent in accident reduction is great progress.

We are organizing what is probably one of the most vital features; that is, we are acquainting the management with the problems attending the management of labor, something they have shifted to some one else. This is a very vital link.

Although this committee was appointed to be a safety committee, we found very quickly, in addition to safety work, other lines of effort opened themselves up for consideration, and a very significant feature was the necessity for some sort of cooperative medical effort. We found, when accidents occurred, that the men were being sent to some doctor,

possibly one who had never been seen, a doctor appointed by the insurance company, and as matter of such practice the ship owners or operators felt little concern because it was the insurance companies' business. Again there was that remoteness in operation the same as in the labor question. Our medical expenses were all out of line.

When I left there we were fast coming to the point of having a medical director for the combined shipping business. This medical director can look over the X-ray plates; he doesn't necessarily have to do the work, just control the situation. If Mr. Brown does the work he can report to this medical director and he would tell Dr. Brown, "I have looked at this X-ray plate and in my judgment this man who was injured should be discharged in three weeks. Dr. Brown, will you see that he is discharged in three weeks?"

That is the obvious method of handling medical direction. A great many operators and owners are paying unnecessary amounts to the medical profession. They are really being bled; not through unethical methods, but it is simply a case of dealing with human nature. It is a case of turning a bunch of doctors loose and paying any bills they send in. Human nature is such that when a doctor is in doubt he will string a case along two or three weeks or a month. He thinks the corporation is rich and he is doing a good job and far be it from him to turn down the case.

Safety a Factor in the Problem of Efficiency

We also began to discover the necessity for cooperation in legal work. Too often the companies don't know how to handle these cases. The P. and I. insurance clause reads that the P. and I. people reimburse for ship's liability. You have to pay your claim if the ship is liable and present it to the P. and I. underwriter and show the ship's liability and claim in order for you to be reimbursed. In many cases it has to be referred to an attorney, and, always, for the last analysis, to our own attorney; and many and many a time we have had a \$200, \$300 or \$500 legal bill; so we are fast getting to the point where we are going to get legal direction.

These things are very significant. They all show we have been recklessly spending our money and this safety program is only one very small factor in the whole program of efficiency.

Now with your indulgence I want to mention a couple of points that tie up with the work I am doing in the Department of Commerce. As you know, Mr. Hoover has long been interested in the elimination of waste in industry. Mr. Hoover's work has been of such a character that his name has been coined into a new word. We all know what it means to "Hooverize," save, economize, and eliminate waste. In the development of this he has done great work in standardizing business practices, and I think there is a significant message in that work and development for all the ship operators. That is one of the things that appealed to me and one of the reasons I am there. The shipping industry is woefully deficient in all this business of Hooverizing.

In other words, we found, as in our committee work, that (to use our commonly accepted term) the shipping industry was 25 years behind the times. The better class of industrial operators and executives had, during the past 25 years developed most efficient, significant practices. Americans had gone to the forefront in business. They had gone far and wide in the matters of cost accounting, taking of stock in their business, paying attention to the lighting and heating factors, personal old age pensions, life insurance, saving methods, and all the multitude methods of welfare education, club houses, and so forth.

These things have been significant and industry has gone to the forefront in such a way that American practices are considered so unique that European countries want to know what they are. Commissions have come over from England to study our American practices. To use Mr. Hoover's terms, "They come over to see how we do it."

Commissions have also come from France, Italy and Germany and they find to their astonishment that we are paying the highest wages in the world and yet are able to compete with people paying starvation wages. They want to know how we do it. These countries send commissions and expect to find some magic formula of mechanical operation, and when they have found we have social factors entering into this business as well as economic factors they have gone home and told their people lots of things and many have gone home a little exercised over what they found because of the peculiar American social status which can not be imposed on European society.

In America the poor boy can climb to the top, but in Europe, because of their social conditions he can not do that. The result of this opportunity, this massed education (for instance, as Mr. Hoover points out, we have more students in institutions of higher learning in the state of California than they have in all Europe) this constant selection of brains, is we are getting people to head our industries that are progressive, that think and act scientifically.

Overlooking Some Very Vital Things

While this economy and progressiveness have been going on in industry we in the maritime industry have not taken the trouble to pay any attention to it or to profit by the better business practices and so forth, and this matter of safety is only one of them.

The cooperative effort in the medical direction and in legal work, in claim adjustment, and settling claims economically and quickly, will create good will from the man and will cut out the lawyers' fees which are usually 50 per cent of the settlement. You know all that, of course.

We have been overlooking some very vital things, overlooking the standard practices as practiced in the best industrial plants.

One more point is this: my idea has not been expressed in this meeting here. The only way to put over this safety program is to do it cooperatively. To me it is a source of disappointment that in this meeting, in our expressions, we are giving individual experiences. What we

should be doing is organizing our industry and getting these things done cooperatively. That is the message I want to give you, if our experience means anything at all. There is only one way to get this thing done and that is cooperatively. We are leading to a unified Pacific Coast program, and heaven knows that on the Atlantic Coast you need the same thing. The situation there is terrible.

I can maintain that we are 25 years behind in our industry and one thought I wish to put forth is this: that on the Pacific Coast we have demonstrated one way to do this, and that is cooperatively.

I am so sorry that there are not more of the American Steamers' Association here to imbibe some of the spirit we get out of the National Safety Council meetings. They will give us again the same thing that we encountered on the Pacific Coast. If they don't do it voluntarily it will have to be done involuntarily—and it will have to be done cooperatively.

CHAIRMAN WELCH: That is a very fine outline of your work on the Pacific Coast, but about the Atlantic Coast—I am not going to say anything. We have been trying to do something for three or four years. We have started something. Is there any discussion?

Have a Single Objective to Work Toward

MR. HEINRICKS (Assistant Superintendent, Engineering Division, Travelers Insurance Company, Hartford, Conn.): The speaker's remarks have been so pointed and have so directly hit the main objective, as I see it, it rather inspired me to say something that bears along the same line, and this is the thought that occurred to me.

The business of cooperation, of course, is a necessity; it is a thing we must have to get results. But above all things this Section must find some one thing that is the main objective to shoot at, something that has got to be accomplished, and then spend time along that particular thing with other things as incidentals. Having one thing as a main objective and working on that intensively, we will get farther ahead and in a quicker manner than if we try a dozen things at once.

Now what I have to suggest is a specific thing to do that will have for its end the reduction of accident toll losses in stevedore and allied maritime compensation records. Along the line of costs the consideration of insurance rates is rather important. I am now talking about an incentive, the humanitarian one, and everyone in this Section knows that the humanitarian business incentive is money. Insurance rates are too high—*absolutely* too high; they are ruinously high for stevedore and other allied operators, and they can be reduced.

The example just quoted of excess over manual premium, to me, means simply this that this particular industry is being penalized by that excess and further by the fact that it would be possible to get a reduction of that same manual rate if a portion of accidents was eliminated.

I want to talk along the line that, as a specific point, the Travelers

Insurance be the chief objective. Now a further business incentive is the cost to the owner, employer, or steamship owner. The cost to the man who employs labor and has accidents is not represented so largely by the premium he pays, for which his liability is assumed by the insurance company, but it can be directly measured by this one way of looking at it. He knows he has other losses.

Let me cite one case. A stevedore had losses amounting to \$10,000 a year for over five years. In five years to that stevedore the insurance company paid \$50,000. That stevedore paid \$200,000 at the same time out of his own pocket, not including the insurance premiums, but in overhead on account of losses due to accidents. That is something that should be considered; it is a four to one cost because if the cost of the claim is \$5 the cost to the employer is \$20, and that is usually the average. However, if the compensation cost is \$10,000, naturally in that sort of case the owner does not pay four times \$10,000 or \$40,000. But in other cases a \$5 cost has meant hundreds of dollars in loss to the employer from the standpoint of property damage, especially if the accident is due to defective materials (for instance if a draft of goods falls upon a wedge or down into the hold); he loses several times the cost of the claim to the injured man, to say nothing of the cost of time lost; because even in the case of a man being scratched or bruised, he is laid off from work and goes home and somebody goes with him and in most cases the cost of a taxicab is involved.

I have taken 10,000 cases involving stevedore accidents and made a fair average, and including all these other things, it has been definitely proved that the cost comes out four times the amount of the insurance paid to the carrier. Add that to the premium he actually pays on his insurance and you get some idea of what his accidents are costing.

The One Big Thing Back of Accident Prevention

Now as to the specific remedy I have in mind. In stevedoring it has been our experience that the one big thing that lies in back of accident prevention is not so much the fit condition of the men, nor the kind of tools used; it is not so much the condition of the rollers, or the gears, or the blocks, or the inspection of that material (although those things are absolutely important); it is not so much that as it is the business of believing first of all when accidents occur somebody is responsible, and there is necessity for fixing that responsibility. No matter how small or trivial that accident is, there is a responsibility and that responsibility lies chiefly upon the man, the foreman, the supervisor of the gang, the man directly in charge of the fellow doing the work.

Stevedores hire gangs employed by other stevedores not their own men, and there lies the big point. If you hold the foreman or the supervisor personally responsible for the accident when it occurs under his direction, you can control the situation in the stevedore and allied industries, and it is fair to hold that man accountable; and you will have an awful lot of trouble if you don't believe you can hold him

responsible. It can be done, and you can make that man admit that he is accountable when a man slips, falls or stumbles: because a foreman's duties are such that even though he is supervising 30 or 40 or 50 men they must include, besides getting out production, the business of watching and handling his men, of knowing the careless habits of the men, of knowing their peculiarities of disposition: and if he handles his men right he knows long in advance whether a man is liable as a potential accident producer. If he knows that and knows that the boss knows it, it makes him personally accountable, and that rule will get results.

MR. FOSBERG: With the last speaker I agree on the point made of the necessity of fixing responsibility in the effort to prevent accidents. I think, however, I disagree over where that responsibility rests primarily. He would fix it, by way of illustration, upon the person immediately responsible for supervising the operation where the accident occurs, in this case on the foreman.

I think our experience is slightly different, or at least our reasoning takes us to a different end. In our point of view the responsibility and opportunity are practically identical in theory with management. I rather think that the speaker, if he analyzed those illustrations where he found that responsibility had been fixed and therefore had decreased accidents substantially, would find that the management, in that business clear up and down the line had analyzed each and every person's responsibility and had reckoned that all persons involved, particularly the executive, were definitely being checked up on.

The Main Difficulty Is Inertia in Management

We believe, in other words, that the principal difficulty in accident prevention is due to inertia in management, and with progressive management all of the factors, perhaps the primary one which is responsibility, are carefully evaluated. I don't think there is any single remedy such as the principle of fixing responsibility for accident prevention work.

Referring to Mr. Titus' address, I think I must absolve myself from some of his charges. Out on the Pacific Coast we do stand together. There we form a mutual admiration society and that fact is best evidenced in the cooperative spirit existing there, an atmosphere from which Mr. Titus has been lifted into the highest form of a cooperative job in the leadership of shipping interests centering in Mr. Hoover's department.

The business of cooperation in shipping is peculiarly dependent on this spirit. Compactness of organization among the highly diversified shipping interests is the problem that squarely confronts it. How to secure that is what I hope to speak on tomorrow.

CHAIRMAN WELCH: I have one short explanation to make to Mr. Titus. He was disappointed in one way in some of our activities. You should know what you are really doing because you did start this Section.

When we first organized the Marine Section about three or four years ago, I read an article on Stevedoring and it fell into the hands of my good friend, Mr. Foisie, out on the coast. He immediately got in touch with me, saying, "This is pretty good. We haven't been doing anything out here. We want to get in touch with this movement. My company belongs to the Council, but we haven't been doing much."

I got in touch with Mr. Foisie and before long he had hired a safety engineer, so he started ahead and because of that you got some valuable guidance from him as to what was to be done.

In connection with the east, we have done everything imaginable to get the shipping industry interested. We were supposed to have Mr. Raymond here, but he notified us he could not come. You can't hold the Section responsible for that. We have had articles written by Mr. Hand and George Marr and we sent them to all the managers and presidents of the steamship owners in New York City, and they are dead. As you say, they are 25 years behind. What do you want us to do? We tried to interest them in every way and when you gentlemen out in the west show the Atlantic Coast up as being dead, dry, and rotting, as they are, that will, perhaps start some cooperative work.

A Combination of Effort Very Essential

MR. TITUS: As I said before I am speaking bluntly, but that is the only way to get any constructive benefit and criticism, and I think that is what we need to start this cooperative effort. There has been a wonderful pioneering work done; however, the point I want to convey is that if we are going to do the big work, if we are going to capitalize, some sort of concerted onslaught should be made on them. This can not be done entirely by individual, voluntary effort. You have to have a salaried personnel. You can't get a salaried personnel through individual subscription, you must get it through cooperative associations. That is the thing I would like to see started. A scheme could be evolved through this Section for making a presentation, or have something done to try to arouse the American Steamship Owners' Association to undertake this cooperatively. I venture to say that if they don't do it voluntarily they will have to do it involuntarily.

We didn't enter this work through any spirit of research or uplift; it was done simply because the underwriters stood us up against the wall and pointed a gun at us and told us we would have to dig up the money to get our coverings.

CHAIRMAN WELCH: I want to explain our side, too. In connection with the American Steamship Owners' Association, what would you think of a management who said, "We have never had any safety engineering on our ship, and never will have?" As you say, Mr. Titus, it will come to that point sooner or later when they will have to have.

MR. TITUS: On the Pacific Coast we found that some of our biggest operators (I don't care to mention names) were very much in the same position as this concern you speak of. One of them finally went so far that their representative met with us and collaborated with us in giving

us his ideas. The representative of the other was appointed on the committee, but resigned because his association didn't want to get involved.

The greatest joy which indicated a great measure of success, after months of effort, was when that company which said they would have nothing to do with us changed their ideas and said they were interested and would probably join because they began to see some results.

I don't care what cooperative plan you evolve, you will find objectors, and my theory is that you get started; if you haven't 20, start with five and get going. The thing is so easily demonstrable, I think. When folks find out that the water is fine they want to get in and swim around with the rest of them.

MR. HEINRICKS: Just a word, Mr. Chairman, in rebuttal. I am a very poor speaker and I feel that I have not made the point I wanted to make as clearly as I should. I am entirely in agreement with Mr. Foisie in what he says in regard to the responsibility of accident. Not only should the foreman be held accountable, but in the cases I had in mind it was most decidedly the management also. There was a spirit of recognition of responsibility that pervaded the whole line. I did not mean to omit that; I was merely making the assumption that the management was sold, that they wanted safety, was determined to have it and conveyed their impressions and thoughts so thoroughly that the foreman was finally held accountable unless these previous conditions didn't exist. I was assuming something that I had not stated.

The Foreman All Things to All Men

MR. FOISIE: I was interested in elaborating on Mr. Heinrich's word. We are rather in agreement. It has been my experience in industry that the foreman is held responsible without being given, at the same time, adequate assistance. He has too often been made the goat of bad management. In the case of the stevedore organization he is in a peculiar position aboard the ship, the plant of his employer, but quite remote from the management itself in an office on the waterfront. He has a boss directly above him who is usually an irritable one.

The supervising of cargo has become a training school for immature and inexperienced men who have the authority of the uptown office which in turn controls the stevedore management's business frequently in a dictatorial and inconsiderate way.

Then, of course, the foreman must be all things to all men. He has the difficult task of having to organize a group of men from a highly disorganized and chaotic group, men from many ports—floaters, if you will call them so. So at least the stevedore foreman from our point of view is much in need of assistance: not necessarily more authority, but assistance and enlightenment and consideration from the management. I have yet to hold him responsible for many things within his control, and many things that are not.

I want to pay tribute to the Atlantic Coast. Not to the whole, but to

a few. Mr. Welch called attention to an article which he wrote. I had it mimeographed and distributed among employers, men who were operating in Seattle. It had to do with men and management having equal authority—joint authority in all matters; and the keynote in that text gave as one of the clues to safe operation the recognition of men.

The conclusion I wish to draw from his paper of that date is that without recognizing the work of the men in shipping, whether it be the stevedores, the dock wallopers or the seamen, without some effort by the management to make their jobs reasonably worth while, reasonably stable, you are never going to have adequate safety operations in shipping. If shipping expects to get the cooperation of employees the management of shipping must show the spirit, at least show the way. The management is the group who, in American industry, has the opportunity or ability to furnish the leadership. You can't expect much of such a situation. One of the essentials for fixing responsibility is that you must recognize the employment of men far beyond that which is the case at the present time, for with casual workers you can only get casual results.

CHAIRMAN WELCH: We have about ten minutes more and I would like to introduce to our group our very distinguished chairman for the ensuing year. I think it is only proper that he should come up here and make a few remarks.

Chairman-Elect Kain Is Introduced

CAPTAIN KAIN: Mr. Chairman and Gentlemen: I am not a speech maker. I came here solely in the interest of safety work because I, personally, and the organization with which I am connected, have been interested in safety work for the past 10 years; in fact, we have been preaching safety work for 10 years, but it has fallen on deaf ears.

As Mr. Titus pointed out, the real urge on the Pacific Coast was the boost in rates which the various steamship companies got last year and the year before. Up to that time I think it was possible to get insurance in the British market after we had insisted on paying adequate rates for risks we were assuming.

I think he has hit on the real key to the situation when he speaks of cooperation. I think there is, on the Atlantic Coast, a woeful lack of cooperation in the maritime industry. The stevedoring work, to a large extent, is conducted by independent contractors. Those independent contractors are carrying their own insurance. The steamship companies are getting the work done on a basis of so much per ton and are therefore not interested in the accidents occurring to the stevedores.

Of course this is reflected upon what they have had to pay for stevedoring, but they have always felt that they had no reason to be concerned with it.

Now, so far as the steamship business on the East coast is concerned, if Mr. Titus, for instance, could find a means of appearing before the Steamship Owners' Association and give them a talk such as he gave us

here this morning I feel reasonably certain there would be some radical changes in the attitude of the shipping executives. I think they are afflicted with the same trouble his organization discovered, and that is the management is not familiar with what is going on on the ships and on the docks. I think the cooperation should go even farther than that. I think it should be plain to the naval architects when plans are laid down for the building of ships that accidents are due to the improper design of hatchways, and that a study of the accidents occurring both to seamen and stevedores should be made and an effort made to correct the design of the hatchways.

The architects who designed those hatchways are interested in certain forms of classifications. The regulations of classification societies are very largely general in this nature. I see no reason why most of the hatches should not be of the same size. On different steamers, unless they are of identical type, it may be a necessity for a difference in the size of the hatches. We find, for instance, that on certain ships the weather deck hatch is of one dimension, the hatch on the deck below is of another dimension and so on to the bottom of the hold. Not only that, but adjoining hatches have different dimensions. Now in a good many instances the hatch covers are painted a vivid color to indicate to which hatch it belongs, but you can not get these longshore men to take an interest and the covers go back helter-skelter with the result that they are put on the wrong hatchways and sooner or later somebody goes into the hold.

I have seen, in some instances, three tiers of wooden covers and instead of having those three tiers all of the same length there would be a difference of maybe three inches in the lengths of the different batches of covers; and the landing surface of the hatch strongback or beam may have been three and a quarter or three and a half. In nine cases out of 10 the wrong cover is put on the hatch: nobody notices it because it is bearing fairly well, but in a short time it shifts and before it is noticed and corrected a man goes down the hold.

Many of these instances come to our notice and I think the owners and ship's officers do not have knowledge of those conditions. I think if the different interests were connected in building and running ships and a safety man employed or consulted when drawing up plans for building ships, that a great many of the injuries which are now due to mechanical hazards would be eliminated. I don't think there is on board ship such a small proportion of accidents as you might think from reading some of the articles that have been produced.

ADJOURNMENT

THURSDAY MORNING SESSION

October 28, 1926

The meeting was called to order at 9:30 o'clock by Mr. W. E. Welch, chairman, who presided.

CHAIRMAN WELCH: First number of our program this morning is a paper by Mr. F. P. Foisie of Seattle, Washington.

**THE URGENT NEED OF ORGANIZED SAFETY, AFLOAT
AND ASHORE**

F. P. Foisie, South Seattle, Washington

Shipping, particularly port cargo handling, appears in need of taking not merely a leaf but a whole sheaf of leaves out of the book of accident prevention, as practised by progressive manufacturing industries. Costs of personal injuries are mounting sharply; competition is compelling the elimination of waste. Safety by legislation looms large on the horizon unless responsible management voluntarily removes the preventable causes of loss of life; and such corrective legislation will be attempted perhaps without the benefit of practical experience.

Believing that there is an urgent need for organized safety in shipping, and looking to the Marine Section of the National Safety Council as a means for collective action by the industry, I inquired of the officers recently whether it is feasible to stimulate prevention of personal injuries in shipping by staffing the Section with a qualified paid executive. Mr. Bush, chairman of our Program Committee, responded by extending an invitation to present the matter to the membership at his Congress.

What, then, are some of the high hazards inherent in shipping?

First among these are the many varying operating conditions coupled with elusive control of the men, especially longshoremen, which present problems in safety organization peculiar to this industry. In the second place the predominance of machinery, tended by constantly changing operators, brings in its wake notably severe accidents as well as numerous ones. If it proves to be true, as alleged in this Congress, that too much is being said about safety education and too little about safeguarding machines, then the responsibility of marine management is the greater thereby. A third feature is the excessively severe strain, speed and long shifts common to longshoring which brings fatigue more pronounced than in any other industry. A fourth factor not generally known is that the usual reliance of industry upon highly competent foremen for constant activity in accident prevention is less possible in longshoring, because many, probably most, "hatch-bosses," "straw-bosses" and even "walking-bosses" are hourly men, without a guaranteed wage, getting only ten cents an hour more than the least skilled longshoreman. Often these foremen are not attached to any one

employer, and more likely than not are foremen today and workmen tomorrow. The foregoing inherent high hazards can be and have been moderated substantially by progressive shipping firms.

There are other hazards commonly alleged to be inherent in the industry which have proven otherwise, however, in actual practice. One of these, high labor turnover, was given in the 1923 Congress as an inevitable obstacle to organizing safety in marine affairs. But Mr. Bush pointed out at last year's Congress that personnel management, highly effective in reducing turnover in factory industries, is conspicuous by its absence in shipping, and for no recognized reason.

That high labor turnover is no more necessary in port cargo-handling than in other industries is evidenced in the Port of Seattle, which has as little turnover among the longshoremen as a well regulated factory. The reasons for this are that sensible employment selection is practised, safety work is organized with steady reduction in accidents, the earnings of the men are fairly high and steady, and the men deal in an organized collective way with the employers. These results have been secured by a joint organization of longshoremen and truckers and waterfront employers. They can be duplicated in any other port. Seemingly the outstanding obstacle to be overcome is management inertia. Some phases of safety in shipping present real challenges, to be sure, but that is the most that can be said of them. For example, lumber is said to be a high-hazard cargo, yet one Puget Sound lumber stevedoring company enjoys a low stevedore liability insurance rate, well below general cargo simply because the management exercises constant safety vigilance through competent foremen employed at good salaries.

Absence of Statistics Is a Serious Difficulty

A second alleged inherent difficulty is the comparative absence of worth-while accident statistics. This defect can be remedied best by collective action of the industry, but this would seem to offer no greater problem than that presented in other industries. Shipping and port associations, insurance clubs and the clearing facilities of the liability insurance underwriters could no doubt give us a good beginning. However, it is more than likely that it will take an act of Congress to require the reporting of injuries as a means to establishing compensation for injured seamen and longshoremen, before we can know the extent and causes of our marine personal injuries. However, the Pacific Ports are already beginning to exchange causation figures. Mr. R. F. Edwards, chairman of the Committee on Statistics, can no doubt give us a satisfactory set-up for statistical reporting if the shipping interests will respond.

One evidence of lack of progress in safety 'longshore is the limited literature, the library of the National Safety Council yielding just 19 references, none of them larger than small pamphlets, and most of them the work of members of this recently-formed Marine Section.

Foreign shipping is not so sterile, the accident prevention movement in Europe having gone the lengths of sound safety legislation developed by leaders in the industry, and used principally in compelling observance of minimum safe practice standards by unfair competitors. A similar development may hopefully be predicted in this country; that is, it may be necessary to enlist the authority of the government to compel unwilling employers to guard against preventable accidents, but the industry itself should provide the sound, tested safety regulations.

But Why the Urgent Need?

Such a picture as the foregoing is an old, familiar one in shipping circles. The need for accident prevention is well known. Are there any recent developments justifying the statement that there is *urgent* need for safety activity?

There seems to be a number of situations coming to a head which call for organized safety activity. Foremost is a sharp and continuing increase in accidents, as reflected by mounting insurance costs, refusal of many stevedore risks, advance in deductible amounts, and agreement among marine insurance clubs not to compete for personal injury business. The industry has been charged with lack of interest in reducing its accidents, and with the loss of that homely feeling of individual responsibility for accident prevention among many shipping members. Although we lack knowledge of the number and causes of accidents, we may nevertheless take it for granted that insurance costs furnish a reasonably accurate barometer over a period of years, despite some indications of restricted bidding for insurance business.

Not less important than the severe increases in costs as a stimulus to reduction of personal injuries is the prospect of a Federal Compensation Law for longshoremen and harbor workers. Although it is limited to these groups and has been opposed by seamen, there is reason for believing that it will later be extended to include them. The compensation principle is now accepted in industry generally and we should welcome it if extended to shipping. The bill before Congress calls for the most liberal provisions of any compensation legislation yet adopted in this country, including the following:

(1) Weekly compensation of 66⅔ per cent of earnings, with a maximum limit of \$25 per week, a 25 per cent increase in the country's maximum; and there is a tendency in compensation legislation to remove the maximum limit altogether.

(2) Occupational disease is treated as personal injury, and there are none of the restrictions and safeguards attached to this provision which have been found necessary in state compensation laws. There is danger that through lack of exact medical knowledge almost any sickness may be attributed to the job and claim made for compensation; in effect, this means that shipping (later other industries) may come to be required to insure the good health of the worker.

These are but two of the advance provisions of the proposed law; indicating liberalizing tendencies in state legislation generally. Liberalizing the law has been brought about through three instruments: changes by legislature, discretionary rulings of industrial boards, and court interpretations. Not all of these tendencies are being wisely safeguarded and guided in the light of sound experience. Unless administrative technique, moderation in legislation, and soundly based court decisions prevail, fraud, malingering and other wastes are certain to result.

The alternative to the compensation principle is an extension of Employers' Liability Acts under which, as in the Merchant Marine Act, the age-old employer defenses of "fellow servant," "assumption of risk," and "contributory negligence" are made invalid. This, coupled with the increase in size of recent jury verdicts, and the always unsatisfactory "sue or settle" situation, makes it clear that it is to the advantage of management in shipping to accept the principles of workmen's compensation.

Government May Soon Prescribe Safe Practices

A third factor calling for organized safety in shipping is the likelihood that a government authority will shortly be created to prescribe safe practice standards. This authority is contained in the clause of the proposed Federal Compensation Law for shipping (H. R. 12,063, Sec. 61). "The commission shall study safety provisions, the causes of accidents and occupational disease among the employees covered by this act, and shall from time to time make such recommendations as it may deem proper to Congress and to employers and carriers as to the best means of preventing such accidents and occupational diseases." Is the shipping industry, through collective action and practical leadership, going to lead in developing a constructive safety program, or will it allow itself to be placed at the disadvantage of appearing to oppose all safety legislation because forced to take exception to excessive or impractical measures advanced by labor or introduced by government agencies?

A final urge to accident prevention is the increasingly severe competition within shipping in this country; between shipping and rail transportation; and between the shipping of this and foreign countries. Moreover, the whole system of distribution, in which shipping is an important factor, appears due for overhauling because of the need for reducing the spread between production costs and the price to the consumer. Such a substantial item of waste as staggering personal injury losses through failure to minimize them will not be overlooked.

When one considers the combination of increase in accidents and costs, the liberalizing of compensation laws, the almost certain Federal legislation prescribing safety practices, and increasing competition's demands for elimination of waste—isn't it evident that there is abundant need, and *urgent*, for organized safety afloat and ashore?

Although this picture may appear gloomy, there are relieving bright spots. Progressive management in shipping is beginning to accept its responsibility for accident prevention work, this is particularly true in a number of the large shipping firms with stable management, which are making a deliberate effort to reduce costs of operation and improve the well-being of their employees, with a consequent increase in goodwill. In many ports there can be found here and there an individual stevedore manager or dock operator alive to the situation who is practising constant vigilance, and this is reflected down through the management including the foreman, and results in a good experience rating with lessened insurance premiums. Such companies are likely to be found on the roster of the members of the Marine Section.

In addition to individual effort, group effort through port organization for safety is a thing already accomplished along the Pacific coast, beginning in Vancouver, B. C., and extending down through the California ports. Of course, the Great Lakes offer the classic example of group effort in shipping circles to reduce personal injuries.

Perhaps the brightest spot in the foreground is the prospect of stimulus from the Department of Commerce. There is a group affiliated with the department under the title of American Marine Standards Committee, which represents the leaders of the country in ship design, construction, ownership and operation. Marine safe practice standards are beginning to issue through this clearing organization of practical experience, and are scrutinized, tested, and finally promulgated. In addition we are fortunate in having the initiative and leadership of Mr. Norman F. Titus, who has just left the service of the McCormick S. S. Co. to become Chief, Division of Transportation, in the Department of Commerce. Mr. Titus led in the recent inauguration of safety work in the Port of San Francisco, both on board ship and along the waterfront. He goes to his new work with a determination to put the influence of the government behind efforts to extend accident prevention work throughout the country's shipping.

Proposals

My excuse for this general discussion is that it seemed necessary to attempt to appraise the conditions before submitting the two proposals which I wish to put to this membership for consideration. They appear to me to be thoroughly practical—not at all chimerical.

The first of these is that the section proceed to staff itself with a qualified executive, who will devote his entire energies to accident prevention in the industry through enlisting the financial and moral support of the organized shipping interests of the country. The practical obstacle to be overcome is raising the first year's budget of \$10,000. When one considers the magnitude of the insurance premiums paid for personal injuries in the shipping industry of the country, such a sum is infinitesimal.

A second proposal is that we submit to the shipping interests and to Congress a plan for an administrative set-up under the proposed Fed-

eral Longshore Compensation Law whereby a practical shipping man and a representative of longshore labor be appointed to any administrative commission that may be responsible for the development of marine safe practice standards enacted into legislation.

No mention has been made of the two motives leading to interest in accident prevention. The first is the humanitarian, which is frequently ineffective. The effective motive is self-interest; it is fatuous to blink the fact that usually it is as workers only, when injury is brought close home to us, that we exert ourselves to prevent recurrence; and employers are commonly galvanized into the prevention of personal injuries by increasing costs. This is not strange, merely human, for fear moves the one, and cost, as a measurement of the toll of accidents, moves the other.

I realize that skepticism may attend the consideration by the shipping interests of such proposals. The value of personal injury prevention work is still doubted, especially by those most in need of practising it.

Faraday, the electrical inventor, was urged by his friends to exhibit his invention, the fore-runner of the electric dynamo, to Gladstone, premier of England. He passed a metal core through a magnet and as a result an electric current was established. Mr. Gladstone exclaimed, "Interesting! very interesting! but of what practical value is it?" Faraday replied: "Mr. Gladstone, some day you may be able to tax it."

Now if there is anything which possesses great practical value in the eyes of a country's premier it is something he can tax. So it is with accident prevention work. Interesting! more than interesting! of immense practical value, which can be definitely measured, both in human lives spared and in large sums of money saved.

Discussion of Mr. Foisie's Proposals

CHAIRMAN WELCH: Mr. Foisie's first proposal is in connection with the employment of a secretary for the Marine Section, to be obtained from the maritime interests. I would like to have your opinion on that, gentlemen; it is up to the Section.

MR. TITUS: I was very much impressed with Mr. Foisie's paper. I think it epitomizes the points that have been brought out in the papers of the other two days.

I think the thing we need is a plan; if this Section is really going to accomplish what it could accomplish, it must have some concrete plan for putting this proposition into real action.

I notice that there are two distinct suggestions made by Mr. Foisie; one for the Section to do this work itself, or possibly for the government to undertake it. I think the best thought in the country now is that the correct way of accomplishing anything in any form of business is for the policy to originate in the business itself; the plan must come from within.

The best thought seems to be that it is not the function of the government to superimpose any organization or any method of action upon an industry. It is believed now by the best leaders in Washington that it

s the function of government to aid and assist industry. So I think, if you went to Washington, you would find the biggest men there disposed to tell you to go ahead and make out your own plan, complete it in every way and then come to the government and ask for assistance in putting it across. I think if you do that you will get wholehearted support.

As a corollary to the proposition, if the government did undertake it, the plan would be too harsh and certain things be imposed upon the industry that would not be satisfactory in the end. We would be forced to do things that we would not like to do. There would be rules and regulations introduced and the government would be too paternal if it started in.

I notice that Mr. Foisie suggests that a subscription list be drawn up whereby funds can be raised to get a permanent salaried secretary for his Section to carry on this work. I would like to make one further suggestion, in the light of experience that I have had; and if I may be pardoned for referring to what I mentioned yesterday, within the last six months, on the Pacific Coast, we have gone through the same proposition and have had to face the same thing in a small way that you are facing now in a big way.

A Subscription List Was the First Plan

We sat around a table, some 30 or 40 leaders. Captain Robert Dow, chairman of the meeting, had the biggest men of the shipping business on the coast sitting around the table and we had to consider how we were going to tackle this proposition. It didn't seem feasible for the organized bodies to undertake it out there. The answer was made very much as Mr. Welch said yesterday. "What are you going to do in an organization of steamship people when so many leaders are not in sympathy with the movement?"

There were not very many sold on the idea so the committee who finally handled the matter came to the conclusion that the only way to get started was to get a subscription list and hire some engineers and inaugurate a real program. We prepared a subscription list and when we got about 8 or 10 signatures we came to the conclusion that the people who really were progressive in the shipping business were putting up the money which was to be used for the advantage of every one; so human nature asserted itself and our group said, "Why should we put up the money to let some of the big fellows who have more than we have ride in on the big things we are putting across?"

So we said, "Let's use common sense and equalize this thing and get every one in." We then abandoned our committee work as a subscription proposition and went before the Steamship Owners Association and said, "This is really a cooperative matter for all steamship concerns. We are in this association to put it across." We were the nucleus, the people who had signed the subscription as a working body, and by presenting a united front we were able to show the logic of the situation as it should be borne by every one, with the result that the association appropriated the money.

So the thought I have in mind is that in the end you may have to come to this; it is your last resort. Get a subscription list; you must do that to put across a plan, but my suggestion is, that you organize a committee to call upon the American Steamship Association to see if we can't "attack the enemies in their lair" and see if we can't get them to undertake this as a cooperative measure.

If they were facing a strike there would be no question about the money being forthcoming to fight the strike; and it seems to me a reasonable thing to ask for a modest sum to develop protection from within. In this matter of organization I think if we get a plan to put before the American Steamship Association we will have a good chance to put the thing across.

On the Pacific Coast they all said it couldn't be done and that is why we tried the subscription list first.

I think we can put this across through an organized body on the Atlantic Coast; organize thoroughly first and then it will be a simple matter to have them all cooperate and put in a real American plan in every way. I think then if we could attack the New York operators through their association, get this thing started, it would be the only way to do it. If we can't, we can then fall back on the subscription list and get together through the instrumentality of this Section.

CAPTAIN KAIN: If we were to attempt to appropriate money and take over the work that properly belongs in another organization, or rather another group, we would not accomplish what we really want to accomplish. I think if the Steamship Owners Association could be sold on the idea we wouldn't have any trouble getting the money. The obligation is their's, not ours. There is no doubt but that we have got to show them the way, but I think it would be a mistake to assume their responsibility. As long as we did it they wouldn't have the interest unless they spend their own money.

CHAIRMAN WELCH: As you know, Captain Kain will take charge of the Marine Section the coming year, and I think he has in mind calling a meeting of the Executive Committee the first part of next month. It is quite possible Captain Kain can get in touch with Mr. Foisie and Mr. Titus at that time, if they are in New York, and maybe at that executive meeting come to some satisfactory conclusion.

We will now hear from Mr. Andrew J. Smith of the Marine Office of America, New York City.

PROTECTION AND INDEMNITY INSURANCE IN THE UNITED STATES

Andrew J. Smith, Marine Office of America, New York City

In view of the able paper on a specific protection and indemnity experience with accompanying data and comment, presented before this Section two years ago, this will be in the nature of a general commentary on the subject with more particular regard to the history and development of Protection and Indemnity Insurance in the United States.

It is probably unnecessary, but it may not be out of place to say here that P. & I. Insurance is of course, insurance taken out by shipowners to cover their liability for death or injury to seamen and passengers, for damage to cargo for which they are liable under their bills of lading, and also liability for damage to piers, etc., which is not covered by the policies of marine insurance on the hull of the vessel. These latter policies are not liability policies but cover physical damage sustained by the vessel; although it is true that in one or two respects the marine policy has been extended to cover shipowners' liability—namely, his liability for damage to another vessel caused by his vessel in collision and his liability for general average and salvage charges. It will be seen, therefore, that for complete protection a shipowner needs not only his marine insurance policy, but also a policy covering his various types of liability to third parties.

Early Times and Conditions Reviewed

To trace the beginning of P. & I. Insurance, it is necessary, as in so many other phases of shipping and shipping insurance, to go back to the early days in England. The first record I have been able to find bearing on other coverages than granted by marine policies is concerning the early mutuals or clubs in England, which were an outcome of a Parliamentary Act early in the Eighteenth Century, creating a monopoly in marine insurance in favor of two companies. This, naturally, led shipowners and shippers to seek more favorable rates and conditions than granted by the monopoly, and the result of the search took the form of mutual association. These outlaw mutuals, so far as I can learn, at first were merely used as rate-cutting devices, insuring practically the same risks as covered by the authorized companies and being permitted to exist and operate more through the influence of prominent interests than by force of law.

It should be understood that ship's liability for cargo damage in ancient times was practically nil. The owner of the shipment accompanied his goods and took complete charge of loading, protection, unloading and disposal at destination. Later, and existent at the time of the formation of the mutuals, a practice had grown up of merchants shipping to the same ports employing a traveling representative known as a supercargo to act in that capacity for them, the shipper still continuing to bear the risks not covered by the single document of insurance against perils of the sea, fire, pirates, salvage expenses, etc., which was considered of sufficient scope to protect the shipowner or operator for his liability to all concerned, as it was then interpreted. The trend, however, was to make the vessel more and more responsible for safe delivery of goods, particularly after the abolition of the monopoly about 1790.

As the extent and accompanying complication of overseas trade grew, the mutuals were the natural recipients of offerings to cover risks excluded under the marine policies, possibly such as water damage or damage to property other than another vessel. These offerings and the acceptance of at least some of them by the mutuals were the beginnings of Protection and Indemnity Insurance.

In America, from colonial times until the middle of the last century, the relations between vessel and cargo as to the former's liability were practically the same as in England; i. e., the strictly marine coverage was considered adequate, or at least all that was obtainable, and the shipper stood the balance of the risk. I can find no record of any American attempt to insure such residual risks, though in some cases the British facilities may have been used.

The aforementioned trend developed and while the liability of the shipowner of a century or less ago was in no way comparable to what it is now considered, he gradually found himself less free from liability to both crew and shipper and more subject to heavy financial obligations arising from injury to persons and property.

Realizing these facts, the shipowners in England took further steps to protect themselves and indemnify their libellants. This was done about 1860 by the formation of Mutual Protection and Indemnity Associations along the lines or as direct continuations of the old mutuels, in which each member was assessed on the basis of tonnage entered in the Association.

It is also recorded that as early as 1866, at least three British marine insurance companies covered protection and indemnity risks in conjunction with the hull insurance by the simple expedient of attaching, for an additional premium, the following clauses to the regular hull policies, which remain the basis of P. & I. clauses in both England and America:

Insurance Clauses in the Nineteenth Century

"And we further agree that if the Assured shall become liable to pay and shall pay any sum or sums in respect of any responsibility, claim, demand, damages, and/or expenses or shall incur any other loss arising from or occasioned by any of the following matters or things during the currency of this policy in respect of the ship hereby insured, that is to say:

"Loss or damage in respect of any other ship or boat or in respect of any goods, merchandise, freight, or other things or interests whatsoever, on board such other ship or boat, caused proximately or otherwise by the ship insured in so far as the same is not covered by the running down clause hereto attached.

"Loss or damage to any goods, merchandise, freight or other things or interests whatsoever, other than as aforesaid, whether on board said Steamship or not, which may arise from any cause whatever. Loss of life or personal injury and from payments made on account of life or other salvage.

"Loss or damage to any harbour, dock, graving or otherwise, slipway, way, gridiron, pontoon, pier, quay, jetty, stage, buoy, telegraph cable or other fixed or movable thing whatsoever, or to any goods or property in or on the same, howsoever caused.

"Any attempted or actual raising, removal or destruction of the wreck of the said Steamship or the cargo thereof, or any neglect or failure to raise, remove or destroy the same.

"Notwithstanding the foregoing, this policy is warranted free from any claim arising directly or indirectly under Workmen's Compensation Acts of any State or Nation."

In short, this form of insurance as previously stated, undertakes to indemnify shipowners for any sums for which they may become liable under existing civil law or practice. The clauses are the constants of the problem, the range of liability, the unknowns.

As time passed and the courts defined more and more clearly the obligations of the American shipowner as regards cargo, the situation seems to have been met by limiting to a minimum liability on his part through contracts with his shippers rather than through procuring insurance protection. This, of course, produced a situation that marked a hardship on the shipper, as it left him no recourse but to accept the conditions stipulated by the shipowner and himself stand any loss for which the ship would otherwise have been liable or to ship his goods in foreign bottoms where at least some protection could be obtained against loss uninsured by marine policies.

Congress Finally Passed the "Harter Act"

This situation is doubtless one of the contributing causes to the decline of the American merchant marine following the Civil War, for it could hardly be expected that a shipper would assume these risks when by availing himself of foreign facilities he could to a considerable extent avoid them, and to a degree this was also an indirect cause of the wane in popularity of a seagoing career for the young American.

These practices existed in this country until 1893, when Congress passed what is known as the "Harter Act," the general effect of which was to make owner and ship liable for fault or failure in proper loading, stowage, care or proper delivery of shipper's goods. The first section of the Act reading:

"It shall not be lawful for the manager, agent, master or owner of any vessel transporting merchandise or property from or between ports of the U. S. and foreign ports to insert in any bill of lading or shipping document any clause, covenant or agreement whereby it, he, or they shall be relieved from liability for loss or damage arising from negligence, fault, or failure in proper loading, stowage, custody, care, or proper delivery of any and all lawful merchandise or property committed to its or their charge. Any and all words or clauses of such import inserted in bills of lading or shipping receipts shall be null and void and of no effect."

The passage of this Act made it imperative for the shipowner to protect himself in the same manner as the English shipowner did earlier in the century and as there was no market in this country for this class of insurance he naturally availed himself of the market in England.

As the work of the National Safety Council is the protection of life and limb from accident and the avoidance of loss of time and money consequent thereto, the foregoing stress on the cargo phase may appear

somewhat out of sphere, but the personal side of P. & I. Insurance is an outgrowth of the development of liability for cargo, which has been noted at some length, and of the ancient rule of common law whereby the seaman is the ward of the vessel and entitled to maintenance and cure. The combination of the developed principles of the former applied to the latter has produced the "Jones Act" of today. It is interesting to note that, while indemnification for this type of loss has become an important feature of protection and indemnity insurance in recent years, at the time of the establishment of Protection and Indemnity Clubs to England it appears to have been considered of secondary importance and in this country even less than it was in England. The main object was to protect merchandise rather than life and limb of those handling or transporting it.

The principles of the liability on the part of a shipowner to his shipper, passenger or seaman, or in fact of any employer to third persons as we understand them today, are of comparatively recent development. It being only during the last 25 years or so that either our national or state laws have clearly recognized them.

The first market for this class of insurance in the United States was established in 1914 by the formation of the American Steamship Owners Mutual Protection and Indemnity Association, Inc., which, as its name implies, was a mutual organization to which a number of American steamship companies subscribed and were assessed according to tonnage entered, this being along similar lines to existing English clubs. A nominal assessment was made at the time of entry, which was in the nature of a fee to take care of managerial expenses, etc., followed, of course, by whatever assessments were necessary in order to reimburse members for losses.

Progress During the Years Since 1920

In 1922 the Government established the U. S. Protection & Indemnity Agency, Inc., for the underwriting of P. & I. Insurance on vessels owned or operated by U. S. Shipping Board, the functioning of which has already been ably described before this Section. This marked the establishment of the second market for this class of insurance in the United States.

Due to legislative restrictions no effort was made on the part of the old line American marine insurance companies to enter this field until about five years ago, when the restrictions were removed. Despite the fact that from the first there has been an open market in England, that is, a market where an owner could pay a stipulated premium with no chance of further cost to him through assessment, the Club or Mutual P. & I. Insurance seems to have met with more favor, until of late when there has grown, on the part of the American owner, a noticeable demand for protection other than on the Club basis.

As this demand has developed within the last five years, it might be safe to assume that it has been inspired somewhat by the Merchant Marine Act of 1920 and the resulting exceedingly large verdicts for loss of life and personal injury, based on the exclusion of seamen and marine

workers from state regulatory laws. At that time, with the Merchant Marine Act just passed, such companies as entertained this business at all did so in most conservative manner, feeling their way and practically confining their underwriting to the Great Lakes, where they had the benefit of largely permanent and organized crews, cargoes that were 90 per cent bulk, highly efficient loading and unloading machinery at both ends of voyages, and in a great many cases safety committees on the steamers cooperating toward a reduction of personal hazards.

To summarize, today there are but four or five offices in the American market writing Protection and Indemnity Insurance, all but two of which confine their writing solely to the Lakes. I use the word "offices" rather than "Companies," as several companies are represented in each office. The two mentioned write general protection and indemnity business, working in conjunction with the old established market in respect to rates and policy conditions.

The American Shipowner Has Many Handicaps

The P. and I. underwriting business in the United States is young. It is obviously difficult to initiate such an enterprise in competition with older established foreign concerns under the handicap of indefinite demarkation between scope of state and admiralty laws and the lack of a federal maritime compensation act. Such an act, you doubtless are aware, is under consideration by the present Congress, but as it is now drawn excluding the crews, it defeats the object toward which compensation should tend, i. e., definite protection of mariners and other workers on vessels at sea or in port. It still leaves both employees and employers a prey to litigation to adjust injury claims, and benefits only the legal talent prosecuting the case.

The result is long deferment of compensation payments, excessive costs to the plaintiff often nearly equaling the amount of his verdict, and higher P. & I. rates to the owner and operator where such are necessarily based on a wager against the probable action of a non-maritime jury. This situation in the highly competitive international or intranational sea carrying trades contributes heavily to the handicap under which the American shipowner operates and can not but be reflected in the long run to the detriment of his employees in the form of a curtailed market for their services and consequent increase of enforced idleness.

Outside of the personal liability end, the business is on at least a workable basis.

The Marine Section of the National Safety Council is looked upon more and more as a source of information and assistance in building up this "infant industry" on a sound basis and toward what we firmly believe will be the lasting benefit of all concerned.

CHAIRMAN WELCH: If there are no questions on this paper we will hear from Mr. Mitchell, who is with us and will read his paper now instead of to-morrow, as stated in the program. Mr. Mitchell is Director of Personnel of the New York, New Haven and Hartford Railroad Company.

MARITIME SAFETY

F. W. Mitchell, Director of Personnel, The New York, New Haven and Hartford Railroad Company, New Haven, Conn.

Marine safety, when considered from the standpoint of the average railroad operation, resolves itself into three main headings for consideration:

First: Construction and physical condition of equipment involved.

Second: The fitness, knowledge and experience of the captains and crews actually operating the vessels.

Third: The care and watchfulness on the part of these men in avoiding personal injuries.

In the consideration of the construction and physical condition of the equipment the management must accept the major responsibility.

Assuming that the operation is similar to our own operation in New York harbor—that of towing heavy car floats and shifting lighters and barges in and out of piers and slips—it is of course essential that the tug boats be structurally strong enough and sound enough to do the work expected of them with a reasonable guarantee of safety from minor collisions, grounding and other incidents of the day's work. They must be designed with proper stability for safe operation during squalls or high winds. The boilers, engines and steam piping must be properly inspected from the standpoint of safety as in the case of any other pressure power plant. The tug boats must possess enough power to perform their ordinary work with a margin of reserve so they can be prepared to respond to any demand that may be reasonably made for maneuvering to avoid collisions or other traffic accidents.

These considerations are for the most part taken care of by the rules and regulations of the United States Steamboat Inspection Service and by the rules of the insurance societies, and with careful inspection, on the part of the operating management and careful attention to repairs and maintenance, there is little reason for injury or accidents to the equipment or to the personnel from lack of consideration in this direction.

Most railroad marine operations are conducted in congested harbors or water-ways. As a rule these operations are continuous (as ours are) for 24 hours in the day. This day and night operation, during all kinds of weather, in and about busy water-ways, requires knowledge, experience, good judgment and coolness on the part of the tug boat pilot or captain and the best of cooperation from all the other members of the deck and engine room crews.

The pilot's experience must be such that he will know what his boat can do and what it is going to do under conditions requiring prompt action in slowing, or stopping, or changing course, and he must be able to rely on prompt response from the engine room to his signals.

The crew of the tug boat is literally a team, subject to the orders of the pilot or captain, and as a team they all share in responsibility for safely performing the day's work.

The captain, from his station in the pilot house, must make decisions and give the orders. The safety of those on board and of the equipment depends on the prompt and intelligent response to these orders. The captain must have a thorough knowledge of all of the peculiarities of the local waters in which he is working. In addition to his general knowledge and experience in handling tug boats and tows he must know the peculiarities of the tide in the local waters and the physical lay-out of the bridges, docks and slips in and out of which he is working day and night.

In all in-land or harbor operation there are local conditions which make the work different from similar work in other waters. For instance, in our operation of tugs and car floats between the Jersey shore and Oak Point bridges, we have the unusually strong tides running back and forth through Hell Gate at the upper end of the East River. The river here is very narrow and sweeps about in a sharp curve, so that a vessel approaching from the south can not always see another vessel that may be approaching from the opposite direction. The local rules here require that a vessel approaching this curve from either direction give one long warning whistle to indicate its approach. The local rules further require that a vessel approaching Hell Gate against the tide shall make way for a vessel coming in the opposite direction with the tide, the reason for this rule, of course, being that a vessel coming through this narrow water-way with the tide and probably with a heavy tow cannot stop or change its course as easily as the vessel proceeding against the tide.

Accidents in this particular vicinity often take place because of failure to observe this local rule.

The Large Anchoring Ground in New York Harbor

In our operation of towing car floats back and forth between Bay Ridge, on the Long Island side, and Greenville, on the New Jersey side, our course takes us directly through the largest anchoring ground in New York harbor. On the chart there is indicated a fairway 1,000 feet wide leading through this anchorage, which space is supposed to be kept clear, but this demands constant watchfulness on the part of our captains because anchored vessels often swing around across this lane.

Fog or storm on the coast turns many vessels into the harbor for shelter and they are liable to drop anchor without regard to, or knowledge of, the local traffic and it is often found that the fairway is obstructed in ignorance under such conditions.

The every-day safety rules governing the operation of tug boats and other vessels about a harbor by day and night are much the same as the rules we are learning to recognize as governing the operation of automobiles on crowded thoroughfares. The captain must know what he wants to do and signal the other fellow so that he will know what is wanted. He must watch the other vessels and try to decide what they are trying to do. It is customary to pass to the right on meeting another vessel whenever conditions will permit, or to signal in time to avoid misunderstanding, if another course must be taken.

When one vessel is overtaking another going in the same direction, the overtaking vessel must not crowd the other unnecessarily or interfere with its course. If by doing so any injury or damage is caused to the overtaken vessel, then the one approaching from the stern is responsible.

The most careful judgment and experience is required for operation at night and during foggy weather. At night it is essential that proper signal lights be displayed and that they be in good condition and clearly visible and the captain's knowledge of local conditions becomes much more important because all vision is more or less distorted.

During fog, when the range of vision is restricted and the direction of sounds misleading, the captain has to rely almost entirely on his sense of location acquired from experience in the vicinity, and when he becomes the least bit confused as to his location and the position of other vessels the only safe thing he can do is to stop and wait for the fog to lift enough for him to regain his sense of location.

In the third phase of safety, as applied to marine operation, that of personal care and watchfulness to avoid minor injuries to themselves or others, the crew is only called on to exercise the same kind of judgment that they must exercise in any work ashore.

There is always danger in loading and unloading the floats, just as there is danger in any switching operation in the yards. There is always some danger in the engine room and boiler room of the tug boats, due to moving parts of the engine and the firing of the boilers. In this regard protection must be given the men as much as possible by properly covering moving parts and by instructing them in proper carefulness to avoid accidents and application of first aid in case of minor accidents.

On deck, in handling lines for picking up and towing car floats or barges, the men must exercise care in order not to be caught in the bight of a rope and not to leave the lines carelessly coiled in such a manner as to endanger anyone else.

On the part of the management—due regard for the condition of its equipment; on the part of the operating men—careful selection of captains and crews; and on the part of the crews themselves—consideration of the welfare and safety of each other. On all these depends the safety of the whole operation.

CHAIRMAN WELCH: Is there any discussion on Mr. Mitchell's paper? If not we will proceed to our honorable friend, Mr. George A. Marr, Secretary and Treasurer, Lake Carriers Association, Cleveland, Ohio.

INVENTIVE GENIUS DEVELOPED BY SHIP SAFETY COMMITTEE WORK

George A. Marr, Secretary-Treasurer, Lake Carriers' Association,
Cleveland, Ohio

At the meetings of the Marine Section of the National Safety Council in preceding years I endeavored to point out the working method of the ship safety committee as introduced on the Great Lakes by the Lake Carriers' Association, the extent to which severe personal injuries have

been reduced, the extent to which fatal injuries have been curtailed and to show in particular how the men on a lake bulk freighter have accepted this feature of our welfare plan.

I may repeat what I said in other years, that lake sailors, like seamen the world over, are reluctant to take up an idea that is an innovation and contrary to well established, if not traditional, customs aboard ship. One might say, "they are from Missouri and have to be shown," but when once the merit of a welfare plan feature becomes a settled fact in the lake sailor's mind he gives it whole hearted support. In this connection I would like to set forth at this meeting still another side of the seaman's interest in safety first, which has not only been found helpful in a material way, but has served to keep awake a general interest throughout the fleet.

I refer to the inventive thought the men aboard ship have given to this work. When you find men who will give thought and time to working out devices to safeguard their shipmates from injury or death you may be sure they are keenly interested from a point of view other than one of dollars and cents and that is what the men on our boats are now doing in increasingly large numbers. The ingenuity displayed is indicative of the constructive thought induced by the committee work, and a gratifying phase of the whole matter is that the devices suggested are inexpensive and in every case so far have been made aboard the vessel. In this work they have exhibited mechanical skill, and some of them have proved themselves adept draughtsmen.

The Hazards of Mail Carrying in the Detroit River

Obviously nearly all the devices invented aboard ship are applicable on lake vessels only, but if these men have naturally, voluntarily and intuitively come forward with these inventions, the conclusion must be drawn that if ship safety committees were established in other waters that the seamen in those waters would likewise turn their attention to the invention of devices applicable to the type of vessel on which they are employed and which will overcome dangerous conditions with which they come in contact.

What makes for a dangerous situation, not encountered elsewhere in seafaring, is the picking up of mail matter in the Detroit River—letters, telegrams and parcels—by vessels both up and downbound. As with very few exceptions all the vessels in the lake trade navigate through this waterway, the government maintains a floating postoffice on the Detroit River and mail is delivered by a small launch to passing vessels under way. In a season of navigation 30,000 vessels pass Detroit and one and one-half million pieces of mail matter are handled. Approximately 9,000 telegrams and special delivery letters are delivered. Although the freighters check to half speed when the launch comes alongside, she is still under fair way and care has to be exercised that the men handling the lines do not sustain injuries or that the launch men are not jerked overboard. In former days the mail boat's painter was held by the sailors on the steamer and occasionally burned their hands and slipped from their grasp. If it was thrown around a timberhead the mail boat's line

was frequently parted by suddenly coming up taut, and consequently the receiving and delivery of important mail in either case was missed.

It was to overcome these last named difficulties that the superintendent of the Detroit River postoffice in 1918 suggested that snubbing posts be installed on the boats. Shortly afterward George F. Anderson, at that time second mate on the bulk freighter "Hugh Kennedy," sent in a drawing of a snubbing post he had devised. These snubbing posts are installed, two on each side, abreast of No. 3 hatch for loaded boats, amidships when the freighter is light. There is little tendency to jerk, as when the mail boat fetches up the spring of the snubbing post on the wire fence relieves the sudden strain on the mail boat's painter. These snubbing posts are now in general use.

Severe injuries were frequently sustained when men were handling the steel hatch leaves for the purpose of oiling the under side. Fingers were pinched and crushed. In order that hatch leaves might be safely lifted for oiling, a clever device was rigged up on the steamer "Augustus B. Welvin." Shortly after this, the illustration of the device was printed in our monthly *Bulletin* and suggestions came from the ships that enlarged reproductions be made and placed in the crews' hallways.

A Landing Pole Insuring Safety of Men in Landing

Also we had reports of burned feet sustained by firemen who stepped on hot ashes and clinkers while cleaning fires. These were so numerous printed in our department of "personal injuries recently reported," that the ship safety committee on the steamer "Sierra" submitted a drawing of a simple device to safeguard firemen from such burns. This device is applicable on steam boats anywhere.

Another device, commonly known in the lake trade as a landing pole, is a boom fitted with tackle for the purpose of landing men on the dock at the loading or unloading ports, or on piers at the Sault locks. Until this device was brought out the custom of landing men when making a dock was the same as elsewhere; a monkey line was used, or the men went over the rail and jumped for the shore or pier, sometimes falling short and going into the water between the moving vessel and the dock. A number of seamen have been drowned while endeavoring to get on the dock to handle lines, and these fatalities brought forth a description and illustration of a landing pole that had been installed fast to the forward bulwarks of the steamer "Michigan."

This boom not only made it possible safely to land a man in every instance, but to place him on the pier anywhere as soon as the vessel was within 15 feet of it, thus avoiding the frequent bumping of piers and damage to the ship as formerly. The original landing pole was considered light in construction by some vessel managers, and this fault together with the demand for general installation led to the designing of various other types. Under our rules these landing poles are now tested to 800 pounds weight in order that they may be safe beyond possibility of doubt and in time of need be used to hoist barrels of oil, coils of cable and other heavy ship material for which no other provision had been heretofore made.

There are now few, if any, steamers in the membership of the Lake Carriers' Association not equipped with this device. Many vessels in the lake trade and not in the membership of our association are so equipped and this extends to vessels in the Montreal grain trade, where the pole comes in most opportunely when passing through the 60 odd locks of the Welland and St. Lawrence canals.

Also suitable for general application is the attachment of a bar on the hatch engines in a manner to prevent the cables from backwinding on the drum. For a long time the fouling of cables was a source of personal injuries aboard ship. Then the ship safety committee on the steamer "Henry G. Dalton" in 1920 reported that a bar had been fitted on the hatch engine of that steamer which would prevent the cable from jerking the man carrying the bridle off his feet and possibly into the cargo hold, or, if on the dock, jerking him into the water. Numerous inquiries were received as to how the bar should be fitted to the machinery, thus indicating that the men evinced genuine interest in safety devices.

Putting his head out of the deadlight was one of the most dangerous practices a lake seaman indulged in. Resultant serious injuries were frequently reported; in fact, only a few years ago one of the most competent of our chief engineers was instantly killed when he violated the rules against such practices. As a primary result of this fatality the Lake Carriers' Association had stencils made and sent to every ship in the membership in order that a warning against putting heads out of deadlights might be placed adjacent to every deadlight. Inasmuch as all seamen do not observe warning signs we soon received sketches of devices that would serve as a prevention of such practice.

Seamen Often Think of Safety Devices Simultaneously

Evidence that the thought of our seamen runs in the same channel simultaneously was furnished about two years ago when a ship safety committee suggested that grappling irons on the order of those used by the U. S. Coast Guards be installed on all boats, for the reason that when an emergency arises it generally finds the crew unprepared. Concurrently we received the sketch of a grappling hook designed by Captain H. A. Leish and made by Chief Engineer C. H. Savage of the steamer "George Stephenson." The cost of the material to make this simple and effective device is only 40 cents.

Ladder guards, that could profitably be employed on any vessel whenever the ordinary type of ladder is used, are the recent invention of Captain Charles Gegenheimer, master of the 600-foot steamer "Homer D. Williams." When our vessels are in port loading or unloading one or two ladders are always out, and to prevent sliding he designed two kinds of guards and both work successfully. The one can be used only at one place while the other can be used anywhere on bulwarks. There are two rivets out of beading on bulwarks far enough apart for the ladder to go between and a one-inch rod bent to fit in the rivet holes and around outside of ladder. The rod is threaded on both ends with a lock nut inside

of beading. The bend in the bar must be large enough so as not to bind the ladder. This has to be adjusted to the boat, but will answer the purpose on any dock. The other guard is made with clamps. One-half of the clamp is screwed on a rod iron of three-quarter inch diameter and the other half is held up to the beading with a lock nut.

More personal injuries, often resulting in the amputation of one or more fingers, occur to men who carelessly handle the lines when tying up, or shifting at a dock, than from any other single cause. They have persisted in handling the cable by the eye, instead of the becket that is installed on every ship's mooring lines. With the hope in mind that if the man handling the lines had something solid to hold to he would use it, instead of the eye, the captains in the fleet of five steamers of the Bradley Transportation Company adopted a becket made of five-eighths inch rod-iron, bent triangle shape with 4-inch sides and ends welded together. This is fitted to the cable by a patent link of a size to slip up and down in the eye of the cable. By this arrangement in the becket the man handling the wire could slide it clear after placing it on the pile. In favor of this becket was also the contention that it could not pull out as a wire becket sometimes does.

A Contrivance That Was Severely Criticised

Less than a month elapsed, however, before several ship safety committees tore the merits of this contrivance into bits, and I am dwelling on this subject to show that our ship safety men are critical of the devices proposed. They are as equally quick to recognize the practical application and benefits of the meritorious ones. The main objections to this becket were that in the event of the eye of the cable flopping over the bulwarks or the drum and hitting some one it would result in a more serious injury than if the old style becket were used; that there was room for using only one hand and that this iron would be dangerous to use in frosty weather. As a substitute the men on the "H. S. Wilkinson" submitted the drawing of a becket that is in satisfactory use on that steamer, and which any sailor can make in a few minutes. It consists of a piece of seven-eighths inch manila line, 22 inches long, with eyes spliced in both ends and attached to the cable by means of two five-eighths inch split links placed around strand of cable.

In connection with beckets, I may add that our ship safety rule provides, where wire beckets are used, that they be suitably covered either with half-inch garden hose or canvas, and this recommendation, too, originated on the vessels.

Beyond doubt the ship invention possessing the greatest merit from a safety first point of view came to us only last year from the steamer "R. L. Agassiz." It is a jack for jacking up well plates. The cleaning of boilers is always attended by danger if carelessly done and many bad accidents have occurred on the lakes from this cause. In removing man hole plates one man was drawn in by the tremendous vacuum created, others have been scalded by escaping steam and hot water. On one vessel the second assistant engineer and a fireman came every near to being badly scalded by the use of a slice bar, which was generally used

in this work. They thought all the water was out of the boiler, but when knocking man hole plate in they found that the water was not all out. To insure against such a condition this jack was devised on the "Agassiz." It consists of one and one-half inch tee with slot cut in it; one and-half inch pipe connecting flange and tee flattened with hole in it, also hole in tee to put pin or bolt through in order to move in different positions; one and one-half-inch pipe connecting three-quarter-inch pipe slotted and three-quarter-inch pipe flattened with hole in each for bolt or pin. On boilers that are close to deck it is necessary to have the three-quarter-inch pipe in two parts, as full length can not be put on hand hole bolt. This device holds the plate up and lets the water out while cleaning out top of boiler and it has proved to be very successful.

A hatch device to keep all the men on one side of the ship and to save too frequently hauling of the cable, a wire pennant was devised by the men on the steamer "Wm. J. Olcott."

In order to bring before you another good point of our ship safety committee, I revert once more to the skepticism the seaman is apt to exhibit when a new idea is presented. At the beginning of this safety work there were many who could see behind it only an ulterior motive, hence had there then been the slightest suggestion of economy in the use of ship's material, prevention of damage and things of like nature, this feeling would have been widespread. Left to their own resources to work out this ship safety work and personally to find out where the benefits accrue, they have themselves come to the point where they recommend the elimination of waste and provide means of action to avoid damage aboard ship and to the vessel itself. Thus the suggestion for a long line reel, while not a device for the prevention of personal injury, is a protection as well as a neat way of taking care of the log when not in use.

When the Steering Engine Gets Out of Order

When our lake vessels navigate in restricted areas, particularly the rivers and channels, a sudden accident to the steering engine or gear is likely to be attended by disastrous results. In rapid succession a few years ago there were four boats that found the steering engine out of order at a time when it was badly needed. A thoughtful chief engineer, sensing the necessity for some device that would prevent such situations, wrote as follows:

"I do not know that the matter was with the engines, but I do know if they are drilled and pins put in, that about 90 per cent of the trouble would be removed.

"On most steering engines only a collar with a half-inch or five-eighths set screw set through it, holds the valves. The constant moving of the valve is very apt to loosen screw and permit the valve to blind the ports. The same is true of the eccentric end.

"The steering engine is a very important piece of machinery and should be kept in first-class shape. There is practically no expense connected with this and it can be done on most any steering engine. It is

poor policy to wait until it has done a lot of damage before rectifying, when a few hours of work might save a big bill of expense."

In passing along information of this kind to other engineers in the lake fleet great care is exercised to impress upon them that they are not to accept suggestions as rules to be observed, particularly anything involving fundamental changes that might lead to a deal of harm, and not until approved by our Industrial Committee and endorsed by the Executive Committee of the Lake Carriers' Association.

This year we have had any number of suggestions from the ships in regard to more carefully operating the deck engines in order to prevent parting of the cables and damage to the engine; also suggestions that ropes of various kinds be more carefully kept.

And only a few days ago I was much impressed with a complaint that came in from one of the big bulk freighters. The committee on this boat condemned the use of flood lights on the ground of "being dangerous to other ships, especially to ships making a dock and having to pass a ship on which the glare from such lights cause the navigator to misjudge the distance and fetch up against the dock, resulting in damaged plates and fittings." Both vessel owner and underwriter can appreciate this thought.

Ship Safety Committees Improving Their Work

From what I have recited I think it is clear that our ship safety committees are going on to better and still better work as the years pass on. While it is true that these committees are not employed on all the steamers in the membership, interest in ship safety is by no means confined to the ships that have committees. Every vessel receives its quota of each issue of the *Bulletin* and hence the men are kept well informed on the subject, this applying particularly to worthy suggestions from committees and reports of personal injuries. A few weeks ago I received two sketches of safety first devices from a steamer that never employed a committee.

In addition to the payment of \$2 to each of the six members of the ship safety committee for attending each monthly meeting, our regulations provide for a bonus of \$10 to each member if the season's work is concluded without there having occurred on the vessel a personal injury sufficiently serious to have caused a man to leave the ship. It will interest you to know that at the end of 1925 there were in the fleet belonging to one company 10 steamers on which this bonus was paid for four consecutive years; eight other steamers for three consecutive years and on still 10 other steamers for two consecutive years, while for the season of 1925 itself the committee on 39 of their boats in operation received the bonus. In another fleet 11 committees have received the bonus for three consecutive years, while in 1925 there were 24 committees that received the bonus out of 42 ships in operation.

This year the Welfare Plan Committee revised the rules to meet the conditions covering the payment of a bonus to members of the ship safety committee in the event an accident had occurred during the fit-out before the forward end crew arrived.

Under the original conditions of the bonus the forward end men were

deprived of the extra compensation if such an injury occurred, although they were not aboard ship and obviously there was no organized committee to guard against possible injury to any of the men employed in fit-out work.

In order that the men of the forward end may not be deprived of their bonus in case an accident occurs in which they are in no wise connected, the Welfare Plan Committee has added to the general rules the provision as follows:

"On the arrival of the chief engineer with his crew to fit out his vessel in the spring, he shall, within 24 hours after his arrival, appoint his members of the safety committee who shall at once hold a regular meeting, and any accident occurring during the fit-out to other than a regular member of the crew shall not militate against the payment of bonuses in case the ship's employees (regular crew) went through the season without an injury. But in case a regular member of the crew was injured during the fit-out, that will nullify the payment of bonus the same as would an injury occurring during the season of navigation; provided, however, that this last clause is applied only to such members of the committee as are in the service of the vessel at the time of the accident."

Our method of having the ship safety committees make a written report of each meeting held (which gives us approximately 1,400 reports in a season of navigation) furnishes the medium by which one committee may express its views to other committees and whenever a suggestion of value is so made it is printed in the *Bulletin*. Reports of personal injuries are also printed in order that they may be read by all the crews, discussed by the committees and measures be taken to prevent a recurrence on other ships. This method that we have constantly employed since 1918 is in complete accord with the statement made last July by Mr. George Hodge, assistant manager, Industrial Relations Department, International Harvester Co., as follows:

"No matter how much accident prevention is discussed in committee meetings, unless the information is passed along to the man on the job, little will be accomplished. The objective, therefore, of the safety committee should be the purpose of disseminating safety and educational data to employees."

Discussion Following Mr. Marr's Paper

MR. SMITH: Of what use is the grappling iron?

MR. MARR: To pick up a man when he goes overboard. A year ago a man went overboard and did not come up. The coast guard was summoned and they got there in about half an hour and then they did not have a device of this kind and they could not locate the man. If they had brought a grappling hook of their own with them they could have got this fellow out. If they had had this little device on their boat that fellow's life could probably have been saved.

MR. TODE: I want to ask, Mr. Marr, how you appoint your safety committee? Do you have a safety committee for each ship?

MR. MARR: Yes, for each ship.

MR. BUSH: Are these ship committees purely optional?

MR. MARR: We have never made it a rule of the Lake Carriers Association for the reason that some of our fleets feel that they have safety relations and safety programs of their own. That is what they claim and I never yet, in discussing this matter with the owners that make such claims, have found that they really had a systematic safety program operating on the ships.

I might say the original idea was an officers' committee. The officers of the ships held meetings on shipboard once a month and they still have their officers' committee on most ships, and some of the fleet managers that have those officers' committee meetings have never looked with great favor on the appointment of a committee exclusively of officers to make suggestions as to how a vessel should be operated. They have had to go through that educational procedure in order to bring this into an active field that was extensive enough to be worth talking about.

The Problem of Injurious Information

CAPTAIN KAIN: Have the carriers ever found that any of this data which was recommended from time to time by the association was used against them, for instance something for which you had loss or personal injury? Do they oppose these recommendations or is it considered good practice? And in the ships where they do not have it, is it considered a detriment to the ship owner?

MR. MARR: Ship Safety Committees hold their meetings once a month. Their minutes are autographed by the captain and the chief engineer without any commitment on the part of the captain and the chief engineer that they concur in any recommendation made. That is clearly understood. The minutes are made in duplicate and one copy goes to the manager and one copy to the Lake Carriers Association. I have seen evidences that the managers generally look at those recommendations but I don't recall that any manager has ever taken any action with regard to sending out a bulletin to his fleet.

Every meeting report that comes to my office is examined; many of the recommendations are of interest purely local to the vessel on which the recommendations originate. A very large majority are of that kind but here and there, scattered all through them, we find recommendations that appear to us in the office as being worthy of consideration by the Ship Safety Committees generally, and those are published in our monthly bulletin and furnish good information for discussion at those meetings. Personal experiences of interest also furnish food for discussion at the meetings in the light of conditions that arise on board ship where that meeting is being held.

We have a winter committee. As you know, our season of navigation is only during spring, summer and fall. In the winter we have a meeting of what we call the Industrial Committee which is composed of active masters and chief engineers. They take this whole stack of reports from the Ship Safety Committees and read them through and they pick out from actual knowledge of conditions and actual experience of work on the boat what appear to them to be recommendations worthy of adoption.

We have also a Shore Captains' Committee which is composed of vessel managers who have graduated from the bridge of a vessel and are holding executive positions in the various fleets.

After the Industrial Committee has made its selection and its recommendations from the mass of recommendations that have come in from the ships, the Industrial Committee's recommendations are again scanned by the shore captains. Some of those recommendations are of such a nature as to come within the scope of the Welfare Plan Committee, so those two committees scan the recommendations of the Industrial Committee, and when they have approved the recommendations that have thus far come through, the residue goes to the Executive Committee for final adoption and goes into that book and becomes a rule of our association.

Now, getting back to Captain Kain's question. At the meeting of the Executive Committee last spring one of our members raised that very question as to whether these recommendations, if not carried out on the vessel, might not involve the vessel in damages and unpreventable law suits, and it looked for a little while as though this whole safety committee movement was going to be thrown into the air. I had to make a defense of it and I told them this thing had been operated since 1911 or 1912, and we never had such a question arise. It had never militated against any vessel owner in any settlement he had been called upon to make.

Objections to Reporting Accidents on Pacific Coast

Well, the Executive Committee didn't accept the situation and were instructed to take the matter up with a general counsel, Mr. Newton Baker. I went over it with Mr. Baker and I got an expression of opinion from him, and he concurred with our policy and advised us that there was no danger in submitting to any such recommendation and that we could go ahead and follow our procedure as heretofore. In reaching that conclusion Mr. Baker made a thorough investigation of what we had been doing, including the recommendations that had gone out in rules to the business.

Mr. Titus: In our work on the Pacific Coast on this new association program we found the same objection to the member companies reporting their accidents to the central organization for the scrutiny of the two safety engineers. We took the same position that you mention in which Mr. Baker concurred, that there was no practical danger of this cooperative effort being used against the carriers; but much to our astonishment we found the attorneys for one of the very largest companies operating intercoastally, advising them not to make any accident report to our association until after the claim arising from the accident had been adjusted. We felt, however, that we should have the reports from all the associations so we could check the recurrences of certain classes of accidents, so we hit upon the scheme of reporting the accidents without any reference being made to the steamer. We just had them say they had a man fall down a hatch, or jump off a deck

to avoid a swinging load. In that way we got the nature of the accident.

I was just wondering if, in your experience, that had proved a practical difficulty? The president, vice president and general manager of that particular big company stated that much as they might personally be in sympathy with the desire of the association, their attorneys so frankly advised against it that they did not think it advisable to go against such advice.

MR. MARR: We have been receiving these reports of personal injuries since 1909; there have been no objections to any one on our fleets making these reports. I think I am getting them from every vessel in the association.

In most cases the reports come direct from the captain. In some instances the vessel owners have instructed their masters, following out a general policy which they have carried in connection with all other reports, that no reports be made by masters direct to the Lake Carriers Association or any one else. All such reports must pass through their office management. So in a number of fleets I am getting reports through that round about channel, but I am getting them. There isn't a fleet in our association that makes any objection to furnishing us with statements.

Files of Accident Reports Remain Confidential

MR. TITUS: You have never found it a practical difficulty?

MR. MARR: We have never been called upon to show accident reports to anybody; there has never been an occasion where any outside person has demanded to see my files of accident statements. My accident reports have the name of the vessel, name of captain and owner, name of man injured, age, pedigree, and everything else, and still there has never been any demand on us for a showing as to what the nature of the accident was that was reported or how it occurred.

MR. WARFEL: In connection with industrial accidents resulting from lack of proper guards on machines of some kind, frequent reports will come in to our Inspection or Safety Engineering Division of that accident. We make an investigation but our Claim Department will not allow us to make an investigation to correct the cause until after the matter has been completely settled.

CAPTAIN KAIN: My question was brought about largely because of conditions which exist in the port of New York. They may not exist in other ports to the same extent. There they are tried and brought before a jury. In every case where equipment is involved, they raise the issue of fact on some condition existing aboard ship which in their allegations should be there or should not have been on the ship.

Take a thing like the snubbing post on mail boats. I gather from your talk to us that it is almost universally used on those ships. I have in mind some similar contrivance on ocean going steamers where the owners might not have installed that feature, and in the event of an accident there is no doubt in my mind but that the attorney having that case in court would cite the fact that any association such as yourself had recommended what is almost universally used, and this owner

not having it was negligent; and I think he would convince the jury that the ship was negligent in not having that equipment.

MR. MARR: I wish I could express to you in the very fine language of Mr. Baker what he said. He covered that. It does not appear to him to be compulsory to the ship to adopt the ship safety work and abide by the published rules.

MR. STEVENS: Have you Mr. Baker's opinion printed or published in writing?

MR. MARR: No, I haven't.

MR. EDWARDS: Isn't it possible that Mr. Baker's opinion was given because you have such an efficient outfit?

MR. MARR: I think not; I think he is influenced probably by the fact that the safety movement is a very general movement. It doesn't cover ships and longshore men alone. It covers street cars, railroads, factories, automobiles and everything else. I think if any such conclusions were definitely reached, that failure of an individual to carry out a recommendation as made by the organization to which he belongs would make him liable for personal injuries, that you would throw your whole safety movement in the air. You wouldn't get automobile manufacturers or shoe manufacturers into your organization if they had to protect themselves against lawsuit because they omitted the recommendations which come from their conventions.

CHAIRMAN WELCH: Do the recommendations of those Ship Safety Committees take effect at once, immediately after the meetings are over?

Guards on Gauge Glasses on Water Boilers

MR. MARR: They do not take effect until they have been sifted and found worthy. Then twice a year we publish all the recommendations that have been adopted since the previous publication.

CAPTAIN KAIN: I have in mind one little feature that I know has come up on numerous occasions and will come up again and again. That is the matter of guards on gauge glasses on water boilers. I believe your committee recommends a guard. We have a great many accidents on ocean going steamers arising out of carelessness in renewing gauge glasses—carelessness on the part of the men doing the job. When a case of that kind comes up for trial the opposing attorney will invariably contend there should have been a guard and the owner not having it is liable for the injury.

You will find a great many steamship men who do not believe it practical to use the guards, and if they were used they would have to be made of a mesh so small, in order to be of protection, that the water boiler tenders would not be able to watch their glasses. I think that on a great majority of vessels with which you come in contact on salt water, you will find no guards being used on those gauge glasses. Notwithstanding that, those personal injury lawyers try to raise a doubt in the minds of a jury about the good will and fair practice of the owner in operating the ship under those conditions. It seems to be an open question with practically all the men who are really using them.

MR. MARR: I think you will find that recommendation in our book. My impression is that it was one of the first recommendations that came to our association. I haven't heard of a water gauge accident as far back as I can remember. I haven't heard of a man being injured by water breaking a gauge glass.

CAPTAIN KAIN: They are very numerous on ocean going steamers. It is quite serious because it involves a man's eye.

MR. TODE: Do they employ those guards universally on the lake steamers?

MR. MARR: I can't speak as to that. I have not been down in a boiler room for a long time. But the fact remains, we have not had any accidents.

MR. TODE: Are the boilers any different as to the height of gauge glass above the boiler room floor? It would be hard for us to install those gauge glass guards because of the difficulty of the water tender being on the level, because it is so high up.

Shipping Statistics Should Cover Extended Periods

CAPTAIN KAIN: I am not thoroughly familiar with boilers on the lakes. I don't believe there is any great difference in the type used there as used on the salt water. Of course, as a matter of fact, accidents do happen when gauge glasses are being removed. Even though it is quite possible to operate gauge valves before opening, you still might have these particular accidents, although some have happened while they were not removing the glass.

I have had personal experience in trying to induce engineers to use glass guards and almost invariably have met with opposition. They contend they are not practical. Nevertheless, cases brought to trial are won by opposing attorneys as they never have any difficulty in bringing some of the so-called experts to testify that guards are practical and should be adopted and are used by competent and careful steamship operators.

MR. TODE: How many ships does your association control?

MR. MARR: About 415 ships, and about 11,000 men at one time and about 15,000 including the floating element continuously; and perhaps, with turnover in the course of a year, 20,000.

MR. TODE: I think Mr. Foisie mentioned in his paper, and it has also been referred to in several other papers, that there is considerable agitation over keeping statistics on man hours lost. Have you found it so?

MR. MARR: No; however, I should prefer to go back to statistics only as they are kept over a long period of time. I don't raise the question as to how many accidents we have had in one year in comparison with another year; but if you will take a number of years and compare that period with the average of another similar period, I think you get some results. By comparing 1926 with 1925 you don't get any information of any value because 1925 might have been a fortunate year; 1925 might have had fewer vessels in operation; 1925 might have had a very small turnover, and all those conditions reversed in 1926.

In 1926 you might have a shortage of men and had to go out into the highways and byways and pick up any kind of man you could get to fill out the crew as required by law, without regard to his ability, and for that reason you are likely to have had extensive personal injuries.

MR. TODE: For the benefit of some of the gentlemen representing insurance companies, I have been asked several times, and I know other steamship companies and operators have also been asked, as to the desirability of obtaining statistics on man hours lost, and they have tried to show me how successful that has been in shore operation, but in steamship operation that is an awful hard thing to try and get.

For instance, you hire at different ports and discharge at different ports and you can't get an injury report from the ship until months after the man was put in the hospital and discharged, and there is no record kept of hours lost. So considering such incomplete statistics I think it is going to be a pretty hard matter for steamship companies to compile statistics on man hours lost.

MR. BUSH: Is your fleet of 415 vessels entirely made up of bulk carriers?

MR. MARR: No, we have one fleet of 24, another of 5 and another of 4, making a total of 33 package freighters. Then there are a couple carrying fares, and there are three Standard Oil tank steamers.

MR. TITUS: On the 33 package freighters do you get into shore safety work at all? They must discharge and load?

MR. MARR: I think all their stevedoring is done by shore crews.

Various Methods Employed in Unloading Cargo

MR. TITUS: They are paying an indirect cost on any inefficiency on the shore because it is reflected in the charge if shore accidents are numerous, and that would naturally fall upon the operator or stevedoring company and the owner would have to pay the charge. Sometimes the consignee pays the charge of handling.

MR. MARR: With our bulk freighters handling is all done by machinery; no part is hand work. We have very large and very efficient machinery and loading is done at the expense of the dock companies whether it is ore, coal, or grain. In the case of limestone the limestone companies own the boats, shore equipment and self-unloading equipment on the boat.]

With regard to unloading: in the case of ore it is the railroad that does the unloading; with coal it is the coal companies; with grain it is the elevators, and the cost goes with the grain; in the case of limestone it is unloaded by their own unloading equipment on the vessels except where vessels not so equipped are chartered. In that case they are unloaded by the purchasing company.

MR. TITUS: Do you happen to know what is the custom on the Great Lakes in regard to charges? Does the rate charged by the carrier and paid by the consignee include all the terminal handling or do you have a ship's tackle charge and does consignee pay warpage and handling as well?

MR. MARR: The Lake Carriers Association does not involve in any traffic.

MR. TITUS: Your work is ship safety work?

MR. MARR: The association has many other features in its work. We are very active in the matter of securing navigation improvements and improvements on channels; objecting to and opposing improper legislation; aiding the employees, et cetera.

MR. TITUS: No stevedoring at all?

MR. MARR: No traffic matters or shore matters. The package freighters come under the Interstate Commerce Act and also under the Shipping Board and they enter into traffic arrangements through the railroad companies. Whether there are portions of the handling of their through business not handled by through rates, I don't know.

At the close of the year when the crop movement is under way some of these boats come into the handling and carrying of grain, and then they run as wild vessels or tramp steamers, just the same as our bulk freighters; and on a port to port rate and not under the Interstate Commerce Commission or the Shipping Board. In those cases the handling charges for the grain are handled the same as our bulk freighters.

A Tremendous Lesson for Ship Safety Men

MR. FOISIE: This situation which you have developed for us so fascinatingly, of the possible conflict between good business values in safety work with the legal protection that a business wants against any abuse of those values, is a situation which, I think, is not adequately understood by business interests generally.

We had the same difficulty to encounter and have not overcome it in Seattle, as Mr. Titus mentioned, in the refusal of some companies to give us certain educational material of their accidents because of a belief that it would jeopardize them in case of suit.

To my way of thinking your staying with and believing in the value of your safety work, backed with the good fortune of Mr. Baker's opinion, is a thing which has a tremendous lesson all the way down the line. We find our business men are prone to turn to the legal opinions of their lawyers, contrary to their own good judgment at times, as your situation so clearly sets forth. The conflict seems to arise between the legal mind which interprets law in the light of precedent and the law, as it is interpreted by an ever increasing number of able minded lawyers, by its effect. I don't think that situation is well enough drawn for business men generally; and I believe if there was any possibility of getting the opinions that Mr. Baker enunciated perhaps it would be a great help to us all. We have this conflict in the Supreme Court quite frequently and the Federal Supreme Court has a majority and minority decision in many cases.

Usually a minority, and occasionally a majority of the Supreme Court differ and attempt to show a changing condition of business calls for a change of decision in the law. There is nothing that has occurred in this conference as illuminating to me as the very situation described,

plus your sense of values governing it, fortunately supported by Mr. Baker's mind.

MR. TITUS: Did you say Mr. Baker's opinion was made in the bulletin?

MR. MARR: No, we published the recommendations of Mr. Baker's opinion.

MR. SMITH: In regard to giving opinion based on precedent, we had a case recently where our lawyer dug out of his common sense his interpretation of the case. He thought it was sound, but the loss adjuster and broker said: "He can't do that; there is no precedent for it." I think if there is any possible way of getting the opinion of Mr. Baker, (at least something to pick out of it), it would be a good move.

MR. MARR: Of course I can't tell what Mr. Baker's personal opinion might be nor what the feelings might be of my own superiors in the Lake Carriers Association as to giving out a complete or skeleton copy of Mr. Baker's opinion; I will be very glad, however, if they have no objections, to endeavor in some way to give you a copy of it.

CHAIRMAN WELCH: We have a paper here by Mr. H. H. Raymond, president, Clyde Steamship Company, New York City. In the absence of Mr. Raymond, Mr. A. R. Bush will read this paper.

GENERAL OBSERVATIONS ON THE SUBJECT OF MARINE SAFETY

**H. H. Raymond, President, Clyde-Mallory Steamship Companies,
New York City**

The work which the National Safety Council is doing is a very worthy and highly commendable one. I have noted with interest the progress you have made from year to year and, as we all know, such a worthy cause, is bound by fundamental right to succeed.

There now exists a tendency of opinion that the major portion of industrial accidents are caused chiefly by defective machinery, etc., and the effort has been towards safety guards and devices. We find that the accidents which occur through defective machinery are rather a very small percentage of the total number sustained.

In the shipping industry, as well as others, I believe the majority of accidents are chargeable to hand labor, such as handling material, tools, material falling on persons, stepping on or striking against objects, falling objects and such causes which will not be prevented by more mechanical guards or better safety devices.

It is my opinion that these accidents can be prevented by better supervision and more effective education. Train the minds of working men against carelessness and chance-taking and you will eliminate a large portion of the industrial accidents which occur constantly.

We must look at safety work from two standpoints: first, humanitarian; and, second, from the viewpoint of dollars and cents as affecting business.

It is our duty to the state and the men themselves so to conduct our business as to eliminate accidents as far as it is humanly possible. A

crippled man is a burden both to himself and society. The relation of employer and employee is similar to father and child. The employee, like the child, has to be taught.

No man wants to be injured, but nevertheless many are careless and to overcome this they must be educated and particularly made to see the folly of carelessness. Likewise, the foremen must be taught to take care of men as though they were their own children. The foremen should instruct the men under them, warn them of danger, tell them the right way and the best way, and teach them to be more careful in their relations with fellow workmen.

We should also hold to strict account those to whom authority is delegated to inspect equipment. Insist on inspections being made frequently and replacements made of defective parts. Keep a record of the date when equipment and parts are installed and replaced. When equipment or parts are found to be worn out or just able to stand the strain, do not use again, but replace with new equipment or parts immediately. By waiting to replace faulty equipment until it gives way, serious injury often results.

It is also necessary to provide immediate medical attention to the injured men. This should be rendered as near the plant of operation as possible, which will save many dollars in lost time, especially where the injury does not warrant any period of disability and the man is able to return to work immediately. We are all aware of the high cost of industrial accidents, whether they are compensatable or not.

Tides Play a Big Part in the Handling of Ships

I also note, with a great deal of interest, that the National Safety Council is doing good work in other than the shipping industry. We must admit that the problem in the steamship business is different on account of the circumstances surrounding marine work, especially the 'longshore work—loading and unloading of ships. Ships must be loaded and discharged under circumstances over which the management has no control. Tides play a big part with ships having side ports, making it difficult at times to use skids. Then, again, when there is a lighter alongside the ship, discharging freight such as lumber or steel rails, the men must be very careful and be educated in performing their work in the proper and safe way.

The human element which is used in 'longshore labor is made up of all nationalities. Usually the men are uneducated, consequently placing a serious burden upon the employer. In employing unskilled labor, more care must be exercised than in any other industry that I know of. Also the labor is of a migratory character from one employment to another. For that reason, our foremen and stevedores have to be more highly educated in safety work.

By applying safety education, you will find that the reward is not merely a saving in the cost of accidents but a better relationship between employer and employee. The men become infused with confidence and loyalty to their employer.

On the whole, I would say that industrial safety is more of an educational problem than an engineering problem.

CHAIRMAN WELCH: Mr. Bush has also received a letter from Mr. William S. Wollner, General Safety Fire Prevention and Welfare Agent, Northwestern Pacific Railroad Company, San Francisco, Calif. Mr. Bush will also read his paper.

ACCIDENT PREVENTION WORK IN PASSENGER AUTOMOBILE AND FREIGHT FERRY SERVICE

**William S. Wollner, General Safety, Fire Prevention & Welfare Agent,
Northwestern Pacific Railroad Co., San Francisco, Cal.**

I have been asked to speak about safety in passenger, automobile and freight ferry service. Because my knowledge of this subject is limited to San Francisco Bay and its tributaries, what I have to say will deal only with ferry service in that section.

During the year ending June 30, 1926, the number of persons carried as passengers on San Francisco Bay ferry steamers was 57,775,456. During the year 1925 there were transported, in addition to passengers, 2,269,937 vehicles nearly all of which were automobiles and motor trucks. Practically all freight moving into or out of San Francisco must be ferried across the bay, due to the geographical location of the city, which is situated at the end of a peninsula. This also accounts for the very large number of passengers and vehicles transported by ferry, San Francisco having only one land outlet, that to the south which is not nearly sufficiently provided with highway communication facilities.

Those who have visited "The City by the Golden Gate" know that the fleets of ferry steamers there are the finest in the world and are maintained to an unusual standard of efficiency. Their cleanly appearance is the occasion of frequent remark by visitors. All passenger and vehicle ferries are of the double end type, while freight in cars is transported on both double end type ferries and barges propelled by tugs. The importance of ferry service on San Francisco Bay is demonstrated by the fact that there now is under construction for this service 12 vessels, two of the steam turbine electric drive type and ten of the Diesel engine electric drive type.

It is more than 20 years since a passenger lost his life in a San Francisco Bay ferry accident, and a report recently submitted states that more than 750,000,000 passengers have been handled during the last 15 years without the loss of a single life. I understand that you wish me to tell you how this has been done.

With one exception the ferry fleets on San Francisco Bay are operated by the rail transportation system, of which they are a part, and as the ferry which is the exception has been operating for only a comparatively short period, this paper will deal only with those operated by railroads. These are the Southern Pacific Company, Western Pacific Railroad Company, Atchison, Topeka & Santa Fe Railway Company, Northwestern Pacific Railroad Company and the Key System Transit Company. One

of these companies, the Southern Pacific, operates on San Francisco Bay and its tributaries the largest railroad ferry system in the world, its fleet consisting of seven passenger carrying steamers with a capacity each of from 2,200 to 3,500 passengers; eight automobile carrying steamers with a capacity each of from 45 to 75 automobiles; two composite steamers; three freight and passenger car transfer steamers, two of these being the largest in existence today; and a fireboat used exclusively to protect the company's ferry system.

The Southern Pacific's ferries are handling an average of 77,400 persons daily, the average number of vehicles transported during 1925 having been more than 4,000 daily. The Key System Transit Company, which handles foot passengers only, transports an average of about 43,000 passengers daily.

Unquestionably, the reason why there has been such a high degree of safety in San Francisco Bay ferry service is because of the policy of the railroad companies operating the fleets—that nothing that will assure safety is to be left undone, coupled with the high ideals of safety that have always been a part of maritime life.

At this point I would like to give the credit which is due it to the United States Steamboat Inspection Service, which, in this territory, as elsewhere, has one standard only, this being that only the highest type of material, workmanship and personnel will be permitted in any vessel over which it has jurisdiction. While its militant attitude may at times chafe the vessel owner or operator, the Steamboat Inspection Service deserves its part—and a very large part—of the credit due for the excellent safety record that has been established on the high seas and the inland waterways.

Safety of Employees

The occasion for my having been invited to prepare this paper is that the Northwestern Pacific's Marine Department went through the entire year 1925 without a reportable accident to an employee. As a matter of fact, there has been only one marine worker injured during the past 24 months. Interest having been shown in the Northwestern Pacific's marine employee safety record, I am going to tell you how this has been accomplished.

"Accidents do not happen; they are caused," is a favorite safety slogan. I am going to paraphrase this in so far as what I have to say is concerned with, "This record did not happen; it was caused," and the cause is that the value of accident prevention is fully recognized by those in charge of Northwestern Pacific activities, and the entire personnel has been educated in the value of safety and the means by which it may be acquired.

I will digress from the marine service for a moment to say that while over a period of a good many years there was a Northwestern Pacific employee accidentally killed on an average of every four months, it is now nearly 37 months since an employee on duty met his death in an accident, the no-fatality period immediately preceding the present one having been nine months which was in itself a record on this road.

The Northwestern Pacific's marine fleet consists of four large double end ferryboats plying a course of more than six miles in each direction, a smaller vessel serving points on the Marin shore, and a launch; in addition to which there are now in course of construction three steel hull Diesel engine electric drive boats which will be the last word in ferry equipment. There are 155 employees in the ferry service, not including those in the steward's department.

The ferry service is a part of the road's motive power and equipment department, at the head of which is a general superintendent of motive power and equipment to whom all credit for the safety accomplishments of the marine service must go. The general superintendent has inculcated into his subordinate officers his enthusiastic belief that safety is well worth while and makes for more efficient service and a dollars-and-cents, as well as sentimental, credit on the balance sheet. The general superintendent holds each of his subordinates strictly accountable for every accident that occurs, and this applies to the marine service as well as to the shops, locomotive and car departments. Every captain and chief engineer knows that if one of his men is injured, no matter how slightly, he will have to explain to the general superintendent personally the condition that made the occurrence of this accident possible.

A Thorough Investigation of the Accident

This interview is no perfunctory matter; it is in truth an investigation to determine the underlying, as well as the immediate, cause of the injury and there are present, in addition to the officer, the injured man, his immediate supervisors and other employees, if they are involved. A stenographic report is taken of the investigation and the points it produces are made known to all others concerned, so that the occurrence of similar accidents may be forestalled. An outstanding feature of these investigations is the fairness with which they are conducted. The general superintendent demands the facts, but just as truly as he insists upon responsibility being placed where it belongs, he also insists that discipline shall not be assessed where it is not deserved.

The procedure in investigating the one accident that occurred during the past 24 months is illustrative of the general practice in the motive power department. A deckhand received lacerations and a broken knuckle when his hand was caught in the steering gear of one of the ferry steamers. The deckhand and first officer, under whom he was working at the time of the accident, and the captain of the vessel were called into conference. The man was working on the steering gear when the tool slipped off a nut when the gear was moved, catching his hand and inflicting the injuries stated. The report covering the accident, which not only went into the motive power department's files, but was also forwarded to the president and general manager and the general safety agent, recited these facts and in addition stated, "This accident could have been avoided if this work had been done when the vessel was not under way."

In other words, there is no inclination for the department, as such, to

escape responsibility for the occurrence of an accident or to cover up such an occurrence, and this being the attitude of the department, the same spirit circulates through the organization. The underlying causes of the accident (in this case the work unnecessarily being done while the steamer was under way) having been determined, the facts are broadcast so as to avoid a repetition. The name of the first officer, under whom the deckhand was working at the time of the accident, was given in the report, and, needless to say, neither he nor any of his fellows were anxious to have this occur.

Another practice that has gone to the minimizing of accidents is that a statement of the accident and a copy of the transcript covering the investigation is attached to each employee's personal record and it is easily determined whether a man falls into the "careless" classification, or not.

A feature that has added much to the safety of workers on the Northwestern Pacific ferries, as well as fire protection, is that the boats are at all times completely electrically lighted and have full fire pressure on the water mains, even though there is not a pound of steam in the boilers. This is accomplished through the establishing of shore line connections to the vessels. High capacity electric lines are run to receptacles located in each ferry slip and at tie-up wharves. When a vessel is tied up a jumper cable, with which it is equipped, is plugged into the receptacle. This cable is carried in conduit to the vessel's electric switchboard so that all that is necessary, after the cable has been connected to the shore line, is to throw a switch on the board in order to give full electric light service to all parts of the steamer. Similarly, a hydrant on the slip or wharf is connected through a hose to the ship's fire main and this gives 90 pounds of pressure to any hydrant on the boat. Fire hydrants are generously placed about the wharf property and in addition there is at least one fire monitor placed within practical reach of each slip.

Protecting the Public

You have probably been saying to yourself that all that has been recited merely represents good management and this is absolutely true, yet it is also true that on very few properties is this particular phase of management stressed to the extent to which it is carried on this property. The same degree of care that is exercised to protect the worker is also used to avoid injury to passengers. Nothing, no matter how unimportant it may seem at the moment, that will make accident occurrence less likely, has been allowed to remain undone.

As an instance, it was noticed that when the gangways at terminals were lowered to load or discharge passengers from the upper deck, there was a space through which a child might fall. An accident of this kind had never occurred and the possibility of one occurring seemed extremely remote. It was a condition hard to correct as the space was located at the hinge of the gangway. It was, nevertheless, decided that if the proper amount of ingenuity were exercised, a guard could be devised and the road's bridge department designed an appliance that fully met the situa-

tion. It did not cost a great deal of money to safeguard this point, but it did take will and a persistency that refused to be balked because the solution was not easy to find.

The handling of automobiles offered a problem that was worthy of the best effort of any safety engineer. It should be remembered that this road's ferry steamers transport vehicles and passengers on the same trip. Its largest steamer, the "Eureka," can transport 3,500 passengers (2,590 of them seated) each trip, in addition to automobiles carried in the main deck gangway. The settees on the main deck are removable and when they are not in place 95 automobiles can be carried on this deck and 1,453 seated passengers in addition can be carried on the salon deck.

Transportation of automobiles and passengers on the same trip offers peculiar hazards, smoking being the gravest. The first problem was to isolate the foot passenger smoker from the motor vehicles and while on the "Eureka" this has been done, it is not so easily accomplished on some of the other vessels. The means used on the "Eureka" has been the installation of folding gates that can be used exclusively for the placing of automobiles. These folding gates or railings have been ingeniously placed so that space may be allotted to anything from a few automobiles to the entire capacity of the deck. Foot passengers are not permitted to go within the inclosure.

Other Hazards in Ferrying Automobiles

Another smoking hazard comes from the automobile driver or passenger who stays within the vehicle and endeavors to insist upon smoking. The solution of the smoker problem on the Northwestern Pacific, which has now been adopted by the other companies operating on San Francisco Bay, was the inauguration of a "Pyrene patrol." During all the time that there are automobiles on the ferry, even though there be only one car, one or more deckhands armed with a Pyrene extinguisher, which he carries in his hand or in a leather holster, remains in the vicinity of the car, or patrols the space where cars are placed. This is done for two purposes, first, to see that there is no smoking and, second, to extinguish immediately any fire that may occur. The second officer of the vessel makes it his business to see that the patrol is constantly alert to its responsibility and the general safety agent makes inspections at frequent intervals to see that this matter is being given the attention it deserves.

It is very often difficult to get people to discontinue smoking in the vicinity of motor cars and at times the road's police department has been used to add argument to the request of the patrol that smoking be discontinued.

Another duty of the patrol is to see that drivers do not start their engines until the boat is moored in the slip and the vehicles ready to move. This not only lessens the fire hazard, but materially decreases the quantity of carbon monoxide. A mechanical device meant to assist in solving the smoker problem is the placing of electrically illuminated signs in the gangways on the main deck of the boats. When there are automobiles in that portion of the boat the illuminated sign reads, "NO SMOKING,"

while the word "NO" is covered when that portion of the boat is not being occupied by cars. There is of course the usual complement of carbon tetrachloride extinguishers, soda and acid extinguishers, water buckets and sand buckets on the boats, while in addition the steamer "Eureka" is equipped on its main deck with two 40 gallon American La France soda and acid tanks with the usual equipment of chemical hose, etc.

In concluding this paper, I must again take occasion to say that the Northwestern Pacific has done nothing in its effort for fewer accidents that is not dictated by good management. What it has done is to place greater stress on good management features, such as safety, fire prevention and the careful selection of employees, than is usually the case. It has been only through the generous interest of every officer of the company, starting with the president and general manager, and the twenty-four hour a day supervision of those charged with this duty that has occasioned the record that has been made. Doubtless, many companies have accomplished as much or more by the same method, and it is certainly true that many other companies could accomplish as much or more if they would undertake this means of reducing accidents.

CHAIRMAN WELCH: We have one more number on the program. Mr. A. C. Warfel, supervising engineer, Safety Engineering and Inspection Department, Hartford Accident and Indemnity Company, St. Louis, Mo., desires to relate some personal experiences in stevedoring work.

SAFE PRACTICES IN STEAMSHIP TERMINAL OPERATIONS

A. C. Warfel, Supervising Engineer, Hartford Accident and Indemnity Co.,
St. Louis, Mo.

I first want to establish a background in connection with my marine work. Aside from being a mechanical engineer, I am a licensed marine engineer, having come up from wiper, oiler, water tender, and thence through the assistant's grade to first assistant; consequently I know a little something of what I am about to say in connection with safe practices in steamship terminal operations.

My early contact with things of this nature was obtained while off duty and lolling over the rail, watching longshoremen at their work, and later as an army officer in charge of discharging freight transports loaded with box car material, at La Pallier, France, during the war.

My observations were such as brought to my notice men falling down hatchways that should have been covered as they were not being worked; men having their arms and legs caught in the bight of a fall or guy rope; slipping on icy decks; improperly loaded drafts of cargo falling on their heads either while working in a hold or on a pier, as drafts jammed between side of ship and pier due to improper listing of the vessel; dropping truck handles on their feet; or severe injuries while handling scrap iron cargoes.

In some of these accidents frantic efforts were made to telephone for police patrol, ambulances and for the nearest doctor, and in the resulting

confusion all three agencies called were late, or had no first aid applications, and the man either died while waiting, or as a result of the long wait, died enroute to the hospital, so that when my company put me in charge of safety engineering work in connection with one of our stevedore assured who operated from Boston to Norfolk, Va., I had already a well formulated plan of attack and an objective to consolidate, once I attained it.

The work first was to establish at each port a doctor who had had some experience with injuries of a water front nature. A doctor was needed who was connected with a hospital to which men could be sent, if their injuries so demanded, by either the hospital ambulance or any other vehicle of transportation that could be used.

It was also necessary that the hospital be so located that it would be quickly reached from any portion of the water front. By selecting one doctor so connected with a centrally located hospital, we would be able at all times to keep in close contact with the assured injured. The element of Admiralty laws enters here and claim settlements with signed release must be quick or a tied up ship may result from injuries received while working on the ship.

A First Aid Station Fully Equipped

Having once established our major medical feature, we next set about to establish at a centrally located point, preferably on a leased pier of our assured, a well equipped First Aid Station in charge of a competent First Aid man.

The problem in selecting a First Aid man was to get one who was familiar with shipping conditions, since I was going to use him on two duties, primarily and mainly as a First Aid attendant, and secondly as an inspector. I was successful in obtaining such a man in each port from the Naval Fleet Reserve in the person of a pharmacist mate, first class.

These men were almost doctors and far superior to the ordinary nurse; they save the assured as well as the insurance company many dollars in sending men back to work with a light dressing who ordinarily would have gone to a doctor and ended in a lawsuit. These men have an acquired hardboiledness that is needed in getting water front workers back to duty.

I have just stated that the First Aid man was to be used as an inspector. In starting my work with this particular assured, I instituted a regime of rigid inspection of piers, docks, ships and men, so that by force of necessity we had to get a First Aid man that was familiar with ships and their loading.

Briefly the inspection consisted of knowing and correcting flooring or decking conditions on docks and piers, piling of cargo on the piers, inspection of slings, sleds, airplanes, ships and house falls, especially wire cables with projecting strands, and all equipment pertinent to the loading or unloading of ships; keeping decks free of strewn gear or

tripping hazards, and seeing that good illumination was provided for night work.

Another duty of the First Aid man was to observe and weed out men who, in his opinion, were weaklings and not physically strong enough for the duties of a longshoreman; men not properly clothed against freezing cold or with shoes with rubber heels or shoes that would invite splinters or nail punctures; and naturally investigate the cause of all accidents, obtain witness statements and take steps to correct the cause.

An operating company having its own ships can very readily correct conditions of an accident producing nature as reported to them, but the stevedoring and operating firm can not very well do this, because the ships do not belong to him, nor do the piers; and the frequent press of "tons per hour" is a factor that often precludes any thought of safety; however, they can effect corrections on piers that are leased to them, so if any different conditions ought to be overcome on other piers or ships the cooperation of ship captains, chief engineers, and the managers of piers would have to be obtained to correct conditions which had existed for years.

Posters, Signs and Moving Pictures All Helped

Another feature that had to be injected was the matter of education, equally as valuable as the correction of physical hazards. This was the instituting of some safety education among the longshoremen unions. In Boston, Baltimore and Norfolk we had to contend with the International Longshoremen's Association, and in Philadelphia, the I. W. W. None were found to be hostile to my efforts. In the latter city, due to a water front Beneficial Association fostered by several of the stevedoring companies, the I. W. W. did not give very much trouble, nor did the I. L. A. after serious talks were had with their business managers.

Safety posters of an educational nature were posted on the piers, at time offices and Union Halls. Caution signs in Polish and English were posted, as well as signs requiring all men to report injuries, no matter how slight, for first aid treatment. I took numerous photographs of accident producing conditions which our company later made into vivid posters that appealed to the water front element. With my own Bell and Howel portable motion picture camera I took several reels of accident causing conditions with men at work. I used a telescopic lens, so when displayed the men were at a total loss to know how and when the pictures of themselves were taken, and the benefits derived were considerable.

Talks were had with gang foremen, whether elected by their own gang, or appointed by the stevedoring corporation, or where possible, periodical assemblages were made by the longshore foremen, stevedore bosses and pier superintendents, all of which had a tendency to produce a good morale among the entire organization. Monetary prizes were offered to the gang foremen going a given length of time with a no accident record.

Regardless of the precautions taken, accidents would, and will continue to occur, but in the main, they will be of the unavoidable nature—the cracking of a boom, or giving way of a block at a point which can not very well be inspected—these accidents will continue to occur, mostly on foreign ships, as our own are better inspected and under a more rigid control of the United States Steamboat Inspection Service. However, once the men know their safety is being looked after, they report many things that would ordinarily be overlooked.

In order to obtain proficiency among the longshoremen gangs, it was successfully tried to keep gangs together under the same foreman and wherever possible to have the same gangs always doing the same work. That is, a certain number of gangs under the leadership of the same foreman would load and unload steel; other gangs would handle an inter-coastal type of cargo, while still another gang would handle automobiles or motor trucks, so that they became more efficient in their work—and efficiency is safety.

The inspection service thus instituted and carried on by our combination First Aid inspector enabled us to see that ships were properly breasted from piers; that savealls were properly used; that proper ladders were used from barges and piers to the ship, so secured as to permit of the rise and fall of the tide, and to discourage the use of a plank through a hawser pipe, or any other unsecured means of getting from or to the ship; to replace by a rope barrier any section of rail that had been temporarily removed for the handling of cargo; to lay hatch covers athwart ship on the deck instead of piling them in a wobbly fashion along the hatch coaming, where such a cover has often precipitated a hatch tender into the hold invariably with fatal result; further, to see that all hatch beams were removed from hatches being worked.

Within a Year Accident Frequency Dropped Greatly

After a year of this work, our assured found that they had so reduced their accident frequency and the cost resulting from breakage that they determined to carry their own insurance which, in itself, reflected the energetic work that we had done with this assured.

In conclusion I might say that if any number of steamship operating companies or stevedoring companies along the Atlantic Coast would combine their efforts along the above lines, they would be materially benefitted by reduced rates from their carriers, or be enabled at a later date to carry their own insurance. But, in any event, such safety work that they would start would have to continue or there would be immediate reversion to the old accident producing conditions. Further, there would have to be harmonious cooperation of all concerned or a chaotic condition would result.

CHAIRMAN WELCH: That is a very practical paper, Mr. Warfel.

CAPTAIN KAIN: If those photographs have not been disposed of they would be very valuable to the Council.

MR. WARFEL: I have one reel left; one reel was lost. But I have the

Bell and Howel portable camera and could let them have it any time they want it.

CAPTAIN KAIN: Have you any still photographs?

MR. WARFEL: I don't have any more; they were turned over to our service.

CHAIRMAN WELCH: Is your company a member of the Council?

MR. WARFEL: Yes.

CHAIRMAN WELCH: We greatly regret that Captain Asa F. Davidson, who was on our program for a talk upon safety from the operator's viewpoint, could not be here to participate in our interesting sessions. His brief remarks will, however, appear at this point in the published volume of Transactions.

SAFETY FROM AN OPERATOR'S POINT OF VIEW

Captain Asa F. Davison, Vice-President, Black Diamond Steamship Corporation, New York

From an operator's point of view, the question of safety is one of increasing importance. In the past, safety considerations have not always been given the attention they warrant. Today, from both the humanitarian and economical standpoints, we must recognize the obligations of operators to encourage every condition that will tend to promote the safety of their organizations.

As those who are familiar with ship operation know, there exists at all times a large element of risk in the handling of the miscellaneous commodities which comprise our general cargoes. For example, the carrying away of a topping lift or cargo fall is attended always with more or less damage to the vessel and cargo, and frequently with injury to members of the crew or stevedores in attendance. The obligation of maintaining cargo handling equipment in good condition is of vital importance.

Safety of life at sea is a feature that has always demanded serious attention from the operator. Safety appliances and equipment must lie on board in sufficient quantity to cope with any and all hazards which may arise. Hence the question of safety lies close to the heart of the operator.

But, in order to get results with certainty, we must have at all times the cooperation of our personnel. There exists constantly the "human element equation". Frequently men will take unnecessary risks which may result in serious injury to themselves and the owner's property. To guard against this, we must encourage "Safety First" principles.

One interpretation of "Safety First" is "First Aid to the Injured". Bearing in mind that a disabled employee is a liability (often severe) and not an asset, it should be apparent to all that the operator can not afford to neglect safety methods. Rather, he should encourage the adoption of the same, as thereby he undoubtedly enhances the security of his employers and his property.

CHAIRMAN WELCH: This closes the activities for today and for our Section. Many are going home today; therefore, I want to take this

opportunity to say how deeply obligated I feel to all you gentlemen for your presence here and the very fine program that you helped to make; it certainly was a splendid one, and I desire to state as retiring chairman that I thank every one who has helped in this movement in trying to do something in the Marine Section.

MR. SMITH: May I have the privilege of presiding at this meeting for just about a moment? I know you all appreciate the obstacles our chairman has overcome in getting this Section under way, and I think every one of us is willing to voice this in the form of a resolution of appreciation which I would like to have proposed from this floor at this time and formally recorded.

CAPTAIN KAIN: I move that Mr. Bush be asked to draft such a resolution.

(The motion was seconded by Mr. Edwards.)

MR. MARR: As temporary chairman, Mr. Smith, may I, a rank outsider, make a few remarks?

MR. SMITH: You certainly may.

MR. MARR: I want to call to your mind the opening remarks that our chairman made on Tuesday morning when this Marine Section was first called into session. He started off with an apology for his Marine Section and what it had accomplished and then went on to tell of the things it had done. It might have been a very politic thing for him to do, to start with an apology and wind up with a declaration of his accomplishment.

I want not only to compliment the Marine Section and officers on what they have accomplished, as stated by the chairman at that time, but I think the Marine Section is to be congratulated on overcoming the obstacles it has met in endeavoring to get well established. It has had an uphill road but through the persistent and effective efforts of our chairman it has vaulted over the obstacles and through the hazards to a well established Section, and I want to compliment him and congratulate him; and I also want to congratulate the incoming officers for having a Section come into their own control that is so well established. (Applause.)

CAPTAIN KAIN: Mr. Bush has requested that we give him a little time to prepare that resolution. I think that would be advisable. I, therefore, move that we, at this time, extend a rising vote of thanks to our chairman and let the resolution we are preparing be incorporated in the records later.

(The motion was seconded by Mr. Edwards.)

(In appreciation of the work done by Mr. Welch, as chairman for the Section, the assembly arose and applauded.)

CHAIRMAN WELCH: You know, gentlemen, this has all been a great pleasure to me because I have met some very fine men that I would not have met had I not been in this Section.

ADJOURNMENT

Metals Section

New Officers of the Section

CHAIRMAN: F. G. BENNETT

The Buckeye Steel Castings Company, Columbus, Ohio.

VICE-CHAIRMAN: J. A. NORTHWOOD

Bethlehem Steel Co., Johnstown, Pa.

SECRETARY: E. G. QUESNEL

Commonwealth Steel Co., Granite City, Ill.

Committees

PROGRAM: JOHN P. EIB, Chairman

Illinois Steel Company, Joliet, Ill.

POSTER: FRANK H. ROWE, Chairman

Wheeling Steel Corporation, Portsmouth, Ohio.

MEMBERSHIP: H. G. HENSEL, Chairman

The Youngstown Sheet & Tube Co., Chicago, Ill.

ENGINEERING REPRESENTATIVE: EARL F. BLANK

Jones & Laughlin Steel Corp., Pittsburgh, Pa.

EXECUTIVE COMMITTEE (The Officers and)

A. C. GIBSON

Spang, Chalfont & Co., Pittsburgh, Pa.

T. H. McKENNEY

Illinois Steel Co., South Chicago, Ill.

JOHN A. OARTEL

Carnegie Steel Co., Pittsburgh, Pa.

J. M. WOLTZ

The Youngstown Sheet & Tube Co., Youngstown, Ohio.

October 26, 1926

A. C. GIBSON, Chairman

Manager, Industrial Relations, Spang-Chalfont & Co.,
Pittsburgh, Pa.

THE first session of the Metals Section, Fifteenth Annual Safety Congress, National Safety Council, was called to order at 9:30 o'clock, in the Grand Ball Room, Book-Cadillac Hotel, Detroit, Michigan, Chairman A. C. Gibson, presiding.

CHAIRMAN GIBSON: It gives me pleasure, as chairman of the Metals Section, to welcome you to this Congress. I am very well pleased with the registration and also with the attendance this morning. It has always been the aim of the Metals Section to get started promptly.

The first thing on the program is the report of officers and committees.

As chairman of the Metals Section, I wish to report that we have had quite a busy year and the result of our work will be shown in the program that we present here. We have had a very fine spirit of cooperation throughout the meetings which we have held and I wish to thank everybody who has been in any way connected with the preparation of the program and the getting up of the present Congress.

We will now hear from the vice-chairman, Mr. Fred C. Bennett.

MR. BENNETT: I don't believe, Mr. Chairman, there is anything I can add. I haven't found that the vice-chairman has very much to do. I have always been glad to help the chairman, but I have no report as no specific duties have been allotted me.

CHAIRMAN GIBSON: Next is the report of the secretary, Mr. J. A. Northwood.

SECRETARY NORTHWOOD: Mr. Chairman, I have no especially written report. I only want to say that I have had quite a job this year, one of the biggest jobs I ever had, getting out that news letter. I am just wondering what you think of it; whether it has answered the purpose, whether we have reached the mark? I feel it is worth while, to keep us in touch with each other if nothing else, and I hope that the man who follows me as secretary will be assisted a little more, perhaps, than I have been this year. I am going to plead now that you fellows make a note in your note-books that you will help the secretary the coming year in getting out the news letter, thereby making it worth while to us all.

CHAIRMAN GIBSON: This news letter, as you know, is the life of the Metals Section, practically; it carries us over from one Congress to another and keeps us in touch with one another. It is really important work and one of the big jobs of the Section.

The next report is that of the Program Committee, of which Mr. E. G. Quesnel is chairman. I have that report here, and in the absence of Mr. Quesnel, I will read it, as follows:

REPORT OF THE PROGRAM COMMITTEE

I wish to report the completion of the Metals Section Program for the Detroit Congress, and to thank you and the officers of our Section, the National Safety Council Staff, and Metals Section members for their help and cooperation in the preparation of our program.

It has been a pleasure to me to have been associated with the activities of the Metals Section during this year and I wish you to know that I appreciate the guidance and timely advice which helped me so much in carrying out my work.

I trust the program will be received by the membership in the same spirit of service that it has been conceived.

E. G. QUESNEL,

Chairman, Program Committee, Metals Section.

CHAIRMAN GIBSON: I wish to say in regard to the fine program we are having this year, that it is due largely to the good work of our friend, Mr. Quesnel.

We will now have the report of the Poster Committee, of which Mr. John P. Eib is chairman.

REPORT OF JOHN P. EIB, CHAIRMAN, POSTER COMMITTEE

In presenting to the officers and members of this Section the report of the activities of your Poster Committee since the last Congress, I ask the indulgence of those present for a brief period.

To my mind, and I am sure to many others, especially those who have had the honor and privilege of serving on this committee, the issuing of monthly posters represents a number of important functions, chief of which are as follows:

First, a very important part of the services rendered members by the National Safety Council. Second, an excellent and in a large degree the only medium of contact between members from one Congress to another. Third, the best thoughts of the committee members. Fourth, affords an opportunity for not only committee members, but all members of this Section, to assist in and perform a real educational service in the great cause of conserving human resources.

I have often wondered just how many members of this Section realize both the responsibility of preparing such a program and also the golden opportunity for service, provided the attention and cooperation of every member could be obtained.

Having this problem clearly in mind, the selection of members of your committee was made with a view of obtaining a representation of the various industries forming the Metals Section.

We have endeavored to give you timely and appropriate posters and have presented to the Council a large number of suggestions and photographs, enough, in fact, to permit two Metals Section posters each month.

We have tried through individual letters and monthly "News Letters" to obtain suggestions from all members but I regret to state that the response has not been very large and I sincerely wish that some means might be suggested whereby this response could be obtained. We have also introduced "Timely Topic Bulletins," and I am happy to state that this introduction seems to have met with very favorable response. This item will be discussed elsewhere in our program at another meeting.

The personnel of the committee for the past year consisted of the following additional members:

- F. A. Lauerman, Interstate Iron & Steel Co.
- H. D. Herron, International Harvester Co.
- S. D. Jackson, American Bridge Co.
- A. Berquist, Youngstown Sheet & Tube Co.
- W. E. Watters, National Malleable Co.
- D. Medalie, By Products Coke Corp.
- T. J. Cordon, General American Tank Car Corp.

I wish to record and acknowledge at this time my especial thanks and appreciation to Messrs. H. G. Hensel and Arthur Berquist of the

Youngstown Sheet & Tube Company; Mr. F. A. Lauerman, past chairman of this committee; and also Mr. R. T. Solensten, formerly of the National Safety Council and to Mr. Lee H. Gardiner, his successor.

CHAIRMAN GIBSON: Regarding the work of the Poster Committee, I think they have done mighty fine work. This is another real job in the Metals Section. Both the Poster Committee and the Program Committee require a lot of attention by the chaps who are in charge. We have been very fortunate in having Mr. Eib as chairman of this committee on posters during the past year; he is in touch with a vast source of supply in the Chicago district and we are indebted to the company with which he is connected for the fine lot of posters we have had.

The next report is that of the Membership Committee.

REPORT OF H. G. HENSEL, CHAIRMAN OF MEMBERSHIP COMMITTEE

Our committee, which was so widely scattered over the United States, has tried to function as well as possible with the contact we could obtain through correspondence. No doubt many of you will be interested in knowing the personnel of this committee, which is as follows:

- J. W. Dorsey, Safety Engineer, Solvay Process Co., Syracuse, N. Y.
- C. E. Fouhy, Safety Engineer, Willys-Morrow Co., Elmira, N. Y.
- A. C. Germain, Safety Engineer, Minnesota Steel Co., Duluth, Minn.
- A. E. Matlack Manager, Comp. Dept., Wheeling Steel Corp., Wheeling, W. Va.
- J. A. Voss, Safety Director, Central Steel Co., Marion, Ohio.
- N. V. B. Ziegler, Personnel Director, U. S. Aluminum Co., New Kensington, Pa.
- M. H. Stearns, Safety Director, Duquesne Steel Co., Buffalo, N. Y.
- Fred Thomas, Safety Engineer, Keystone Bridge Co., Beaver Falls, N. Y.
- J. M. Hennigan, Safety Director, Pittsburgh Steel Co., Monaca, Pa.
- D. C. Thomas, Manager, Employment and Safety, Lorain Steel Co., Johnstown, Pa.
- D. V. Medalie, Manager, Safety Service and Employment, By-Products Coke Corp., 112th and Torrence, Chicago, Ill.
- T. J. Cordon, Safety Engineer, General American Tank Car Corp., East Chicago, Ind.
- F. T. Pulse, Accident and Safety Inspector, American Steel & Wire Co., 208 S. La Salle Street, Chicago, Ill.
- Wm. P. Biggs, Manager, Industrial Relations, Wolff Manufacturing Corp., 255 N. Hoyne Avenue, Chicago, Ill.
- F. C. Bennett, Safety Director, Buckeye Steel Castings, Columbus, Ohio.
- C. J. Kaufman, Supervisor of Labor, Standard Steel Car Co., Hammond, Ind.

I am told by the National Safety Council that the members of the Metals Section have approximately 722,230 employees, so that as representatives of the various companies who are members of the Council

you may have some idea of the vast army of employees that you are representing.

The record of memberships in the Metals Section briefly is as follows:

Number of Members in Metals Section, September 24, 1925.....	670
New Membership During Year.....	68
Memberships Reinstated During Year.....	9
Memberships Cancelled During Year.....	46
Memberships Transferred From Drop Forge Section.....	39

I wish to take this opportunity to thank all members of the Membership Committee who so generously gave their time and put forth efforts during the past year to secure members for the Council. Many of the members of this committee furnished the National Safety Council headquarters office with some very good lists of prospective members which assisted the Council greatly in their membership drives.

I also wish to say that many individuals who are not members of the committee voluntarily offered their assistance in this work and we, of the committee, wish to thank them for their efforts along that line.

CHAIRMAN GIBSON: I should like to say here that all of the members of the committee have done a very good work. It is a widely scattered field; they have to reach out all over the country, not only for new members but for those who are on the delinquent list.

Mr. Ralston, have you a report as representative of the American Society of Safety Engineers?

C. E. RALSTON (Pittsburgh Plate Glass Co., Pittsburgh, Pa.): No, I have not.

CHAIRMAN GIBSON: Mr. McKenney and Mr. Carter are our special representatives on the Executive Committee of the Metals Section. We will now hear from Mr. McKenney.

Conventions Are Very Much Worth While

T. H. MCKENNEY (Illinois Steel Company, South Chicago, Ill.): Mr. Chairman and Gentlemen, you will note from the program that it is to be "just a word from Tom and John." But that was the program committee put such an allowance as "just a word" I don't know, although it exactly fits in with my limitations. However, I don't think it was fair to John because he will need more than just a word to tell you what it's all about.

When I saw the advance copy of this program it made me think of a story of a Polish vaudeville team appearing in a London theater. They were billed as "The Great Tom and John," which, of course, has nothing to do with us except as to their being manly in size.

It seems that in this act, Tom was the first to appear. When he came out and was doing his stuff, about half the audience started to hiss and they hissed him until he left the stage. Returning to his place back of the wings he said to John, "Say, what is the matter with that audience? They don't seem to appreciate hard."

Then John strutted out to do his stunt and when he got half through, the audience began to hiss him, too. He made a stand but finally got

the hook and had to go back of the wings again. About that time the manager came in and said, "What is the matter, John?" John replied, "Don't you know what is the matter? Tom went out and only got half way through his stunt when the audience started to hiss and they hissed him off the stage; and then, when I went out, I hadn't got over half way through when they started to hiss Tom again!"

What I have just said doesn't count in my work so I should like to say very briefly that we have two questions to consider. Why do we come to conventions, and are they worth while?

To the first question, why we come to conventions, I believe we all know the answer and that we fully appreciate the intents and purposes for which conventions are called. The second question (what do we get out of them?) depends entirely upon how conscientiously we have carried out the real reasons why conventions are called, plus the degree in which we participate in the proceedings and endeavor to put forth efforts to secure that information and general knowledge which will assist us in solving some of the problems confronting us and straightening out some of the little kinks which we have back home. If we have done all of this, then I think the last question can be answered, "yes."

CHAIRMAN GIBSON: I forgot to mention, but I am sure it was not at all necessary, that Tom is our past chairman and has been a great standby in the Metals Section. He has done some very fine work for us. The next speaker is Mr. John Oartel.

Accident Prevention in the Metals Industry

JOHN A. OARTEL (Carnegie Steel Company, Pittsburgh, Pa.): Mr. Chairman and Fellow Members of the Metals Section: I think there was just a little mistake made in getting this program out. I think instead of Tom and John, perhaps it should have been Tom and Jerry. I say that sincerely for I mean our good friend, J. M. Woltz.

This is the third time a National Safety Congress has been held in Detroit; it is just 10 years since the first one was held in 1916; not a long time, 10 years, and yet a lot of things have been accomplished in safety in that time. Let us go back and see what we have done.

I know of a company engaged in the iron and steel business that in July, 1916, sent nearly 1,000 men home from work with accidents. This year they sent less than 100 men home. Ladies and gentlemen, that is what we are doing in the Metals Section in this basic industry of ours.

I was very much interested in the report given to us that we represent a million men in the iron and steel business. It used to be thought dangerous, when we used to drag them out dead and dying; I have done it, myself, and you, too, perhaps, have helped to do it, and yet today we are getting somewhere in safety and I am glad to be identified with the safety work and with this business. I am glad to be associated with this cause; it is a real work.

CHAIRMAN GIBSON: We are ready now for a motion that the reports of the executive officers and committeemen be approved. Do I have such a motion?

(The motion was made, seconded, and properly carried.)

CHAIRMAN GIBSON: Now we will start on the program.

The next is the appointment of the Nominating Committee: Tom McKenney, J. M. Woltz, and Earl Blank.

You will notice our program for the first day has been devoted to inspirational talks. Our first speaker will be Mr. Clarence H. Howard who needs no introduction to the Metals Section because he has been working for us and with us for quite some time. While he has not spoken to us in the Metals Section before, he has spoken to us many times in the General Sessions.

**POSITIVE AND CONSTRUCTIVE THOUGHTS ON SAFETY—
OR THE FUNDAMENTALS UPON WHICH SAFETY
IS BASED AND RESULTS ACCOMPLISHED
BY THEIR APPLICATION**

Clarence H. Howard, President, Commonwealth Steel Company,
Granite City, Illinois.

Well, friends, I am very happy to have my part in so worthy a cause. There is nothing more important than the safety of our people.

Arriving at this meeting put me in mind of a young fellow who asked the old man for a young lady's hand. The old man looked the young fellow all over and said, "You haven't arrived yet." The young fellow became very much concerned and hunted up the young lady and talked it over with her.

"Well," he said, "I am going out west, perhaps to Detroit, I don't know." (He was down in New England.) "I am going to make a record so the old man will have to give you to me."

So the young man went away. He went to the west and he made a wonderful record. You know how a young fellow can work when he has a sweetheart, and especially when he comes from New England.

After a while he wrote to his sweetheart, making such a report as he thought she could read to her daddy, telling her how he had really accomplished such wonderful results. He got a little poetic, too, and after the young lady had read it, she said, "Well, now, father will be delighted," and she hunted him up. While reading the report to him she forgot for a moment that he was hard of hearing and when she got to the final part where the young fellow wrote, "I builded better than I knew," the old man exclaimed: "Just what I thought!. He bit off more than he could chew!"

So I am not so sure that I am not in that class; but the safety first program is my Prince Albert, my long suit, because it is all positive.

We tried to visualize some of the negative things, thinking we could learn the positive from the negative, but we soon found out that it was impossible.

Now, the positive is the constructive, eternal side of life. If I am able to make you see what I see, I will feel that my trip to Detroit has been worth while because the positive side is the only side of safety. Take

mathematics; the only thing you are responsible for in mathematics is the principle. You don't guess numbers, you don't select numbers, you don't grab them from somebody when you are using them, but you supply the principle of mathematics and the principle gets the numbers. How does it get them? In perfect order. The wrong number doesn't come; it doesn't come upside down or wrong side out, but it just fits.

So I like to think of the mathematics of safety. There are only nine numbers but you can use more than one at the same time without their interfering with each other or becoming exhausted. They are boundless, limitless, exhaustless. You can't conceive of a number going wrong.

If you went to the bank tomorrow and asked for your bank balance and were told that Clerk No. 6 was on his vacation and that they couldn't make out your balance, you would laugh and say, "Absurd."

I liken this to mathematics because to deal in numbers is 75 per cent of any one's business. Just think it over. No one can steal a number from you. What would you say or think if a man would say, for instance, "Well, I know Howard has a lot of problems to work out tomorrow; I will lock up No. 9 in my safe so he can't use it." He would have a full man's job.

The Fundamentals of Safety Thinking

We got a big order for some tender frames from South Africa not long ago. Now supposing I had had to send some one to South Africa to calculate the stresses and strains. I wouldn't want the work. But it doesn't cost any more to think to South Africa than it costs to think sitting in my office. I can sit there and work out the stresses and strains because the same principle applies in South Africa that applies all over the world.

Radio gives some idea of this. In Washington, for instance, a message was sent around the world in a fifteenth of a second. That is going some. We don't, however, think much of a message going through the walls; there is no obstruction to principle or thought.

All of you hire a good many men, no doubt, but do you consider what kind of mustaches they have or how heavy they are or what is their general condition? No, you consider his think tank; how well he performs the duties brought upon him; how well he harmonizes and adjusts himself. That is the thing I am interested in; really I am hiring his thought. I am getting the benefit of his thinking, not how much he weighs. The little fellow can think as well as the big one; it doesn't depend upon *avoids* but upon a clean sense of the positive.

Let us go back now to the subject of safety and its fundamentals. You know, I rather like this subject because it is fundamental. I try never to think in details, for primarily that is where all your troubles come from, because any 10 men will think details differently. I bet, though, I can start out with a fundamental and everybody will agree with me.

For instance, you have all been to churches. I knew a church one time where they all agreed that they would have more light in that church and they put windows in it that let in plenty of light; there wasn't any dispute or discussion about putting the windows in, but when they began

to figure on how large and how colored and what kind of curtains they would have, I want to tell you they had some discussion before they could go ahead. But they all agreed upon the fundamental—do we want more light and what does it mean to us?

When I think of the positive, it carries me back to my real job, which is the Boy Scouts. You know the gang spirit is in any town; the leadership may be good, but if the atmosphere is bad it is negative. You take our Juvenile Court. I tried to tell the police of St. Louis once something of the Golden Rule and fellowship and they laughed at me.

"That is all right," they said, "but it won't work here."

Observations in the Juvenile Court

I went into the Juvenile Court and sat on the bench and I saw the little fellows coming up there. Fundamentally, I knew they were not bad boys. You will say, "Oh, I know a bad boy." Yes, you know a boy who does bad things, and so do I, but you don't know any fundamentally bad boys or bad men, and so the difference is in the atmosphere and the environment; whether it is positive or negative. You can have whichever you choose, the positive or the negative and you will get the positive or the negative result.

These young fellows in the Juvenile Court were there because they broke windows and so forth. They said they knew I was from the police department and they looked upon me as one of their enemies. They were a little suspicious until I said: "Boys, the only things I find on record here are the bad things you have done. That is why I am here to investigate. I want to know what are the good things you have done. I should like to have the books kept, showing a debit and a credit side. All that is talked about is the bad things. Maybe if I had the good things you have done and put them on the credit side, perhaps you are more good than bad, and that is what I want to know."

So these little fellows began to cuddle up to me, for everybody likes good things. It is only the negative that repels, the positive attracts, and these little fellows who were all the way from eight to 10 years old, felt it.

"Boys," I said, "tell me the good things you have done."

A little hand went up and a little fellow said:

"I know a woman who called me a liar and I didn't resent it."

I told him that he was kind. (I know lots of men who couldn't stand that temptation.)

Then another little hand went up and a boy said:

"A blind man was trying to find his way through the traffic and I slipped over and put my hand through his and helped him across, and he wanted to pay me something but I said, no."

I could see that that was a Boy Scout stunt, doing a good turn without hope of reward each day. Isn't that a wonderful way to bring out our boys? A wonderful atmosphere. I could tell you of hundreds of things those boys told me that would make your heart glad to help them. Their misfortune is that they are brought up on the negative; they are taught

He was not to be helped, but punished. That boy, to the policeman's way of thinking, was a prisoner.

"I will take care of that boy," my friend said; and he turned to the boy and asked, "Why did you run away? What did you do to make you want to run away?" He was opening up the way for the boy to answer in the positive; he wasn't trying to scare him or trying to punish him. "What did they do when they brought you back?"

"Well, they beat and licked me," the boy replied.

"And are you better for having been punished a little, my boy?"

"No. It stirs something up in me and I want to do something worse." Another negative.

So my friend said, "Well, I am in charge now. What shall I do?"

"Well, I suppose you will have to lick me, beat me up."

"Boy," my friend said, "I'll tell you what we will do. You and I are going to make a close friendship. I am willing to be your friend if you will be mine. I am not here to punish; I am here to help. I can see that you have good qualities on which to build. Now the first thing I want you to do is a personal favor. I want you to take this \$5 over to such and such an address and bring me a receipt."

You know there is a constant conflict going on between the positive and the negative and he got him quieted down with the positive; but when he thought of going on this errand the negative asserted itself.

Building Character in a Boy Once More

"Well, who will go with me? Don't you know that I can't go outside the grounds alone? Aren't you going to send a policeman with me to watch me?"

"No," my friend answered, "we won't watch you; we are going to send you alone and trust you."

Then the lad came back with: "Don't you know that the minute I get out of here with that \$5 I can run away?"

"Yes, I know you can, but no man or boy runs away from anyone who loves him, trusts him, who is his friend. He runs away, perhaps, from the fellows who punish him, who distrust him. They make him think negatively. But that is not true now. You can't run away because you are imbued with the positive thought of doing a duty."

The fellow stood for a moment or two in thought and then suddenly the tears ran down his face and he said, "No man ever talked to me like that before. No one ever said anything like that. The only friend I ever had was my mother and she died when I was a kid; since then I have been kicked and scuffed around and nobody cared. You are the first one who ever cared."

He straightened up and he said:

"Let me understand you. Do you mean to say that you are going to give me \$5 to pay a bill and bring back a receipt?"

"Yes."

"Well, would you mind shaking hands on it and making it a real bargain, man to man?"

He was gone on the errand about three minutes when he came back with the receipt.

Think of the joy that lad had for having done something some one could approve of instead of condemning and ridiculing him! My friend put his arm around that boy and thanked him for the service, and today that very boy is one of his best, most trusted friends; he has accomplished great things.

Don't you see that the positive is the healer, the restorative? The positive is the thing that appeals, not the negative.

When this safety first movement was started, I remember very well the work of Mr. Arthur Morey who is now general manager of our company. You all know him. He was the first man in history to be made a general manager of a steel plant merely on the human side. He is a lawyer. I hoped he would forget all his technicalities because technicalities don't get you anywhere. He saw that in industry we must have the humanics; that is, we needed human beings as well as mechanics. Machines are easy to deal with; they don't talk back; but the human with whom you have to deal has thinking ability and in view of all this we got up a little magazine. We use it with the hope that the employee and the general public will see it and become interested so that we may have unity, for in unity there is strength. I am sure that many of you have had copies of this magazine and that you approve of it.

The Little Boy Who Wanted a Watch

I remember that once Mr. Morey made a picture for one of the issues in which he showed a man falling over a car—a little car that we use for our furnace. He thought that by showing that man falling he could instill a safety thought in the minds of those looking at the picture. But if that were true, we wouldn't have war; we have had wars enough to teach us we don't want any more. It isn't, then, what you teach people in the negative that gives the positive result, but what you teach them in the positive.

The old saying about a man having to sow his wild oats is old-time nonsense; if he's tempted by it, he finds himself soured and disreputable. He may come out of it all right, but everybody has a little doubt about it. So why not start right, keep right, as the Boy Scouts do?

I am reminded right here of a little boy who used to have to give a verse from the Bible every Sunday morning; and one Tuesday, after he had given his verse, he asked his father for a watch; not only then did he ask for it but he asked so persistently that finally his father said, "Now, when you need a watch, I will get it for you, but don't let me hear you say another word about a watch." The boy, in looking up his verse for the following Sunday, found what he thought was a particularly suitable one in Matthew, so when Sunday came around and the father said, "Are you ready with your verse," he said: "Yes, papa. It is 'What I say unto you I say unto all, WATCH!'" The next day he got a watch.

By the way, the watch is a limitator. It limits you in all your thoughts. Just every time you think of it, you try to strain a point, you limit your-

self. And we don't want any limitations. The only limitations you will have in your life are those you consent to put on yourself. God can't limit anybody because He doesn't know anything about limitations. God is a great Principle; there are no limitations in Him. No one else can limit you if you don't consent to it.

I remember when I was a kid, my father was pretty strict with me; I used to be one of those "can't" fellows and I learned from him that there is no such word as can't. One must give service, service that is unselfish; service to one must be service to all.

There is a wonderful sermon in the mechanism of a locomotive. It says, "I represent fellowship, the Golden Rule, team work, cooperation, and without those fundamentals you could never make me."

Memories of a Mother and Her Advice

I had one of the sweetest, dearest mothers a boy ever had. I loved her, and when a boy doesn't love his mother something is wrong with the boy or the mother. A boy never wants to be preached to, but I remember very well the five things my mother asked me to remember when I became a business man: Remember your home. Never drink or go where drinking is done. Never gamble or go where gambling is done. (In those days it took only a six-shooter and a pair of deuces to take four aces.) Smoking is not so bad, she said, but you have to have money to get through school so you find out just how much the other boys you go with spend for cigars and tobacco and you put that much away until you can use it for school. Last, but not least, if you are invited to go anywhere, before you accept be sure that it is where your mother would rejoice to know you were, or where you could take her with you. If you couldn't do that, then don't go.

I had in mind that when I became successful I would have a private car. I don't know why I wanted that, but it listened well and I knew it wouldn't be mine unless I earned it. So I began to work in a machine shop.

During a lunch hour I went in and saw all the engines in various stages of repair and I tried to find out how the steam was generated and found its way through from the boilers and just "what made it turn the wheels around." I couldn't work it out; I didn't have head enough to find out.

So I asked a machinist who was standing there, "Tell me, how does the steam operate the engine?"

He looked me over and said, "You know it costs a lot of money to learn that."

"Yes," I said, "I suppose so."

"What will you pay me to teach you?"

I had only about \$20 then and you know a boy needs something besides eating and sleeping so I said, "I can't pay you at all;" and he said, "Then I won't tell you."

Well, I was disappointed and I might have answered in kind, but I remembered what my dear old mother told me, never to answer in kind, that those who answer in kind are destined to be failures.

You must remember I was only a small boy then and I couldn't understand why a man wouldn't help a boy who was earnest. I figured out that maybe this man was joking; that maybe he didn't know either and he got away with it that way. So I forgave him. I knew I had to be humble and meek and that if I answered in kind I couldn't feel that way. I remembered the things my mother had said and that some day, if I always remembered them, I should have my own plant, lots of friends. It was then I said, "I will do them." In the presence of God I made a real declaration that I would do them and I was in earnest about it.

A great revelation came to me at that time. The question arose in my mind, "Supposing you have your plant, a plant of your own, and some boy is answered as you were, what are you going to do about it?" I said to myself at once: "I will start a school and any boy or any man in my employ will be able to get anything that you can get for him."

Of course, that was a crude idea, but it was a fundamental and it started me so that when I got the plant I started a school. Education is wonderful for the young man; I saved my money and went to school afterward. Education is like a seed; it may grow if it is just thrown upon the ground, but plant it carefully, hoe and harrow the ground about it and it is certain to grow and multiply, but it can't be done haphazard.

Starting a School for the Handicapped Worker

So we started this school. We realized it took the average boy four years to finish high school and then four years to get a trade. "Isn't there some way," we asked school authorities of Illinois, "of helping working boys by combining that? If we give these boys a high school education, a diploma, will you enter them in your colleges?" They said they would. And so, to make a long story short, one of the greatest achievements of the Commonwealth Steel Company is their school.

We will take a boy and in four years graduate him from high school and teach him a trade. The first student we had was a man by the name of Dombrosky; he was a foreigner, of course. He was compelled to stop going to school when he was only a child. He entered into this work and he graduated from the school and on the next day he was on his way to the University of Illinois to complete his education; in the meantime he had earned his living.

I want to touch again upon the positive, the constructive. I don't know anything about time when I get on that subject, for it is one that is nearest my heart. I think how wonderful it would be if all men could work together in safety and could work together harmoniously and not spend a lot of time in strikes, in friction. You know if any of you men had mechanical friction you would immediately remove the cause. You sometimes would call the man responsible for it all kinds of names; you would make him unfit for work. If one of those fellows whom you have bawled out—not a very elegant term—meets another who is laboring under a similar grievance, you have the start of a strike. All negative, all destructive.

Now, if the foreman is a fellowship man, a Golden Rule man, he would

say, "Here is a man who has made a mistake. I will say to him, 'There has been trouble and I am disappointed. I rather looked for a better thing from you because I have intrusted you with the management of this work. You have stopped our shop, spoiled our plans, with friction. If I were to fire you, I should have to find another man who doesn't know all that you know. I shan't say anything more about it, but I want you to get on the positive side and try to do better.'" That man then becomes humble and meek and he starts out to endeavor to do what is right and he therefore is a much better man than any one else you could hire.

A man will get hurt much more quickly if he is mad or disgruntled than when he is happy and contented. The smiling man is safer. A man can't have a burden and have a smile at the same time; he must give up one or the other, for one is positive and the other is negative. So a man with a smile is worth a whole lot more than the man with a frown.

Safety is Positive; Danger is Negative

I never could talk from notes. I expect you wish I did. I very seldom write anything because I can't write very well, but some of these fellows induced me to put some of my talk in writing and I did. I started with fundamentals, tracing back to the beginning of Creation because that, of course, is where all fundamentals started.

In the Bible we find that the first chapter of Genesis gives a complete record of God's creation as perfect. In this first chapter there is no mention of evil, sin, disease, sorrow, death, danger, accident or limitation. On the contrary, we read that "God saw everything He had made, and behold, it was very good." This record of creation may be rightly called the positive for it is constructive and thus it gives one buoyancy, strength, confidence and courage. The negative is the suggestive opposite of these qualities.

In order that we may consider the subject of safety in its proper term, that of the positive, and its opposite, danger, as the negative, let me take as illustration a dark room, for darkness and danger both suggest fear, doubt and confusion, all of which are negative qualities. One enters into this dark room with a light and immediately the darkness is dispelled. Now, where did the darkness go? It did not break through the doors and windows getting out, nor did it offer any resistance whatever. It was merely annihilated for it did not really exist as an entity, but was only the absence of that which is real. Light is a symbol of the positive and the Bible declares that "God is light, and in Him there is no darkness at all." Therefore, as we understand the subject of safety in the terms of the positive, we have the light of intelligent thinking which eliminates fear and danger resulting in accidents.

I have often talked with my engineers about their difficulties, and while I often knew but little of what they tried to tell me, I found that keeping the positive in mind while they talked to me brought improvements. The improvements suggested themselves while we talked.

Another term of the negative is "counterfeit," and as there can not

be a counterfeit without there first being the true bill, we may rightly consider the positive as the true bill. A banker does not necessarily need to know all about the various counterfeit bills in circulation in order that he may be protected from accepting one as genuine. All he needs to do is to acquaint himself thoroughly with the true bill, and that which does not resemble in every respect this true bill, he knows to be a counterfeit and therefore valueless. Thus, it is not necessary for us to visualize hazards and dangers in order to impress upon the thought the idea of safety first, for we are always safe when we are thinking in the terms of the positive.

The other day I read an article that said this, and when I speak of love I speak of it not as maudlin sentiment, but I speak of a Principle. They say that "God is love," that He is a Principle, the same today, yesterday and forever, always present, always effective. Love is especially dear in time of temptation, of negatives, hatred, envy and jealousy; it will render good for evil. Think of what a changed world this would be if everyone would remember that.

Golden Rule the Boss of the Company

I have chosen the Golden Rule as the boss of our company; I am only the president in so far as I deal in the Golden Rule. I look at things in the light of the Golden Rule; if they will render service, I will use them. That is the first step. If I am thinking about some one who has disappointed me, and the temptation is to say something, to get ugly, before I do that I say to myself, "What is it that I am going to say about Bill? Would I be joyous if he said it about me?" You know this method brings up a lot of questions and you begin to think how wrong you are, and you begin to deny those negatives until you reach a point where you say the things you would be glad to have said about you. Then a sense of calm, a relaxed, peaceful sense comes over you, the consciousness of God's approval. You have thought that out successfully, and being approved by the great Principle is wonderful, isn't it? It makes you feel like you do when you see a great game, as I did recently when I saw the Cardinals play—and by the way we have a real team in St. Louis.

There isn't any joy like it. When that game was played, I listened over the radio. When, in the seventh inning of the last game, they put Alexander in, I was awfully excited, and when at last the final score was given and they gave St. Louis the championship I was like a dish-rag—no doubt I describe your condition at that time, too.

We are proud of our baseball team in St. Louis. That reminds me of what a man told me the other day of an incident that occurred when the Eucharistic Congress was held in Chicago. A fellow standing by him looked the cardinals over and said to him, "What are they?"

"Why," he said, "those are the cardinals."

"Oh," the fellow said, "which is Rogers Hornsby?"

I am sure I should rather tell stories than be serious, but really when you think of this safety movement you are thinking of a tremendous fundamental.

Now I will have to refer again to a little more of what I have written, to put on the appearance of having presented a paper. If you asked me what "safety" is, I would say, "positive thinking." You can't get hurt when you are thinking positively, intelligently.

It is not necessary for us to visualize hazards and dangers in order to impress upon the thought the idea of safety first, for we are always safe when we are thinking in the terms of the positive.

You won't learn the positive by thinking of the negative, and you won't prevent accidents by impressing them on your mind by trying to show how they happen. When the first Safety First Calendar came out, the illustrations and the warnings would have made any fellow chase his grandfather up a tree with a shotgun; it was all negative. I kept hammering at it and harping about it and now if you will look at the last one you will see it is all positive.

Positive thinking is the utilization of man's greatest gift from God—the ability to think, and he who does this in an intelligent manner is bringing himself into harmony with the law of God, the law of universal good.

The desire to safeguard pedestrians has become so general that in all cities and many towns "Safety Zones" and "Safety Platforms" are provided in the middle of streets where one may stand secure from the swiftly moving automobiles and street cars. As it is against the law for any vehicle to come within these safety zones, so it is against the law of the positive for the negative qualities of confusion, doubt, and fear to enter the thoughts of one who thinks only in the terms of the positive. In this haven of positive thinking no accidents can occur for we have the divine promise that nothing can enter that "defileth, or maketh a lie." (That's pretty good authority and I think He knows pretty well what He is saying.)

Cooperation Will Help to Perfect Anything

Only a small percentage of accidents can be prevented by mechanical safeguards; the balance must come through the practical application of the Golden Rule, which is constructive, positive safety. Safety first, when properly analyzed is the expression of fellowship.

I think we all agree there isn't anything on which we can not benefit by cooperation. Safety first, from the standpoint of the positive, results in the scientific study of the right and orderly way of doing things, and the safety first movement has proven to be one of the greatest agencies toward the realization of the brotherhood of man. It develops high individual efficiency which results in greatest service, and when service is rendered, confidence is gained and success is assured. Service must be expressed in safety, efficiency and economy, with character building as its goal, which enables one to profit with his fellow man and community, but never at their expense—to live in a city but not on it.

Do you know that service and competition have entirely different fundamentals? The fundamentals of competition are expressed in the question, who shall be the greatest? The greatest sin in the world is competition; if it goes far enough it ends in war. It is negative. Service,

however, is positive and its fundamental is, who shall be most perfect? Who shall resemble the teachings of Christ Jesus most perfectly? That is service, and it must not have one pin point of selfishness in it because when you get any selfishness in service it ceases to be service. People will find out and will be willing to pay and compensate you for the service when it is unselfish. "The hole you make in giving is the hole you have to receive through."

If you go to some man and command something of him, without offering anything in return, you are likely to get a fight out of it.

I went to see President Harding the first day after he was elected and he said to me, "Well, what can I do for you?" I said, "You can't do anything for me. I only want to fit into your program and try to render you service; I want to serve my country and I want to do the thing that will bring the greatest happiness to the greatest number of people." President Harding said, "Shake. You are the first man who has been in this room today who didn't want something."

Poise is an Important Factor in Safety Work

Another important factor in positive safety is that of poise, which has been splendidly defined as follows:

"Poise is that state of consciousness which is at rest and peaceful when no one praises, and undisturbed when opposed, censured, or misunderstood."

"Opposed or misunderstood." Anyone who can take hold of the two horns of that dilemma and still maintain his equilibrium is safe. Judge Gary was perhaps one of the greatest men in the safety movement. You know Bob Campbell; his son-in-law was your first National Safety Council president. The Judge said to me one day, "Howard, you have got to have things balanced. You can't get the best of a bargain if you don't. Just keep in mind that in a controversy, or in anything, keep your balance, your equilibrium, and you will be able to render good for evil."

A man who does something wrong is like a man with a lion attached to him; he needs your friendship and it will not help him more to put another lion there, but you want to take away the one he has. That is the brotherhood of man; that is true brotherhood. You can't get safety unless you are well balanced.

To lose one's poise because of any disturbed condition is not safe, and only makes a bad thing worse. A broad-gauged, public-spirited citizen must be consistent and compassionate. When difficulties and misunderstandings arise, he must be wise, brave and unselfish, which will awaken a spirit of fellowship and thus maintain for himself and his fellow man an atmosphere of safety.

The only problem any of you have is that of your own self. Howard makes me my only trouble; when I can take care of Howard, I am safe. If I go to you and give you a dollar and then you give me a dollar, we each have one, but when I go to you and give you an idea I enriched myself in trying to formulate that idea to give to you and so I haven't given it away. I still have it, and it is better because I tried to give it

away. Giving enriches while withholding often makes us poorer. When you give, give open-heartedly, in a spirit of "I want to render you a service; I want to help you." I learned these things through hard knocks. One of the definitions of safety is "freedom from danger."

You know, I haven't a danger signal in my plant. It is a hazard, a real hazard to call attention to the negative. I turned it upside down and made it safety. Doesn't safety mean more? I find it works much better since I substituted the safety signal for the danger signal in my plant.

The Constitution of the United States does not imply that arbitrary human force resulting in fear shall regulate man; rather does it imply that righteousness shall permeate our laws and our relations. Mankind will be rightly and safely governed in proportion to the utilization of the Golden Rule in law and its practice, in industry and in commerce, which will insure the rights of man and hold sacred the liberty of conscience, thus expressing the positive (safety first).

There is just one little thing more I should like to say: One time a man said to me, "Howard, I think you are the most sacrilegious man I know." I was surprised and said, "Why?"

"Well, you talk about God as though He were your business partner."

"So He is," I said, "and the best I have been able to choose. He keeps me always in the positive and He keeps me right."

I have thought of this safety movement a great deal, ever since I was a boy, and I have had it instilled in me. After the Armistice, I took the first boat to Europe and talked with the boys there. I knew President Wilson and Colonel House. (I used to be a partner of Colonel House in Texas where we had a gas plant.) I was a member of a committee on peace arrangements at that time and, as I said, I went to those boys and talked to them. I said, "This isn't the positive; there is some way in which we can have all our men working together in a fine, big family." I thought this over coming back on the boat and I formulated a plan.

My idea was to turn our shop into 14 counties, each county to have representatives, three from each county to represent their particular division, each group headed by a chairman. That gave me 14 chairmen and 28 committeemen. We had to have a platform, principles on which we could cooperate, and I wrote one of three or four pages; but when I had it finished, I said, "That won't do; the men won't read it." I thought of a young fellow, a smart little fellow, and I went to him with this platform I had written and told him that I thought it was too long.

He said, "Let me have it. I will fix it. I was raised on condensed milk." I am going to read the fundamentals of our business platform as they were finally gotten up:

COMMONWEALTH PLAN
(Equal Opportunity for All)

Of, By and For the Commonwealth Family.

FOUNDATION: FELLOWSHIP

Fellowship is a comprehensive, vital power. It broadens our views, increases our abilities, enriches and purifies character. Its chief foundation-

stone is cooperation, which brings the Golden Rule in practical application to all human relations and needs.

Fellowship is the Golden Rule in action, the motive power of Human Engineering, the life-blood of service, insuring equal opportunity for all.

The Commonwealth Plan recognizes all problems as mutual, wherein and whereby absolute confidence exists in the honesty of purpose and truth of character of each other, thus blending brotherly love in all activities and enabling each to develop his several talents.

Human engineering governs this Plan, and demands our being willing and able to treat men as men—not as machines. The welfare of the man is more important than tools and machinery, for man thinks, and acts as he thinks. Therefore, we must practice Humanics as well as Mechanics.

The Commonwealth Plan provides an excellent and practical basis for putting all (from the Office Boy to the President) upon the same Plane. Then as a unit we can work out the problems of the day in such a way that each one feels he or she is a co-worker in the great purpose of the Commonwealth Steel Company, which is to express Safety, Efficiency and Economy through its cast steel devices—in other words, rendering SERVICE and building character.

Giving Each Man a Chance to Increase His Abilities

We don't mean you can make all men equal, but we believe in giving each fellow a chance to increase his abilities in accordance with the abilities he already has. Our business is to make castings, but we also want to build homes, atmosphere, character. My one ambition in life is to establish a practical industrial relationship, not for my plant alone, nor for Illinois or Missouri or the United States, but for the world. So much happiness is sacrificed through the negative. The shop ought to be the most pleasant place outside of home; you are there more hours than anywhere else, and we should have a joy in doing for others. As Secretary of Labor James J. Davis has said: "You can't buy happiness for yourself without buying it for your fellow men." The important part is unselfishness.

I want to thank you very much for this opportunity to speak to you. It is a great pleasure. I was in New York less than a week ago, then I had to go to St. Louis, and I have to go back tonight. It would be a great joy for me to remain here. If I have said anything to help you, I am pleased.

Remember this: the positive is safety and the negative unsafety.

CHAIRMAN GIBSON: That was wonderful. It was inspirational as sure as white is white. Do we have any remarks? Any questions?

I am afraid I can't add anything to what Mr. Howard has said.

Our next speaker is Mr. Harry A. Schultz, Assistant Manager, Bureau of Safety, Sanitation and Welfare, United States Steel Corporation, New York City.

EVERY DEPARTMENT HEAD A SAFETY DIRECTOR

Harry A. Schultz, Assistant Manager, Bureau of Safety, Sanitation, and Welfare, U. S. Steel Corporation, New York City

Twenty years ago, when intensive safety activities were inaugurated, the belief prevailed that to prevent accidents in industrial plants it was necessary only to make certain engineering revisions in equipment design and to guard dangerous parts of machinery which had in the past been responsible for many serious and fatal injuries. Employers, working on this theory, appropriated and spent large sums of money to make necessary physical corrections.

Accidents were reduced, but not to the extent anticipated, and it was realized by those who were closely associated with the work that a more careful study of accident-causes would have to be instituted. An exhaustive investigation evinced that the human factor entered intimately into the situation and that if further progress was to be made, organized activities must be established, not only to correct physical conditions, but to secure and maintain the interest and the hearty cooperation of the workmen.

With the inception of better organization the results obtained have been very gratifying and they are growing consistently better. We could hardly have dreamed a few years ago that large industrial plants, such as steel mills with all of their involved risks and employing many thousands of men, could go a week, much less a month, without a disabling accident; yet this is today a very common occurrence, and records have been made in some of the largest operations not only of one month, but three and four successive months in which no accident occurred. To all of us in the metal industry, this is indeed encouraging. It has proven beyond doubt that accidents can be prevented, and I believe we are justified in anticipating the day when accidents will have no place in our industrial establishments.

But much is to be done before this goal we are ultimately striving for may be reached. We must not only hold the ground and maintain the reduction in accidents which thus far has been gained, but we must carry on with renewed vigor. We have ground and buffed away the rough edges, so to speak, and are ready for the polishing and the finishing touches—the refinements.

This means perfection of organized endeavor, the development and establishment of perfect cooperative interest and effort of all concerned, from the highest plant official down to the rank and file of the workers. The entire accident prevention machine, in other words, must be organized and maintained so as to function in all its parts without fail. Each and everyone must play his important part daily, and in every hour and every minute of the day. It is only through such refined organized effort, with everyone working harmoniously and cooperatively, that results commensurate with the fondest hopes may be obtained.

Those identified for many years with the accident prevention movement

are cognizant of the important position which the department head occupies in a safety organization. He has been characterized as the key-man in such an organization and beyond question is a dominant factor in its success. The department head responsible for operations and production in his department naturally is the one morally responsible for operating conditions and for the safety of the men under his jurisdiction.

Much is to be expected from him in establishing and directing the character of activities which will prevent accidents. If he is in sympathy with the movement and signifies his desire to leave nothing undone to educate and protect his men, an important advantage in the elimination of accidents is gained. If, on the other hand, the department head is not in sympathy with the movement and is a member of the old school who believes that production is the main and ruling factor in his department, regardless of the sacrifice of human life, a stumbling block is immediately encountered; and until it is removed, all efforts in the elimination of accidents, in so far as his department is concerned, will be unavailing.

Much Depends Upon this Operating Official

Any department head whose unsympathetic feeling toward his fellow men allows him to harbor such a viewpoint may be classed as a liability and not an asset to his company. He has failed to realize that, while primarily the safeguarding of employees against bodily injury is a humanitarian movement, founded upon high principles, it has also an immense economic value directly in his favor.

Now, why does so much depend upon this operating official? The department head occupies a unique position in an industrial organization; he is what may be termed the middle man in industry, the medium and point of contact between the management and the workers. He is the one particular agent who is daily in constant touch with the department and the men. He knows the practices of the department and every phase of the work. He is acquainted with the hazards and knows better than any other individual how they may be overcome.

If he gives the proper thought and study to the problem, he can do more than anyone else to educate and to influence the men to overcome careless and thoughtless habits, responsible for many injuries, and to instill that degree of caution into their movements which will go a long way towards preventing accidents. Men are naturally influenced by their leader, and the department head, by showing the proper interest, will soon gain the interest of every man which, accompanied by the necessary disciplinary measures, is bound to produce good results.

Our past experience indicates that accident prevention work is governed by two important factors: engineering, relating to the physical side, and education, pertaining to the enlightenment and instruction of employees in safe working methods. Both of these activities, we have learned, are of the utmost importance and are interdependent. Time will not permit a discussion of these subjects in all of their ramifications, but let us consider briefly some of the more important things that may be

expected of the department head in both of these branches of endeavor.

It must ever be borne in mind that the interest and hearty cooperation of all employees are of paramount importance in a successful campaign against accidents. This is a phase of organized safety work which must be highly developed, and nothing should be left undone which will bring about such a happy condition. One of the first things conducive to this cooperative interest is the development and maintenance of a high physical standard. The house must be set in order, so to speak, if the good will of the men is to be gained. This means that new construction and new equipment should embody every practical feature incident to safety; existing machinery hazards and other physical hazards should be corrected; and good housekeeping, ever a dominant factor in the prevention of accidents, should receive the utmost attention. To the management, engineering staff and department heads we must look for the solution of this problem.

The management, engineering staff and department heads all, naturally and rightfully, seek the most desirable arrangement to accommodate the manufacturing processes and to facilitate the handling of material and product in the most commodious and efficient manner. However, in the construction of a new department or shop or in the installation of machinery or equipment, it stands to reason that in this day and age safety should take equal rank with construction features, and that after the initial design of the department to suit operating conditions has been completed, a careful study should be made to ascertain whether the necessary provisions for safety have been fully taken care of.

Department Head Should Take Nothing for Granted

To this end the department head can and should play a very important part. He should always have at heart the safety of the men who must carry on their daily duties and operate the machinery in his department. Being familiar with the operations and with the machinery involved, he should never lose sight of the man at his work or of the opportunity placed in his hands to effect revisions which will relieve the possibility of an accident. By establishing close relationship with the engineering and safety departments, at the time new construction work is planned the department head will be able not only to see that necessary safety features are properly considered and included, but to secure the best of operating conditions from both a safety and a production standpoint. The department head who appreciates his responsibility will take nothing for granted, but will look after such important details himself and will make it obligatory on his part to see that any new machinery or equipment installed in his department fully provides for the safety of his men.

In the foregoing, brief consideration has been given to measures incident to new construction; but the department head must also take cognizance of the correction of physical hazards in connection with present installations. It is essential that careful study be given to machine guarding and to all features associated with the operating

processes which will permit work to be done safely. Safety engineers and committee men have been repeatedly cautioned that when making a safety survey they should study each situation carefully, taking into consideration the position of the operating man responsible for the production of a department or for a machine. This is only right, for safety as it may be construed today stands for efficiency.

But should not the department head be fully conversant with the fundamental principles of safeguarding as well as with all other remedial measures which will insure the preclusion of accidents? If he is, he will see that all guards installed in his department are equally satisfactory from an operating as well as from a safety standpoint.

There are a number of things which should be carefully considered in the design of safeguards. Primarily, they should comply with the laws of the state or community and should embody the necessary features for adequate protection against all existing hazards; but it is important that an endeavor be made to design guards which will in no way interfere with or impede operation, but which will rather increase the efficiency and production of the machine through freer and more skillful operation. Neatness is a dominating factor, and the proper weight of material and substantial construction are most important from a maintenance standpoint. A guard not properly designed is an added expense, from the standpoint of both production and maintenance. Sooner or later such guards will cause dissatisfaction and will be subjected to abuse, with the result that, after a short period, they will have served their usefulness and be relegated to the scrap heap.

Housekeeping Necessary in Maintaining a High Standard

The department head who is on the job as he should be will not wait for others to point out defects in his department or to pile up a mass of recommendations indicating a laxity in one of his most important responsibilities; but rather he will study these things out for himself painstakingly and methodically, day by day, and create a physical status in his department which not only will be beyond criticism but will harbor an atmosphere of real safety and efficiency.

Of ultra importance in line with creating and maintaining a high physical standard is good housekeeping. In no place does the old and familiar axiom, 'A place for everything and everything in its place,' apply more definitely than in the industrial plant. The degree of safety and efficiency which prevails in a plant, or shop, can usually be judged at a glance by the house that is kept.

Let us picture in our minds a plant, or department, in which tidiness and cleanliness are sadly neglected—an unsightly shop with machinery unkempt and poorly guarded, and tools and material strewn about in disorderly fashion. Let us reflect, for an instant, just what effect such discouraging environment will have upon the make-up, energy, and efficiency of the individual if he must live and work under such conditions day by day. Good housekeeping is a basic and most important factor in the prevention of industrial accidents and is a phase of the

work which should receive the special attention of department heads.

Now let us consider the other side—the human equation. Experience in the prevention of accidents indicates that, while some of the most serious injuries are due to machinery and other physical causes and that the plant must be physically fit, from 70 to 80 per cent of all accidents which occur are directly attributable to carelessness or thoughtlessness on the part of either the workman himself or his fellow workmen. It is evident, therefore, that every attention must be given to educational measures in which the workman is taught the fundamental principles upon which successful accident prevention is based, and to the inculcation of care and forethought which will overcome careless habits.

It is a matter of record that the new and inexperienced man is particularly susceptible to injury, owing to his unfamiliarity with the hazards of his new occupation. At the time of his employment, the department head under whom he is placed should take personal interest in seeing that he is carefully instructed relative to his new duties and all the hazards involved. He should be fully acquainted with the safety organization, what it is trying to accomplish, where the dangers lie in his occupation, and, above all, how to perform his work safely.

The Real Work of Education With the Department Heads

While considerable can be done generally in the way of educational activity by large safety meetings and rallies, safety bulletins and literature, motion pictures, etc., the real work of educating the man on the job must be vested with the department heads. It is the close personal contact of department heads with their men that is the most direct means of reaching and educating them and appealing to them for their interest and support in the safety work. They must be continually on the job, constantly active day by day. They must have the safety of their men uppermost in their minds and must guide and direct them in the employment of safe methods at all times. A keen eye, with a word of encouragement here and a word of caution there, as they move daily among their men, will bring the importance of the safety movement home to the men and bind them into an organization which will prevent many an accident.

The department safety meeting, at which the department head brings all of his men together periodically for the purpose of discussing accident prevention measures, offers an excellent opportunity to fix firmly in the minds of the men the position and attitude of the company and of their superiors with reference to the prevention of accidents, and to secure their cooperative interest. I believe that a great deal of the success of some of our largest companies in the prevention of accidents may be attributed to these departmental safety meetings, as they serve as a medium for the men to set forth their thoughts and ideas; and once the men are impressed with the importance of accident prevention and are impregnated with the safety spirit, many excellent and valuable suggestions are brought out for the correction of bad practices

and accident hazards which might otherwise go unnoticed for a long period, or until an accident occurs.

It is a common expression that the head of a department who has the safety of his men at heart and who does everything in his power to protect them is usually a progressive and efficient operating head. That this is the rule rather than the exception, I believe has been demonstrated time and again. Such a department head besides being a humanitarian and entertaining a wholesome respect for his fellow-men has appreciated the importance of safety. He has recognized that the prevention of accidents is not a hobby or an idle conjecture, but a proven, practical business proposition, based on business principles; that the conservation of the worker is simply another responsibility in modern industrial activity which must be faced fairly and squarely by operating officials and organized on the same plane with other production factors.

He has learned that stability, contentment and efficiency of the working force are vital factors of efficient management, that upon such a happy condition depends not only economic production, but his success and ultimate advancement. He has been shrewd enough to realize that the attitude of the worker at his daily task is as much a psychological condition as it is a matter of physical strength and skill, and will be determined to a large degree by the influences and conditions by which he is surrounded. He appreciates that his plant environment should be of a character which will contribute to his happiness, health and comfort, foster within him a spirit of contentment and cooperative interest in his work, and insure him against serious injury or physical disability which may in any way affect his earning power or standing as an efficient producer.

The Safety of His Men is a Serious Matter

The safety of his men is really a serious matter with this department head. His reasons may be analyzed as two-fold. In the first place, he is human. He has recognized that any movement which primarily has for its object the conservation of life and limb is entitled to and should receive the sincere and unqualified support of everyone who can, in any way, contribute to its success. Secondly, he has learned by bitter experience that accidents are deplorable; that they are productive only of suffering, waste and inefficiency. They wreak havoc and help to undermine the very principles upon which an efficient operating organization is constructed. To him as an operating man they are a source of irritation and a constant menace. They corrupt the morale of his men, breed discontent, and curb production. Literally to him they are bad business, morally and economically.

What is the antidote? There is only one remedy—organization. This we can safely leave to him; accidents will have no place in the domain over which he rules. Industry needs and is looking for such men, who can shoulder and measure up to all of their responsibilities; men who

can manage without accidents. And when the time comes for advancement industry will choose such men to conduct its affairs.

CHAIRMAN GIBSON: Are there any questions? The subject seems to have been very well covered.

CLINTON E. SANKEY (National Tube Company, Ellwood City, Pa.): I should like to ask Mr. Howard about the safety signs. It seems to me that in connection with the high tension lines such as we have in our plant it would be very dangerous to eliminate the danger signals.

MR. HOWARD: We do not eliminate the signals but we substitute the word "safety" and "danger," because we want to give the employee the idea that he can protect himself with the positive.

CHAIRMAN GIBSON: A question has been passed to me which reads: "To what extent are accident statistics being used by executives and what are the benefits?" Mr. Frank L. Wanzer, of The Steel Company of Canada, is asking this question of Mr. Schultz.

Post Accident Statistics on the Bulletin Board

MR. SCHULTZ: Very careful statistics are of course prepared on all accidents in all companies and this is sent out to the companies so that a general comparison can be made. The various plants are compared as to their accident record so that a sort of competition is started among the various units to reduce their records to a minimum. Does that answer your question?

MR. WANZER: It is fairly well answered. I know it is a hard question and that is the reason I took the liberty of asking the chairman to read it. The thing is to get these statistics correct beyond dispute and get them operative among our workmen.

MR. SCHULTZ: They are posted right on the bulletin board, the number of accidents in each department.

H. R. WHITNEY (General Industries Company, Elyria, Ohio): Mr. Schultz made reference to the new help and the old help in the industries. Where do you draw the line between the new help and the old? In making out statistics, what do you consider a young man and an old man? How much time do you give them to become old men?

MR. SCHULTZ: That is pretty hard to say. What I meant in my remarks is that the new man who is newly employed should be properly instructed as to his duties under an experienced man until he is fully acquainted with his work.

MR. WHITNEY: If you are drawing a line on the percentage of accidents where are you going to draw the line as to age?

MR. SCHULTZ: I think the only way you can make up statistics in that light is to take the man who is employed from one to six months and from six months to a year and from groups in such a manner as that.

DR. ETHELBERT STEWART (Commissioner of Labor Statistics, Washington-D. C.): You mentioned that 75 or 80 per cent of the accidents were chargeable to conditions other than machinery and I think later on you said something about the larger part of these accidents being due to

carelessness and thoughtlessness. I wonder whether that carelessness and thoughtlessness can be attributed to the individual who is hurt?

It has been my experience in accident work, and I have been in it for quite a while, that you hit the keynote of the accident problem when you talk of the man who is in personal control of the one who suffers the injury. I have found that the man who is foreman, or, as you call him, the director of the department, must be selected on the basis of his worth in this respect and he must be provided with the proper facilities and have the courage to use them. He must have the courage to select men who can do just the kind of work he needs done, and when he sees a man go after a job in a way that isn't safe, he must have nerve enough, rather courage enough, to show that man where to do it, how to do it, when to do it.

MR. QUESNEL: In regard to the department heads being responsible for the prevention of accidents, we have found by past experience that there is a certain amount of responsibility on the shoulders of the foreman and superintendent in the majority of cases where an accident occurs, from the fact that the greater number of accidents are the result of unsafe practices repeated. In other words, a man usually is not hurt in our plant or in any other plant the first time he does something wrong but it is the continued repetition of this wrong practice that gets him into trouble, and that is where the foreman and superintendent enter into it.

It should be their job as overseers and supervisors to see that unsafe practices are discontinued in their departments. They may not be able to prevent them from the start, but they most assuredly can prevent them from continuing; their becoming too busy, too absorbed in their own work to prevent their keeping wide awake to the activities of the men who are not so efficient allows the law of accidents to work. A careful person, working right, is immune, while those who take chances, who do things in an indifferent way and sometimes get by with it should be watched.

One of the big duties of the superintendent and foreman is to be absolutely sure that they know, themselves, the safe way the work should be done in their department and then check up to see that their men are doing their work in the right way, establish confidence, security in their department so that their men can rely upon their judgment, so they may feel sure they are doing things in the right way.

If everything that is done has the approval of the department head, the majority of accidents will drop automatically. It has been proven without question that accidents are caused by repetition of wrongdoings or unsafe practices. It seems to me that the foreman and superintendent have a wonderful opportunity to catch these unsafe practices long before the accidents occur if they will instruct their men as to the safest way in which to perform their jobs.

In our own plant this education of the men has made them better and more efficient men, and every foreman realizes that the responsibility rests strongly upon his shoulders.

ADJOURNMENT

WEDNESDAY MORNING SESSION,

October 27, 1926

The second session of the Metals Section was called to order at 9:15 o'clock, Chairman Gibson presiding.

CHAIRMAN GIBSON: We have a very good program this morning so let's not waste any time in getting started.

I want to bring out the suggestion that we are always glad to hear of any ideas you may have about improving our next year's program, or anything that will pertain in any way to the betterment of our Sectional activities. I hope you won't be a bit backward about your suggestions, either in presenting them from the floor or by writing to the secretary of the Section. It is a real job to think of all the things to be done for the next Congress in order best to benefit everybody. Of course, you know we can't prepare enough papers to cover every individual question but we are glad to have suggestions and we will try our best to arrange a program that will be suitable to the majority of our members.

The first thing this morning is the report of the Nominating Committee by Mr. T. H. McKenney.

REPORT OF THE NOMINATING COMMITTEE

GENTLEMEN: Your Nominating Committee after due consideration begs leave to submit the following candidates for your consideration to fill the respective offices for the incoming year:

Chairman, F. G. Bennett, The Buckeye Steel Castings Co., Columbus, Ohio.

Vice-Chairman, J. A. Northwood, Bethlehem Steel Co., Johnstown, Pa.

Secretary, E. G. Quesnel, Commonwealth Steel Co., Granite City, Ill.

In accordance with a resolution passed by the Metals Section at the last Congress, the retiring chairman automatically becomes a member of the Executive Committee, together with the officers and other chairmen of such standing committees and such members at large as the chairman may see fit to appoint.

We believe that the incoming chairman should have the privilege of selecting such members as he may care to appoint on the various standing committees and to name the chairmen thereof.

Respectfully submitted,

J. M. WOLTZ,

E. F. BLANK,

T. H. MCKENNEY,

Committee.

CHAIRMAN GIBSON: Now you have heard the nominations for the coming year. Do we have any further nominations? If not, I will entertain a motion that the nominations be closed.

(The motion was made by Mr. McKinley, seconded and carried.)

CHAIRMAN GIBSON: I am ready now for a motion that the secretary be instructed to cast a unanimous vote electing the officers named.

(The motion was made, seconded and properly carried.)

SECRETARY NORTHWOOD: As instructed, I have so cast the unanimous ballot.

CHAIRMAN GIBSON: We are ready now to go ahead with the first paper of the morning program, which will be presented by Mr. W. C. Wright, National Founders' Association, of Chicago.

SAFEGUARDING FOUNDRY HAZARDS

W. C. Wright, National Founders' Association, Chicago, Ill.

This problem differs from that presented by the shops usually connected with it, such as machine shop, pattern shop, etc., due to several conditions. There is much less machinery in most foundries than in the other shops, so that after all machinery in the foundry has been mechanically safeguarded, only a beginning has been made in foundry safety work. Molten iron, being rapidly handled in all directions, presents a new problem. The personal equation in the foundries should be carefully considered.

Another fact that must be kept in mind is that the time of greatest hazard comes at the latter part of the day, when the men are physically tired, for foundry operations require greater physical exertion than in most other shops. Then, too, "pouring off" causes a tense nervous strain on all those directly connected with handling the molten iron.

According to an analysis made by the American Mutual Liability Insurance Company, out of 1,176 lost time accidents, 87 per cent were classed as non-mechanical, and about 13 per cent mechanical. Of the predominant non-mechanical causes, "burns" accounted for practically 29 per cent, and "handling material" just a little less.

Can we not learn something from the foregoing facts and conditions that will help us in making the foundry safe? It appears from these figures that after all machinery has been well safeguarded, 87 per cent of hazards are still unprotected. How can we best reach this large proportion of accidents? I believe the best way is through a constant, persistent, campaign of education; from the superintendent through the foremen, "straw bosses," down to the laboring men, this campaign must be constantly carried on.

To organize for such a campaign requires that a man well up in the management must have personal connection with the effort and he must be one who thinks, talks—yes, even dreams of safety. Unless the management demonstrates that safety in the foundry is more than just a part of the day's work, it will soon amount to a few bulletin boards and will not impress the common man sufficiently to be of any material value. If the foundry is of sufficient size, there should be a safety engineer to plan and follow the campaign.

If the foundry can not have such a man, the foundry superintendent should head the campaign, and before it starts he should be carefully "sold" on safety, and brought to realize that he is the one who is mainly responsible for the health and happiness of his men. It will pay to spend

considerable time to get this man in proper condition to make this work effective, or the campaign will simply prove another "spasmodic effort" instead of establishing an entirely new condition of things.

It has been well said that the foreman is the key man in industry. He, too, is the key man in this instance. He is the man who interprets management to the men, and he is closest to the men and directly in charge of the work in hand. Unless he thinks safety, talks safety, preaches safety, and lives safety—in fact, *compels* safety, he will hardly get his men sufficiently impressed with the spirit.

The task of putting the superintendent and foremen in proper frame of mind is the work of whoever heads the campaign, be he the owner, manager, general superintendent, or "what you will"; he must keep working at it every second of the day, and working best when all is hurry and his men are physically tired, with nerves almost ready to snap.

Well blessed is the foundry whose superintendent and foremen are real leaders of men, and not simply production getters. If you have such a superintendent and foreman, your task is an easy one, and will "go over" with little effort.

Safety Committees Appointed from Among Workmen

The appointment of safety committees from among the workmen themselves, having the foreman as chairman, helps to bring the cause of safety directly to the workmen. In a case of carelessness a rebuke or talk from a fellow workman, if given in the right spirit, goes home better when coming from the foreman. Five or six watching for cases of carelessness are sure to be more effective than where the foreman only is on the lookout.

When the campaign is launched, the company must at once safeguard every piece of machinery in the most effective way possible, to demonstrate to the men that the campaign means something, and that the company is determined to do its part fully.

Most workingmen do not realize that it is the little careless acts that produce most accidents, for they see these things being done daily without accident, and do not sense that the careless act can occur 99 times without trouble, and on the hundredth time someone be seriously injured. For this reason, the committee will at first suggest safeguarding stairways, machinery, and points that they believe should be safeguarded, and the company must at once act on their suggestions or the real good of the movement will be lost.

Little by little, as this safety committee meets to talk over its work, the safety engineer or superintendent can bring to their minds the point of personal carelessness and urge the committee to watch for and correct all such acts as fast as they see them.

To show you just what I mean, a short time ago I was in a foundry watching the pouring off. A workman just in front of me was nearing the end of his floor. It was a hot day and he was getting tired. He was also getting careless in handling his ladle and was slopping considerable iron on the cement floor, which was then thrown in all direc-

tions. His foreman saw it from a distance and came up at once, saying: "Jack, be more careful with your ladle, or you will surely burn yourself or someone else."

After "Jack" had emptied his ladle the foreman showed him how he was carrying it wrong, how he should carry it, and then said: "You know, Jack, we are all trying to do all we can here to keep from hurting ourselves or each other. You know you might spill iron 99 times and do no harm, and the next time you might put some fellow's eyes out, and then how would you feel?" The rebuke was so well timed, the remedy so carefully demonstrated, and in such a fine spirit, that it greatly impressed me. I watched the man finish his floor and he did not spill one single drop of iron.

This preaching safety and demonstrating safety must go on all the time, for new men are hired frequently, new situations in handling materials are constantly occurring, so that the safety point of view is lost sight of unless someone constantly pushes it to the front and insists upon it.

But if the foreman and safety committee are constantly on the lookout for cases of personal carelessness, and then quietly, but firmly, talk to the man or men involved, insisting that safety to all must come first, there will be developed a mental safeguard among the men that will prevent more accidents than all mechanical safeguards together. Mechanical safeguards are important and must not be neglected, but getting men to think correctly with full attention as to what they are doing, is a real big job, and very important from a safety viewpoint.

Along with this should go a move for "good housekeeping." An orderly foundry is the exception, and not the rule. Still, unless good housekeeping prevails, many accidents will occur. Good housekeeping in a foundry is hard to maintain, but it can be done and should be insisted upon.

Discussion Following Mr. Wright's Paper

CHAIRMAN GIBSON: Now Mr. Fred Bennett of The Buckeye Steel Castings Company of Columbus, Ohio, will take charge of the discussion.

MR. BENNETT: The subject that Mr. Wright has just presented covers foundry work, and the committee in arranging this program had in mind to give the foundrymen, the persons connected with foundry work, a good part in this program.

Mr. Wright's paper very nicely covered the educational features of foundry work, and I agree with the last portion of that paper relating to good housekeeping. May I ask how many present are interested in foundries?

(A large number raised their hands.)

MR. BENNETT: That is what we found in analyzing the Metals Section, that the majority are directly or indirectly interested in foundries and I suppose the large iron and steel plants have many more employees who are interested, judging from the number of hands raised. I think we should get this matter pretty well thrashed out.

In the matter of good housekeeping at our plant, which is a large one, first we have the brick floor throughout the plant. That has helped an awful lot in piling the flasks, for on an uneven floor the pile will sometimes topple over. We think that has been a very important factor in bringing about a reduction in accidents. Recently we spent quite a bit of money to bring about some changes in our core room, in the handling of the cores. We have about 15 large core ovens, and the cores are made in the core room and then placed on the core rack and never removed until they are put in the molds. In that process they are carried to the cranes and placed in the core car, then into the transportation bay by another crane. (I am speaking of a large open-hearth steel castings foundry; I know there are people here who are interested in the malleable gray foundry where the pouring is done by ladles. We have only one of those.) However, it is as important in the large foundry as in the small one, that this good order be kept before us at all times.

I think, Mr. Chairman, you want each subject cleaned up. Let's hear what you men have to say on good order, or good housekeeping in foundries. You know there are always at these meetings people who come for the first time and I would say that everybody is here with the sincere thought that they find out what is new. In the open discussion is where that is brought out. Sometimes a paper doesn't cover all these points but there are a lot of fellows here who have things to say that will help us. Let us hear them.

Good Housekeeping Helps to Reduce Accidents

MR. QUESNEL: Good housekeeping has always been considered by us as extremely important in reducing accidents. It has been one of our big problems. We have a foundry that is 1875 feet long and it is a mighty big place to look after and keep clean. The nature of foundry work tends to allow material to become more or less scattered and misplaced and in a great many cases it is hard to find out just where material should be kept, especially when you have to use so many smaller pieces. In our work we use thousands of dogs, rails, wedges, short pieces of two-by-four planing and numerous other boards in holding down the forms for pouring; this is always a problem, to keep this material where it will be ready for use, out of the road, and still maintain the efficient, good order of the foundry.

We didn't solve this problem until about a year ago when the superintendent of the foundry, himself, after spending some time studying over the situation and not being able to find a satisfactory solution, determined that he was going to put the job on the men, and this is the way he did it. He told each job leader: "Now, when you finish your job, before you go off the shift, I want this form to be in readiness for each turn that comes on. I want every man on the job ready for the next; every tool in its place, all the boards piled up, and I don't want to see a moulder leave the shop until everything is in apple-pie order, everything swept up and everything piled up in neat order. Your job is not done until that is ready so that the next set of moulders finds everything ready to start working."

That worked both ways. It not only improved the condition of the foundry but it made for more safety and it also increased the efficiency of the workmen. It used to be the men went all over the shop, stealing material from each other and spending a half hour arguing about it. The way we do it now, when the new shift comes on they start immediately to working; everything is ready and it is right there where they can put their hands on it. It is a transformation compared to what we used to see when we went through the foundry a year ago. Everything looks neat and clean; there is nothing to stumble over. We have found that to be a wonderful help in our accident situation, and we have gone a considerable length of time without accidents in the foundry.

One Accident in the Whole Foundry Last Month

It used to be these accidents were to be expected, but last month we had only one accident in the whole foundry. Up to the time I left, the foundry had been operated in this manner for just about a year.

Of course, we maintain a walk-way. Everywhere men walk it is a brick walk; they do not work in the sand.

MR. SANKEY: Mr. Bennett, in your talk you specified brick. Why did you say brick in your foundry? Could you use wooden blocks?

MR. BENNETT: We tried that on a small portion. We used the paving brick, and we tried it by sections, and we now have the entire foundry floor of that material.

MR. SANKEY: Your experience, then, is brick. I know some make the mistake of using cement. The heat will destroy your flooring, if you do. There is a specified brick you can use that will stand wear and tear of the shovel.

CHAIRMAN GIBSON: What Mr. Quesnel brought out is that a foundry can be kept clean and orderly even in view of the tradition that it can't be done.

SECRETARY NORTHWOOD: I should like to ask Mr. Quesnel how long it takes for the men to fall in line for the clean-up and to keep it clean? Did you use any discipline?

MR. QUESNEL: It was rather a fly-by-night proposition. It happened so quickly that we were all astonished because, as I say, it was almost expected that the foundry should be a messy place and that it had to be; but in one week's time after the new order of things went into effect, the foundry was changed from a disorderly place to one of cleanliness and neatness.

SECRETARY NORTHWOOD: It was not brought about by a serious accident? So often after a serious accident occurs we can get a good clean-up very fast but the real prevention in safety work is to get the clean-up before the accident occurs.

MR. QUESNEL: You might be interested to know just what did inspire the superintendent. You know the scrap, to a foundry superintendent, is almost his bible. He thinks of scrap above all else and tries to eliminate the percentage of scrap. In changing his attention from scrap to safety we have almost performed a miracle, for our superintendent was,

like other superintendents, interested in production and also in his men but especially in scrap.

One day our general manager said to him: "Of course, you are interested in keeping your percentage of scrap low but I wonder if you really are more interested in your scrap than you are in eliminating all the accidents in this foundry that you can?"

Now he had been talking with this man hundreds and hundreds of times, but it just happened that he hit him this time at the psychological moment.

MR. BENNETT: You might say that we carry out that plan. The day's work is not done until the men have cleaned up so that the moulding gang is ready to go to work.

Insufficient Clearance Between Moulds Dangerous

W. J. HANFORD (National Malleable & Steel Casting Company, Cleveland, Ohio): In regard to the floors: our foundries were built during the war and wood-block walks were installed with the exception of the one man gangways, and we found that these wood-block floors would burn up so we replaced them with brick which proves very satisfactory.

In connection with good housekeeping, in regard to the moulds, I want to say that we have had in the last few months two very serious burns caused by insufficient clearance between moulds not set in straight lines. Now there is something that you can all consider in foundry work.

We have a kind of joke in our foundry that you can always tell what kind of a moulder a man is by the way he sets out his moulds.

We are making auto parts, housings. They are very high and we had a moulder who was going down between these aisles where, in some places, the parts had not been stacked straight. The foundry was full of smoke from the fire, you know how it is when they are pouring off heat, especially early in the morning, and this moulder came to one of these crooked lanes, and not being able to see, stubbed his toe and burned the off foot. Since then we have substituted a long legging for the short one on the opposite side to prevent a recurrence.

A. W. BRADFIELD (Industrial Works, Bay City, Mich.): I am interested in the floor proposition. What provisions are made for making large excavations for large castings?

MR. BENNETT: It happens that in our plant we don't have that situation. I have noticed in the National Safety Council's safe practices, they use a railing.

MR. QUESNEL: We have quite a few castings to excavate for; these forms are all shapes and sizes. There is no set way, no size of pits to use permanently for that kind of work because the location and the size are always changed. When we do excavate we put a temporary railing around the form if it is left until another is ready. Otherwise it is filled around. Those forms are about three feet from the rock walkway on each side and the space allotted for them is just large enough to receive them. When they are finished, of course they are filled up, or the hole is filled up so that a smaller one can be put in its place. The forms are,

of course, under personal supervision and we don't leave an excavation open when it is not being used.

C. W. RIKE (N. C. R. Co., Dayton, Ohio): May I inquire, referring to the pit mould, don't you have a permanent pit?

MR. QUESNEL: No.

MR. RIKE: In our foundry we have four pits and when not in use these are filled with sand, and when in use they are roped off.

There are some objections to a brick floor that I will call your attention to now. I don't think the 100 per cent foundry has been discovered. Little drops of iron when spilled on a wood floor are dangerous and when a workman steps on one of those, he is very likely to go down, especially if he is in a hurry or makes quick moves. That is one objection to a wood floor. The cement floor blows up; it explodes. It transforms the moisture in cement to superheated steam and when it explodes it throws iron in all directions.

The best floor, from a safety standpoint, in my opinion, is a properly maintained blue clay floor. It is hard to maintain and keep in shape, but from a safety standpoint I think it is the best.

Two Periods Daily When Most Accidents Occur

JOHN M. GULL (National Tube Company, Lorain, Ohio): We find we have two periods during the day when we have the most accidents; one at the time of pouring castings. There is danger connected with that and we sometimes get accidents there. The next period when we get accidents is at night when we are cleaning up and pulling the castings out of the moulds.

Just how this gentleman manages to have everybody clean up before they go home, I don't see. Our moulders finish their castings. We pour once a day. It happens we start generally about 3:00 o'clock or 3:30 to pour the moulds and when they go home the night foreman with a gang of men takes the castings from the moulds or from the flasks. That is one period of the time when we get more accidents than we do at the time of pouring. Now, we have no trained men on the job, we have laborers at night; we have no moulders, mechanics, they don't stay, we couldn't get the men to do it and I don't see how we could operate in any other way. We never do our pouring at night.

We make large and small castings.

GEORGE W. YOUNG (The Eberhard Manufacturing Company, Cleveland, Ohio): I have been listening to the talk about the foundry runways, where they have trouble sometimes, and I have heard mention of the fact that a cement floor will explode and throw iron all over the place.

We have cement runways in our foundry, and for 15 years we have never had any trouble. Of course, heated cement will explode, but if you lay your cement floor at least five inches thick, placing wooden joints every 40 or 50 feet, you are not so likely to have trouble. As far as the pitting is concerned that is really an advantage because it makes the floor rough.

We do all small work, around 15 pounds. We have never had any

trouble with the concrete and pitting. In fact I would say that a gangway, if laid properly and with the right mixture of cement, would be preferable to the brick in a lot of cases because a moulder will find the iron will cool more or less quickly when it strikes the cold floor. On clay floors you are likely to slip, and where you have sand pits, they are out of the question.

MR. BENNETT: Let's take the next two subjects, now : "Hot and Cold Metal" and "Foundry Flasks." They all relate to good housekeeping. Foundry Flasks certainly do, and there are dangerous stages in hot and cold metals and certain ways of handling them that are better than others. Can we hear from some one on this subject?

Compulsory That the Men Should Wear Goggles

SECRETARY NORTHWOOD: I just want to ask a question as to how many transfer the flasks from their open hearth to the foundry and how they transfer them, whether on small cars or just how it is done?

MR. SANKEY: I can tell you how we do it; we use a crane. It is compulsory among our men to wear goggles, and shields on their knees. Any man not wearing them gets two to 10 days' lay-off, although the feet belong to him and not to the company.

SECRETARY NORTHWOOD: The point I had in mind was this: we transfer our flasks from the open hearth down to the foundry after they are poured. We have had a very serious accident; a flask fell off a narrow-gauge car onto a man. These flasks should have been chained together before they were moved, but they neglected to do that although they had about six flasks. I wonder if any one else has a different method of transferring this material?

MR. BENNETT: It is one of the most dangerous things we have, this moving of the flasks from the pouring room to the foundry. We have eliminated some of our trouble by better piling, arranging the flasks so that we have a uniform load of flasks just so high. It is some time since we had these to deal with, but in the past they have been a bugaboo.

We can go right into this flask subject now and close up the discussion.

L. B. BIDENKAP (Metropolitan Casualty Insurance Company, Chicago, Ill.): I had a very interesting experience recently in a plant in Wisconsin. You know, the foundrymen like to indulge in a little hard liquor once in a while; I suppose it depends upon the kind of personnel a foundry has whether this is true, but this foundry happened to deal in the smaller type of castings. It has a number of Mexicans, Italians and Japs among its employees and they had a lot of accidents in connection with the pouring and handling of flasks.

They got the idea that if they could substitute something for the moonshine that was so easily available, something that would affect their minds like that does, they might get around the accident question, so they decided to fill them up with milk so they wouldn't have room for liquor. A milkman sells about 200 bottles of milk at about a penny a flask and it is going over big.

MR. BENNETT: We are using that same method at our plant, although I don't know that the same thing inspired us.

MR. QUESNEL: There is just one thing in regard to smoke. I think smoke is one of the contributory factors in accidents. It is always disagreeable. The smoke from the castings is almost impossible to eliminate, but you can improve it by seeing that the windows are properly operated. Any of you who are operating at this season of the year know that it is salamander time. We have hundreds of them in the morning when we start a fire and the salamanders make more smoke than the castings; it is especially hard on the craneman who nearly gets smoked out. However, this year we have gotten over that almost entirely by installing a steam heating plant.

MR. MCKENNEY: We sell about 5,000 bottles of milk in our plant. If the gentleman who spoke about the milk knows how much milk a man would have to drink before he wouldn't have room for more liquor, it would be of some aid.

R. N. PHELPS (Link Belt Company, Indianapolis, Indiana): I should like to hear a little discussion on the wearing of goggles in malleable foundries, the advisability of wearing goggles in pouring from ladles. Some say they are more dangerous than working without them. I should like to know what is the general opinion about that?

MR. BENNETT: The wearing of goggles in a malleable foundry is not on our program. Mr. Hanforth, have you anything to say about that? For what reason are they worn?

The Problem of Fog on the Goggles

W. J. HANFORTH (National Malleable and Steel Casting Company, Cleveland, Ohio): We have had trouble with them; they fog in the summer and the perspiration works down under the goggles. We pour everything from hand ladles, and I took some of these goggles to some of the men who pour and asked them as a personal favor if they would try them out. There were several different kinds of goggles.

I said to the men, "I will give you this pair and if you don't like them, you let me know and you can try another kind." I started them out with a clear white glass, and told them we would try colored glass if they thought they would be better. I asked these men to try these out conscientiously and make the experiment for me, and I do believe that those two or three men did wear them conscientiously. They came back to me and said they wouldn't work on account of the perspiration.

MR. PHELPS: That has been our experience exactly, and so I contend that they are not successful.

MR. SANKEY: I am a convert of John Oartel's. Three years ago a play was put on about the foundry, and he showed there, where they made the flasks and so forth, the men wearing goggles, and in his crew of moulders he had one man who had been in an accident or an explosion. He was wearing goggles and he took them off and showed what had been done to his face; it was all scarred. Another man removed his goggles; he was blind. Don't say that you can't make your men wear them. I

make every one of mine wear them. If the perspiration is too heavy they can wear a band across the head, a safety band that costs about three cents apiece. Don't let them go without these goggles; make them wear them. It may save their eyes.

I had the same experience with my men about getting them to wear these goggles; but when I saw that playlet I went home and I told my men, "Don't look too much to your output" (we pay a bonus on their castings and so forth) "but pay some attention to safety."

E. E. ARMSTRONG (Chapman Valve Manufacturing Company, Springfield, Mo.): A year ago this very same question came up. At that time I got up and made the statement that we were then trying out these goggles, the non-fogging kind. Five years ago our men would not wear goggles because the manager did not ask them to; they thought they were a nuisance; but our iron and steel foundries, employing about 5,000 men, are now strong for them, and I venture to say that we could leave here in an airplane now and arrive in that shop about 3:00 o'clock and we would find 100 per cent of the men wearing goggles.

A Foundry Thrashes Out the Goggle Question

If a foundryman who is about ready to pour his heat tells you that he can't wear his goggles, you just tell him it is nonsense.

We want our chippers to use them. Among our chippers is an old man who has chipped for 15 years and has never lost an eye. I worked for years trying to get that man to wear goggles, but he insisted there was no danger, and he kept some of the boys from wearing goggles. We pleaded with them, tried to persuade them, and when a man finally lost an eye we thought it about time to compel them to wear goggles. For those men who needed an eyesight correction we had a special pair of goggles made, for that is where the trouble sometimes occurs; in many cases a man needs a glass that is especially adapted to his vision.

We forced those men to wear goggles, and in about 10 days after that you could hardly get out of those men to start his job without them. At first it was hard for them to do their work while wearing them, but they got used to them and got confidence in them.

The moulders claimed they could not wear goggles, but we insisted they also wear them. We sent a man around to every man who was pouring heat; the goggles were wiped off and handed back to the men.

MR. STEWART: Just one second. You can't make your men wear goggles? Can you make them come to the foundry on time? What do you do when they don't come to the foundry on time?

Let me ask another question. Whenever the manager or any of the officers comes into the foundry, does he put on goggles? Do you give them to understand that a flying object is just as likely to hit the manager going through the chipping room as it may the chipper? Do you make it perfectly apparent that you believe in goggles?

With your own discussions and all of our studies, it seems to me we have got to admit that if we would do the things we know must apply to

this problem, we would put an end to 75 per cent of the accidents. So I say that this question of making the men wear goggles simply raises the other question of whether we can make them come to work.

MR. BENNETT: Tomorrow you will have the opportunity to continue this subject by your question cards in the "Your Hour" part of the program.

MR. WRIGHT: I just want to come to the rescue of this gentleman down here who specified malleable foundries. Now, there is a great distinction between pouring iron in a gray iron and a malleable foundry, and they are absolutely two different things, an altogether different proposition. I just want to help that fellow out. You see the goggles will fog about four times as much and the perspiration is about 10 times greater than it is in the ordinary gray iron foundry. It is a crime to make the men pour in a gray iron foundry without the goggles, but it is a mooted question if it meets the requirements of a malleable foundry.

MR. BENNETT: I am sorry we have no time for further discussion on this subject.

CHAIRMAN GIBSON: I understand that Dr. Ethelbert Stewart, Commissioner of Labor Statistics, Washington, D. C., is here, and we are going to hear from him at this time.

DR. STEWART: Mr. Chairman, I had expected up to a few days ago that Dr. Chaney would be here. The arrangement was agreed to three months ago.

Cooperation of the Bureau of Labor Statistics

About 10 days ago, Dr. Chaney came to me and said that the work on his report, which is due from the printers now and has been due for two weeks, was so far behind that he couldn't see his way clear at all to stop long enough to come out here. I very much regret it, as does he, but Dr. Chaney, since the death of another officer, has been a very much overworked man.

He wanted to be here; he has the material he wanted to present to you, at least he had it practically prepared when he decided he couldn't come. He is with you here in spirit, I know. This is the first Congress he has missed in years. He doesn't want you to think we are slowing up on our work. I won't want you to think that the Bureau of Labor Statistics has any less interest in your work than before. It is simply a case where Dr. Chaney himself decided that he couldn't come. I want you all to feel that the Bureau is interested in getting the best information, putting it up in the very best shape and handing it out to you, and if once in a while a man 70 years old can't meet an appointment, it doesn't mean that we are losing interest.

CHAIRMAN GIBSON: I am sure you all know how we appreciate the doctor's report from year to year. As Mr. Stewart has said, this is the first time that Dr. Chaney has missed a meeting.

I think it would be well to entertain a motion that when Dr. Chaney's report is finished it be included in the minutes.

(A motion was made, seconded and properly carried.)

CHAIRMAN GIBSON: The next thing on our program is "Electrical Hazards in the Steel Industry," by Mr. Frank W. Cramer, Assistant Electrical Engineer, Cambria Plant, Bethlehem Steel Company, Johnstown, Pa. However, because of some unforeseen circumstance, he will not be here, but Mr. C. L. Baker, the manager's representative, of the Cambria Plant, is present and will read Mr. Cramer's paper for him.

ELECTRICAL HAZARDS IN THE STEEL INDUSTRY

**Frank W. Cramer, Assistant Superintendent, Electrical Department,
Cambria Plant, Bethlehem Steel Co., Johnstown, Pa.**

The association of Iron and Steel Electrical Engineers, for several years, has been working to devise a plan that would bring home to the average workman the dangers involved in tampering with electrical apparatus. In the solution of this problem, the natural opinion was that the safety engineers could give most assistance, but since most of these men have been trained along mechanical lines, a means had to be created whereby they would be informed of the behaviour of electrical apparatus.

With this thought in view, it seemed logical that if we could induce these men to attend joint meetings, and take part in the discussions, we could all work closer together, and make more progress toward the elimination of the electrical hazards in the Steel Industry. Accordingly, this paper has been written with the idea of bringing some of these hazards to your attention, and perhaps, after a general discussion, the electrical side of the question will be better understood by the safety men.

Most of you, I believe, are familiar with steel mill practices, and know of the many traditions that have grown up with your local mills. These have been created perhaps over the past 50 years, and have been boasted about and talked over so often that they almost form the operating code of the mill. Comparisons are often made of repair work done years ago with similar work at the present time, but mills have gone through a lot of changes during that period. Some of the old timers hardly realize that the old steam drives, with which they were very familiar, and could make all repairs, have been replaced with motors which they really know nothing about, and are requested not to attempt to repair. They knew when the main valve was closed on the engine that it was safe to work on the rolls—now, we expect them to believe that by locking out some small control switch, it will be impossible for the motor to be started.

The electrical engineer has simplified the control of these motors until a small master controller or a few push buttons are the only equipment left for the operator to manipulate. If the motor fails to respond when these are used, the operator is instructed to blow the whistle for the electrician, and not attempt any repairs himself. If we can get the mill men to follow this practice, one of the so-called electrical hazards will be eliminated: but if they are curious and attempt control or motor

repairs, several dangers are created, for this strange and remarkable force, which we call "electricity," must be understood, in order to be worked with safely.

An example of this hazard happened a short time ago when an operator thought a certain mill motor was not running at its normal speed, and sent a helper to see what was wrong. In the motor house, the helper noticed a large contactor that was open, and believing he had located the trouble, forced it in with a stick of wood. Now this particular contactor was properly open, and was locked out both electrically and mechanically, and could only be closed by force. It was the main reverse switch, and as the forward switch was already in, a short circuit was made on the high tension lines. The fact that the resultant fireworks did not seriously burn the man is one of those remarkably close calls that happen every now and then. After the damage was repaired, a test showed that the motor had been up to normal speed, and the trouble had been imaginary. A few pulls on the whistle cord would have saved considerable damage.

Blow the Whistle for the Expert Electrician

Most any electrical foreman could give you similar examples of these "created hazards" which can be eliminated, if we can convince the mill men that the safest and quickest way to repair electrical equipment is to blow the whistle for the electrician.

The Electrical Department, too, is often guilty of creating a hazard in repair jobs. This condition probably had its origin in the first electrical installation in the mill. For a long time the electricians were looked upon by the operating departments as outsiders—non-producers who just kept the motors running and the lights burning. Electrical delays were looked upon in too critical a manner by the operating departments when comparisons were made with the mechanical and rolling delays which were charged to their own department. This condition, which either exists or has existed in every steel mill in the country, has served to create a spirit of pride and determination in the electrical fraternity to keep delays to a minimum, and unless you are one of the department, or have been in close touch with the men, you have no idea how deep rooted this tradition is, and the inward satisfaction the electrician gets when he can pull through a job without a delay.

Now the hazard lies in his anxiety to rush the job through, either in starting to remove guards before the equipment stops, or signalling the mill to go ahead before the job is completed. This is rather a hard problem to handle. We are in business to roll steel, and when the mill is down, the revenue stops, and sometimes delays are hard to explain. Modern equipment, with gear guards and cover plates, takes longer to dismantle and assemble than the older installations, and the mills are of larger capacity. These facts make speed in a repair job very desirable.

You will find that even though the electrical man has tried his best to buy high grade apparatus of ample rating, installed the most reliable

control he can find, protected the motor from abuse in most all possible ways, perhaps installed duplicate equipment—yet machinery is machinery, and some day it will fail. Then the “hazard” of doing the quick repair job is again present. You may also find the inspector or the man in charge of the job is a man of long experience and that he knows all the tricks of the game; but will his determination to keep down the delay cause him to start work before the equipment is stopped, or to signal to start before the job is completed?

There is a means for the removal of this hazard that is being better applied every day; the mill men and electricians are beginning to understand each other, and a fair allowance of time for an electrical repair job is being recognized. The safety men are helping bring this about, and all we electrical fellows ask is a reasonable length of time to do a job in a safe manner.

There is another item on the electrical side of the fence that is rather difficult to discuss before a gathering of this nature without creating a misunderstanding, or having the remarks misinterpreted. I refer to the practice of making electrical equipment “safe” for everybody but the electricians. Unless you are schooled in electrical work, this hazard is rather hard to see, and to attempt to show that by making a thing safe for everybody, except those whose duty it is to repair or work on the apparatus, means delving into the technical side of the electrical profession.

The “Safety” Switch was a Misnomer

Let us consider for a moment the original “safety” switch, which from the electrician’s standpoint was one of the most dangerous pieces of equipment to install that was ever brought on the market. The word “safety” put the switch across, and when the steel mill electricians back in Pennsylvania protested against its adoption, they were accused of blocking safety progress. If you believe this switch was safe, locate one, and see if you can connect it up or repair it without getting burned or shocked. But it was called a safety switch, and its adoption forced the mill men to install them. After this, we had to rely on our ingenuity and pressure on the manufacturers to force them to change the designs, until the modern safety switches, that are really safe, were brought on the market. A lot of grief would have been avoided, if the adoption of the safety switch had come through the electrical engineers, rather than from salesmen capitalizing the word “safety.”

Another example of this item can often be seen in screens and guards around electrical equipment. The outsider is protected 100 per cent, but jump over the fence and be the electrician who has to repair the equipment. Often, you will find hardly enough room to squeeze through, let alone work on the switch or bus, and a slip of the pliers, or a falling wrench or screw driver will cause a blinding flash making a short. We all believe this equipment should be protected and made safe, but we expect you men to help us in making it safe for the electrician as well as for other employees.

There is another hazard, a created hazard in the industry that is usually overlooked, yet it is present in a majority of our mills—that is the extension cord hazard. In the modern mills this hazard has been cut in half by the installation of fused plug-in boxes where the extension cords, with a permanent plug on the end, can be attached. The number of extension cords used in the larger mills runs into the thousands, in fact, we wonder how repairs were ever made in the days when torches and lanterns were in style. If we eliminate the plug-in type of cords, we still have a multitude left that the workmen take upon themselves to attach on any live switch or line they find.

The modern safety switch has reduced the number of places where these can be attached, nevertheless, a place is often found. By attaching them to the heavy lines, with heavy fuses, a shorted line or globe will cause a miniature explosion, and sometimes this happens when the second wire is "hooked on." Then, on the other end of the cord, we have the lamp, which at some time has been equipped with a guard. Common sense limits the size of lamps on extension cords to 50 or perhaps 100 watts, but in these days, workmen often think an "arc" light is required, and proceed to borrow a larger size lamp from another socket, and replace the smaller one.

If he does, the guard will not fit, and must be removed, and thus the safety valve is eliminated. Then, most all plants have both 220 and 110 volt lights and if a 110 volt light is placed in a 220 volt circuit, it blows up, and without the guard, the glass is thrown in all directions. This problem of extension cords is worthy of your serious consideration: and our suggestion would be to help us enforce the ruling that most plants have which require the electricians to replace the lamps: and give us your support to install more fused plug-in boxes, and insist on guards on all extension cords.

Electricity a Peculiar and Dangerous Power

Another line of thought that is brought to our attention might be called the "invisible hazard." Electricity is a peculiar power—it can not be seen, we know it only by its actions. There is no difference in the physical appearance of a transmission line when the power is on, and when it is off. Neglecting the corona effect on the extremely high voltage lines, you can not tell by looks whether the line voltage is 110 volts or 33,000. It is true that the construction of the lines would be different in detail, but these are familiar only to those following this line of work. Even they can not be certain, for conditions around blast furnaces and coke ovens cause a steel plant to use the same insulators and spacing on 6,600 volts that a cross-country transmission line would have for 23,000 volts.

Again, we never know if a low tension line is crossed with a high tension line by just looking at it—we must use the test sticks, or some other method before this can be ascertained. The painters, roofers, carpenters, etc., are not aware of these conditions, and all wires look alike to them. Our practice is to send an experienced lineman with these

men when they are working near high voltage lines, and, if possible, have the power shut off.

But the hard part is to have them notify the electrical department when the work is to be done. It often happens that the electrician will notice a bucket of paint hung on the wire before any notice of work has been given. These workmen have had marvelous escapes, mostly unknown to themselves, by being too friendly with transmission lines but every now and then "luck" deserts them, and a fatality is the result. You will find the modern tendency is to try to keep transmission lines high on poles, and out of buildings, but this is not always possible, and as was mentioned before, all wires look alike to those outside the profession.

A paper on this subject would not be complete without a reference to the most widely advertised of the so-called electrical hazards in the steel industry—the hazard of crane operation. As an introduction to this subject, it might be mentioned that the problem has been studied by the National Safety Council, and the Association of Iron and Steel Electrical Engineers from the time these associations were formed. The National Safety Council has brought about the adoption of a uniform set of hoisting and lowering signals that enable the crane men to understand the wishes of the ground man. The A. I. & S. E. E. has devoted its energies to the adoption of a set of design specifications that enable the mill man to buy a crane built for steel mill service, and capable of being both operated and repaired without danger to the workmen.

No Uniformity in Supervision of Cranes

We also have been able to get a safe means of access to these cranes, as well as repair platforms which formed another link in the chain. During the past year, the Safety Section of the A. I. & S. E. E. secured the adoption of a set of operating rules which will further assist in this work. Various states, with their inspectors, have aided in seeing that these various rulings were carried out. Having accomplished all these things, we would suggest that still another code be attempted by the safety men, and for want of a better name, it could be called the "accident code."

You will not find any uniformity in the method of supervision and maintenance of cranes among steel mills. In some few mills, the electrical department has complete control of the operators as well as the electrical and mechanical maintenance of the cranes. In other mills, the operating department employs the operators and maintains the cranes mechanically, leaving only the electrical equipment to the electrical department. In other mills, you will find a different division of the supervision and methods of operation. All of these schemes, are working successfully so far as operation goes.

Now, with all these schemes, we find just as many plans for recording crane accidents, so that a comparison between mills on the crane accident charts does not mean very much. Some of the accidents are due to the ground men, and should not be held against the crane or be listed

as electrical accidents. Some are due to faulty signals or other similar causes, yet, on some charts, they show as electrical accidents. A very few are due to the failure of the electrical equipment. What the electrical engineer wants is some standard way of having these crane accidents codified, so that he will have a quick way of finding out where the dangerous spots are.

Likewise, those responsible for the ground men would appreciate knowing how often faulty signals are given, unsafe loads are lifted, how many chains are broken, etc. Then, if he had this data, and could make a fair comparison with similar data from another mill, he would know if he was making progress toward the removal of these crane hazards.

The above suggestion may sound simple, but there are as many ways of tabulating these accidents as there are steel companies in the country. If we can get a standard method, and definitely locate the weak spots, then we will know where to concentrate the hardest drive.

In conclusion, we would leave with you these thoughts pertaining to the Electrical Hazards in the Steel Industry:

- (1) Train the mill operator to blow the whistle for the electrician when the equipment needs attention.
- (2) Allow the electrical department a fair amount of time for repair jobs.
- (3) Make electrical installations safe for the electricians as well as the other employees.
- (4) Look into the extension cord abuse.
- (5) Have all workmen consider transmission lines dangerous until they have consulted the Electrical Department.
- (6) Secure a uniform method of tabulating crane accidents.

CHAIRMAN GIBSON: Mr. John F. Kelly, Managing Secretary of the Association of Iron and Steel Electrical Engineers, will have charge of this discussion.

Discussion Following Mr. Cramer's Paper

MR. KELLY: Mr. Chairman and Members of the National Safety Council: Your Chairman has conferred an honor upon me which is more or less undeserving, as I came here this morning merely to listen and to learn. I don't feel qualified to lead in the discussion, but I will do my very best.

I have reviewed Mr. Cramer's paper and I feel as we say when we talk about Mr. Dooley, "it's a scream." It could hardly be improved upon. Cramer, to my mind, has a world of knowledge that he has gathered around in his operating experience and he is fully qualified to put down on paper his thoughts.

I should like to take, first, his conclusions. I think they sum up his paper.

"Train the mill operator to blow the whistle for the electrician when the equipment needs attention." In a foundry you perhaps don't have a whistle but a signal or a bell, and if you will train every one who is an

executive head, or in an executive position in your plants, to immediately call for the electrician you will eliminate about 75 per cent of the accidents.

A lot of things happen to the men because they don't know how to rely upon the electrician; if they did, many of the accidents could be eliminated. They never will be entirely eliminated, of course, but we can cut them down an awful lot if we educate the people who have anything to do near the hazards; the high transmission lines are a hazard to those who are painting, window cleaning, carpentering, or doing structural work. There is where the greatest hazard is, to my mind, in electricity—around high tension lines. Practically all electrical apparatus can be made fairly safe.

There is a point that comes to my mind, that the purchaser when he comes to buy electrical apparatus should include in his specification that the manufacturer furnish him with this stuff with all the devices to properly maintain it in order not only to eliminate failures but also eliminate hazards. In my opinion, I don't feel that has gone far enough. The manufacturer should use his ingenuity in eliminating these hazards.

"Look into the extension cord abuse." Some plants have gone into that very thoroughly and have cut down materially their men's injuries, you might say, in connection with cords. I think a good way to eliminate the accidents in this case is to instruct the men that when something happens to an extension cord, always let the electrician repair it.

Waste in the Use of Lights in This Plant

I should like to mention here the economic side of this. I used to be in a plant where we used 6,000 lights a month, not at all the correct proportion to the amount of voltage we used. There was an awful lot of carelessness and waste until an order was issued that no lamps would be given out by anyone except the properly authorized men in the electrical department. As a result, 6,000 lamps were actually cut down to 300 during one month, and the biggest lot issued was 700. So you see there is not only the elimination of accidents to be considered, but there is an economic side to it as well.

"Have all workmen consider transmission lines dangerous until they have consulted the Electrical Department." I want to bring up just one example of why this should be done.

I have in mind a case where the foreman as well as his helpers neglected to go to the electrical department before they repaired a roof. They got up on the scaffold with tools and worked along the high tension lines. It was just a miracle that some fellow came along who knew better.

"Secure a uniform method of tabulating crane accidents." I believe it would be a good scheme if the steel industry or the Metals Section of this Council, or some other society, were to prepare such a uniform method, because I believe that if all these accidents were classified as to how they happened we would be better able to approach the question by knowing the type of accident that predominated.

I should like to conclude my remarks by paying my respects to the National Safety Council. I happened to pick up a paper when I rode up here in which there was an article saying that this Safety Congress is being attended by safety executives and safety directors from all over the United States; and I felt that if that is the case then all the eyes of this nation are directed here because this, for the moment, is where greater safety is developed. It came to my mind that perhaps the safety man doesn't get all the recognition that he should, but I think the safety director and the safety engineer represent the noblest profession of humankind.

I am brought to that conclusion by this reasoning. If we study what law means we find that we honor our lawyers, for they preserve our property rights; if we study medicine we find that the doctors are honored because they keep us well. Now here is a body of men gathered together for the noblest purpose on earth; they are here for human preservation, the preserving of life and bodies. Some day you will all be called doctors; with your singleness of purpose you can go ahead and accomplish what you are aiming for. Because of your work there will be fewer legless, armless, sightless men, and no doubt fewer bodies over which to mourn.

MR. SANKEY: I noticed in Mr. Cramer's report that he said we should make better electrical installations. How are we to improve on these?

The Amateur Who Tinkers with Electric Devices

MR. KELLY: I feel that this, from a safety standpoint, requires that the electrician should be better educated to handle the things that they now know little or nothing about. I have found in my experience that men are employed in the electrical department who claim they know a great deal about their work who really aren't qualified. There should be a standard that a man must measure up to before he is employed as an electrician. A man who has had to fix a light or has worked upon an automobile will sometimes take a screwdriver and a pair of tongs and call himself an electrician and make application to a great number of plants. If he is employed, he is sent out on one of these boards with the hot stuff on it and, not being educated in that kind of work, sustains an injury.

The electrical department should educate their men just as we educate our men as to where dangerous conditions exist, because I know this from experience. Just about two months ago a man went back to the board in our plant. (We require them to wear glasses and we require that all men get an O. K. before they go back there, but this was one of the sub-foremen; they are sometimes called straw bosses, a name which I don't like to hear, for any sub-foreman is as good as a foreman.) This is what he did: he went back and put on his glasses and then he reached in with a screwdriver to make what he thought was the right move. He burned his hand dreadfully.

The man in charge of the electrical department admitted he didn't

know whom he was sending over to that board. Therefore, you can see that these men must be educated. Don't let a man tell you he is an electrician unless you make sure he is before you employ him.

CHAIRMAN GIBSON: I don't know whether Mr. Woltz will say anything or not, but we should like to hear from him. You know him better than I do; he is one of the hard-wording members of the Metals Section. We wanted him to talk yesterday but he slipped out.

MR. WOLTZ: This is rather embarrassing. I feel something like the woman who attended the funeral of her husband who was a worthless, no-account cuss who mistreated her. They had had some difficulty in getting a minister to say a few words at the services, but finally one was secured and he came in at the proper time and proceeded to eulogize, saying what a wonderful husband the deceased had been, what a wonderful character and so forth, until finally the bewildered widow turned to her little daughter and said, "Would you-all mind looking in that coffin and see if that is your father?"

But it is a pleasure for me to attend these gatherings, since in 1917 I helped organize the Metals Section and was fortunate to be its first presiding officer. I know many of you intimately, and even if it was nothing else than having an opportunity to talk to you, clasp hands with you, it would be inspiration enough to take back home.

I have to talk to you tomorrow night.

WILLIAM W. JANZE (Mayville Iron Company, Mayville, Wis.): I should like to know the method of inspection of extension cords.

MR. KELLY: Right off the bat, he asks a delicate question! I might say that the entire lot of extension cords should be kept in one place in the plant. In our plant we practically control all extension cords outside of the railroad shop. We have a man go over these about once a week. You will be up against it if you don't have regular inspection. Rubber insulated cord or cable avoids a lot of damage; you can run trucks over it without doing much damage. One of the big dangers in the use of the ordinary insulated cord is that dragging it across the ground will sometimes tear the insulation off.

Further Discussion of the Extension Cord Problem

In order that they may always be kept properly inspected, they should all be under one head. We had one man who did nothing else but go over the cord, and he was supposed to be 100 per cent efficient; it was a demerit on him unless he was.

MR. KELLY: You may be interested in this extension cord subject further. The electrical department, you know, gives out the cords to the man who uses them and he uses them over and over again until they become dangerous. Now there isn't a safety man in this room who isn't interested in this problem, but you are all sitting back thinking that some electrical engineer is going to jump in with an idea. I should like to hear from you safety fellows on this electrical subject. You are all having your accidents with it, and it is a live, a hot subject.

MR. JANZE: Now I brought up this question about the electrical extension cord. In our company the electrical department puts up the extension cords, but the trouble is that they never get to take them down. That stuff just disappears when the job is done and no one ever sees it or understands where it went to. There was a lot of fuss raised over what becomes of the extension cord, hundreds of feet of it, so we looked around to see if we could find where it went, and we found it in almost every conceivable part of the plant—even in the scrap pile, and perhaps that wasn't so bad. We cut down a big loss.

We have an arrangement now in our plant where if there is a construction job the electrical department puts the cords up and takes them down, and there is a permanent electrical repairman who comes along and looks over the cords. It is no small job to look after all these cords, but it's well worth while. If there's anything wrong with a job, the repairman immediately fixes it. It's just a little common-sense plan.

MR. QUESNEL: We have had considerable trouble with the use of the extension cord and we have found that when an extension cord is to be used, if there is no plug to which it is to be attached, they must get the electrician to do the job. Where a department uses an extension cord, and has to have one, they must tell the electrical department of what use it is to be put, for we find there are several kinds of cords suitable for different kinds of work. A cord may be perfectly safe on one job and hazardous on the other.

When an order comes in to the electrical department, they must state on that order for what it is to be used, and if it is the cord most adapted to the work, the order is filled.

Static Develops If the Motor is Set on Cement

These cords are not transferable from one job to another, and we find this prevents cords from being used for any other purpose than that for which they were designed. We will not issue a cord built out of ordinary lamp cord in the shop. The only places that kind of cord might be used would be in the office, and even there it must be approved by the superintendent of the electrical department with a special permit. We will not build an extension cord with a lamp cord as a means of connecting a light with the socket. We find by doing that we have diminished the repair of our lamp cord.

H. C. HOLFEY (Pittsburgh Plate Glass Company, Ford City, Pa.): I should like to ask whether if a motor is set up on cement you get a condition of static caused by friction?

MR. KELLY: Well, a man will get a pretty heavy shock from static current. If your motor is set on cement you may get a leak through the cement that will cause the shock, if the conduit is connected with the motor, which is supposed to be grounded, and lots of times you get against the conduit which has been grounded and, the motor frame not being grounded, probably short circuit yourself in that way. It is a case of static current.

I remember one time probably 13 years ago, in one of our plants the electrical department was called upon to find a leak. It hunted and hunted but everything was found to be clear; everything was found properly protected and grounded, but the trouble was finally found by the electrical department. A steam gasket had blown out, giving off just a vapor and causing a static current.

That condition you all know how to eliminate. Putting on a good ground from that pipe line to the ground, and making a good ground contact, straightened out our difficulty. Proper grounding should be made; some men will ground to a steel column, which probably will not be grounding at all, or maybe to a cement block which isn't in the ground. I believe if you will take the precaution necessary, you will not have any trouble.

A belt-driven machine will cause a good bit of friction. I am sure you have seen the experiment of holding an old carbon lamp up to a belt machine where it is filled with static current and then you have seen a fellow employee touched with it. There is a great deal of fire hazard connected with the belt-driven machine.

WALTER S. SMITH (Safety Director, Milwaukee, Wis.): I wonder if you have any trouble with the indifference of employees towards local hazards; these fellows who are not afraid. The reason I speak of it is that I met a superintendent who used to take hold of the 440 every morning as a sort of tonic. I just wonder how you can offset that?

MR. KELLY: It has been suggested that every wire be designated a live wire; that every wire above 110 volts be so designated. I find that to be very much the case. It is sometimes considered a marked distinction to be able to withstand the heavy voltage and it is sometimes done to win the approval of the other workmen.

ADJOURNMENT

THURSDAY MORNING SESSION**October 28, 1926**

The meeting was called to order at 9:30 o'clock, Chairman Gibson presiding.

CHAIRMAN GIBSON: Our first paper this morning in our round table discussion is on contests.

This is the educational forum. We expect that it is going to be a very lively session and that we are going to get a great deal of good out of it. This is the session we are putting a bet on that we shall get the real meat of the Congress out of it.

Mr. J. A. Voss, Director, Safety and Compensation, Central Alloy Steel Corporation, Massillon, Ohio, will first present his paper.

CONTESTS

J. A. Voss, Director, Safety & Compensation, Central Alloy Steel Corporation, Massillon, Ohio

To launch a safety campaign does not entail much effort. But to keep that campaign going under high pressure continually, month after month, year after year, and to maintain interest long after the novelty of the initial effort has worn off, is not so easy. Inasmuch as we must plan on making safety work a permanent factor in industry, we must also plan on developing a will for safety in the worker.

Among the many ways of creating the safety spirit in the worker, one which has accomplished results is the safety contest. In this, it must be remembered, it is the safety spirit that should be developed, rather than victory in a contest. The rules of the contest should be drawn to develop the safety spirit rather than to appeal to various hobbies of workers. The real purpose of contests should be the awakening of every employee to the seriousness of personal responsibility and continual alertness for the prevention of accidents, thereby establishing and maintaining an enviable safety record on the accident chart.

Personally, I do not favor individual prizes in safety contests. The reward for such contests should be in the form of honor rolls. There is nothing more enviable for a foreman to strive for, than a record of no serious injuries or deaths among the men under his jurisdiction, and such a record can be attained if the men in charge of work insist at all times that the work be done only in a safe way.

Guarding the dangerous machine to the utmost does not prevent accidents, and the making of a hazardous place safe does not eliminate injury. From the safety contest standpoint, therefore, we must work to create the will for safety in those hazardous places; and when we have placed in these jobs the best safety device known—a careful man—we shall have no more accidents.

Contests bring about a closer relation between the safety department and the superintendents, foremen and workmen and assist greatly in keeping the subject of accident prevention uppermost in their minds.

They are important factors in any well organized industrial safety organization. Industrial accidents can be avoided; not by keeping secret the accident and its results, but by giving the occurrence wide publicity in the plant. When contests are on a competitive basis they arouse a certain friendly rivalry, thereby creating an atmosphere of great interest and enthusiasm. This can be followed by a letter of appreciation by the general manager to the department head with the best record, who should post the letter where it can be seen by all employees.

Comparative Ratings Are Published Monthly

Another feature of our accident prevention work is based on departmental competition, where each department competes in the elimination of accidents. Such competition has injected an excellent spirit of team work which can only be secured through coordinated effort, rather than individual performance. To encourage and keep alive the interest in this work, comparative ratings are published monthly, showing the number of days lost on account of accidents which are divided by the number of days worked, and the department having the best percentage is placed at the top of the safety report. This report also shows the rank of the various departments to date for the year, and their percentage for the year as compared with the same period of the previous year.

In one column of this report is shown the standing of the various departmental superintendents, and the superintendent heading the list at the close of the year is sent to the National Safety Congress and all his expenses are paid by the company.

It is our opinion that these contests and reports furnished monthly to all department heads and posted in each department throughout our entire operations have been contributing factors in our successful accident prevention activities because they have injected something that is very essential in this work, which is the spirit which comes only through the pride of accomplishment. It is fundamentally right to apply the principle of cooperative effort to accident prevention, but the success accompanying the application of this principle depends upon the ability to arouse and continue the interest of all superintendents, foremen and employees in the work. No means offers itself so promptly to arouse this interest and continue it as does the placing of accident prevention on a competitive basis.

Only those accidents which result in one full day or more of lost time are counted for competitive rating purposes. All accidents, are, of course reported and studied to prevent a recurrence, but it was found necessary to base the rating only on those involving lost time, in order that there might be a standard for determining just what constituted an accident for rating purposes. If minor accidents are included in a competitive rating plan, there is always a tendency to avoid not reporting them and the fairness of the plan is thus jeopardized.

In any game of sport where the selection of the winner rests upon a score, the contestants themselves must understand and believe in the rating scheme or it will fail. In the establishment of rules governing a

contest no special consideration should be given one contestant over another because of hazard. The mill that knows all its hazards can promote safety through the very fact that they know the dangers well, and it does not deserve special attention on that account.

The contest should be planned on the basis of individual carefulness alone under whatever conditions may exist, and each contest should lead us to a better set of rules than those used in previous contests. There should be a central body to make these rules. Each rule should be understood by each workman in every mill, and its reasonableness be shown to them. This is the only way that we shall obtain universal cooperation in safety contests with all that this means to the contestants.

Contests have been a great help in minimizing accidents, and therefore have become an important part of the accident prevention program. Our experience has borne out the conclusion that contests are a valuable factor in securing cooperation and accomplishing in an effectual way the education of employees along accident prevention lines.

Discussion Following Mr. Voss' Paper

CHAIRMAN GIBSON: Now, gentlemen, we will throw this paper open for discussion before we go on to the next subject.

E. A. ARTHUR (Elyria, Ohio): How do you determine the department that wins the honor, when some departments having 50 people are more dangerous than other departments in which there are 100 or more? For instance, a punch press department with 50 people is more dangerous than an assembly room.

CHAIRMAN GIBSON: Mr. Voss' contention is (and we will get more discussion on this subject) that he does not believe in giving one department an advantage over another. The people in the punch press department are familiar with their hazards and know just what to look for and how to guard against these hazards; consequently the condition there should be no worse than in the other departments.

P. G. WOODWARD (The Viscose Company, Marcus Hook, Pa.): We have in our plant probably 4,500 employees. The engineering department has about 600. The mill proper, the operating part, does entire routine work and in that routine work everything can be well guarded, but the engineering department is here, there and everywhere on maintenance work and there is that discussion between the two groups. In my work with the engineering men, they have always complained, saying, "Well, the engineers have more dangerous work to do," and the only way out of that that I have found is to compare last year's record in each department with the record of the present year and then use as your measure a percentage reduction over the last year.

A. T. MOREY (Commonwealth Steel Company, Granite City, Ill.) I think Mr. Voss is right when he says that all accidents are avoidable. How can we set a handicap and say, "Now, this department can have so many accidents, or such and such a condition will even it up?" It seems to me that if we hang up the positive condition, the ideal condition, the department which has the fewer hazards would find that to them an accident

would be very discreditable, and in one that has the greatest number of hazards, the performance without accidents would be all the more creditable. I don't see how we can hang up the thought that some accidents are excusable, to even up the rating. We have to put the standard at 100 per cent.

MR. MCKENNEY: I quite agree with Mr. Voss. My brother over here talked about a punch press department. How would he compare it with laborers in the yards?

Every Department Should Be Placed on an Even Basis

Several years ago, when we entered into that work, the furnace people said it wasn't fair, that they were not the most hazardous; they claimed it was the open hearth. It simply meant that the department in which the hazards were great had to organize and work all the harder against accidents. Every department should be put on an even basis with every other department, and then go to it.

CHAIRMAN GIBSON: It is certainly true that, as Mr. Voss said, the only proper way to go about it is to put all departments on an even basis, especially when running a contest.

If you want to use this competition idea to get your contest across, you certainly will have to do it fairly, put it over on an even basis because as has been pointed out, when you give one a handicap you certainly are putting the rest of them in a hole. It has been suggested that in some contests you compare the accident record with the previous record and if there is any question as to just how they are doing, this comparison will clear it up.

As Mr. McKenney said, their blast furnaces seemed the most hazardous of their occupations, but their experience has brought about a condition that has entirely reversed it, so that proves what can be done in using accident records.

MR. VOSS: May I add another word to give you an idea of just how we recently merged with another plant of 7,500 men and found the railroad department in this new plant was at the bottom of the list? The superintendent thought his department was very hazardous. I know a plant that employs 3,500 men, quite a few of whom work on the locomotives, and they have gone a year without an accident.

It just goes to show, men, that you can improve the records of these departments.

CHAIRMAN GIBSON: We don't want to take too much time on one paper, but before we go on to the next subject, Mr. Morey of the Commonwealth Steel Company is here and I wonder if he has anything special to say to us.

MR. MOREY: I am delighted with Mr. Voss' paper. It holds up a wonderful standard. We couldn't have taken that standard several years ago, and I think we who came here from St. Louis are well paid by that paper alone. You have a good program and I am sure you haven't time for anything else I might say.

CHAIRMAN GIBSON: We will go on to the next subject, which is "Posters." This will be presented by Mr. Quesnel.

POSTERS

E. G. Quesnel, Safety Engineer, Commonwealth Steel Co.,
Granite City, Ill.

I am afraid I fell down as chairman of the program committee because I couldn't find any one to talk posters, so I had to be the victim myself. I hope you will excuse me if I don't make any speech; I didn't put myself down for a speech but for a discussion.

Bulletin boards, of course we all agree, must be placed so as to display posters best; they must be accessible, well lighted, and they must be kept clean and changed often; and, lastly, don't put too much material on your bulletin boards. That is a fault that I find is very prevalent; the boards have too much on them so that the value of any one display is lost.

Bulletins, posters, have got a very great part to play in accident prevention work. The eye, as we all realize, is an educator, and as our posters reflect our ideas, what a man can see and read without effort measures our success. When we stop to think that ideas have power, we must picture those ideas in such a way that they will convey the true thought to the men as accurately as possible. How to do that, we know by looking at periodicals that are gotten out by the publishers; they are displaying that to a wonderful extent. You take the Saturday Evening Post or any of our national magazines or advertisers and you will notice how they play up an idea, and it must be worth while because they are spending thousands of dollars on one issue.

So in the safety work in our plant we should capitalize on that one thought, presenting an idea as briefly as we can, covering some new development that will go a long way in backing up your other safety work as you go along.

Now these posters that I have here are going to constitute the talk I have to make, and I want to say before I start that they have not been selected by any bulletin committee or poster committee; they are not here because they are thought to be 100 per cent. They are the regular run of posters and they have been used in the plant. They are not prepared for this Congress, but they were prepared to put an idea across. Now whether or not in your estimation they do I want to leave to you.

There are four distinctive types of posters: one an inspirational type which gets over some thought, some general idea; the second is a practical type, one which will show some mechanical or material device or method that you wish to impress on those who see it; the third is an amusing type of poster, the kind that aims to put over neither an inspirational nor a practical idea, but something that will appeal to the men from an amusing side; the fourth is an unusual type, something that the men do not expect to see, something that may be entirely foreign to their business, so that they will stop to look at it out of curiosity to see what it is; in this type you have your thought woven into it so that they may get it.

For instance, the first poster is an inspirational bulletin. It appeals to the new men and to the old. In it the old employees in the shop are shown welcoming the new men. This poster was taken out of an Eliot service bulletin. It reads, "Don't wait for an invitation to say 'hello' to the new man. Get acquainted with him now. Make him feel at home on the job." This is purely an inspirational poster; it has two purposes. One is to bring to the attention of the old employees the new employees, and the other is to let the new men know that we are thinking of them and that we have asked the older men to be their friends.

In this next poster there is just one thought expressed, but it is a new thought. "The year 1926. The light of experience shows that accidents are generally the result of unsafe practices." This thought was revealed during 1926; that brings it up to date.

Here is another of the inspirational type, about sowing the seeds whose fruits are success, prosperity and happiness. Now that will appeal to certain men while others will pass it by.

The Men Will Look at the Picture

Here is one that, while it has an inspirational idea in it, is on the border line. "Stop carelessness, look carefully, listen attentively." The photograph of the entrance to the plant, at the bottom, gives it the personal touch. The men may not be attracted to this sign, but they will look at the picture because it is a very good photograph of the gates and, once stopping, they unconsciously absorb the safety thought above it.

The contrast in the coloring of this picture is one of the features of this poster, something unusual. Here is one of the inspirational type again. "Never start anything you can't finish safely." "Start everything right, work carefully and you will finish safely." You will notice now the difference in colors in all these posters; we never put up two bulletins of the same color following each other; there is always a change.

There is another service poster that has been elaborated upon: "Every man his own safety manager." I think we had at our first meeting of the Metals Section a subject which covered that. I think every superintendent is a safety director. Now this is appealing to the men that they are their own safety managers. "You alone can act so as to prevent accidents. Think before acting."

Here is another of the inspirational type. It shows action. We try to impress on the men the fact that it is necessary to do something, not only talk about it; so this is a poster to inspire them in that, to show them the way to accomplish our goal of no accidents: to get busy and actually do it. "Think, act and win."

This poster borders between industrial and public safety but it brings out the personal responsibility of the men. It is a National Safety Council poster. "Make safety your responsibility." We got a great deal of complimentary remarks about that.

In this poster is used the hand signal which all of us know but which some of us don't heed. "Stop the little accidents and there won't be

any big ones." I think we have all proved that that is the case. Traced back, we find that the majority of our accidents have been caused by little things and not some great failure. The secret of success of posters of this kind is that they must be displayed attractively and not too long; they should be taken down after they have been up for a week, sometimes less.

Now we go from the inspirational to the practical type of posters. In this one is something that the men can visualize very cheerfully as something in the shop. It is a simple type of lock that we use in the shop in the locker-rooms. Security. "Use it, it protects, you can't go wrong when you lock your locker." This lock is used on all the men's lockers where they lock their clothes. It is not used on their machinery. It's a Yale lock that has only one key. This lock is closer to most men because they use it; that is the reason why we display this rather than the safety lock. Only the engineers, the mechanics and electricians have to do with the safety lock but every employee has this lock, so in order to get it over we used this emblem to suggest the thought.

A Picture That Illustrates Good Housekeeping

This is another practical poster, on good housekeeping. It shows a photograph of material that most men say can't be piled in order and neatly. That is the first answer. We have so many little things we can't keep them piled up right, is another answer, especially when they are out in the yard where someone is always tearing the pile to pieces. This shows that piling orderly and neatly can be done. It is the stock pile where all the various sizes of material are piled neatly; in the background there are railroad trucks which reflect our own business. The men can see that this is their own plant; they can't say, "Well, that picture was taken somewhere else, we couldn't do that here." But you can see in this picture there is a steel plant involved in it.

In this poster there is a combination of engineering thought expressed in a simple, practical way—the safe pile. The thought was to bring out that the pile should be vertical or slope inward as it goes up; it shouldn't have an overhang. We tried to bring that out. Here is a pile, a safe-line piling. It inclines gradually upward—a safe line to pile to. Here is one leaning outward, the unsafe way, the overhang. Lots of times you can convey in a picture what you couldn't tell the men otherwise, especially the yard labor men who are piling.

Now we are getting into the electrical hazards. We had quite a discussion on that yesterday. "2300 Volts. Keep away from electric wires." This type of sign is used in our plant on all our high tension lines. "2300 Volt Wire." The same wording, the same proportions, and hung the same way, so that a man will recognize the sign he sees here in the shop, or if he goes down to the foundry, the same thing is seen no matter where he is in the plant, the same sign hanging on the walls. We are just speeding the educational thought along; it represents a practical idea.

This one is on goggles, an extremely important subject which has to be played up in a very great many ways. "Wear your goggles."

We just happened to find a picture of a man wearing goggles and framed it. It shows a very good fit. "Wear your goggles." it reads. "the safest thing to do." They don't look uncomfortable, you will notice, or cumbersome. When the men see goggles fitting properly it overcomes some prejudice.

Again we have the subject of right piling in this poster. The picture shows the overhanging in one pile and the correct line in another pile. "It is much easier to pile right and it is safer." We found that out several times in our plant; we put several of the larger flasks on the bottom and then when we had to get them we had to tear the pile to pieces. We keep them separate now, so when we want a large or small size we can get it without creating a disorderly condition.

A Goggle Picture with Its Important Lesson

In this poster we see something that I think we all use. There is a set of tools. "Keep the burrs off your tools." Wherever an instructive poster is brought up, wherever it is necessary to show the wrong way, it is absolutely necessary to show the right way; otherwise you have lost your opportunity and you may cause more harm than good because some men will not read the title and will only look at the picture and thereby carry away the wrong impression.

Here is one that shows how to guard against the ladder problem. A ladder shouldn't be left out unused; if it is in use it should be equipped for safety; it should have a safety sign on it to indicate that men are working above.

This is another goggle poster. It is a National Safety Council poster which has been elaborated on a little. "Eyes—take care of them; they belong to you." I think I heard that same expression here yesterday. "Your eyes belong to you; your feet belong to you," and so on. The thought seems to be pretty universal.

This one is another electrical poster, showing a large electric light bulb. These posters are not put up haphazardly just when an idea comes along. They are put up when the idea is suggested by something in the plant that we may be talking about so that it comes in its proper place at the proper time when it has the most weight and does the most good. I remember when this was put up. We were having a lot of trouble with the electric lights being broken and some of them were broken because the wrong kind of light was put in. We went into it very thoroughly and this poster came out during the time we were making the investigation.

It says: "Please do not borrow bulbs from nearby sockets; you will leave these places without enough light. Some one may stumble and an accident will result before a bulb can be replaced. If you need a lamp, get it from your store foreman or at the stockroom."

This poster was made up principally because it is a very good picture of an eye. It would be necessary for a man to get up to this poster very close in order to read it, but even if he doesn't read it all, the fact that the eye was brought out in such a splendid way would cause him to think of it automatically. "A good eye is worth a lot. As a

boy, were you a member of the knothole gang? Now, as a man and working, your eyes are even more valuable to you. Protect them." I think that was sent out by one of the optical people.

Now we are coming to the amusing type. If we put up the handle of a pick and say, "Don't use this, it's cracked," it is not nearly so effective as when we draw a picture of it and put three little fellows sitting on the end of it, discussing it. "See that crack? Get a new handle at once." The amusing part is injected by these three little men sitting on the end of the pick-handle; they say, "That is right, fellows." A fellow is attracted to the board by the pictures and he reads the message.

This one shows men sitting down almost anywhere to eat their lunch or while waiting for material; they are likely to sit on scaffolding which is not built for a seat. "Get off, buddy, a spring seat isn't always a safe seat."

Putting the Safety Thought in an Amusing Way

The idea in this one is the same, that of putting over a thought in an amusing way. "Should you see a broken board, report it at once." Here are the same three fellows, one of whom is this time going to the carpenter shop and the other doing what most of us do sometimes, saying it is too bad, it ought to be fixed, but doing nothing about it. But this one little fellow is hurrying to the carpenter shop to see that it gets fixed.

In this one is something very familiar to us all, that of a man carrying a long bar on his shoulder. He is likely to turn around very quickly with the result that the fellow in back of him is likely to be struck. What is the idea? "Think of the other fellow, too." There are the same three little fellows who are this time saying, "No place for us. Hey, look out!" "Only carry boards on your shoulder when there is a man carrying the other end. Safety pays." We got quite a lot of comment on that poster.

This one reads, "I will tell the world that it pays to work safely. Steady income; no time lost through accident." It is a kind of inspirational funny poster.

The last one of the amusing type is about something that is done every day in most shops. The men will throw themselves off their balance in order to pry something or pull down on a wrench. The result is that the wrench slips and they fall, skinning themselves or doing more serious injury. Here are the three little fellows again, down here, looking at the fellow who is hanging on to the handle of the big wrench; they are asking, "Is this a crime?" There was a big reaction to this one in the shop.

In this one we find something that can be used in any business, not in the steel business particularly because it doesn't apply to steel. It is a flower, the state flower of Oklahoma, the mistletoe. We may have some men in our plant from Oklahoma and I suppose if I asked you gentlemen right now what is the state flower of your state the majority of you could not tell me. But if you see a picture of it, you may stop and say, "Well, hello, I didn't know that. I will remember it." It is something on the

bulletin board that the men don't expect to see; when they see it they will say, "What in the world are they putting a flower on our bulletin board for? What has that got to do with steel?" So if we put that question in their minds they will go to the bulletin board and read the message, "Be ready to help and guard and protect others."

This is another state flower, that of California, the golden poppy. "Always be ready to help, guard and protect others."

Here is the state flower of Maine, the white pine cone. "Care and right thinking develop safety habits."

This is the state flower of Utah, called the Sego lily. "It is up to us. We must drive now. The old team won't take us home any more."

The last one in this series is the state flower of Illinois, Wisconsin and Rhode Island, the violet. "Safety is an integral part of the operation of the plant." There is, of course, a more complete series of these, one for each state, and you can use in the same way the birthstones, for every one is interested in his birthday. It is an unusual thought that you can't use all the time; it must be used very sparingly. But once in a while you can use it to get over ideas in a poster that you can't get over in any other way.

As I said at the start, these posters were not picked for their merit, but they are the regular run of posters. There are 30 or 40 more of them up here which you may look over after the meeting to see how we adapt other ideas to safety work.

The Poster Idea Should be Constructive

CHAIRMAN GIBSON: Now are there any questions to ask Mr. Quesnel? There is one type of poster that didn't appear and I should like to know your reaction to that poster, the kind that appeals to fear.

MR. MCKENNEY: Well, you won't find them in the Commonwealth Steel Company.

CHAIRMAN GIBSON: If you had heard our first speaker at our opening session, you would understand what Mr. McKenney means.

MR. QUESNEL: Of course, we don't approve of putting anything into the minds of our men that we don't think is constructive and that we don't want them to have. We believe that we will progress more rapidly and be of more service to a man if we tell him the right and orderly way to do his work rather than tell him of the unsafe way to do it. The only time we will display an unsafe condition is when it is accompanied by the right and orderly condition so a man can see why the thing is wrong. In other words, we are replacing fear with confidence and the right way to do things.

CHAIRMAN GIBSON: Now I think we should pass on to our next paper which is on "Committees," to be presented by Mr. G. M. Clearwater.

I understand, though, Mr. Clearwater is not here so I have asked Mr. Jacob W. Benner, Safety Director of the Homestead Steel Works Carnegie Steel Company, to give us a short talk on this particular subject of "Committees."

COMMITTEES

**Jacob W. Benner, Safety Director, Homestead Steel Works,
Carnegie Steel Co., Munhall, Pa.**

Mr. Chairman, Members of the Metals Section: This was sprung on me when I came down to get my breakfast. If some of it is more or less disjointed you will know it was on account of my not having had time to prepare anything.

The subject of safety committees is the backbone of safety work. The only way I can talk about this is to tell you what we do at our own plant, which is the Homestead Steel Works of the Carnegie Steel Company.

We employ practically 14,000 men. It is a large plant, scattered over practically 160 acres with 25 different departments. The way we are organized for safety there, we have a general safety committee consisting of the superintendent of employment, safety and welfare, who has the position of chairman; the secretary is our safety inspector. The other members of the committee consist of three department superintendents and our works surgeon. This committee's duty is to review all activities of the other safety committees, also to conduct personal investigations of all serious accidents and faults and make definite recommendations.

Our work on the general safety committee is reviewed by the general superintendent of the plant. We meet at a definite time and place; we take no vacations. We have 12 meetings a year, regularly scheduled, with a lot of extra meetings in between, I am sorry to state.

Each department has at least one committee of which the department superintendent is chairman, or the assistant superintendent. The fixed membership of the committees of each department are the foreman in the department (for instance, the mechanical foreman, the electrical millwrights) and another foreman in that department; in addition to that we bring in the men from the rank and file, the cranemen, laborers, stokers, rollers, heaters—men from every branch. Some of those committees, depending more or less on the size of the department, run anywhere from six to 36 men. They meet once a month at a fixed time and place and the men are compelled to attend, on the company's time.

Some of the departments have gone further than this. They have split up their departments into smaller committees and yet they have one large committee to represent them.

We have a definite program to be carried along at each meeting: reading the minutes of the previous meeting, new and old business, discussion of accidents. In addition to that we go around to each member and ask him if he has anything to suggest on safety. At every meeting we ask the men to feel free and frank in their suggestions or remarks irrespective of whom it hits, whether it hits the company, the foreman or his brother employee. We have our men educated on that point so that they are free and frank in their remarks.

Last year we had over 300—pretty close to 400—safety meetings.

One of the duties of the member of the general safety committee is that he must attend whenever the committee meets, and must attend the mill or branch mill safety committee meetings.

That is a general outline of the Homestead Steel Works plan, which is practically the same scheme used throughout the different plants of the Carnegie Steel Company of New York and, I believe, also of the subsidiary companies.

CHAIRMAN GIBSON: Before we throw this subject open for discussion, I am going to call on Mr. N. V. B. Ziegler, of the United States Aluminum Company, of New Kensington, who will talk to us on the same subject.

MR. ZIEGLER: Mr. Benner took my excuse away, and so I won't make any except to say, what Mr. Benner said in his remarks at the outset applies to me.

The chairman has asked me to tell something about the history of our safety work, of the safety committees in particular. Our plant is not so large as those of the steel companies. We have about 3,500 in all.

Too Many Committees May Be the Trouble

At first, some years ago, we had a safety committee in each department with a safety director over all and these committees met regularly, but somehow or other the safety director sort of dominated those committees and the men did not seem to be getting anywhere. Then we decided to get all these department committee men to merge into one with the safety director leading all, and we got a little further because in union there is strength. However, we still didn't seem to be getting anywhere and so we decided to organize this big committee, composed of all of the small ones, and then select a chairman, elect him in the general way, and this group now meets once a month. All the committees in the various departments meet now at the same time with one of their own number as chairman of this meeting and, of course, as Mr. Benner says, we ask the men to be very free and frank in their remarks on safety measures.

Since we have organized in this way, we have found that the safety work has gone forward much more satisfactorily than it has ever gone before and we are very much pleased. How long it can be kept up, I don't know. Some one this morning made the remark that we should always get something new along the line of safety and perhaps next year we shall have something new, but for the time being we are satisfied with this improvement. Our accidents haven't entirely disappeared, I am sorry to say, but they are decreasing in an encouraging manner.

We have this year put on a very extensive campaign. The safety director and myself go into every department and when the whistle blows at noon for the men to stop their work, we take certain sections of them and get them into a corner and talk safety to them. We don't lecture to them, we only ask them for their help. Our talks don't last over 20 minutes and the principal thought that we tried to get across this year was personal responsibility.

We tell those men that we want them to feel and know that it isn't enough to have a safety director, it is not enough to have a superintendent and a manager who are interested in safety, it is not enough to have safety committees appointed, but something else has to be done and that something is the personal interest of every man and woman. We

have been trying to drive this home to our people all this year, all through the summer, and we are still at it. On this subject of personal responsibility, we tell them we want every one of them to feel they are assistant safety directors, and we tell them that if they are, they will be able to conduct themselves safely through the plant and they will be doing something along the line of being their brother's keeper. We have found that this is getting results.

H. B. BENJAMIN (Haynes Stellite Co., Kokomo, Ind.): You mentioned that you took suggestions from the men in the ranks, and I should like to ask (although you don't find very many cases of it now) if you have any trouble with the foreman making life miserable for the man who happens to have made a suggestion about a hazard that he has overlooked.

MR. ZIEGLER: No, I am glad to say, Mr. Chairman and gentlemen, that we are beyond that now.

MR. BENNER: I think those days are past. I suppose there are some companies just starting in who may experience that, but I don't think it happens with many who are engaged in safety work.

CHAIRMAN GIBSON: The next subject is "Rule Books," and will be presented by Mr. J. M. Woltz.

RULE BOOKS

James M. Woltz, Safety Director, Youngstown Sheet & Tube Co.,
Youngstown, Ohio.

The company I am associated with, The Youngstown Sheet & Tube Company, has had a rule book for many years. Before I was associated with them the rule book had undergone two revisions, and the fifth revision is now on the press and will shortly be ready to issue. The first edition had 44 pages, the fourth 111 pages and the fifth has a number of additional pages.

Rule books are of many different kinds and evidently intended to accomplish various purposes. Some are combined rule books and specification schedules. Some are beautifully bound and lavishly illustrated. Some are printed in foreign languages, as well as English. Others contain the rules of all the operating departments under one cover, as well as information on correlated non-operating departments. Still others have only the general rules and specific rules for each department printed together in books. Some of these rule books are made to be observed, but some appear to have been printed more to say that the company has such a thing as a rule book than for any other reason.

It is no easy task to make up a new rule book or revamp an old one. Our new book has been about a year in the making. First we took each department's rules and sent them to the head of that department with a letter saying it was the intention of the central safety committee to revise the rules. The superintendent was asked to take the rules affecting his operations and at a meeting of his foreman go over each one, make such changes and additions as was thought necessary,

and return these to the central safety committee. Any rule that it was impossible to enforce was to be eliminated. Rules covering new operations or process were to be submitted. All specifications were to be entirely eliminated from the rules.

When a set of departmental rules was ready, the department superintendent, and such others as he might care to bring in, were asked to sit in with the central safety committee, while his rules were discussed. Each person had a copy of the proposed rules and the old rule book. Rule by rule these were taken up, discussed from every angle, not only operation, but from the medical, electrical, mechanical and safety points. It was frequently found that it would take an hour or more to decide upon one rule. Sometimes they were referred back to the department for further consideration. Sometimes a sub-committee of the central safety committee was given a problem to work out.

Rules Must Be Adapted to the Individual Plant

At times, it was found that where a rule was necessary or satisfactory at one plant, it could not be used or was not applicable at another. Old installations required certain methods and precautions that the later designs and installations made entirely obsolete.

After all departments had been given a hearing before the central safety committee, the results of the conferences were written up and the rules again submitted to department heads, asking that they go over them carefully to see that there had been no errors, that the obsolete rules had been eliminated and all the needed new rules added. When these were returned to the central safety committee they were gone over and the changes considered and the final approval given for printing.

All this requires an immense amount of correspondence and typing, as well as reading and checking. Even with these precautions an occasional error creeps in.

Now that we have a rule book, of what use is it?

It has been our custom to have these books distributed by the foreman to the new employee as he comes on the job. The foreman reads the rules of his own department and such other rules as may be applicable to the new man, and then tears out a form on the back page of the rule book, fills it in and sends it to the safety department. The top part of this sheet is a receipt to be signed by the man to whom the book is given. The safety department keeps these slips on file and we have been able to produce them when employees were called on the carpet for infractions of the rules, who claimed they had never been given a copy.

If an accident or near accident has been caused by a failure to observe a rule, this is brought out in the investigation and then the man at fault has a chance to make his explanation. Disciplinary action can follow as the case warrants. Do we actually discipline employees for failure to follow the rules? We do. This is left up to the department head. The investigator gives him the facts developed while checking up on the accident, and the department head can then go into it as deeply as the condition warrants. The central safety committee

acts as a check to see that this is done and the action taken is read in its sessions, which are held every Tuesday morning.

If a rule is impracticable or non-enforceable, cut it out of your rules.

I do not advocate anyone having a rule book. We have one and our executives are convinced of its utility. As a safety department, we feel the rule book is a real help to us in our work. Department heads make their own rules and say they want them. The foremen are not all convinced it is a good thing, but the employees generally have a very wholesome respect for it.

Of course, you must bear in mind that I am talking of a company with at least 16 years' experience with a rule book.

Manifestly, you can not go into a plant that has never had a book of rules, write one, hand it around and expect things to move smoothly under it. It is a matter of years, careful study and experimentation, education and enforcement.

Freeing Men's Minds of Outside Worries

C. A. ORTH (American Car & Foundry Company, New York City): The speaker has given us a very fruitful theory on the causes of our accidents, but he has not given us anything on how to free the men's minds properly to prevent distraction.

We must have something practical. We have in our employ about 30,000 or 40,000 men and for 15 years we have had some very bad accidents due to the cause cited by Mr. Woltz.

MR. WOLTZ: I don't think I could answer that in any better way than to say if you have a personnel department that would be part of their work. We have to educate those men to think properly and, to my way of thinking, that is their job.

There are two books published on that subject, one of which came out just recently; Boyd Fisher's "The Mental Causes of Accidents;" and Professor Swift (from your town, I believe, Mr. Morey) has written a book on "Psychology and the Day's Work." There is enough material in those books, if you will get them, to last you for years. Every man engaged in safety work should read them.

MR. BENNETT: I should like to say to the gentleman who wanted to know how he could tell if a man has outside troubles, that if a man has been working for any length of time, his foreman should be able to tell practically from looking at that man whether there is anything wrong with him.

I know from my own experience with those with whom I associate from day to day, I can tell whether a man is up to snuff and able to do his work. The whole sum and substance of the question is in the hands of the foreman.

JOHN M. GULL (National Tube Company, Loraine, Ohio): We have at the present time about 800 mechanics, most of whom can't speak English, so we have difficulty in getting over to those men what they should know so they don't get injured. What we do to care for those men is, we send them in to the foreman. We don't expect those men to understand all

the rules, it would take a well educated man to observe all that we have in the rule book, but we send them to the foreman and he places those men on some particular job on which he sees they are fully instructed in regard to the hazards. He also places those men connected with that job on their honor to see that these men do not get hurt.

When it is necessary for them to change from that job to some other job, there is a repetition of what they went through before; the next foreman acquaints each one with the hazards connected with it. He is fully instructed on every new phase. In that way, passing from one job to another, on each of which he has been well instructed, he gradually gets to know what our rule book contains although he may work there years without being able actually to read it.

MR. SANKEY: All those who were here at the opening session heard the talk by the Commonwealth Steel Company's president. Every safety man must use psychology and do unto others as he would have them do unto him. There are few problems greater than the employees who can't speak English, so it is your duty to see that they know the safety rules. Don't say, just because he is a Mexican, that he can't be helped. Teach him all you can about safety; take the attitude that you are your brother's keeper; that you are just as much interested in his welfare as you are of the English speaking employee.

Gentlemen, don't give their inability to speak English as an excuse for your not protecting them against injury.

H. M. CROGHAN (Inland Steel Company, East Chicago, Ind.): I wonder if any one here has a copy of one of these rule books?

MR. WOLTZ: They are sometimes in pamphlet form; here is one from the open hearth department.

MR. CROGHAN: As a point of information, are those given out by the employment office?

EDWARD A. YELLIS (Bethlehem Steel Company, Bethlehem, Pa.): They are not given out by the employment department; they are distributed to the men by the foremen.

CHAIRMAN GIBSON: Now, gentlemen, we have two more topics on this educational forum. The next topic is "Letters to Foremen," which will be presented to us by Mr. Frank H. Rowe, of the Wheeling Steel Corporation, Portsmouth, Ohio.

LETTERS TO FOREMEN

**Frank H. Rowe, Safety Director, Wheeling Steel Corporation,
Portsmouth Works, Ohio.**

Letters to Foremen can be conveniently grouped under four general classifications, namely—

1. Letters of Praise; 2. Letters of Criticism; 3. Letters of Information; 4. Letters of General Interest.

Each type will require a different tone and method. What would be good for a letter of one type will not be of value in a letter of another.

Letter writing should play as great a part in the activities of the well

organized safety department as any of the other well defined methods of obtaining the cooperation of the supervising force in safety measures. A well written letter on a timely subject in the hands of a foreman will sometimes accomplish what a day of talking fails to do. At the time he reads it he is usually in his office or at his desk and is wholly or partially relaxed, making him, to a certain extent, more inclined to fall in with your suggestions or criticisms. If you had paid him a personal visit or hailed him while out in his department, the chances are that he would have had his mind occupied on his work. He would no doubt greet you pleasantly and listen patiently to your suggestions and remarks but his mind would be far away from the subject in hand.

However, letter writing has its hazards as well as any other form of publicity, and because one letter goes well is no excuse for breaking loose with another immediately. A personal visit the second time would possibly be better. To choose the lesser of two evils, we would say that one letter less is better than one too many, especially to a foreman.

I will take up each classification in the order I have named and read some letters which I believe appeal to foremen and have a good effect in obtaining and holding their cooperation in safety work.

Letters of Praise to Foremen Have Their Value

In letters of praise to foremen we must be careful not to over step the purpose we have in mind. We want to convey the impression that we appreciate the fact that he has made a good safety record, and that this is due to cooperation in trying to prevent accidents. By going too far with letters of this type we can easily make their value very small. An occasional letter of praise to a foreman will have a tendency to hold his interest and get his cooperation in safety measures. I have found this the best and only way to deal with some foremen who appeared on the surface to be hard-boiled and impossible to approach from any other angle. A sample of a good letter of praise, in our estimation, is the following which the writer addressed to the foremen of the different service departments at our Portsmouth Works:

We have another system used by our safety committees at their weekly safety meetings. - We ask each safety committee member to report the number of men he has talked to during the past week concerning safety. Picking up a copy of our mechanical department safety minutes I found that the members of the mechanical department safety committee had talked to a total of 187 employees during the past week concerning "Safety." I took advantage of this opportunity and addressed the following letter to their superintendent:

I believe that the safety director who neglects to write letters of praise to his foremen is passing up a valuable opportunity to obtain the foreman's cooperation in safety work. It does not necessarily follow that because you write a letter of praise to a foreman he will always be a 100 per cent safety man with a 100 per cent safety record; but it does mean that you can go out into his shop or department and ask him to do a job and he will do it without arguing all day about it. This type of

letter should be written whenever an exceptionally good accident prevention record has been made and when a very hazardous repair maintenance job has been completed safely.

The second class of letters to foremen are letters of criticism. This class requires a different tone. The first thing in a letter of criticism is to be sure that you have correct information when an unsafe practice has been reported to your office, before you attempt to criticize the foreman for any such action. It is sometimes necessary to hold in abeyance reports of this nature until you obtain further reports of the same nature. By doing so you will make your case stronger and be better able to obtain your point. For instance a letter such as the following was written to a foreman concerning an unsafe practice which resulted in the loss of a man's eye:

A Critical Letter That Produced Results

Another critical letter to a foreman came about due to the fact that in checking up the accidents occurring at certain machines we found that the employees on two machines were having 100 per cent more lost time accidents than the employees on two other machines. These machines were in different departments. We believed the cause to be a lack of interest on the part of the gang foreman and consequently we wrote the following letter:

Since that time the foreman has been on the job and only one lost time accident has occurred. Another letter on unsafe practices is as follows:

This man is now wearing leggings and has continued to do so since that time. Another important thing with letters of this nature is for the foreman to understand that they are not forgotten. A copy of every letter of this kind is sent to the employment office and filed with the employee's card. Two complaints of this nature are sufficient to cause his dismissal from the company's employ. Of course, not all unsafe practices are handled by letter. By far the majority are taken care of by seeing the men personally, and in practically all cases the man admits his mistake and agrees not to do it again.

Another very important thing in letters of this type is to follow them up by a personal visit and a talk on the subject written about.

Under the head of letters of information to foremen we believe it is a well established fact that the head of each department should be kept informed of the accident record of his particular department. Without this information placed in his hands each month he can have little interest in safety work. It is an established rule in the safety game to issue each month accident statistics to the various department heads in the form of an accident frequency and severity report. In addition to this monthly report the writer sends out a personal report to each department head giving him as complete an analysis of accidents as time and personnel will permit. In addition to this, we take an opportunity to place in this letter a paragraph appealing to their departmental pride to make a better record. A sample of such letter is as follows:

By issuing letters of this nature the bond of cooperation between the

safety department and the operating departments is strengthened; I believe it serves to keep different foremen on their toes in order to make a better record and a better showing. Another suggestion regarding this type of letter was given the writer by a department head one day. When this particular department head receives communications from the safety department covering his entire department he has each subforeman read the letter and sign his name at the bottom of it, showing that he has read it and understands the instructions.

The last class of letters to foremen are those of general interest. Such letters will also frequently be sent out to safety committeemen and employee representatives. In fact this entire classification of letters could be grouped under the head of mimeographed letters or bulletins to all gang foremen in the plant. Sometimes the members of the various safety committees are taken in this classification. These letters include varying subjects all the way from letters written by the management at our central office concerning a serious accident to mimeographed instructions regarding safety rules.

Letters Can Be the Channel of Important Information

Our purposes in using this method of propaganda are (first) to keep the foremen informed of the records of other companies; (second) to maintain their interest in safety work; and still another purpose which is in our estimation most important, is to maintain a connection between the man who must prevent the accidents and the safety department. In other words it is a channel of communication between the front line trenches and headquarters. To show the diversity of subjects covered by this class here are a few subjects covered by these letters.

Derailers and their use—Rules pertaining to same.

Foreman's safety bulletins regarding a near accident.

Foreman's safety bulletins regarding instructions to new men and information to use in instructing new men.

Letters regarding fatal accidents occurring in one of our subsidiary plants.

A mimeographed talk entitled "THINK" by Mr. J. W. Schwartz, a foreman of the American Steel and Wire Company. This was mimeographed and sent to each gang foreman in the plant.

An article on the foreman's responsibility in safety.

An article from a power magazine entitled "They Took A Chance."

Someone was kind enough to send us a copy of a newspaper containing an account of the wonderful safety record of the Gary Works, Illinois Steel Company. We had it mimeographed and sent to all gang foremen.

Copy of a letter on accidents written by the chairman of the Board of Directors of the Wheeling Steel Corporation.

Bulletins for members of the safety committees. These bulletins were also mailed to each foreman and superintendent. This bulletin was issued in answer to a safety committeeman's query one day, as to whether or not it was worth while to attend safety meetings.

Information made up and given to each foreman to be used as material from which to make a talk to his employees and fellow workmen, just previous to a safety campaign.

Letters written to newly elected employee representatives under the representative plan in force at our plant.

LETTER I

Monthly Comparative Report of the Wheeling Steel Corporation

Gentlemen:—

No doubt you have noticed the report mailed to you which shows the standing of the various Service Departments of the Wheel Steel Corporation. Perhaps you have noticed that the first four departments listed are the Mechanical Department, Electrical Department, Brick Masons and Yard, Switching and Labor Departments of the Portsmouth Works, and all of them have a 100 per cent safety record for the month of March. A total of 1246 full time employees worked 31 days without losing a single day on account of accidents. This is the first time that these four departments have all been in the 100 per cent class during the same month. It is a record that each superintendent concerned and his foremen can be proud of. It is a record that no amount of luck can ever achieve. These things do not happen but are caused by the interest taken in safety work by the superintendents and their foremen.

The record made by these departments so far this year has been the means of putting the Portsmouth Plant in first place among all the plants of the Wheeling Steel Corporation, both large and small, for the first three months of 1926. Had certain other departments in the mill diminished their accidents in proportion to the reduction of these departments, our lost time on account of accidents would be what we would term the irreducible minimum.

You no doubt recollect that the writer made several comments in his yearly report about the various Service Departments being in last place with respect to the number of serious and fatal accidents for the past four years. It is certainly gratifying to the management to note that these same departments are setting the pace for all other departments of the mill for a good safety record during 1926.

During the first three months of this year production has been at the highest peak, which naturally tends to produce more accidents in the plant. While certain operating hazards in our Operating Departments are always present and are of a more or less serious character, the fact still remains, however, that the work done by the Major Service Departments listed in this letter constitutes the most serious hazards of the entire plant. We would like to call your attention to the fact that serious accidents are more apt to occur during the months of April, May, June and July. Just why this is we are unable to say, but the records and experience of other companies follow closely along the lines of our own personal experiences.

We are, therefore, asking you to get your foremen together and show them what they have accomplished during the first three months of this

year; also impress upon them the absolute necessity of being with their men as much as possible during the important repair jobs. Impress upon your foremen the importance of little things which if left undone will result in difficulty and trouble and possibly accidents if they are not taken care of. Discipline must be maintained among the men, but in the end discipline alone will not maintain a good safety record, nor will it make a good production record; yet a certain amount of discipline must be maintained and meted out occasionally to violators of safety and operating rules, in order to show that the management is 100 per cent for "Safety." The real foreman will lead his men into safe practice and habits. He will educate them along lines of cleanliness, efficiency and production.

We believe that by your continued cooperation and the cooperation of your foremen you will be able to bridge over the apparently hazardous period mentioned. Having accomplished this feat the satisfaction is knowing that you have prevented a serious or fatal accident to some one of your employees through your combined efforts will certainly be reward commensurate with your efforts.

I want to mention just one other fact in this letter and that is that because of the use of goggles we have been able to save the eyes of six of our employees in the past five months. One of our state inspectors who inspected the plant recently paid us the compliment of saying that he had never seen a place where the men wear their goggles as well as they do here. These two items show that the foremen are cooperating and are leading their men into safe practices.

Yours respectfully,

LETTER II

Safety Committee Activities

Dear Sir:

In looking over your minutes of the Mechanical Department Safety Committee for the week of April 17th, I notice on the bottom of both the Day and Night Committee reports that the various committeemen of your department talked to a total of one hundred and eighty-seven employees during the past week concerning Safety. This is a mighty fine report to be handed in at our safety committee meetings, and we are sure this is producing results as is evidenced by the safety record of the entire plant. Will you therefore, convey in some way, to the different members of these committees, the appreciation of the management for their interest along safety lines?

Thanking you for your cooperation, I remain,

Yours respectfully,

LETTER III

Injuries to Thos. Burton, No. 2415, and Thurman Meed, No. 211

Dear Sir:—

Mr. Thomas Burton, No. 2415, had his eye injured on March 11th, due to a piece of scrap flying up and striking him when he threw a small bundle of scrap in the scrap crate. Again on March 29th, 1926, Mr. Thurman Meed, No. 2118, had his eye injured in practically the same

manner. Fortunately Mr. Meed did not receive as serious an injury as Mr. Burton did. The nature of these injuries is as follows:

Burton—Contusion of eye with total loss of the vision. The doctor states that he may be able to save 25 per cent of the vision of Mr. Burton's eye.

Meed—Small cut on outer corner of right eye; one clamp used.

Please be advised that the loss of an eye costs this company \$1875.00. This \$1875.00 will buy 2083 pairs of goggles.

In investigating Mr. Burton's accident, Mr. Burton suggested that we furnish the scrappers with goggles to prevent a recurrence of the same accident. He stated that he would be only too glad to wear them and that he thought the rest of the men would do the same if the proposition was properly put up to them and the hazards explained by the foreman. Mr. Lee, your shear room foreman, thought that this suggestion was right. I told Walter to see you before furnishing them to these men. Later you told me that you had decided not to furnish these men with goggles.

The writer is of the opinion that the scrappers behind the shears should be compelled to wear goggles. Accordingly we are asking you to furnish each of your scrappers with a pair of goggles and issue instructions that they must be worn at all times while working behind the shears.

Anticipating your cooperation in this matter, I remain,

Yours respectfully,

LETTER IV

Accidents at No. 5 and No. 6 Picklers

Dear Sir:—

I desire to call your attention to the fact that entirely too many lost time accidents are occurring in your Pickling Department, at No. 5 and No. 6 picklers. This is so noticable at this particular place because we are not having any lost time accidents at No. 3 and No. 4 picklers.

Three lost time accidents occurred in this one place from August 27th to September 14th. This we believe you will readily admit is entirely too many accidents in one place. We suggest that you get after these foremen and see that more attention is paid these men so that these accidents will not occur.

Anticipating your cooperation in this matter, I remain,

Yours respectfully,

LETTER V

Unsafe Practices

Dear Sir:—

From time to time the company has purchased leggings for the men in the Open Hearth Pit to wear when pouring steel. Some time ago Mr. Fred Wheeler, Pit Foreman, was in your office with Ely Brown when the writer was present. We were talking about the use of leggings while pouring steel and Mr. Wheeler was advised at this time to wear leggings which were furnished him by the company. Recently while in the Open Hearth Pit, I noticed Mr. Wheeler pouring a heat of steel

without having his leggings on. On this occasion I called Mr. Brown's attention to his failure to have leggings on and asked Brown if he would instruct Wheeler that he must wear these leggings. Brown said that he would.

Notwithstanding this fact, Armour Piatt caught Mr. Wheeler without his leggings on while pouring steel on the 29th and 30th of December. He asked Wheeler to wear the leggings and Wheeler told him that the leggings were a nuisance and that his pants were ample protection for him.

I understand that Mr. Wheeler is a pit foreman. One of the chief duties of a foreman is to educate his men in safe practices by cautioning and telling them the safe way in which to do their jobs and to set an example for his men to follow. Mr. Wheeler evidently does not realize the importance of his position along these lines. It is more necessary for him to wear leggings than it is for his men. Please advise Mr. Wheeler that a continued violation of this safety rule will result in his dismissal. Please refer to Mr. Geo. W. Moore's letter of recent date regarding the procedure to be followed in cases of men who refuse to obey safety instructions.

Anticipating your cooperation in this matter, I remain,

Yours respectfully,

LETTER VI

January Accident Experience

Dear Sir:—

Following is a report of your accident experience for the month of January 1924 showing the foreman, kind and number of accidents to your men occurring in the Electrical Department.

FOREMAN	A	B	C	TOTAL
Carver	1	2	---	3
Price	1	3	---	4
Terrel	3	---	---	3
Mosley	1	2	---	3
Manley	---	2	---	2
Saxby	1	1	---	2
Milt	---	1	---	1
TOTALS	7	11	---	18

Your department had no lost time accidents during January, 1923. You are now working on the fifth month without a lost time accident. Due to a mistake in the December report the Evans accident at the Rod Mill was charged to the Rod Mill but it rightfully belongs to the Electrical department. No doubt you are interested in keeping this record up. Why not try to make it for the entire year? During 1923 you had six lost time accidents and lost 186 days time on account of accidents. Can you beat this record during 1924?

Our goal for the entire plant during 1924 is "A 50 per cent reduction in lost time on account of accidents." This may seem to be a difficult goal to achieve but, like everything worth while, it takes lots of good hard work to accomplish it. Will you please call a meeting of the foremen in

your department and make plans to achieve this goal in your department? Several of our departments have started out to go through the year 1924 without a lost time accident. So far their records are perfect. Your department should also have a definite aim to work toward.

Best results are obtained in accident prevention when you outline some specific work to be done or goal to be accomplished.

Yours for Safe Operation,

LETTER VII

Monthly Accident Statement

Dear Sir:

Below you will find listed the accidents occurring in your department together with the foreman's name, kind and number of accidents:

FOREMAN	A	B	C	TOTAL
Price	1	1	—	2
Manley	1	—	—	1
Carver	1	1	—	2
Saxby	3	1	—	4
Terrel	1	—	—	1
TOTALS	7	3	0	10

Forty per cent of our lost time cases occur to men who have been in our employ one year or longer. For the past 18 months we have been keeping an accurate check on lost time accidents in order to obtain information of this kind. A man who has been working in this plant for one year should be familiar with the hazards of his job and should be less susceptible to an injury than a green man. I believe that this high percentage of accidents among experienced men shows that closer supervision on the part of the foreman is needed to bring down the rising frequency of accidents to this class of workman. Accidents occurring to this class are usually more severe and cost the company more money than accidents occurring to men under one year's service.

Forty-eight per cent of our lost time accidents have occurred within the following occupations:

Pickler Helper	Laborer	Stocker (Jobb. Mill)
Crane Followers	Machinists	Matcher (S. Mill)
Doubler (S. Mill)	Drag Up (S. Mill)	Catcher (S. Mill)
Welders		

The other fifty-two per cent of lost time cases are spread over forty-six different occupations.

Thanking you for your cooperation in Safety Work, I remain,

Yours respectfully,

E. E. ARMSTRONG (Chapman Valve Manufacturing Co., Springfield, Mo.): I should like to ask what signature is used on letters going to the plant, whether they are signed by the superintendent or the foreman?

MR. FOWE: I sign them if I consider them important enough, then there is no chance of the buck-passing that might occur if I left it to the foreman or the superintendent.

CHAIRMAN GIBSON: If there is no further discussion on this subject, Mr. Oartel will now present some lantern slides.

LATE DEVELOPMENTS IN SAFEGUARDING

John A. Oartel, Chief of Safety Bureau, Carnegie Steel Company, President Western Pennsylvania Safety Council, Pittsburgh, Pa.

(A Series of Lantern Slides Shown on the Screen)

Figure 1: Guard with magnifying glass, hand milling machine.

(Editorial note: Under the above caption Mr. Oartel displayed a striking series of pictures depicting safeguarding devices that have recently come under his observation. The number shown totaled 122.

They were accompanied by a running fire of comment, made extemporaneously, and of particular value from the fact that it called attention to features of the devices with which Mr. Oartel had personal experience.

(Due to the voluminous character of these pictures, and the fact that the discussion could only be of value in connection with any particular

Figure 2: Fire protection hood, sheet metal annealing machine.

picture shown, the editors of these Transactions have been compelled to make a selection of a few only from the whole number exhibited, and have therefore confined Mr. Oartel's brief remarks to descriptions of those pictures now reproduced.

(It has been very difficult to make this selection. But the 12 pictures

shown will give at least a partial idea of the interest and value the members of the Metals Section found in Mr. Oartel's contribution to the program.)

Figure 1 (which was No. 12-D of the series) shows a guard with magnifying glass for the point of operation of a hand milling machine, as developed by the Westinghouse Electric and Manufacturing Company.

Figure 3: Device for lifting sheet material from furnace.

The magnifying glass not only protects the operator, but also enlarges the working center, thereby increasing efficiency and reducing the spoilage of material.

Figure 2 (which was No. 13-D of the series) shows a fire protection hood for a sheet metal annealing machine, developed by the Westinghouse Electric and Manufacturing Company. When the roll catches fire, the hood is pulled down, thus smothering the fire.

Figure 3 (which was No. 23-D of the series) shows a device for lifting sheet material out of an annealing furnace. The sides or jaws of this device are opened and closed by a large hand operated jack screw.

Figure 4 (which was No. 39-D of the series) shows an I-beam extension for material racks, developed by the Westinghouse Electric and Manufacturing Company. These extensions are portable and are used merely to guide the material which is being lowered by the crane. After the rack has been loaded these extensions are removed and used elsewhere.

Figure 5 (which was No. 41-D of the series) shows a modern milling machine point-of-operation guard developed by the Westinghouse Electric and Manufacturing Company. This guard is counterbalanced so that it

Figure 4: An I-beam extension for material racks.

may be easily moved up out of the way when tool adjustments are necessary. The enclosure may be adjusted up, down, in or out.

Figure 6 (which was No. 50-D of the series) shows a device for lifting bar material and placing it on racks. This device consists of two channels made of very heavy plate with welded joints. Note that the left hand fixture has an end plate to enable the crane operator to push the material into the rack.

Figure 7 (which was No. 2-E of the series) shows a modern plate shear

now used at the Chicago plant of Joseph T. Ryerson and Son, Inc. This is an 84-inch shear, having a capacity of two inches. Clutch is electrically operated and controlled from any one of the four push buttons mounted on the hold-down. This feature eliminates the hazard and fatigue of the foot-operated clutch.

Note the small roll table, directly in front of machine bed, which can be raised and lowered by compressed air. This eliminates extremely heavy manual lifting and reduces the possibility of accident.

Figure 5: A milling machine point-of-operation guard.

This shear is also equipped with a magnetic hold-down in addition to the cam-actuated mechanical hold-down.

The motor controllers operate the large roll table used to feed this machine.

Figure 8 (which was No. 3-G of the series) shows a one-handed gas tank carrier now used by the Youngstown Sheet & Tube Company. They also use two-handed carriers of similar design.

Figure 9 (which was No. 24-G of the series) shows a sword used to open sheet "stickers" employed by the Youngstown Sheet & Tube Company. Note the guard for the operator's hand.

Figure 10 (which was No. 3-H of the series) shows a two-handed control for rope-drop hammer, now used by the International Harvester Company. Note the "safety latch" above the operator's right hand, which is used to block the head when die adjustments are necessary.

Figure 11 (which was No. 3-I of the series) shows a self-dumping box used by the Edgar Thompson Works of the Carnegie Steel Company. The photograph shows the box in the dumping position. In the carrying posi-

tion the stirrup is at the top of the guide. It is not necessary for a man to go into the railroad car when this type of box is dumped.

Figure 12 (which was No. 10-I of the series) shows a slab holder used for chipping blooms or slabs, developed by the Duquesne Works of the Carnegie Steel Company. Note that this holder can be adjusted to hold various thicknesses of slabs.

Figure 6: Device for lifting bar material upon racks

CHAIRMAN GIBSON: Will you please remain seated? I should like as many of you to remain who can for discussion.

I know that some of you are anxious to leave, but we have before us yet one of the most important and best parts of the program.

This part of the program is known as "Your Hour." We have here a list of questions that have been handed in, and some of them represent the real reasons for some of those members coming to the Congress.

The first question is, "Do you have any record of accidents incurred through the failure of refractories in the metals industry?" This was asked by Mr. Henry W. Perry of the Laclede Christy Clay Products Company, St. Louis, Mo.

(No response.)

"Do we not too many times attribute carelessness as the cause of injury instead of to the direct cause of ignorance?" This was asked by a Pittsburgh Plate Glass man. That might come under the paper by Mr. Woltz on "Rule Books." It's a question of becoming educated as to what the safe rules are.

Figure 7: A modern plate shear with many safety features.

MR. WOLTZ: Ignorance is a failure on the part of the foreman, and yet a man may know and not think, or it may be for the reason I spoke of a moment ago, there is some underlying cause that is not brought out.

CHAIRMAN GIBSON: "What is the experience of coke plants that do not have railings on front and back platforms with reference to men falling from platforms?" This is being asked by Mr. A. Berquist, Youngstown Sheet & Tube Company.

SECRETARY NORTHWOOD: I might say we have had men fall from those platforms. I don't think it is practical in any way to put a railing on that coke-oven side. We had a man fall in cleaning the coke off the platform. We were then using a little arrangement with a plate and a handle on it, pushing it with a pusher bar, and in some way the handle got caught in the side railings and tangled up in the man's legs and he

Metals Section

Figure 8: A one-handed gas tank carrier.

Figure 9: A sword used to open sheet "stickers."

fell into the car. We immediately made arrangements to prevent that, but I can't offer a suggestion as to the matter of rails on the coke side.

MR. BERQUIST: The reason I asked the question was to find out just

Figure 10: A two-handed control for rope-drop hammer.

what experience the others had had with these platform railings. I should like to know if there is any one here from the Bethlehem plant at Lackawanna. They have railings on their platform and have cut them down so there is only one section, 18 inches high.

In our plant we have railings on front and back and offsets in between. There is a great tendency for the men to sit down between the offset of the railing and they may fall.

We have been contemplating removing the top of the railing and leaving a railing 18 inches high, although our conscience isn't quite clear in creating what we know will be another hazard, that of a man tripping over that small railing.

D. MEDALIE (By-Products Coke Corporation, Chicago, Ill.): We have talked over the question of railings and the hazards connected with them.

Figure 11: A self-dumping box, shown in the dumping position.

There is a certain sense of security that the men get from these railings which I don't think they should have. By having no railings at all they must be careful. We have had very few accidents in this respect.

CHAIRMAN GIBSON: "Regarding transfer cars in foundry shops, and so forth, what means of locomotion are being used? Electric locomotives, gasoline tractors or manual labor? With what result?" This question was submitted by Mr. James L. Mills, Illinois Steel Company, South Chicago, Ill.

MR. MOREY: We simply pull them over with the crane. We tried the motor to pull them over, but they got so clogged with dirt from castings and core ovens that we went back to the old method.

MR. BERQUIST: But does it particularly apply to core ovens?

MR. MOREY: No, in our core ovens we use the electric transfer cable; the trucks come out and run along opposite the ovens from the foundry to the finishing department.

Figure 12: A slab holder used for shipping blooms.

CHAIRMAN GIBSON: Is that a sufficient answer to your questions?

The next is a question that is unsigned: "What is the experience of those using a toe guard as a means of preventing injuries to feet? I understand some people use a guard that is worn over the shoe. It is found to be clumsy and do the men object to wearing this guard?"

MR. SANKEY: Safety men some years ago found that by taking all of the accidents in a plant and classifying them, there were more accidents to the fingers and toes than to any other part of the body. There was nothing we could recommend as a remedy at that time and it was not until we came home from the war with our metal helmets that we realized that if they could protect the brain with one of these helmets then it should be a simpler matter for us to protect the feet.

We tried first several grades of iron; we tried different sizes; we tried ridges in the tops, and finally we perfected a foot protector. Now the problem is to get the men to wear them. We put the responsibility on the department superintendent. We asked him to give us a list of the occupations in his department where these protectors should be required, and we went over that together. One fellow handled brick, another fellow handled couplings, and so on. But they shed the responsibility, they blamed the safety department. They always belittle the safety inspector, anyway.

Making Good Use of Toe Guards in the Mills

These toe guards will stand a weight of 300 pounds. I want you to see them so you can take the idea home. Some of them protect only half the foot, and the safety shoes protect all the foot.

MR. BERQUIST: To what extent do you use them in tube mills?

MR. SANKEY: First, in handling couplings and things of that nature. The men in the annealing department use them; anywhere that conditions exist where anything may fall on the employees' feet.

You have heard me talk a great deal, but I love the safety work because it is building up mankind, what God has made. You are saving what has been given to them with which to earn their daily bread. We should do our utmost to save the men from losing their hands and arms and eyes. If God had seen fit to make one-armed men He would have done so, but He didn't. He made them in His image and likeness and found them perfect. It used to be, years ago, when I first started in safety work, that when a man lost an arm it was considered that "it had to be," but the work of the safety men has changed that viewpoint, and I could pin an honor badge on all you men for it.

CHAIRMAN GIBSON: The next question is one from Mr. Medalie on the advisability of using a Burrell gas mask in extremely hot weather.

MR. BERQUIST: How do you mean that?

MR. MEDALIE: Any kind of gas mask. We had a fatality from a man using a gas mask; he was overcome by the heat. It was one of the hottest days we had in Chicago. He fell off the ladder and broke his mask and was gassed.

If you have a man who has a little blood pressure or who has a defective mask, there is danger.

CHAIRMAN GIBSON: You don't attribute that to the Burrell mask?

MR. MEDALIE: Not particularly.

MR. BERQUIST: We have used the Burrell gas mask without trouble.

CHAIRMAN GIBSON: Our session is running quite long, but we want to cover all we can.

The next question is submitted by Mr. A. S. Carr, of the Bessemer Gas Engine Company, "How often should crane chains that are in constant use be annealed?"

Another question, which we will consider first, is submitted by Mr. John M. Gull: "Are you not committing a crime by compelling a workman to wear goggles not suited to his vision, and while blinding this man with such goggles are you not endangering his life in other ways, as you compel him to wear goggles he can not see through?"

MR. WOLTZ: He should have lenses ground to suit his vision.

CHAIRMAN GIBSON: I think that is the procedure of most large companies. If they find his vision is impaired they will, free of charge, have goggles prescribed for him.

Has any one any experience with goggles in the die casting foundry?

JAMES F. FOURY (Smith Service, New York): I asked that question and was referred to Mr. Herrin of the International Harvester Company. I will write him.

CHAIRMAN GIBSON: "In pouring steel from electric furnace to ladle, what is the experience as to use of goggles?" That question was discussed yesterday. "In filling moulds from bottom of ladle are goggles generally used?" I don't know exactly what is meant.

MR. MOREY: He refers to the ladle man and those immediately around.

SECRETARY NORTHWOOD: We use dark goggles.

MR. FOURY: What kind of ladles do you use? I have in mind a large ladle with a drop of two feet before it hits the top of the mould.

SECRETARY NORTHWOOD: I referred to the ladles in the open hearth furnace, pouring in the mould.

MR. BERQUIST: They all insist on wearing goggles and leggings.

ADJOURNMENT

Mining Section

New Officers of the Section

CHAIRMAN: HOWARD I. YOUNG
American Zinc, Lead & Smelting Company, Mascot, Tenn.

1ST VICE-CHAIRMAN: C. A. McDOWELL
Davis Coal & Coke Co., Thomas, W. Va.

2ND VICE-CHAIRMAN: GEORGE MARTINSON
Pickands, Mather & Co., Hibbing, Minn.

3RD VICE-CHAIRMAN: A. W. DICKINSON
The Union Pacific Coal Co., Rock Springs, Wyo.

4TH VICE-CHAIRMAN: J. P. HODGSON
Phelps Dodge Corp., Morenci, Ariz.

SECRETARY AND NEWS-LETTER EDITOR: DANIEL HARRINGTON
U. S. Bureau of Mines, Washington, D. C.

Committees

POSTER: JOHN L. BOARDMAN, Chairman
Anaconda Copper Mining Company, Butte, Mont.

PUBLICITY: THEODORE MARVIN, Chairman
The Explosives Engineer, Wilmington, Del.

PROGRAM: R. V. AGETON, Chairman
Tri-State Zinc & Lead Ore Producers' Assn., Miami, Okla.

MEMBERSHIP: H. W. GIESSING, Chairman
Commerce Mining & Royalty Co., Baxter Springs, Kans.

STATISTICAL: H. G. HENSEL, Chairman
The Youngstown Sheet & Tube Co., Chicago.

ENGINEERING REPRESENTATIVE: R. DAWSON HALL
The COAL AGE, New York City.

EXECUTIVE COMMITTEE (The Officers and)
B. F. TILLSON
The New Jersey Zinc Co., Franklin, N. J.

T. T. READ
American Institute of Mining & Metallurgical Engineers, New York City.

October 26, 1926

B. C. YATES, Chairman
Superintendent, Homestake Mining Co., Lead, S. D.

THE first session of the Mining Section of the National Safety Council, held at the Tuller Hotel, Detroit, Michigan, ~~commenced~~ at 9:30 o'clock, Mr. B. C. Yates, superintendent, Homestake Mining Company, Lead, South Dakota, presiding.

CHAIRMAN YATES: We will ask Mr. J. W. Reed to ~~act as secretary~~ in the absence of Mr. T. T. Read.

We have no minutes of the previous meeting to read and ~~approve~~, since our regular secretary is not present. Our first ~~committee report~~ will be the report of the Program Committee, Frank A. Pollock, ~~chairman~~.

REPORT OF FRANK A. POLLOCK, CHAIRMAN, PROGRAM COMMITTEE

When I received the appointment to this program committee, Mr. Yates asked me to make some recommendations for next year's Program Committee, and I have a few here.

The first is, the chairman should be appointed, I believe, directly after the officers are elected, for this reason—he may be able to get in touch personally with the new officers and the other members of the committee as to what to do for the next year's program. It is quite a strain on a man to go ahead and do things on his own hook without knowing what the other members want done. The committee this year thought, as the walls of our room were always bare, it would be a good thing to have an exhibit, and decided on the one you see here. This Section is showing twice as many posters as the Metals Section. Planning for an exhibit should be taken up for next year, I think, by the Poster Committee rather than the Program Committee.

Another thing that slipped up this year, we had no meeting of the Executive Committee. I think there should be at least one meeting a year, whereby the officers or a few of them get together and decide the policy of the meeting.

The last thing to decide is whether or not in the future meetings we should have a luncheon. All the other Sections are doing that. We come here and only meet half the bunch. You go to the Metals Section and in one meeting you know them all.

I want to take this opportunity, in closing, to thank the men who worked with me on this committee, also Mr. Sherman and Mr. Yates, Mr. Read, the secretary, also the men that are going to take part in this program, who have put in their time and have come here to give their papers; and lastly, the company that I work for that let me take the time to go ahead with this program.

CHAIRMAN YATES: The next in order will be the report of the Poster Committee, Mr. R. V. Ageton, of Miami, Oklahoma, chairman.

REPORT OF R. V. AGETON, CHAIRMAN, POSTER COMMITTEE

It might interest you to know that during the past year, for the first time, the Mining Section has put out all of our 24 small size posters and the one large size poster.

The distribution of posters to the mining companies has increased more than 25 per cent the past year, and Mr. Gardiner and I feel that that is a sort of way you people are helping us out and saying you think our work is acceptable. You perhaps have noticed, but if you have not you can look around here at some of the posters that were put out by the Mining Section. We have tried to use positive suggestions and in fact have used that in the majority of instances rather than the negative, or suggestive of fear psychology.

Mr. Gardiner had to make special trips into the field with a photographer, in order to get poster material, due to the fact that he did not receive sufficient suggestions from the Section members. This is a matter that should receive the attention of the next year's chairman. Mr. Gardiner refers laughingly to what he calls his "fan" mail and says every time he gets out a poster that pleases he does not hear a thing about it; but every time that he gets out one displeasing he hears all about it.

I would suggest, for the benefit of the men in the National Safety Council headquarters, every time a poster pleases you write a little more quickly than if it displeases you, because the fan mail he gets does not help him to do his work a whole heck of a lot. However, he did wish to thank the members of the Section who have cooperated with him in sending him poster material; and he hoped all of you would get behind him this year so the 24 small posters which were allotted to this Section and the one large poster would be more pleasing to all than they were last year.

Regarding the luncheon of which Mr. Pollock spoke, I wish to concur in that. I do not see why the members of the Mining Section could not get together and have a luncheon the same as the other Sections do; in fact, we are the only organization I know of in the country where the miners do not take the lead, and I am wondering what is the matter with the members of the Mining Section of the National Safety Council that we do not get out and show some pep.

CHAIRMAN YATES: The next report is that of the Membership Committee, Mr. Joseph W. Reed, chairman.

JOSEPH W. REED (Director Department of Safety, Consolidation Coal Company, Fairmount, West Virginia): The Membership Committee was very fortunate in having a very good committee although they had an exceedingly bad chairman, but through the assistance of the members of the committee and the officials of the Mining Section we made a gain.

REPORT OF J. W. REED, CHAIRMAN, MEMBERSHIP COMMITTEE

We began the year in September, 1925, with 218 members. Between that time and September, 1926, we lost 26 members and gained 41 new members, or a net gain of 15, making our membership at present 233 active members.

Although the net gain shows only 15 additional members, we have made a net gain in new-member employees of 10,940 over those cancelled.

I desire to thank W. L. Wheeler, Director of the Business Division, National Safety Council, through whose courtesy the above figures were obtained from the records.

Some few cancellations of membership were due to the sale or transfer of member companies to companies who were not members.

Such cancelled memberships as I was able to investigate personally I found were not due to complaint on the service of the Mining Section, but rather to the necessity of curtailing every possible expense during a rather severe business depression. I feel that most of these members will be back with us again next year.

The fact that under the existing conditions we made even a small gain was due to valuable assistance from the officials and members of the Mining Section and the vigorous efforts of those in the main office of the National Safety Council.

CHAIRMAN YATES: Is Mr. E. E. Criswell, chairman of the Publicity Committee here? In the absence of Mr. Criswell, we will call on Mr. R. Dawson Hall, for any reports he has to make as Engineering Representative.

REPORT OF R. DAWSON HALL, ENGINEERING REPRESENTATIVE

I have not been extremely active because I have had no call. I attended one meeting only of the A. S. S. E., and that was a business meeting. I was put on a committee on drafting, at that meeting, owing to a suggestion I made that every drawing for new machinery should be looked over specifically by somebody who really represented the safety interests in the organization, so that these drawings would reflect safety and would result in machinery being made safe. I think that is quite an important matter, that every drawing for a new piece of machinery should be inspected by somebody and should be designed for safety. I think if we just would get a signature on every drawing of a mechanical nature, that it is safe or that it is designed with the idea of safety, it would bring to the minds of those doing that designing the necessity of having everything safe for those who have to use it.

However, I was not called to any meeting. I do not know whether they have gone any further with that drafting committee or not. I went to a dinner that was held at the Country Fair in New York City, but other than that I have attended no meetings.

Another activity is the Mine Collating Committee which is preparing standards of various kinds for submission to the American Engineering Standards Committee. That Mine Collating Committee is headed by E. A. Holbrook of State College, State College, Pennsylvania, and I attended two of the meetings of that organization. The main safety question that came up was the approval of the program of the standards for safety in auxiliary ventilation. The Bureau of Mines, the N. S. C., the American Institute of Mining Engineers and a number of other organizations were on

that committee. The committee brought in the recommendation that the standards be adopted. Mr. Harrington, of the Bureau of Mines, brought in the recommendation that the standards be not adopted until they had been boiled down; the Power Club objected to certain phases of the standards but were not prepared to make those objections definite at the time.

I may say that the other representative of the Bureau of Mines approved the auxiliary ventilation program. However, Mr. Rice, who was there, said he did not approve of them, that he thought they ought to be returned for further examination by the committee, and as a result they were returned to the committee for examination; but a rather interesting thing happened. The following day Mr. Roberts who is chairman of the Mine Collating Committee, submitted this statement to the Engineering Standards Committee—that the standards had been disapproved by the Mine Collating Committee, but in his belief they had absolutely no right under the rules under which they operated to refuse to accept anything from the committee that they had appointed, that they were not a revisionary committee, that the only revisionary committee existing was the American Engineering Standards Committee, and consequently the American Engineering Standards Committee accepted these standards for submission to their various members. They did not consider it final acceptance so they sent these standards around to their various members, and when the time came to count up the votes they found under their rules these standards had been rejected.

So that is the position of the auxiliary ventilation standard. It has been turned down by the American Engineering Standards Committee. I do not know what will happen to it now. The Mine Collating Committee does not seem quite ready to submit it again to the judgment of the committee that it will appoint, because they think there should be a little time given to discuss the matter and think it over. I was present at a meeting held by the A. I. & E., and they decided that they would not submit it just at present, but that they would give opinion an opportunity to be further crystallized on this subject.

REPORT OF B. C. YATES, CHAIRMAN OF THE SECTION

Your chairman has not very much to report this morning. When this job was wished on me last year down in Cleveland I really did not know what I was getting into, but I know now, and I compliment the gentleman who is to follow me, on having some work to do if he carries out the work of this Section, because we have work before us.

I attended two meetings of the Directors and Executive Board in Chicago, also a conference of the Sectional Chairmen in Chicago. There is one recommendation I would like to make. The Mining Section needs a paid secretary. I believe Mr. Tilson, of the New Jersey Zinc Company, brought that up several years ago, and I believe the same condition exists today as at that time, that it is a matter of finance. The national organization has not the funds. I have no recommendations to make

as to how to secure the necessary funds to pay the secretary, but I do know that his services are needed.

The members of the Nominating Committee are R. V. Ageton, chairman, C. A. McDowell and Theodore Marvin. This committee will get together some time during the day, as our election takes place at the session tomorrow.

The first paper presented to you will be by Mr. James L. Davidson, Secretary, Alabama Mining Institute, Birmingham, Alabama.

SAFETY PRACTICES IN AND ABOUT ALABAMA COAL MINES

James L. Davidson, Secretary, Alabama Mining Institute,
Birmingham, Alabama.

In making this delineation, myriads of measures of equal magnitude clamor for precedence. However, because of its sweeping destructiveness and annihilating effect when fired, I will speak first of the suppression and neutralization of coal dust.

In machine mining, water is applied along the cutter bar while the coal is being undercut;

In pick mining, the gob¹ and face are thoroughly sprinkled with water before shooting, and the loose coal and undercuttings watered down before loading on cars.

Empty cars are flushed with water either on the top house or elsewhere before loading; and the tops of all loaded cars are made wet before leaving the rooms, the slope side track or gathering sections.

Furthermore, the employment of rotary dumps, tight cars, precautions against overloading to prevent spillage of coal along the haulageways, the use of gob rock instead of fine coal as ballast under the tracks, together with frequent cleaning of haulage ways, have done much to reduce the production and accumulation of coal dust in Alabama mines. Supplementing this, rock dust stemming is used at some mines as a suppressant of coal dust, as well as to smother the flame in shooting.

In treating the coal dust to render it inert, the prevailing method is sprinkling with water² (the sprinkling systems in some of the Alabama mines are among the best and most thorough in the Nation)². However, rock-dusting is fast supplanting wetting as a means of eliminating the black powder from the magazine to the working places, and fibre (pocket) boxes for detonators, has served to prevent explosions from these sources.

The removal from the slope and haulageways of high tension electric cables; the installation and maintenance of trolley wires so as to prevent arcing; the placing of mine machine cables under the track when it has to be crossed; the fastening and keeping connected of the ground

¹goaf

²I recall now, a mine that has installed around forty miles of pipe lines for sprinkling. Others have proportionate installations depending on the size of the mine.

wire of mining machines to the water pipe while the machine is in operation, and the grounding of all electrical apparatus; the introduction of storage battery locomotives; and the use of explosion proof motors, connections, plugs and switches; have done much to reduce to a minimum the danger of setting off the gas or dust from electric arc as well as injury to the workmen from electric shock.

The proper placing (or balancing) of the blasting holes, and clearing them of dust before loading, restriction of the amount of charge of explosives, the tamping of the holes to the collar with clay or rock dust, the undercutting of the coal, or abandonment of solid shooting⁴; the use of permissible explosives,⁵ firing of shots with electric batteries and by shot firers, are the prevailing precautions against gas and dust explosions from blasting and blownout shots.

The inhibition against going into worked out or abandoned places and against lighting fires in the mine is universally enforced.

The above and other practices to prevent explosions have materially contributed to the bodily security of the coal mine employees of Alabama, to an extent hardly thought possible a few years ago.*

Escapeways: Directions for Escape and Rescue

As a precaution against the workmen being cut off from the regular manway or slope, in case of explosion or mine fire, at many mines additional escapeways other than those required by law are provided. Furthermore, instructions are given the men how to escape in safety, and in the use of self-rescuers, the number of which now in use in Alabama has increased considerably during the past year. Signboards in the shape of arrows, are posted along the passageways and escapeways indicating the best way out of the mine. It is customary to keep at a number of places underground maps of the mine, with the routes of escape and live workings marked in red thereon for the use of the men in emergency. Several copies of these maps are kept available the place made safe before the miner is permitted to return to work. On pillar work, by means of wing brattices, the air current is kept sweeping over the falls of roof, which are examined frequently each day for gas, the inspector going as far up on the falls as possible. Every few days inspections are also made of falls in old workings, as the prudent operators maintain adequate ventilation throughout such old workings so as to guard against dangerous accumulations of gas in any part of the mine. Under provisions of the Mining Law, old workings must be fenced off and "Danger" boards placed at the entrances.

⁴In 1925, 65 per cent of the coal mined in Alabama was undercut by machine and a large portion of the remainder undercut by hand.

⁵In 1925, around 30 per cent of the coal was shot with permissible explosives. Consequently the number of mine fires has been proportionately reduced as the use of permissible explosives increased.

*198 coal mines in Alabama have operated for the past 5 years and 194 have operated for the past 10 years without a major explosion (5 or more killed). 193 of these mines have operated for the past 5 years and 186 of them have operated for the past 10 years without any explosions which resulted in any loss of life at all.

The requirement that the gas inspector or fire boss, in marking up his visits, use a different colored chalk from that used by foreman or safety inspectors, in making their inspections; that he check in and out of the mine with brass check all men on each shift; that he or his helpers must have no open light of any sort while making inspections, or while removing gas³, from the mine and that only approved explosion proof (permissible) flash lights or electric cap lamps and magnetically locked permissible flame safety lamps be used in making inspection for or on removal of gas; and that all flame safety lamps be inspected, lighted and locked before leaving the lamp house, so that the lamp can not be opened or unlocked while inside the mine; are all important precautions against gas explosions. But the most important of all is, that, previous to each shift, all places in the mine be freed of accumulations of gas before the workmen are allowed to enter. Although the Alabama Mining Law requires that accumulation of gas be removed, the principal reason for adopting the practice of removing the gas before the workmen are allowed to enter is, that a large portion of the disasters from explosions in Alabama mines have been occasioned by accidental ignition of standing gas, even though the place was marked out by the fire boss and the workmen thereby given knowledge of its presence; or while the gas was being removed during the shift. Where sudden outbreaks of gas or "feeders" occur all open lights are withdrawn from that affected split or portion of the workings. However, recently the failure to observe this practice in one Alabama mine, cost the lives of nine men. In a number of mines the use of electric cap lamps has eliminated the open light hazard. In these mines prohibition against lighting matches, smoking, or the use of open flame is strictly enforced.

Mining Law and Rules Are Carefully Observed

Here let me interpolate, that in handling explosives, the provisions of the Mining Law and the rules and instructions for handling explosives prescribed by the safety engineers of the explosive manufacturers are generally observed; and that use of powder jacks for carrying coal dust hazard; there now being in the state 31 mines completely rock-dusted and several others where the work is well underway.

Where rock dust is used, systematic sampling and testing is done monthly, to make sure of the non-combustibility of all accumulations of dust in the mine; a record is kept of the tests and a report is made to the management both at the mine and the head office.

Accompanying the matter of laying coal dust much attention has been given to ventilation, and the prevention of gas explosions.

The ventilating systems of Alabama mines are well planned and projected to meet the requirements, as the work progresses. One or more

³That in removing gas, all except the nearest cross-cut to the face be closed and that a wingbrattice be run from this cross-cut so as to carry sufficient air to the face of the working place.

fans of excess capacity are universally provided, many of which are equipped with a gasoline or steam power auxiliary drive that can be changed over with a minimum interruption of the flow of the air. Recording pressure gauges are used on them to indicate and record the fan performance during each period of the day and night.

These fans are offset from the mine opening a sufficient distance to guard against injury from explosions from within the mine. They are also protected by explosion doors on the fan house and in the tunnel leading from the mine to the fan house.

Also at many places fan stop signals are used. These are in the form of electric lights, placed at key positions, which indicate that the fan is operating; or in the form of sirens which indicate when the fan stops, thus warning the surface force to start the fan, or by telephone and messenger to withdraw the workmen from underground. If the fan is stopped for any appreciable time all workmen underground are withdrawn and not allowed to re-enter until the mine is inspected and reported free of gas by the fire boss.

Ventilation Knowledge Has Replaced Guess-work

In aid of the regular fire bosses required by law, at some mines a ventilation superintendent and crew of helpers are employed, to check the fire bosses' inspection, see that all brattices, cross-overs and doors are tight, aircourses sufficiently large and free of obstructions, break-throughs driven at proper intervals, ample air-current on each split; and to plan for sufficient ventilation as the mine workings are extended. Knowledge of actual ventilation conditions has replaced guess-work. At many places readings in each air-split are taken daily, or every few days, together with samples of air, which are analyzed: and in no case is the methane content allowed to exceed one-half of one percent. If in making his rounds the ventilation inspector finds a door propped open, he must leave it so; and having withdrawn the workmen from the part of the mine affected, he must immediately report the matter to the mine foreman; and see that ventilation is restored and the section affected is free of gas before allowing the workmen to re-enter.

It is common practice to have the face of each place examined for gas previous to loading blasting holes, and again after they are fired; and able at the mine office for use of rescue crews from other places, should the necessity arise. At some places a map of the active workings is posted at the mine entrance, upon which colored headed pins are stuck to indicate the approximate position, class and number of the workmen inside the mine on each shift.

At practically all of the gaseous or dusty mines, self-contained oxygen breathing apparatus is kept in good condition and readily available for use in rescue work; and it is rare to find a mine that does not have a large number of men trained in first aid and in the use and care of breathing apparatus. At several large operations these men are trained for the

work at their central rescue training station⁷. Some of the large companies have a modernly equipped mine rescue truck, but most of them are trained at the Birmingham station of the United States Bureau of Mines. These men readily respond to the call when a disaster occurs at any mine in the district.

Transportation and Haulage Ways Accidents

First, provision is made for adequate manways, free of water and obstructions, to obviate the necessity of the men using the slope or main haulageway in going to and from work. This, added to the increase in illumination resulting from rock-dusting the roadways, has rendered traveling on foot in the mines safer than under previous conditions. Prohibition against riding trips; the placing of refuge holes at frequent intervals to eliminate danger of getting caught by trip of cars or motor⁸; sufficient clearance at side tracks and passing places to allow spragging in safety; blocking switches and frogs to prevent those walking the haulageways from catching their feet in such wedge-shaped places; parallel lever switch throws, with ample space between tracks and wall to prevent the trip rider from being struck by moving trip or rolled against the rib; the use of block signals, together with trip lights and markers where two or more locomotives are operating over one track, and block system for protecting trips; automatic signals⁹ indicating the approach of trips around curves and at trap doors to protect the men who are required to travel the haulageways; the employment of underground dispatcher of transportation and motor foreman; and the application of drags on rear of trips being hoisted on the slope, to cause derailment of trip in case of breaking of the rope or the couplings between the cars; the modification of curves and turnouts, easing of grades, proper alignment or gauging of the tracks, the use of heavy rail and crossties, crushed gob rock for ballast, rigid frogs and point switches for slope and mine locomotive tracks; all these are among the things done to prevent haulageway accidents.

In order to prevent damage resulting from runaway trips on slopes, the following devices are used; automatic derails for loaded cars on slope so spaced that they are less than the trip length apart; open derail for empty trip on each tipple approach, causing the operator to hold the switch closed to let the empty trip enter the slope; automatic stopping devices on the hoisting engines to protect the trip, whether being hoisted or lowered, by stopping the engine in case anything happens to the hoisting engineer; the use of gongs or sirens at the foot of all hoisting slopes which give a warning signal in case of runaway trip on the slope.

The following rules are also enforced: No one, except the trip rider, to ride any but man trip. Trip rider must not ride elsewhere than on the front or back end of trip. Couplers or brakemen must not couple cars

⁷Some of the large companies have modernly equipped mine rescue trucks.

⁸These holes are whitewashed, together with a strip along the rib, where the workmen are allowed to travel, indicating the direction of the hole.

⁹In any case, motormen must sound signal gongs when approaching curve in track or at door where men are at work.

while in motion and motormen must not back locomotive upon the trolley pole. No one shall attempt to run a locomotive without permission of the foreman in charge of transportation.

(In handling man trip, the safety rope couples on the main haulage rope above the socket and passes through each car, and is fastened to the draw bar of the rear car. When this trip is coupled to the main hoisting rope a special clevis and coupling pin are used. The pin is threaded, a nut is screwed on and a cotter key put through the pin below the nut. All of which, including the hoisting rope, is inspected thoroughly before starting to lower the trip and a record is kept of those inspections. Two engineers must be at the throttle when the man trips are operated.)

In the up-to-date mines all trolley wires are guarded the entire length on branch entries and at other places where employees have to work or pass; and when making extension of the trolley wires it is guarded before being connected to current.

All trolley wires are placed on opposite sides of cross entries from the rooms.

Accidents From Electric Shock

The last statement brings before us the matter of preventing injury from electric shock. Among other things, the use of explosion proof equipment (and appliances such as oil switches and indirect switch throws), the proper grounding of the cases, frames and supports of all these; insulated seats and platforms, rubber mats for the workman to sit or stand upon and rubber shoes for him to wear; reduction in voltage used inside the mine; the use of armored cables for conveying high voltages; the proper bonding of rails on locomotive track; safeguarding bare, exposed or live wires, switches and connections, and drainage to make dry* the floor and walls under and surrounding these sources of danger; are some of the precautions employed; together with the posting of "Danger" signs, warnings and the like. However, much is gained by observance of the Rules, Specifications and the Code of Standards of the Coal Mine Rating and Inspection Bureau of the National Council on Compensation Insurance, respecting the installation and maintenance of electric equipment in and about the mines.

All Alabama coal mines are operated under an effective State Mining Law. This law was drawn by experts qualified in mine accident prevention and was prepared with the supreme object of protecting the lives and limbs of those engaged in the coal industry. Supplementing this law are comprehensive "Operating Rules," authorized to be promulgated and enforced under the law. These rules and an abstract or digest of the safety provisions of the Mining Law are kept posted at the entrance to the manway, on the top house, and at other conspicuous places in and

*The use of rock dust in the mines has eliminated the moisture hazard and has served to prolong the life of the insulation connected with electrical installations and equipment.

about the operations; and a copy of the rules (after having first been read and explained to him) is given each employee. When additional rules are made they are likewise posted, and a copy printed on a placard which is hung on a nail inside of each empty mine car where it can be readily seen by all. (This means is also used to emphasize other rules and to display safety slogans, the same being changed or renewed every few weeks, to prevent staleness and obliteration.)

Careful Inspections Are Frequently Made

Under the law careful inspections are frequently made of all coal mines by competent officials employed by the state, which, when augmented by the Inspection Service of the Compensation Insurance carriers, have operated to remove many of the physical hazards, much of the neglect of management and carelessness on the part of the workmen; as well as, to cause a more general observance of the safety provisions of the law and the rules above mentioned. The greater portion of the operators employ a chief safety engineer and one or more safety inspectors or bosses and committees, who make continuous inspection at each mine and confine their activities entirely to accident prevention. These men have performed signal service in this line; and it is conceded generally that they are the most important human agency that can be conceived to protect the workmen in and about the mines from accidental injury.

At other places deputy foremen and face bosses, whose duty it is to examine frequently the working places, are employed to great advantage.

Another valuable agency in reducing accidents, is the employment of section foremen, who have charge of from 12 to 25 men. They look after the timbering, security of the roof, handling of explosives and other safety measures outlined herein; especially inspection of each working place before and after shooting. At mines where the "Contract System" is used the contractor acts in the capacity of a section foreman, performs the duties mentioned and is held responsible for the safety of the workmen under him. Both of these systems have proven particularly efficacious in the enforcement of discipline and the elimination of physical hazard and are therefore much in favor in the mines of Alabama.

The actuating force behind these activities, by whom the work is directed and to whom all working forces are individually and collectively answerable, is the safety organization at the mine and at the head office. These committees are composed generally of the manager of mines, the chief safety engineer (where employed), local mine managers, superintendents, foremen, safety inspectors, and section foremen or contractors. Often to these is added a committee of workmen and officials.

Meetings of these are held monthly and oftener if necessary or desirable, at which time reports and recommendations are made to the president regarding the accident record for the past month, provisions for their future prevention and safety measures in general. Where

the section foreman or contractors are not members of the safety organization, they are called together in a separate meeting each month for consideration of these matters.

When a lost-time accident occurs a committee makes immediate investigation to ascertain the cause, place the responsibility for the same and to make recommendation to prevent its recurrence.

In many instances, a drawing is made showing how the accident occurred and beside or under this a picture of how similar accidents can be avoided. These drawings or pictures are then posted where all workmen can see them.

Accidents From Falls of Roof and Coal

The most prolific cause of fatalities and serious bodily injuries to the coal mine worker, in Alabama, as well as elsewhere, is falls of roof and coal. These are occasioned almost universally through the failure of the workmen to observe the provision of the law and the mine safety rules. The reduction of accidents from this cause is effected by the forceful combination of:

(a) Strict application of discipline and compliance with the timbering rules and other regulations regarding roof control, which require the workmen to make safe and keep in safe condition at all times his working place:

(b) Constant supervision and frequent inspections of the roof by the safety inspector, assistant mine foreman or contractor, as outlined herein;

(c) Education and instruction in safety practices and personal appeals to the individual coal digger or loader to refrain from working in an unsafe place and to exercise care and prudence at all times.

Rules as to testing the roof upon entering the working place and often during the shift; systematic timbering; pulling down loose rock; spragging or propping the face coal while it is being undercut and likewise the loose coal after shooting; as well as blocking cars in both directions while the coal is being loaded; precautions against overloading the shots, replacing blown out timbers and the like at many mines where they are unfaillingly observed; have practically eliminated accidents from falls of roof and coal¹¹.

A potent help in educating and instructing the underground employee

¹¹As proof of this there are 86 coal mines in Alabama that have had no fatal accidents from this cause in the past 5 years, and 141 mines that have had none in the last 2 years, since these rules have been relentlessly enforced and since the contractors, section foremen and safety inspectors have been particularly charged with the duty of seeing that they are enforced.

However, this has only been accomplished where provision is made for a plentiful supply of suitable timbers and capboards to be delivered without fail to each working place before the same are needed by the miner; so that he will not have to wait for them, or to work under an insufficiently supported roof. And then, too, the foreman or inspectors are no content with simply warning the miner of the dangerous condition or ordering him to remedy same. He stays and sees (or returns shortly to see) that his orders are carried out and the place made safe before the miner or loader is allowed to work therein. Otherwise, the miner or loader may delay or fail totally in carrying out the order and the injury follow in consequence thereof.

in prevention of accidents from falls of roof and coal, has been the distribution among them of illustrated pamphlets, on the subject, graphically showing and telling him the safe and dangerous ways of performing his work. Many thousands of copies of these pamphlets have been from time to time broadcasted throughout the mines by the Alabama Mining Institute. Following this, each time, a marked decrease in this class of accidents has been noted.

Here let me mention also that shields or guards on the cutter-bar of mining machines and revolving parts of machinery and guard rails or fences, beside pulleys, belts, electrical apparatus, and around openings of dangerous depth, hand rails and safety treads on stairs and passageways are commonly in use.

Accurate Accident Records Are Appreciated

The value of keeping accurate accident records is appreciated by the management of Alabama coal mines and the practice prevails especially at the larger operations. These records prove that over 90 per cent of the accidents are due to the carelessness of persons rather than physical conditions. Therefore, if carelessness could be eradicated coal mining would be one of the safest occupations in which men can engage. Carelessness can only be eradicated through rigid discipline and timely education, (Here is where the section foreman or contractors prove most valuable in accident prevention).

Discipline consists in enforcement of the Mining Law, Safety Rules and Practices, and the instructions given by those in charge of the work. But discipline without education is futile; and education without the willing inclination and favorable disposition of the workmen to profit by and apply the knowledge gained therefrom, is useless.

Discipline is maintained by reprimand, suspension or discharge. For the first infraction or offense, a reminder is served on the malefactor; for the second, suspension; and for the third, discharge.

In connection with the enforcement of discipline, a continuing notice by the management to all employees as follows, has proven effective:

"That the compliance with the mining laws, the observance of all safety rules, the exercise of prudence and care to prevent accidents, are conditions of employment at this mine; and these conditions apply to all operating officials and every person in the employ of the company. That accident prevention is the paramount policy of the management and that dismissal will follow the failure of any official or employee to fully and properly support this policy; and that no person will be employed or retained in the service of the company, who does not give voluntarily definite assurance that he will support this policy."

However, even when the management and operating officials fulfill their duty, to the utmost, and after all possible physical hazards have been removed, little can be accomplished without the constant cooperation of each individual workman. Such cooperation, to a great extent, will eliminate the "human element" in the causation of accidents. Or

in other words, the whole hearted interest in safety and unceasing alertness to prevent accidents, of every one working in or about the mines, is necessary to attain the desired end.

This, as I have said, is a matter of education or instruction and personal appeal to the workmen individually and collectively. It is done through the distribution of tracts and pamphlets¹², display of posters,¹³ motion picture reels and lantern slides¹⁴; and lectures on accident prevention.

Magazine and Prize Contests for Employees

One large Alabama operator publishes monthly an excellent magazine for the benefit of its employees, whose columns are devoted principally to accident prevention. This company also conducts prize contests among the school children and Boy Scouts under 16 years of age, for the best essay written on Safety Practices In and About the Mines. Of course these children know nothing about the subject they are to write on and have to get all their information from their father or some relative who is employed in the mines. The results of these contests have been quite noticeable. The safety engineer goes into the schools, talks with the children, and puts out safety propaganda through them to their parents. Each school child promises that each morning, before a member of his family who works in the mines goes to work, he will caution him about being careful while at work that day. The children are taught safety songs and to draw pictures of accidents showing the cause and how these accidents could be prevented.

In addition, actual photographs of the location of the accidents underground are taken and lantern slides made from them, are thrown on the screen. At each picture show three or four slides with safety slogans are run. Another method of putting over the safety slogans is printing them on the pay envelopes.

An advantageous and effective means of reaching the individual workman, and of enlisting the earnest aid and effort of every one (including the wives and children) in waging a relentless fight against carelessness, is through frequent community meetings¹⁵ of the operating officials, employees and their families at each mine.

¹²Prepared and issued by the U. S. Bureau of Mines and the Alabama Mining Institute.

¹³Of the National Safety Council.

¹⁴Of the U. S. Bureau of Mines and others.

¹⁵The formation of a chapter of the Holmes Safety Association (one for white and one for colored employees) at each mine is a desirable and satisfactory medium through which these meetings may be held and interest in accident prevention aroused and maintained among the workmen.

The chapters which have been functioning during the past year and a half have proven their worth; not only in the maintenance of safety and stimulating prudence and individual responsibility among the workmen; but as an instrumentality for wholesome entertainment for all the people in the community; and for their contentment and good will toward the management and toward each other.

See "Appendix" to this paper.

With the realization that the physical and mental condition of the employee has a material bearing on his prudence or negligence (or the accident frequency among the workmen), the Alabama Coal Operators have done much to provide comfortable and pleasant living accommodations, sanitary and healthful surroundings, including bath or change houses for their employees; together with excellent medical and hospital services and attention for them and their families, at a nominal monthly cost¹⁶. The cost of living is made reasonable through the company stores, and gardens are provided for raising fresh vegetables, fruits and poultry. Good schools and playgrounds are furnished for the children. A square deal and just treatment accorded by the management, coupled with satisfactory working conditions and reasonable safe-guards against injury, enable the worker to go to his work "with a song upon his lips and hope in his heart." This operates for tranquility, stability, responsibility and efficiency of the working forces, and is reflected in a cleaner record for safety, with greater production and fewer accidents.

Furthermore, the coal mine employees of Alabama are, as a rule, intelligent and susceptible to instruction, appreciative of and responsive to the efforts of their employers to provide for their safety and welfare; and consequently loyal and amenable to discipline.

All told, the safety practices obtaining generally in and about the Alabama coal mines, have placed them in an advanced position with respect to accident prevention¹⁷.

Safety Standards Should Be Universal

All of this requires the expenditure of a large amount of money and adds greatly to the cost of production. Therefore, the disregardful operator, who fails to employ ordinary safety standards, may have an unfair advantage in selling his product over the progressive and humane operator, who increases operating expenses by using these precautionary measures.

It has been suggested that the observance of safety standards can be made obligatory, on all producers alike, only by the operation of a Federal Law; and not through legislation whose authority is limited to the boundaries of each state. Even so, it is practically impossible to draft a general law which will be efficacious and yet sufficiently flexible to meet varying conditions; and which will not bear too heavily on some or too lightly on others.

I agree with what was said by Mr. T. T. Read, on the eve of his retirement as Safety Service Director of the United States Bureau of Mines, in substance as follows:

¹⁶Under the "Medical and Hospital Contract System."

¹⁷One hundred fifteen coal mines in Alabama for the past two years and sixty-two of them for the past five years, have had no fatal accidents. One of these employing several hundred men, last year had only four minor accidents causing loss of time to the injured employee.

"We can not hope to do anything effective in regard to getting the safety practices recommended by the Bureau adopted by the industry without first securing the cooperation of the operators. I have no faith at all in making mines safe by laws. If regulations are made that the operators regard as not being necessary, you will merely have a situation like that created by certain sumptuary legislation which people joyously and openly disregard. State officers can not be expected to enforce laws unless the sentiment of the operators is behind them. . . . Even the best qualified mine inspectors find it difficult to make the operators and the workmen comply with the law unless they believe that the regulations are reasonable and effective."

Operators Promptly Adopt Safety Recommendations

My observation is that the Alabama coal operators do not wait for the enactment and invokement of laws, but where possible and applicable, adopt promptly the recommendations of the United States Bureau of Mines, the State Mine Inspection Department, Safety Service of the Insurance Companies, National Safety Council and of the safety engineers employed by them and by operators in other coal fields. For instance, a large portion of the safety practices obtaining at Alabama mines are not covered by the State Mining Law at all and had not been thought of when the law was passed. On the other hand, several of the provisions of the law are now obsolete and ineffective from a practical operating standpoint. And again, certain provisions of the law are applicable in one mine and not in another.

However, law or no law, you may rest assured that the Alabama coal operators and their employees will continue to wage a relentless fight against carelessness and spare no expense when human life is at stake. But those who have to do with raising revenue, levying taxes, fixing liabilities by law (such as Workmen's Compensation), and making regulations which increase the cost of production, should consider the already impoverished condition of the industry, the competition from other coal fields, other forms of fuel and other sources of power before enacting measures or applying regulations which may, by reason of their cost, become burdensome and consequently cause the abandonment of more important precautions and activities for safety that would otherwise be carried on.

This writing would be incomplete if I failed to mention that a number of lives have been saved and the seriousness of many injuries reduced by the prompt administration of first aid to the injured. Several thousand¹⁸ of these men have been trained for service in the coal mines of this district during the last few years by experts of the United States Bureau of Mines and by instructors employed by the individual operators. Some of the operators have a large percentage of their employees trained in first aid and mine rescue work. It is also a rule at some places that all foremen and contractors must be certi-

¹⁸Nearly two thousand were trained in 1925.

fied first aid men. It is unusual to find a coal mine in Alabama that does not have a large number of men (women, girls and boys) trained in first aid and safety methods. Aside from its value in saving lives and benefit to the injured person, the training has proved of great worth in the prevention of accidents. It has been truthfully said that when you train a man in first aid, you automatically make a safety man out of him. The records of one of the large concerns here which employs several thousand men and operates a number of mines, shows that accident frequency was eight times greater among the untrained men than among those who had received first aid training.

First Aid Stations Well Equipped

It is usual also to have equipped and maintained approved first aid stations near the tippie, and at many places these stations are established inside the mine. First aid kits and supplies are kept at convenient places within the mines and about the works. To give and keep up this training entails the devotion of a great amount of time by the employees involved, and a heavy expense to the operator. The interest in the work is kept up through the Holmes Safety Association meetings and by inter-mine or company contests; and each year the Alabama Mining Institute donates the prizes and defrays the expenses of holding a contest for all the mines in the district. These annual contests are largely attended and much enthusiasm for the work is aroused not only among the contestants but among all the employees in and about the mines.

Let me also say that one of the most impelling influences that have made for progress in protecting the people engaged in coal mining in Alabama from personal injury, has been the officers and members of the Mine Casualty Committee of the Alabama Mining Institute. The members of this Institute are deeply grateful for the assistance and helpful information, suggestions and recommendations which have been furnished them by the officials of the United States Bureau of Mines, the Mining Departments and Coal Operators in other states. In appreciation of this the operators of Alabama stand ready to reciprocate in kind and like measure, as occasion may require.

NOTE:

There are 222 coal mines in Alabama being operated on 30 different seams of coal; each of different thickness, and each mine, even on the same seam, encounters different operating conditions. A few of these are strip mines, several are shaft mines, others are drift mines and the remainder are slope mines operated on seams of varying degrees of pitch. Some of these mines are gaseous more or less, and others free of gas. Some are naturally wet and others dry. Some are electrified and others are not. In some the roof is weak and in others strong. Some employ a great number of men and others only a few. Therefore, the writer does not assume or mean to say that all of the safety practices enumerated here are employed at all or in any one mine, as many of them are impracticable, inapplicable, unnecessary and not in use at certain mines but are employed at others.

(Appendix)

THE HOLMES SAFETY ASSOCIATION

H. E. Mills, Assistant to the Secretary, Alabama Mining Institute

In the mining districts of Alabama we now have 35 active chapters, including all mines operated by the State of Alabama with convict labor. Each chapter is self-supporting and self-governing, with a president, vice-president, secretary-treasurer and safety director, elected by the members.

The Newcastle Chapter No. 2, with Frank Parker as president, was the first organized in Alabama and is tied for first place in the United States, as Newcastle and Butte, Montana, were organized on the same day, April 15th, 1922. The records of the Butte Chapter are not available but if their record is superior to Newcastle they have achieved wonders, as this chapter has produced nearly one and three-quarter million tons over a period of seven years without a fatality.

The Alabama Council of the Holmes Safety Association is composed of representatives of the United States Bureau of Mines, Alabama Mining Institute, State Mine Inspection Department, Insurance Carriers, Coal Operators and others interested in the prevention of accidents and promotion of health. It meets in Birmingham each 90 days to discuss future policies, appoint committees and suggest subjects for the consideration of the program committee.

The program committee selects the subject to be discussed each month in each chapter, also assists the chapters in securing speakers and entertainers from other operations elsewhere in the district.

During the past year the following subjects have been thoroughly covered:

1. Accidents from Fall of Roof and Coal and Means of Prevention.
2. Electrical Accidents and Means of Prevention.
3. Haulage Accidents and Means of Prevention.
4. Handling of Explosives.
5. Unusual Accidents.
6. Necessity for Discipline.
7. Food and Care of Children.
8. Mining Camp Sanitation and Personal Hygiene.
9. Care of Machinery.
10. Value of First Aid Training and Rescue Work.
11. Mine Gases and Ventilation.
12. Surface Accidents and Value of First Aid Training.
13. First Aid Training in preparation for Field Meet.
14. What a Miner Should Do After a Fire or Explosion in a Mine.
15. How to Prevent a Mine Explosion.
16. The Careful Miner.

The speakers are selected for their knowledge of the subject, and in addition local officials are called upon to speak, while the members themselves join in a general discussion. To maintain interest and

increase attendance amusement features are also provided, such as moving pictures, music, readings, playlets, and in most cases refreshments are served, so that the entire family attends. (The use of local talent and school children where possible is a good drawing card and many attend through personal interest in the performers.)

The Alabama Council is issuing a series of safety and health papers prepared by competent men and these are read before each chapter and copies presented to all members present. In this way a first class safety library is being built up.

The first safety paper issued under this plan was entitled "What a Miner Should Do After a Fire or Explosion in a Mine," and told, in a very dramatic way, the experience of miners entombed by an explosion and how they saved themselves by erecting a barricade deep under ground where they were finally rescued 13 hours later.

The second paper tells "How to Prevent a Mine Explosion." The Association is indebted to Mr. S. L. Morrow, Birmingham representative of the Link-Belt Company, for these two very excellent papers, which are based on years of experience as chief engineer of a large coal and iron corporation where he was in charge of all safety work.

Other books distributed under this plan were:

"The Careful Miner," by William Goodwin, Associate State Mine Inspector.

"Prevention of Accidents from Falls of Roof and Coal" (Illustrated), by Jas. L. Davidson, Secretary, Alabama Mining Institute.

"Typhoid Fever and How to Avoid It," by Jas. L. Davidson.

The next safety paper originated from such an unusual source that numerous requests for copies were received from all parts of the country.

The paper was written by a negro convict in the Aldrich Convict Mine, who was awarded first prize in a safety essay contest held among the inmates. The title, "And Teach Others," was selected because the writer, Alex Mitchell, used that expression, underscored, many times, thereby showing his appreciation of the fact that "No Man is safer than the most careless man in the mine." The original of this essay is now filed in the Department of Archives and History at the State Capitol in Montgomery, Alabama.

Essay Contest Among Children of the Schools

Following this contest, the DeBardeleben Coal Corporation offered cash prizes for the four best essays written by school children under 16 years of age, dealing with safety conditions in and around coal mines of Walker county.

Among the many excellent papers received, that of Gwendolyn Gentry, Coal Valley, Alabama, and the joint paper by Dorothy Davis and Louise Smithers, of Sipsey, Alabama, divided first honors and are being printed for distribution among the coal mine employees of Alabama.

The State Board of Health and the various county Boards of Health have rendered unstinted help and cooperation in the promotion of this

work and during the months when sanitation and hygiene were the subjects covered they supplied speakers for all of the chapters.

Although with the exception of a few chapters the Alabama organization is only a little over a year old, accidents have been materially reduced, and the Alabama Council plan is being used as a model for organizations in other states.

The Alabama Mining Institute defrays the expenses of printing the pamphlets. Also all other general expenses connected with the work, including transportation of the speakers and entertainers. All administrative and clerical work in connection with the Central Council, together with the arrangement of programs and setting of dates for speakers and entertainers, has been done by the office force of the Alabama Mining Institute.

Discussion Following Mr. Davidson's Paper

CHAIRMAN YATES: We will take about 10 minutes for discussion of this paper. There are a great many coal miners here and they are the ones who are able to discuss it, although we would like to hear from any of you.

J. J. FORBES (Mining Engineer, U. S. Bureau of Mines, Pittsburgh, Pennsylvania): Spending in the neighborhood of five years with Mr. Davidson in Alabama, I was certainly pleased to see this splendid paper. There is one feature of this paper I think he should have harped on more and that is the activities of the safety association. He has it in his paper, but I do want to call attention to the splendid work that has been done through the Holmes Safety Chapters throughout the state of Alabama.

There are 40 of these chapters now operating in the state. This is the first district in which we tried out the council plan of the Holmes Safety Association. The district council is made up of all the forces in that state that work for safety, operators, miners, insurance carriers, state mine inspectors and Bureau of Mines representatives. Every once in a while this council gets together and lays out an appropriate program on some phase of accident prevention work and health. In addition they help to secure speakers that will go out and put on some real live talks on some phase of accident prevention and health. I think Mr. Davidson will agree there has been some very splendid results in accident prevention work that have come from the formation of these chapters throughout the state.

J. T. RYAN (Vice President, Mine Safety Appliances Company, Pittsburgh, Pennsylvania): I have just one criticism of my good friend, Davidson's paper, and that is his modesty. He told you all about the activities for safety in the mines of Alabama, and it is a very wonderful paper, I think. You naturally assume there is something back of this safety organization, some particularly outstanding individual that is responsible for this, but he did not tell you. That individual is Mr. Davidson himself. I think that it ought to be mentioned.

I had occasion this year in the summer to go down to one of his

meetings. I really was astounded. I think there were about 800 at this safety rally, representatives of practically all the coal companies in the state, most of their officials, some had all of their officials at this meeting. I was interested in finding out what agency was responsible for their being there, and I inquired as I went around the following week visiting the mining companies. There was but one answer—Mr. Davidson had practically commandeered them to come.

Another activity, he has a vaudeville troupe he carries around to these meetings. I do not know of anybody that works as hard in the safety game as this man does. He is out almost every night on some safety work and to make it attractive he has developed this vaudeville troupe he takes with him.

MR. DAVIDSON: I will bring over a set of our publications tomorrow morning so you may look them over if you desire.

I certainly appreciate the remarks these fellows made. I am at this time about like the boy at the university when he went to sign his examination pledge. He said, "I have not been given any assistance on this examination, but God knows I need it."

Lake Superior Companies Conducting Safety Campaign

C. S. HICKS (Technical Representative, E. I. Du Pont de Nemours & Company, Wilmington, Delaware): I want to mention the iron mining companies in the Lake Superior district are conducting a safety campaign in connection with the public schools and they have gotten some good results from it.

R. DAWSON HALL (Engineering Editor, McGraw-Hill Publishing Company, Coal Age, New York, New York): Alabama was possibly a little later than some of the other parts of the United States in taking up rock dusting. I am glad to hear so much is being done in that connection now. In some way Alabama could manage to go ahead of almost any other district in that respect. Alabama has a lot of mines which as we know them are captive mines, that is to say they are run by industries, and consequently it does not need to care so much how its coal looks when it goes into the market. Of course those who are in the commercial business have to have good looking coal; those who are supplying coal for coke ovens can supply good coal and that is all that is required. It seems therefore that it would be possible to rock dust the rooms extensively in Alabama, and thus carry the defense clear up to the face.

Limestone dust possibly is a good thing to put in the coke; it is something which will entrap the sulphur in the coal right in the coke and will form a calcium sulphate which will prevent the sulphur getting into the iron, and I think it is well worthy of consideration, this possibility of limestone dusting the rooms. It is being done in some places, I presume mostly in places where the coal is going to be used for coke, and therefore where its appearance does not matter.

Limestone, as you know, is put into every furnace and there is no reason why some of it should not be put in the form of limestone dust in the coke. Then there is the matter of dusting the cars or the rooms; it can

not be done by the stone dusting machinery conveniently because they can not carry the power up into the rooms and it is not desirable in many cases to do so, but it can be done with shovel and done effectively by the men.

MR. DAVIDSON: When Mr. Forbes was with us we built up a dual system, that is the roadways and the hauling ways slopes are thoroughly rock dusted, but the water line is kept in the live workings and water is applied to the cutter bar to keep the dust down; the car is also sprinkled down to prevent the coal dust from accumulating and we find the application of rock dust lasts much longer under that system than where the single system is employed, although the single system is in use, rock dusting applied at the face.

F. M. CORNELL (Safety Engineer, Consumers Mining Company, Harmarville, Pennsylvania): Regarding the statement Mr. Hall made about rock dusting rooms completely, we have a machine that goes to the face of the room and keeps our rooms rock dusted to the face.

MR. FORBES: I think there is another point that should be brought out forcibly. About four years ago I visited one of the first mines of Alabama where water was applied to the cutter bar mining machine. I want to give a contrast; for a number of visits I made to that particular mine prior to the application of water to the cutter bar of those machines. from the shaft bottom back 50 feet you could hardly see your hand in front of you; after the application of the water to the bar you could go out and stand right over the rotary dumps and there would be no dust; at the tippie there would be no dust at all; over the chutes there was no dust in the air. There is a large production of the state now coming from mines where water is applied from the bar, and of course that is supplemented with rock dusting.

The Problem of Water on the Bar

J. W. SMITH (Safety Supervisor, T. H. Mastin & Company, Kansas City, Missouri): I would like to inquire, when you put water on the bar, what effect does that have on slack? Does it run the slack up in the cars? In commercial mining we have to sell clean lump. If we require them to use water they complain of the water carrying slack over into the car.

MR. FORBES: You probably would have some of that. I suppose when the car reaches its destination the water has dried out and the slack is on the bottom and looks bad.

MR. DAVIDSON: In commercial mines that prepare coal, practically all the smaller sizes are washed; in fact, we wash over half the coal in Alabama that is washed in the United States. We have an elaborate cleaning and preparation system and of course the small coal and the undercutting and dust are taken care of in what we call "wash slack," which is clean and good coal and is used for certain purposes. In the coke making mines of course that is worked on in the ovens and along with the other coal because it all has to be crushed to the proper size.

We do not find application of water at the cutter bar makes any dif-

ference as to the amount of fine coal that is loaded out, because (one thing I left out of this paper but it is presumed) if you want to get rid of the dust you have to load it out. It should be loaded out and not left in the mine because after it is wet it dries out and becomes dust again.

MR. REED: Perhaps if you explain how much water you put on the cutter head, as to whether it is sufficient to make mud out of the cuttings or whether it is dampened to make it moist might answer his question.

MR. FORBES: I can answer that question. I will tell you one thing it does, it cuts down spilling along the haulageways and that is another big factor in its favor. In this particular mine I have reference to, six months after the water was applied at the cutter bar, the superintendent told me the road cleaners had been cut in two; in other words, 50 per cent had been eliminated due to the fact that the fine stuff did not sift through the cracks in the cars. I think Mr. Davidson has answered the question—about 65 per cent of all the coal mined in Alabama is washed after it reaches the surface. The amount of water used on the bar in Alabama is 20 to 30 gallons per hundred square foot of running face.

Protecting the Trolley Wires with Guards

CHAIRMAN YATES: Might I show my ignorance in asking Mr. Davidson one question? What means do you use to remove gas from a room? I am a metal miner and consequently I do not know.

MR. DAVIDSON: That is a matter of ventilation. If you have the proper volume of air that takes care of it. Of course you have to close up all the crosscuts in a room except the last one, and very often run a wing brattice to the face to get the gas out.

J. D. KERR (Assistant Superintendent, Oakfield Plant, United States Gypsum Company, Oakfield, New York): I noticed the statement by Mr. Davidson that in all the up-to-date mines in Alabama the trolley wires are guarded. I would like to have a little information on that, because this question came up with us, a man coming in contact with 250 volts, and the question arose whether it was practical to guard the trolley wire? I would like to know what method you use.

MR. DAVIDSON: That matter has given us a great deal of concern, because it has been extremely expensive to guard and maintain the guards in the proper condition, because it is worse, we might say, to have part of them guarded and have them torn down and the men rely on their being guarded when they are not; and for that reason the most up-to-date mines (perhaps I was a little strong on that statement, we have not as many mines that have all their trolley wires guarded as we should have because it is extremely expensive), but in the most up-to-date mines they are guarded.

Our experience is that when we follow the code of standards of insurance carriers by putting the old fire hose and stuff like that on them it does not serve the purpose, and we have just as many accidents as if the wire was left bare and the men know they are going to get killed if they get into it. But it is very important, if you can afford to do it, to guard them all the way where the men are liable to pass.

MR. KERR: They thought all the trolley wires in our mine should be guarded, and in figuring it up in a rough way they found it would cost something like 20 cents a foot, and with 12 miles of trolley wire in a mine it runs into quite an outlay.

MR. DAVIDSON: On the other hand, it costs you \$4,000, \$5,000 or \$6,000 a man for each man killed. That takes the profit out of several hundred tons of coal, perhaps.

MR. HALL: I was wondering what the effect of the trolley wire coming down, when you have a lot of wood there, would be? When you have hose, the hose is a non-conductor and there is not liable to be a fire at that point. If the wood happens to be damp or even wet you will have a fire because the arc will go along the wet wood and ignite.

MR. DAVIDSON: It goes right through it. I expect Mr. Harrington could answer that question better than I, and I think we had better discuss that question when his paper comes.

MR. FORBES: In my paper on "Safety Kinks," I think I could offer some suggestions to help this man from the Gypsum Company.

J. P. HODGSON (Manager, Phelps Dodge Corporation, Morenci, Arizona): I was requesting information from this gentleman who made the inquiry from Mr. Davidson, how high they carried their trolley lines? He said four to five feet. In my opinion, if they are carried only to that height they ought to be compelled to guard them. The law in Arizona compels them to be carried to a height of six feet; if they are below six feet the mine inspector might let us through if we put an inverted board on each side of the trough.

CHAIRMAN YATES: The next paper will be read by Mr. C. S. Hurter, Technical Representative, E. I. du Pont de Nemours & Co., Duluth.

SAFE PRACTICES IN BLASTING

**Charles S. Hurter, Technical Representative,
E. I. du Pont de Nemours & Company**

As my experience in the use of explosives has been gained in metal mines and outside work, this paper treats of safe practices in blasting in operations of this character only. I am not familiar with the latest developments in coal-mine practice and consequently that subject is not discussed. Many of the safety rules given in the catalogs of all explosives companies are so well known that it seems unnecessary to include them here. Likewise the subject of storage of explosives has been thoroughly covered in existing publications. Some repetition is unavoidable but I have endeavored to reduce it to a minimum. Inasmuch as I have spent the last year in the Lake Superior Iron District all specific illustrations of safety practice are drawn from this part of the country.

The need for care in handling explosives begins with unloading them from the railroad car for transportation to magazine or work. The cases and kegs should be unloaded and loaded without rough handling and men engaged in this work should not smoke nor carry matches. Explosives, blasting caps and fuse should be protected during transporta-

tion from sun and rain and sparks from steam shovels or locomotives. Covers for bodies of trucks or wagons can be built of nonflammable materials or tarpaulins of nonflammable cloth can be spread over the cases. Cases should be braced in place so there is no chance of their moving or sliding about in transit. Detonators should never be carried in the same conveyance with explosives.

The route for delivery to the work should avoid towns or at least the thickly populated districts. It should also avoid sparks and hot cinders that might be blown by the wind from steam shovels, locomotives or dinkey engines.

In some outside work it is feasible for the vehicle which takes explosives from the railroad car to deliver them direct to the place where they are to be used. In underground work, however, and frequently in large outside operations, a system of distribution from a magazine or other central point is necessary. Some good systems in use are described later under the headings of Outside and Underground Work.

Opening Dynamite Cases

The cases of dynamite should be opened by means of hardwood mallets and wedges. This rule seems to be lived up to in the Lake Superior district with few exceptions. A few mines use copper wedges. In the past phosphor bronze chisels were used very extensively but because of the brittleness of this alloy and the greater safety of wood, they have been almost completely discarded. Excellent wedges can be made from broken pick and shovel handles. Wedges for opening dynamite cases should be kept clean and free from grit. In fact, friction from grit must be avoided as much as possible all along the line in the handling and use of explosives.

Cases should never be opened in a storage magazine nor close to a large stock of explosives. Some companies have a rule that not more than 100 pounds (two cases) shall be opened at one time before being loaded. Some have a rule that there must be a distance of 100 feet between cases opened for loading and unopened ones. Dynamite should never be exposed to direct rays of the sun for any length of time, no matter what the temperature. The sunlight decomposes nitro-organic compounds, thus not only lowering their efficiency, but also creating the hazard of acid dynamite.

Proper priming of the charge is of first importance, both because of the possibility of accidents in making primers and because of the chances of premature explosion or of misfires from improperly made primers.

Special care should be taken in the handling of detonators because they are the most sensitive materials used in blasting. The lid should be kept on a box of blasting caps at all times except when a cap is to be taken out for use, and every other precaution should be taken to prevent grit or dirt from falling into the cap, for even small particles of grit or dirt might cause enough friction when the fuse is inserted to produce an explosion. Blasting caps should never be extracted from the box by means of a stick, wire or any similar implement. Tip the box

over the left hand and shake it gently until the caps begin to slide out so that one can be removed with the fingers.

If the end of the fuse is distorted do not try to force it into the cap. If it can not be rounded back into shape by the fingers, or squeezed into shape by a cap crimper, make a fresh cut. With a sharp knife and a piece of wood for a base it is easy to make a clean cut end.

The end of the fuse should be brought into contact with the cap charge gently. The cap should not be twisted while being placed on the fuse because of the extreme sensitiveness of the charge to friction. A properly designed crimper, such as is sold by the principal explosives companies, should always be used. Tests have shown that a blasting cap is much more effective when fastened on fuse properly than when it is held in place by the dent from the teeth or the heel of a knife blade or when no crimp at all is used. This shows that even a violent quick explosive like fulminate of mercury requires "tamping" to exert its full explosive force.

The end of a fuse exposed to the air for any length of time should never be placed in a blasting cap, because the powder train may have absorbed enough moisture at the end to impair if not destroy the end spit of the fuse into the cap. Where there is a misfire and fuse removed from the cap shows even a very small shred of the center core thread it means that the end was damp and the fire did not burn through.

In wet work it is advisable to waterproof the joint between cap and fuse. This can be done by smearing it with hard cup grease or tallow, or even hard yellow bar soap; or by dipping the cap and a few inches of the fuse in P B or other asphalt paint or in one of the special compounds sold by the explosives and fuse companies for this purpose. Neither vaseline nor cylinder oil nor any of the lighter oils or greases should ever be used because these attack the waterproofing compounds. When the liquid protectors are employed, the primers should be made up and used immediately because these compounds become so brittle after drying for a few days that they are likely to crack and admit water.

A large majority of the primers are made with the cap in a hole at the side of the cartridge. This is the safest type. The hole for the cap should be large and deep enough to allow the cap to be inserted without resorting to force and it should be as nearly as possible parallel with the axis of the cartridge. The greatest effect of a detonator is in the direction in which the loaded end points. Therefore, placing the detonator in the priming cartridge so that it will point along the charge instead of against the side of the bore hole aids complete detonation and reduces the possibility of poisonous fumes from burnt or incompletely detonated dynamite or unexploded dynamite after the blast.

Some Practices to Be Condemned

The hole for the detonator can be punched with the pointed leg of the cap crimper, and some types of crimper are made with curved leg to facilitate punching the hole parallel to the axis of the cartridge. Hardwood punches are used by many. These should be destroyed periodically

as they absorb nitroglycerin in time. A very serviceable punch can be made from a piece of copper trolley wire of the proper diameter by sharpening one end and bending the other into a rough handle so that it can be hung up. Large nails are not recommended as punches because men have a tendency to drop these when they have finished with them and thus create an accident hazard for anyone passing by. Cutting a gash in the side of a cartridge, laying the detonator in this and then closing the cartridge around it is not a good practice but with some of the delay electric firing devices this is the only practicable method.

The usual method of making cap and fuse primers is by lacing the fuse through the cartridge. This is pretty generally followed except on the Mesaba and Vermillion Iron Ranges in Minnesota and in some mines on the Michigan Ranges. It is a bad practice because it introduces two sources of trouble. The first is sharp bends and kinks in the fuse which may break the powder train, or in the case of wet work may admit moisture to the powder. Very few men employing this method take pains to avoid sharp bends in the fuse. The second source of possible trouble is fuse in contact with the explosive. This may result in ignition of the dynamite by side spit of the fuse before the powder train burns through to the blasting cap. With the less inflammable types of explosives, such as the ammonia dynamites and gelatins, and the improved fuse now supplied, there is little danger of burnt charges from this source, but with straight dynamite care should be taken to have as little of the fuse in contact with the explosive as possible. With straight gelatin, unless this precaution is observed, the highest quality of fuse obtainable should be used even if the work is dry.

In making primers with electric blasting caps, the practice of hitching the wires around the primer cartridge is almost universally followed in spite of all recommendations to the contrary. The principal danger in this is possibility of injury to the insulation on the cap wires when drawing these hitches tight. Most miners realize this danger and use care in this operation.

Placing the Primer in the Charge

When loading the charge, the common practice throughout the east and middle west is to place the primer at or near the top of the charge. This allows the detonator to exert its full force against the bulk of the charge, prevents fuse from coming in contact with the charge and gives the greatest measure of safety in loading. In the west the common practice in underground work, particularly in drifting, is to place the primer in the bottom of the hole or next to the bottom cartridge. The reason for this is that when a round of holes is fired in rotation, there is always a chance that the explosion of one may cut off the collar of the hole intended to follow, thus generally spoiling the round and leaving unexploded dynamite in the broken rock or in the bottom of a partly broken hole. I have been present when a shot of this kind has thrown the primer out into the muck and it has exploded there. If the primer is in the bottom it will be undisturbed even if the collar of the hole is

blown off and usually the fuse will already have burned down below the point where it is severed. Cut off holes are more likely to occur in small dimension faces than in large ones. Where they are feared, it is best to use the least inflammable type of dynamite adapted for the work and the best quality of fuse; load one cartridge in the bottom of the hole so that it fills the space as completely as possible; and put the primer in next with the business end of the detonator pointed toward the collar of the hole.

Complete detonation of a charge is essential to avoid poisonous fumes after blasting and the possibility of unexploded powder being thrown into the muck or left in unbottomed holes.

While the perfecting of low freezing explosives has rendered the thawing of dynamite practically obsolete, there are one or two explosives that have not yet been made fully satisfactory on a low freezing formula. Therefore occasion may some time arise to thaw dynamite. The

Figure 1. Covered car with insulated body used by Oliver Iron Mining Company in transportation of explosives in underground mines.

principle in thawing dynamite safely is to thaw slowly at a moderate temperature with the cartridges lying flat. When dynamite freezes the nitroglycerin separates from the dry ingredients and congeals into small crystals. If these are melted very slowly, the nitroglycerin will be reabsorbed in the dry ingredients as thoroughly as it was before being frozen. If the nitroglycerin melts more rapidly than it can be reabsorbed, it tends to run downward and if the cartridges are standing on end, may collect at the bottom of the shell and leak out. Leaky cartridges are always dangerous.

The recommended temperature for houses or rooms where thawing is done is 90 degrees Fahrenheit. The dynamite should never be placed directly over the source of heat. First, this may cause too rapid thawing with attendant leakage. Second, it is a fact that a drop of nitro-

glycerin falling from the height of one foot on a hot metallic surface will explode. Dynamite should never be thawed in front of an open fire. In addition to the hazard involved in having explosives near an open fire, there is danger that the intense radiation will thaw the dynamite too fast and cause leakage of nitroglycerin. Furthermore, there is the possibility that the outer layers of explosive will be heated to a sufficient temperature (360 degrees F.) to produce accidental explosion.

The old practice of thawing dynamite cartridges in hot water can not be too strongly condemned. Water, particularly when hot, will replace nitroglycerin in dynamite and cause it to leak out—and free nitroglycerin is always very dangerous. In spite of the greatest care, nitroglycerin will occasionally leak from dynamite that is being thawed and, for this reason, where water jacketed kettles are used for thawing dynamite, the water should never be heated in them but should be warmed in another receptacle and then poured into the water jacket of the thawing kettle.

Thawing by manure is very efficacious but the dynamite should never be placed in direct contact with the manure because of the high moisture content of the manure and the chemical action taking place in it which generates the heat. The dynamite should be placed in a moisture proof container and this be banked around with the manure.

Use of Explosives in Pits, Quarries and Other Outside Work

Protecting Explosives from Sparks

In large pits and quarries one of the principal sources of danger with explosives is from sparks from steam shovels and locomotives. If conditions permit, this danger can be reduced almost to nothing by use of an explosive of low inflammability. Explosives should be conveyed to the place where they are to be used in well covered trucks or cars. (Figure I shows the type of car used by the Oliver Iron Mining Company in their open pit operations.) Where there is danger from sparks and hot cinders, primers should be made up only as needed and should be kept covered and at a distance from the main supply of explosives. Detonators should be kept in closely covered boxes until needed.

Loading Holes

In loading deep well drill holes it is a wise precaution to lower large cartridges instead of dropping them. The simplest method of doing this is to place the cartridge on a corrugated wooden peg to which a sash cord is attached. The peg can easily be jerked out after it reaches the bottom. Some operators use a special pair of tongs for lowering large cartridges. If cartridges are to be dropped, it will be found that those 10 and 12 inches in length keep their alignment better and are less likely to hang up and get stuck in ragged holes.

Sometimes the holes are so ragged that it is necessary to remove the dynamite from the paper shell. When straight or ammonia dynamite is poured from the cartridge into the hole, it runs into the cracks and crevices and there is danger that small quantities of unexploded dyna-

mite may be left in the broken rock after the blast. Furthermore, if there is any water in the bottom of the hole, the dynamite will become intimately mixed with it and the effectiveness of the explosive will thus be reduced at the point where greatest strength is needed. Therefore, for loading ragged holes where the explosive must be removed from the wrappers, gelatin is by far the safest and most economical. Having a consistency like putty, it can be cut into chunks and dropped into bore holes, little if any being caught in side cracks and fissures. As gelatin is highly water resisting, especially in the 60 per cent and higher strengths, water in the bottoms of the holes will not lessen the explosive force.

Some blasters have recommended increasing the efficiency of the blast by placing extra blasting caps at intervals in an extended charge. This

Figure II. Chain blasting mat placed over bore hole before springing the shot.

is not necessary with the present types of high explosives and adds appreciably to danger in the operation of loading. If the explosives used are so insensitive as to require a boosting effect to produce proper detonation throughout the charge, it is more effective and safer to use Cordeau-Bickford.

Some operations, such as the open pits on the Mesaba Range, are large enough to require one crew to spring holes while another is loading the blast. A few accidents have been caused by the springing crew hooking on to the wrong set of wires and firing a main blast instead of a spring. The Oliver Iron Mining Company has a rule that as soon as a hole is loaded the ends of the detonator wires shall be twisted together and taped and shall remain so until it is time to connect up and fire the blast. If a springing crew finds any wires twisted together and taped they know they are to be left alone. There is also a rule in all the pits on the Range that no springing shots shall be fired in the immediate vicinity of holes that are being loaded.

The tamping of charges should be done firmly but not violently. For deep well drill holes, a block of wood attached to a rope is one of the

best tampers devised. The block should be from 18 to 30 inches in length and of proper diameter to move up and down easily in the hole. If there is much standing water in the bore holes, a hole can be bored into the lower end of the block and melted lead poured in to give it weight. One large cement company of this country, as a safety precaution, provides a mat made of old cement sacks on which the tamper can be placed when removed from the bore hole. This prevents small particles of rock and grit from sticking to the block and getting into the bore hole. Such particles constitute an additional element of danger in loading because they are likely to create a dangerous amount of friction.

The stemming material should be a clay loam, if possible. It should always be free from coarse pieces of grit for these are likely to injure the insulation or cut the cap wires and cause misfires. The first foot above the charge should be tamped very gently, if at all. Above this the packing can be firmer. To reduce friction and wear on detonator wires, the tamper should be moved through the minimum space necessary to insure good packing. The wires should be kept along one side of the hole and not allowed to cross it.

Springing Holes

Where it is necessary to spring holes it is of utmost importance to be sure that the chamber is properly cooled each time before a subsequent charge of explosive is loaded. Some blasters test the temperature of the hole by leaving the tamper in it for five or ten minutes and feeling it to see if it is hot when withdrawn. Others leave a sprung hole several hours before loading it. One large limestone company provides special thermometers for testing the temperature of sprung holes and no explosives are introduced if it is possible to get a reading above 90 degrees Fahrenheit. Where conditions are favorable, water tamping can be used for the springing shots and this serves to keep down the temperature of the bore hole. Some operators even pour water into the hole after the springing shot to cool off the chamber. Others blow compressed air into the cavity. Paper, sawdust or other inflammable materials should never be used for tamping springing shots as they may leave sparks or embers in the chamber. Investigations of the operation of springing holes tend to show that the danger of loading explosives too soon after the springing shot is due to hot pieces of rock in the chamber and, in the case of cap and fuse firing, of embers from the fuse rather than too hot walls. Therefore it removes one source of danger to fire all springing shots by electricity.

Prevention of Misfires

Misfires are about the most serious source of danger involved in any kind of blasting. The possibility of a misfire is greatly reduced if more than one detonator is placed in each hole. With electric blasting, if the current is not sufficient for these extra blasting caps, they should not be connected in the circuit but left as a reserve in case of trouble.

A frequent cause of misfires, especially misfires of center holes in a long line, and in particular in the presence of certain earthy salts in the ground water, has been leakage of electric current. Even minute

traces of some earthy salts in solution will increase the electrical conductivity of the ground enough to cause excessive current leakage from the wires of ordinary electric blasting caps. The only sure way to prevent misfires where such salts are present in solution is to use electric blasting caps with enameled wires. The enamel on the wire under the cotton winding provides extra insulation. Waterproof electric blasting caps are regularly made with enamelled wires.

I have seen cases where it was necessary to use waterproof caps on what would be called dry work. In fact, the problem of current leakage makes it necessary to limit the number of ordinary electric blasting

Figure III. Portable shelter house used by the Oliver Iron Mining Company. Left, the house in position; right, tipped on its side it is ready to be rolled to a new position.

caps that should be connected in one series, regardless of whether the work is wet or dry and of the source and amount of firing current available. One explosives company puts this limit at 50. Where it is necessary to connect longer lines of electric blasting caps in series, nothing but enamelled wire caps should be used, no matter how dry the work may be.

The surest method of firing electric blasts is to connect all detonators in parallel and use a power current. I would advise that the parallel method be used whenever possible and the connections from the firing line be made cross cornered across the blast to insure an even distribution of current.

While all electric blasting caps are tested within very close limits for bridge resistance, it is impossible for all bridge wires to have exactly the same resistance. Consequently some caps are bound to be more sensitive than others. This makes it undesirable to use a firing current that builds up after it enters the blasting circuit. Such a current is likely to cause the more sensitive caps to explode first and destroy the circuit before others receive enough current to fire them. This build-

ing up of the current is the cause of the failures that so frequently occur when attempts are made to fire more than one shot at a time by means of dry cells or storage batteries. For this reason blasting machines are short circuited until the end of the rack bar stroke, the current being thus built up to full intensity before being thrown into the firing circuit. For the same reason there should always be a load on the dynamo that furnishes current for a firing circuit when a blast is about to be shot.

This phenomenon of building up effect in an electric current also has a bearing on the use of alternating current for firing blasts. The shortest interval of time between the application of the firing current and the explosion of an electric blasting cap is 0.014 seconds. Now, in the 25 cycle current, the half cycle is 0.02 seconds, which is a longer period of time than 0.014 seconds. Consequently, there is a possibility that a current of 25 cycles may be thrown into the blasting circuit in such a manner that a building up effect, similar to that of the dry cell, will take place and cause a misfire in a series blasting circuit. To avoid possibility of misfires, the crest of the alternation must always pass through a series connected blasting circuit in 0.014 seconds. As the half cycle of the 50 cycle current is 0.01 seconds and of the 60 cycle current 0.0083 seconds, which are both less than 0.014 seconds, the 50 and 60 cycle alternating currents can be used for firing series circuits with the same assurance as direct current. The 25 cycle current can be used for parallel connections with perfect safety because the explosion of one electric blasting cap in this type of connection does not instantly destroy the circuit.

Handling Misfires

The handling of misfires is a serious problem. The safest procedure in outside work seems to be always to measure the distance between the top of the charge and the collar of the bore hole and then, if a hole misfires, to remove the tamping to within a few inches of the charge, load a fresh primer and shoot again. One quarry superintendent in the east always measures the distance in his well drill holes and uses a good loam tamping free from grit. If a hole misfires, he takes a sharp pointed wooden stick of about one and one-half inches diameter which he moistens from time to time with water, makes a hole to within a few inches of the top of the charge, loads this with several one and one-fourth by eight-inch cartridges of dynamite and a fresh primer and fires this charge. So far this procedure has never failed to pull the missed shot. Where a missed hole can not be reached, the greatest care should be taken in working around it until the powder charge can be located and either fired or removed.

Secondary blasting requires a number of safety precautions. In the past, it was customary for a man to continue lighting pop shots as long as he thought it safe to do so. Now, most companies have a rule limiting each man to lighting five fuses at one time. Very few allow less than two and one-half feet of fuse to be used and a great many place the shortest length of fuse at three feet.

Some people consider the tamping of pop shots as unnecessary. From

the economy standpoint this opinion has been proved wrong and it is wrong from the safety standpoint also. As fuse burns it twists around and I have known of several premature shots caused by burning fuse twisting in such a manner that the fire from it was directed against the explosive in untamped holes. To prevent accidents all pop shots should be tamped or covered in such a manner that fire from burning fuse can not strike the explosive.

One of the greatest dangers in outside blasting is from projected debris. As a rule this is not so great in large primary blasts unless they are overloaded, but with block holing, mudcapping, hole springing and smaller blasts, care must be taken to guard against damage from

Figure IV. Type of covered car with insulated body, Oliver Iron Mining Co., for transporting explosives in some open pit mines.

fragments thrown by the blast. The first precaution is to see that all approaches are properly guarded to keep people from coming too close. The second is to prevent fragments from being thrown, if possible. This can generally be done by placing rope or wire mats, piles of logs or railroad ties or brush over the hole before firing. (Figure II shows a chain mat which it is the practice in the Oliver Iron Mining Company to place directly over a bore hole before a springing shot is fired.) To prevent spalls from being thrown from springing shots in snake holes, some operators use cylindrical blocks of hard wood bound around with two flat steel bands and provided with two handles. The block is placed directly in front of the snake hole and two or three feet distant.

The Oliver company also uses a very practical portable shelter house. This is cylindrical in shape with a rim set out from the top and another from the bottom to serve as wheels. (See Figure III.) When it is

desired to move this shelter a short distance it is a very simple matter to tip it over on its side, roll it to the new position and set it up again. This shelter also has a ring in the top so it can be picked up by a wrecking crane and placed on a flat car. It is a rule that one of these shelter houses must be kept immediately back of each steam shovel so that there is no reason for anyone taking shelter beneath a shovel when a blast is fired. Additional shelter houses are provided at convenient places where track crews and others may have a place of security at all times.

Underground Work

Transporting Explosives

If explosives have to be transported any distance underground, a covered car insulated from the rails should be used. Insulation is sometimes secured by a layer of thick rubber matting; sometimes by glass insulators. (Figure IV shows the type of covered car with insulated body used by some mines of the Oliver Iron Mining Company.) Where there is an electric hauling system with overhead trolley it is safest to shut off the current and push the car of explosives by hand or pull it by means of a horse or mule. If necessary to haul the powder car by motor, it should be located so that sparks from the trolley can not fall on it.

Storing and Distributing Explosives

Some operators prefer central distributing magazines where the miners receive, each shift, the dynamite and capped fuses necessary for their work. The advantages of this system are that it reduces the time explosives are in the mine before being used, prevents blasting with old dynamite, fuse or caps, assures proper capping of the fuses, and, in short, makes it possible to keep close watch over the entire storage and handling of explosives and blasting supplies.

The dynamite and the detonators should be stored in separate magazines located at such a distance apart that any explosion in the cap magazine will not be communicated to the dynamite. This distance will depend on the maximum number of detonators to be kept in stock at any time. For calculating the proper distance the weight of the detonator charges can be considered equal to the same weight of 40 per cent dynamite.

Where underground magazines are lighted by electricity, the wires should be enclosed in substantial conduits. The lamps should be of the double bulb vapor proof type. In case these are not available, it is best to cut a hole in the front wall, fix on the outside over this hole a box with a glass side next the magazine and place the lamps in this box, thus avoiding having any live wires inside the magazine. Furthermore, a place should be provided at a safe distance from the magazine for the miners to leave their lamps while getting blasting supplies.

Some companies prefer to have the miners keep their explosives in individual boxes, near the working places. This saves time that would be spent in a long trip to a central magazine and does away with the

hazard involved in having a great many men carrying sacks of explosives along haulage ways and up ladders. I believe that where a central storage magazine is maintained with a properly qualified man in attendance, there is less danger of an accidental explosion. However, if an accidental explosion should occur in a central magazine, it would do more damage than an explosion where the men have widely separated individual storage boxes. Mining companies base their practice in underground storage upon their opinion as to the relative importance of these two considerations.

The safest means for carrying explosives in small lots underground is a heavy canvas sack, with a flap and snap to prevent dynamite from falling out enroute and shoulder straps so that a man will have both hands free in climbing ladders. Where central magazines are used there is always a rule that miners must not carry dynamite and detonators at the same time, but as miners naturally dislike to make two trips instead of one, about the best that is accomplished is for them to carry their dynamite in such a sack and their capped fuses or electric blasting caps in their hands.

Since the carbide lamp has largely replaced the old oil lamp and candle underground, the spark hazard has been greatly reduced. A miner when preparing his primers should never wear his light in his hat but should place it at a safe distance from the dynamite and caps and in such a position that it can not fall on the explosives and that the air current will carry any sparks away in the opposite direction. Most of the mines in the Lake Superior district have staples in the timbers so that the lamp can be hung at least 25 feet away from the place where the miner makes up his primers. At no time during the handling of explosives should a lamp be carried so that there is any danger that sparks or flame will come into contact with the explosives or that the lamp may fall into them.

There is much greater likelihood of too violent tamping in underground work than in heavy outside blasting, such as well drill shots where the tamping is done by raising a block of wood and dropping it

Figure V. Blow pipe with brass tip, for blowing out tamping by compressed air, used in the Eveleth district, Minn.

on the explosives in the bore hole. The tamping of charges underground should be done by means of a wooden rod cut square across and having no metal parts. The principal source of danger in tamping holes is from grit. Consequently it is of great importance to clean a bore hole as thoroughly as possible before starting to load. No matter how well a hole may be blown out, however, there is always some grit present. If the tamping is done too violently, so that the rod penetrates the cartridges, there will also be some explosive smeared on the sides of the bore hole. The grinding of a heavy metal or metal tipped rod against the grit may strike a spark which will explode the powder smeared on the sides of the hole and lead to premature explosion of the charge. Some metals, such as iron and steel, are more likely to strike a spark than others, such as lead, copper, brass and bronze, but the weight of any metal or metal tipped rod makes it a dangerous implement for tamping explosives. Even with a wooden rod there is still some danger from grit grinding on grit and on the rock sides of the bore hole, so the tamping stick should never be wielded with great force. A short, firm, but not violent stroke is best. Aside from the safety reasons for operating a tamping stick with care, too violent tamping also makes pockets or air spaces in the charge which reduce its efficiency.

The best material for tamping consists of clay, sand or fine dirt, free from grit or sharp particles, made up into dummy cartridges. The use of dummy cartridges reduces abrasion of the fuse or electric blasting cap wires to a minimum and thus reduces the possibility of misfires. Paper wads should never be used for tamping. I was present on one occasion when the paper wad was used for tamping was found burning out in the open immediately after a blast with a permissible explosive. Such an occurrence would create a grave fire hazard in a dry timbered place. For the same reason, sawdust, bark from the timbers, or other inflammable material should never be used.

Misfires are the bane of all people using explosives and in particular of underground miners. There is no fully satisfactory method of handling them. If the tamping can be picked out carefully down close to the explosive, a fresh primer will generally explode the charge. The Oliver Iron Mining Company in its mines in the Eve-

Figure VI. Blasting switch with padlocked box; handle and cord are separate units.

Figure VII. Two views of blasting machine fitted with Yale lock, of night latch type, used by Oliver Iron Mining Company.

leth district in Minnesota, uses a blow pipe with a brass tip for blowing the tamping out by compressed air. (Figure V.) Whatever the means employed, it is always best to keep the hole drenched with water while the tamping is being removed. A common rule for handling misfires is to drill a second hole alongside at a safe distance, this distance depending upon the size of the charge in the missed hole, load the second hole with dynamite and fire by means of an electric blasting machine. This will generally explode the missed hole. Some companies keep a record of all misfires and classify them as to cause. This has sometimes led to discovery and correction of improper practices when it was found that a large number of misfires were traceable to a common cause.

The Oliver Iron Mining Company has an excellent system of safety precautions for electric blasting by means of a power current. In most mines the regular 250 volt trolley current is used. A cut out switch is located between the firing switch or switches and the source of power. This switch is provided with a chain and padlock, and the key is in the possession of the blaster only. When the switch is open, there is a wire connecting the far side of the trolley line with the rail to take care of any current that might possibly leak across the switch.

The wires then lead from the cut out switch to the blasting switch which is enclosed in a padlocked box (shown in Figure VI), the key of which also is always in the possession of the blaster. This switch consists of two sockets containing metallic terminals and a fibre handle with two copper points. The bringing together of the points and termi-

nals at the proper time closes the circuit and fires the blast. The principal safety feature of the switch is that the fibre handle falls away as soon as the blaster lets go. There is no possibility that he can thoughtlessly leave the switch closed, return to the face to investigate a misfire, mend a broken connection and be caught by the blast—an accident that has happened in more than one mine where safety switches were not provided.

As an additional precaution the circuit is provided on the blast side of the firing switch with two sets of trailer connectors. When not in use, the circuit is broken at this point and the wires from the firing switch and the connectors at the end are locked up in the switch box. This connection is the last one made before firing the blast.

Making Use of the Firing Switch

The method of firing is as follows: first the wires of the electric blasting caps are connected properly at the face either in series or in parallel. Next the cut out switch on the trolley line is opened and locked in place and the ground wire on the dead side is connected to the rail. Then a delay electric igniter is connected across the ends of the leading wires at the face. If this flashes it shows that a dangerous amount of current is leaking into the line from some source and this must be corrected before the leading wires are connected to the wires at the face. After the connections at the face are made, the firing switch box is opened and the handle is connected with the leading wires to the blast by the trailer connectors. The terminals of the firing switch are next brought together, thus firing the blast. The trailer connectors are then taken apart and those with the wires to the switch handle are placed in the box which is locked once more. Finally the trolley cut out switch is closed.

In some of the districts of the Oliver Iron Mining Company blasting machines are fitted with a Yale lock of the night latch type. It does not interfere with the downward stroke of the rack bar but it must be opened by the key before the rack bar can be raised to fire a blast. (Figure VII shows two photographs of a blasting machine equipped with such a lock.)

Pickands, Mather & Company also have a good system for guarding against accidental explosions from stray current. The electric current is taken from the trolley wire of the haulage system, a 250-volt D. C. current in which the two rails are used for a return. As the haulage load is heavy, there is a considerable drop in the voltage in the rail return, which gives rise to voltage differences between the rails and the neighboring pipes, and often between the two rails, with consequent leakage of current from one to another. This is taken care of as far as possible by cross bonds between the rails themselves and between the rails and pipe lines, but careful provisions are also made to protect the blasting circuit from stray current.

The blasting switch is composed of two double pole switches mounted in a cabinet and operated by handles on the outside. The switch, which has its blades connected with the blasting cable, is equipped with two

sets of clips so arranged that in the off position the blades are short-circuited. The other switch is the firing switch proper. It is held in the off position until the moment of firing the blast. When the two handles are pulled, this second switch is thrown in, the short circuit in the first switch is automatically broken and the current flashes into the blasting circuit. Both switches are held in the off position by springs and by gravity and are provided with a locked cover over the handles that can not be closed until the switches are in the off position.

A 20 ampere fuse is used in the leading wire from the trolley wire to clear the line in case of short circuit at the blast. For still further protection, there is a safety jumper in the circuit between the switch and source of power, consisting of a short piece of cable provided with special attachment plugs at each end. This jumper is removed and carried by the blaster until the time comes to fire the shot. As long as it is out, the switch is entirely disconnected.

Instead of ordinary cotton covered leading wire, a duplex covered portable cable is used between the face and the switch, and standard rubber covered wire installed on porcelain knobs for the remainder of the blasting circuit. At the face the caps are connected in series or in parallel as desired, and then a loop of connecting wire is spliced to the two end cap wires. The two leading wires are both joined to the connecting wire loop and this is then cut between the two joints, a galvanometer test being made for closed circuit in the leading wire before these joints are made.

The chief feature of this system is that the blasting circuit between the face and the switch is short circuited up to the moment of firing. This feature together with heavily insulated wiring, a switch that is practically fool proof, the safety jumper, and cross banding between rails and pipes, greatly reduces the hazards of electric blasting underground.

In closing this paper, limited chiefly to safety precautions in handling explosives that, perhaps, are not so widely known, I wish to express briefly my thanks for the assistance and information given me by Messrs. G. J. Barrett and Frank A. Pollock, of the Oliver Iron Mining Company, George Martinson and Lyle Hendrickson, of Pickands, Mather Schaus, of Oglesby, Norton & Company.

Discussion Following Mr. Hurter's Paper

DR. E. M. PARLETT (Safety Director, Pittsburgh Limestone Company, New Castle, Pennsylvania): I was always under the impression the safest method was to connect up the fuse last, I mean from your direct line of battery; therefore just what advantage is that short circuit?

MR. HURTER: My idea is to start at the face and work back.

GEORGE MARTINSON (Safety Engineer, Pickands, Mather & Company, Hibbing, Minnesota): I wish, Mr. Hurter, you might explain to these men the short circuit is in the switch itself.

MR. HURTER: The Pickands, Mather switch is a double switch that remains in the proper position by gravity except when operated. There are two handles which drop unless they are picked up. If you are shoot-

ing on the right side, the right handle automatically closes the short circuit in the lead wires coming from the direction of the face; the other one opens the circuit at the source of the power. When a man operates that switch and pulls up both handles, the right hand one opens the short circuit to the firing switch and the left hand one closes the connection to the source of power. The Oliver people use a different type. They have about 10 feet of wire, with this little contact arrangement, fiber handle with two points on one end and trailer connectors on the other, with their layout. This short wire with the contact and half of the trailer connection is locked up in the box when the firer switch is not in use; the other trailer is connected from the short circuit, the same principle, only applied with a different apparatus.

MR. DAVIDSON: I mentioned in my paper, but ran over it in reading, in handling black powder we have found the use of the powder jack is very valuable to prevent accidents, and also the use of fiber pocket boxes to carry the detonators is also very valuable in connection with that. We have had a number of accidents in our section to children, who have been seriously injured or killed by explosion of dynamite caps, and we procured from the Du Pont Powder Company their little tract dealing with the danger to children and other people from handling the detonators, and we sent those pamphlets to all the schools and superintendents in the mining districts and the public schools in our immediate vicinity. We had so many calls for copies that the Institute printed 5,000 copies and we are receiving extra calls for it every day. I would suggest to you gentlemen to procure copies of that pamphlet and distribute it to your people on the outside.

Detonators Set Off by Extra Current

MR. GRABOWSKY: Mr. Hurter made a statement that the Oliver and other companies in the Lake Superior district go into considerable expense in protecting men in the use of explosives. I wondered if you referred to the use of black powder in that connection?

MR. HURTER: Yes, sir. I want to say I am a metal miner and not a coal miner. I would like you men that are coal miners to get up and give your ideas in connection with blasting and make this thing as complete as possible.

MR. RYAN: In connection with this extra current hazard, I would say it is more of a hazard in the coal mines than in the metal mines. You have the possibility of starting a dust explosion if the mines are not rock dusted. One of our large companies had an explosion which they attributed to detonators being set off by extra current; they made an investigation and found they had about eight or nine volts extra current, so they got one of the powder companies to develop a detonator that required about 11 current to fire. They carried their investigation to another mine, which did not have electric wiring, and they got as high as 150 volts, extra current, so they decided there was not much use going to 11 volt detonators; so I will point this out, that in addition to the direct hazard the indirect hazard also exists.

A. H. TRESTRAIL (Range Safety Inspector, Pickands, Mather & Company, Caspian, Michigan): In connection with Mr. Davidson's remarks about those pamphlets sent out to school children. When I was about nine years of age I found a stick of dynamite laying along a railroad track and I had quite a time with it. I did not know what it was. The superintendent of schools out in our district got hold of a lot of dummy blasting caps, placed them on a large poster with words to this effect: "This is a blasting cap—very dangerous—do not play with it." A lot of children would not know a blasting cap if they found it.

MR. DAVIDSON: I should have said we are distributing dummy caps along with the pamphlets.

If you will permit me just a moment more—the rules of the mining law require when a man gets ready to fire he will holler "Fire!" and we adopted the practice of having the next man to him answer back, to see that he has heard him. Sometimes the man is coming through and does not hear him and he will get hurt.

MR. GRABOWSKY: In connection with Mr. Trestrail's remarks I believe it is the practice of all safety companies on the Mesaba range to work in cooperation with the schools. I believe many schools are members of the N. S. C., and are the proper places for illustrating the dangers of blasting caps.

Cooperation Among the Mining Experts

MR. HODGSON: I wish to say in regard to Mr. Hurter, gentlemen, I have known him for 20 years. My first attention was called to him when I was operating in northern Michigan in underground iron mines. I became acquainted with him in a casual way and asked him if he would come down to my mines and investigate our use of powder to see if any economy could be effected. Of course he is in the game to help his firm sell powder, I presume, but he is a technical man, and he acceded to my request, came down and made a survey for me in the mines I was then operating and as a result of it we cut down on our use of powder and effected a saving of 25 per cent of our explosives.

Again, after going to Arizona, and finding there was an extreme wasting of powder there, I asked for Mr. Hurter to be sent down. This was out of his territory and they had a representative in California, but the powder company acquiesced. He made a very exhaustive investigation and repeated the operation. I want to express appreciation of Mr. Hurter as not only being a safe man to have around to show you how to handle powder but also how to economize in its use.

MR. SMITH: I would like to ask if any one here has had experience in tamping holes with limestone dust?

MR. HURTER: You mean the safety feature of blowing the limestone dust out?

MR. SMITH: Yes.

MR. HURTER: I think the general opinion has been against that because if you have a hole where the tamping is blown out it is not proper. The amount of limestone you get from a tamping blowout is not a drop in the bucket as compared with what you get from rock dust.

DR. PARLETT: Amplifying Mr. Hodgson's remarks, we develop what we call blasters' schools at our plants. We are subsidiaries of the steel corporation, and we invited Mr. Hurter to address these blaster schools. Not only has he helped us to economize, but he has gone into the various safety figures, handling dynamite, transporting it, and matters of that sort, to such an extent that it is an annual feature now to have Mr. Hurter come back to us. Our men now look upon Mr. Hurter as practically the last word in handling dynamite. He has made friends of all our men and the men themselves have learned a great deal about the hazards of dynamite in a way that they never could have learned otherwise.

R. V. AGETON (Safety Engineer, The Tri-State Zinc and Lead Ore Products Association, Miami, Oklahoma): I do not know Mr. Hurter, I am sorry to say. I hope to meet him before the Congress is over; but we find all the powder companies will help us at any time in instruction work of that nature, and we have taken advantage of that down in the Tri-State Zinc district and have held a number of these meetings for the foremen and for men who handle the explosives.

Protecting the Shots for Blasting

We have a little rig along with us today; one of my co-conspirators of the Tri-State district developed what they call a "safety shot." This development is by a couple of men in the ground, and is the result largely of our having been able to get men like Mr. Hurter from the powder companies to talk directly to our ground men and to our shift bosses. I think this proposition of putting your primer in your stick of powder (indicates), and putting that in your container, and then if you notice there is a hole in the end of this dummy that they use to put the spike of the tamping bar, makes it safe. Now our holes down there are 25 to 30 feet deep and through caves and we have to use a spike in order to get the powder in the hole at all; otherwise it will go off to one side; and I think probably this method of protecting your shot, as we will call it, that is the powder and primer, will help a great deal in protecting against that rubbing that Mr. Hurter was speaking about. This is merely one of three different methods of attempting to protect our shots for blasting.

I wanted to call your attention to these in connection with misfire and premature explosion. The big point of the whole business is the giving of these lectures by the men of the powder companies, that has made the men develop these explosive prevention measures.

CHAIRMAN YATES: I presume we ought to stay here until about 1:00 o'clock, as we have no afternoon sessions, and we will have to stay until 12:30 in order to complete our program for today. The other days will be just as full as today, so if anyone has to be excused I presume it will be all right, but we want one more talk on this discussion from Mr. Davidson in regard to the limestone tamping.

MR. DAVIDSON: Some one asked about the use of rock dust tamping. The Bureau of Mines puts out at Washington a pamphlet entitled "Factors in production of lump coal," and in that pamphlet it discusses the use of

rock dust tamping; also in the pamphlet on "Rock dusting coal mines," of the Carnegie Institute of Technology of Pittsburgh, Pennsylvania, there is a discussion of that matter. We have tested it out to some extent in our coal mines and some of the operators favor it and think it adds to the safety from blown-out shots and also increases the production of lump coal where permissible explosions were used.

It is not especially recommended for use with black powder as a safety measure, although it may have some factors; in other words, do not rely on rock dust tamping as an absolutely safe measure in use with black powder. The practice seems to be to make up a loose cartridge out of loose dust and put it on the power as a cushion and the other cartridges are tamped in as tight as possible. A great many of our people still favor the use of clay over rock dust tamping.

CHAIRMAN YATES: We will now have a paper by A. J. M. Ross, General Mine Foreman, Homestake Mining Company, Lead, South Dakota.

METHODS OF PROMOTING SAFETY INTEREST AT THE HOMESTAKE MINE

A. J. M. Ross, General Mine Foreman, Homestake Mining
Company, Lead, South Dakota

The Homestake gold mine is situated in the city of Lead, Lawrence county, in the southwestern part of South Dakota. The mine was discovered April 9, 1876, and with the exception of three periods has been in continuous operation since its discovery.

The Homestake company has always taken the attitude that men's lives and bodies are too valuable to be sacrificed. They have never hesitated in the expenditure of money when it meant protection for their employees. Even with this benevolent attitude on the part of the officials it was not until about ten years ago that a systematic effort was made along safety lines.

The first thing done toward systematic effort was the employment of a safety engineer. This was met with a storm of disapproval on the part of nearly all of the employees, including most of the bosses, who felt it was unjust to hire a stranger to tell them how to work safely when they had been doing it for years. I think I can truthfully say, however, that through education, etc., this feeling has almost disappeared. Our employees as a whole are now at the point where they feel the safety engineer is their friend and that it is to their interest to do all they can to aid him in his work.

Committees are considered an important part of our safety work. At present we have two committees, known as the central safety committee and the workmen's safety committee. The first is composed of the superintendent, assistant superintendent, general mine foreman (this company has never had a general manager, assistant general manager, or mine superintendent), chief metallurgist, chief electrician, master

mechanic, attorney, chief surgeon, employment agent, timber agent and safety engineer. The superintendent is chairman and the safety engineer is secretary of the committee, which meets on the first Monday of each month.

The second committee is composed of nine men from the mine and one from each of the following departments: metallurgical, electrical, mechanical, carpenter and timber supply. The members of the workmen's committee are elected by secret ballot. In the mine, on election day, at the beginning of the shift the boss hands each of his men a blank envelope containing a blank slip. On this blank slip each man writes the name of the employee he wishes to have serve on the committee. He places his vote in the envelope, seals it and turns it back to the boss at the end of the shift. The only restriction placed on the voter is that he must not vote for a boss, but for a man working on the same level or division as the voter.

Meetings of the Employees' Committee

After the ballots are gathered up, two workmen and one of the time-keepers act as judges, counting the votes and making a written report over their signatures of the results. This report is posted at the shaft collar so that the men may see how many votes their favorites received.

This committee meets once in two months with the central committee. A short time before this meeting, tours of inspection are made by the workmen's committee either through the surface plant or through the underground operations. At the committee meetings, all members are encouraged to make any criticisms and suggestions which in their opinion will aid safety.

The safety meetings are open to the public and the State Mine Inspector has a standing invitation to attend them all.

Complete records are kept by the safety engineer of all injuries. Copies of these records are sent to the State Mine Inspector, the U. S. Bureau of Mines and the Commissioner of the South Dakota Workmen's Compensation Board. From the records kept, reports are made showing frequency and severity rates. Copies of these reports are sent to all underground bosses and officials.

Safety suggestion boxes are placed in each shaft house, with a sign above the box reading as follows, "Mine Safety. This box is for safety suggestions. Any suggestion you wish to make for your own or fellow workmen's safety and welfare will be given careful consideration."

A first aid and helmet instructor is employed whose business it is to train new men and give "certificate" men extra training at regular intervals. All classes of workmen are represented among the men trained or being trained, but naturally the largest percentage are underground workers. In addition to the above duties the instructor must see that the helmets are kept in first class condition so as to be ready for any emergency.

We are thoroughly convinced that a bonus system among the men and bosses is one of the best things we have done for safety, and while the amount paid to each person is not large it seems to raise the interest taken in safety work to a marked degree. Each underground employee (not a boss or an official) who has worked 300, or more shifts during the year without a "lost time" injury received for a bonus a ten dollar gold piece. The pride shown by the average man, displaying the gold piece to his acquaintances and fellow workmen, leaves no doubt in our minds that he will be a careful worker during the ensuing year.

Shift bosses, assistant foremen and night foremen are also paid a bonus for good safety work.

Thursday afternoon is known as "visiting day" among the division foremen. On this afternoon they go through a part of a division together, discussing safety, methods of mining, etc. In this way they are kept in touch with what the "other fellow" is doing.

During the winter months, on each "change Sunday" afternoon (twice a month) all of the shift bosses get together and make a trip through the "territory" of one of them. The part of the mine to be covered during this trip is not designated by the general foreman until just before the trip is taken, because, previous to this arrangement, it could be seen that considerable time had been spent "cleaning up" and getting ready for "company" when it was known in advance where the bosses were to visit.

As the shift bosses are not accompanied by any of their superiors they talk freely, criticizing anything they do not approve of. Many good natured arguments take place during these trips on safety. Two and one-half hours are spent on one of the trips. The bosses are paid for this trip and while we like to see them all present it is not compulsory. From a safety and educational point of view I think this is the best thing we do.

Accidents Are Investigated Immediately

Regardless of the hour, day or night, all accidents, such as broken legs, broken arms, or others of a more serious nature, are at once investigated at the place of accident by the state mine inspector, safety engineer, bosses on duty, and general foreman. At such time a member of the engineering department makes a sketch, for filing, showing conditions under which the man was injured.

When a man is accepted by the employment agent he is turned over to the medical department where he is given a thorough physical examination, particular attention being paid to the condition of his eyes. We have in the past had men who were hurt as many as three times a year. After being sure that the men were trying to work in a correct manner they were sent to the medical department for an eye examination. This examination disclosed the fact that a large percentage of the men who were being hurt regularly had very poor eye sight.

In the mine on each level, at the shaft, a bulletin board, with an ample supply of chalk is placed for the purpose of reporting missed holes, etc. Previously it was the custom to cover this board and the station timbers with safety first bulletins. At present no bulletins or posters are put up in the mine. Instead, on top, at the carbide room a board is placed in such a position that any bulletin tacked on it is seen by the man while getting his carbide supply. On the level station, beside the bulletin board, we allow to be posted only the cage signal board—a notice informing the men what to do in case of fire, accident or other emergency—and notice of warning against touching the "bell line."

As protection against fire in our main hoisting shaft, a sprinkling system has been installed at the surface. Once a week this system is thoroughly tested.

Water is piped into each working place in the mine for drilling purposes. This supply is drawn from the city mains which means that practically every working place in the mine has pure water for drinking, besides having water under pressure in case of fire. In addition to this supply, an independent system of four inch water lines has been carried into the mine through our "up coast" air shaft and from this air shaft throughout the different levels to hydrants. The "up coast" air prevents the mains from freezing during the winter months. The hydrants and all lines are tested and inspected at regular intervals by our first aid instructor.

Safeguards in Time of Fire in the Workings

At the surface we have a ventilating fan which is capable of drawing from the mine 225,000 cubic feet of air per minute. Underground there are smaller fans for "boosting" purposes. In case of a fire in the mine these fans if allowed to continue in operation would probably be the means of forcing gases through the working places with deadly effect. As a safeguard against such a possibility orders have been posted to the effect that the fans must be stopped at once in case of fire and can not be started unless orders to that effect are given by the general mine foreman. In case the general mine foreman can not be found the fans can be started again only on orders from the superintendent or his assistant.

Most mines are dirty. By using the term dirty I mean that old or broken timbers, pieces of rails, battered sheet iron and what not are scattered generally throughout the mine. In this matter we have done considerable educational work and now I can safely say the Homestake is a clean mine. The fact that we have a clean mine has, without doubt, been a large factor in cutting down our accident rate.

In finishing this paper I wish to bring before you a thought which has often occurred to me. Do we spend too much of our time making things "fool proof" and too little time on the education of the individual in the matter of protecting himself? I imagine most of you will take

the stand that you are doing all you can along the lines of educating men to be safe workers. Perhaps that is true, but the reason I bring up this question is the fact that most of the safety efforts I have seen are to make things "fool proof." If I am right, then many of us are, in my opinion, going at "Accident Prevention" in the wrong way.

CHAIRMAN YATES: Have we any discussion on this paper?

Keep Men with Bad Eyes Out of the Mines

R. DAWSON HALL: I was very much interested in the remarks made about bad eyes. I noticed in looking around the room 13 people or maybe more who wore glasses. I was at a board meeting recently in which half the man wore glasses, and they were talking about accidents of people due to the fact that they have bad eyes. I do not suppose the miners have better eyes than the generality of us and yet you rarely see glasses.

I think there is a situation which confronts us, that you should try to keep men out of the mines who have bad eyes. It is particularly bad because the glasses steam and it is a disadvantage from that point of view. On the other hand, a man wearing goggles is more or less protected from flying coal or mineral and possibly helped in that way. Most of them are ill disposed to wear glasses because of the film which is apt to coat the glasses when they wear them. We make no attempt to find out whether a man's sight is good or whether he has glasses when he needs them.

I am sorry Dr. Parlett has gone, but he has a little stunt in the Pittsburgh Limestone Company. They have a button along the line of the \$10 gold piece, which a man can wear in his lapel. It is won if he has gone five years without an accident or being the cause of an accident to another man. I think where the company is too large it would be difficult to carry it out. The man gets this button, and perhaps once a year they give him a chicken dinner and the general managers and other officials pat him on the back and keep up the general morale.

H. C. HENRIE (Manager Labor Department, Phelps Dodge Corporation, Copper Queen Branch, Bisbee, Arizona): I would like to ask Mr. Ross what the idea is in having the workmen's safety committee meet by themselves at certain times, and secondly, whether at those meetings there are questions other than safety discussed?

MR. ROSS: The workmen's committee does not meet alone. In years gone by they did meet alone, but they changed it; when they did meet they were free to discuss other things but that rarely happens; they only talk on safety.

WILLIAM CONIBEAR (Safety Engineer, Cleveland-Cliffs Iron Company, Ishpeming, Michigan): What was the advantage of a secret ballot? Do you get better men?

MR. ROSS: The idea of the secret ballot is, it stops the fellow who is always knocking. There are a certain number of men under ground (and I think that holds true in the metal mines), who are always looking for opportunities to say that things are framed and that the safety com-

mittee has been picked by the company; for that reason we try and avoid having anything to do with the election, other than furnishing the paper for the men to vote.

MR. HODGSON: Many physicians are talking to us today about preventive measures in medicine. This organization primarily is organized to prevent accidents and save human life and limb. We have found it advantageous to our property and the same thing is being done to the properties in Bisbee, in hiring all of our new men—they have a physical examination and careful attention is given to their eyes, but beyond that we have a man who is a proven man both in safety and in operations, and all of these new men are put into a certain working place or stope under this particular man's directions, where they are taught the methods that we use in our work, both in regard to operations in general and safety in particular. These men stay in this particular place from two to four weeks, according to their adaptability and their brightness in picking up different points, and are only taken out of this particular stope after the boss in charge says they have learned the ropes and are fit to go into the regular operations.

W. MOOREHEAD (Safety Engineer, Phelps Dodge Corporation, Dawson, New Mexico): We have in our coal mines certain districts set apart to teach new men how to mine coal safely. We have those new men in that certain district, I would say, from four to six weeks, sometimes more, depending upon the adaptability of the men to pick up coal mining, and we have found this a great success.

Conferences for Mine Foremen Were Valuable

MR. AGETON: I was very interested in the last paragraph of Mr. Ross' report where he wondered if we were not attempting too much to make things fool proof and not along educational lines. I do not think from his paper that could be true at the Homestake, but in this regard down at the Tri-State district, in the last year through the cooperation of vocational education boards of Kansas, Missouri and Oklahoma, we got foremen conference leaders and we conducted conferences for our mine foremen, ground bosses we call them, for about six months. One hundred fifty foremen attended these conferences and reports were printed and given to them. I do not know whether all of you are familiar with this work or not, but we found it is a big thing, and at least one of those conferences deals with accident prevention work entirely. Those of you who have not tried your Vocational Board in your particular state, try out one of these conferences. I think I can recommend it very highly as a very efficient means of putting over accident prevention among your ground bosses or your foremen and trip bosses.

B. J. DRYER (Manager Safety and Casualty, Woodward Iron Company, Woodward, Alabama): The Birmingham Safety Council at Birmingham put on one of those industrial schools last year and all of our foremen from Woodward Iron Company whom we could get enrolled in the school went. We noticed right after that conference a large reduction in the

accidents at all the operations, including the furnaces, coal mines and oil mines.

So far as education is concerned, Mr. Ross says you have to depend mostly upon education. We found that out from experience. We have regular safety meetings at each operation, and all the foremen and shift leaders come into these meetings. We teach them to get up and talk, and the meeting is handled much on the order of this meeting, and we have one of those monthly in each department; that is in addition to the meetings of executives and committees and is held at the mines.

MR. GRABOWSKY: I might say most of the people here are coal miners, and perhaps a little word from the metal mine might be of interest. I think the system used by the Oliver is fairly general among the ranges of the iron mines as to the building up of safety organizations. We are operating in Minnesota and Michigan. We have a general safety committee made up largely of the general superintendents and the claim agents. The meetings are held there monthly, attended by the casualty clerks, safety engineers, master mechanics and men from the operating department. All accidents from the mines are reviewed and discussed.

A District Committee for Each Mine Group

At the mines we have a district committee of each group of mines or each district who hold monthly meetings. They make monthly inspection trips, and at these monthly meetings they have in attendance mine foremen and men from the works. This committee is made up of some of the executive heads and men from the mines, so they have some discretionary powers in taking up matters and determining what action should be taken on the ground without going to the management. If it comes to a considerable expense, that question is taken up. Aside from that we have monthly meetings around the works, where the men themselves are brought in, especially men who have been hurt through injuries, and at that time the proceedings of the general safety committee are read and discussed and preventative measures discussed by those present. Suggestions are called for at the same time.

We feel that educating the employee to the fact that he is his brother's keeper is the biggest thing in the movement. There is a conservative purpose, one of the primary factors back of the whole thing, from the top of the management down through the organization. A very intensive campaign was started about four years ago, and the organization I just pictured to you was built from that. I have a few figures here that might be of interest, just a little in the way of a comprehensive statement of what has been done since 1918.

In 1918 our average accident rate per hundred men employed was 17.69; for the first nine months of 1926, it is 1.94. There has been a constant drop since 1918, with the exception of one year immediately following. That is based on the employment of an average of 10,000 men. I think largely the best part of that is being accomplished by the matter of education from the top right straight through. We do not

have the workmen on our district organizations, but they are frequently invited in, and I think education is the big thing.

MR. DAVIDSON: I should have said in speaking of rock dust tamping that Hercules Powder Company also has out a pamphlet on that subject. In connection with keeping up the interest in safety work and education along that line, I suggest that you get in touch with Mr. J. J. Forbes, Safety Engineer for the Bureau of Mines, who is in charge of the Holmes Safety Association work, as we have found that means the most valuable and effective way of reaching the individual.

CHAIRMAN YATES: I would like to add one word to this discussion, and that is, we must begin, I think, with the children, not only in the school but in the home, and what you have said about the Holmes service is something we need. The home is the place to begin safety education—it is a part of our life, something we are living every day.

ADJOURNMENT

WEDNESDAY MORNING SESSION

October 27, 1926

The second session of the Mining Section of the National Safety Council, held at the Tuller Hotel, Detroit, Michigan, convened at 9:30 o'clock, Mr. B. C. Yates, presiding.

CHAIRMAN YATES: The first business in order is receiving the report of the Nominating Committee, Mr. R. V. Ageton, chairman.

R. V. AGETON: Your Nominating Committee met yesterday at luncheon with our president, and I regret to report that after about an hour's argument we were unable to get the present president to accept renomination; consequently that put before us the task of getting another man. We canvassed the field very thoroughly with this thought in mind—that we have five general mining districts in the United States; we have the southeastern consisting of Tennessee, Georgia and down through there, largely metal, some coal; we have what we call the northeastern, Pennsylvania and that country, coal; the Lake Superior district; the Tri-State Zinc district, and the southwestern district; and we tried to get representatives from all those districts for our officers next year. We also tried to nominate men who, we thought, would do the most toward putting the Mining Section of the N. S. C. ahead in the way in which it has been carried on in the past year.

Your committee has nominated Howard I. Young, general manager, American Zinc Company, Mascot, Tennessee, for president, or chairman.

C. A. McDowell, Manager Industrial Relations Department, Davis Coal and Coke Company, Thomas, West Virginia, first vice-chairman.

George Martinson, Safety Engineer of the Pickands, Mather Company, Hibbing, Minnesota, second vice-chairman.

A. W. Dickinson, the Union Pacific Coal Company, Rock Springs, Wyoming, third vice-chairman.

J. P. Hodgson, Manager Morenci Branch, Phelps Dodge Corporation, Morenci, Arizona, fourth vice-chairman.

Following the precedent set by other nominating committees, we have nominated for secretary of the Section Mr. Daniel Harrington of the U. S. Bureau of Mines, who now holds the same position with the Bureau that Mr. T. T. Read did when he was elected secretary of the Mining Section of the National Safety Council.

This, Mr. Chairman, is the report of your Nominating Committee, and I move you the report be accepted and your committee discharged.

The motion seconded and properly carried.

CHAIRMAN YATES: Are there any other nominations?

MR. GRABOWSKY: There being no further nominations, I move the nominations be closed and the secretary instructed to cast the unanimous ballot for the officers nominated by the committee.

The motion was seconded and carried, and the secretary cast the unanimous ballot for the officers named.

CHAIRMAN YATES: Yesterday I brought up the suggestion that we should have a paid secretary, either full or part time. What is your opinion in regard to that?

MR. HODGSON: Mr. Chairman, I fail to see how unless we have a secretary engaged at least part time, how this Section can properly conduct its business, and personally I feel very much in favor of such a secretary.

CHAIRMAN YATES: Perhaps it might be a good plan to appoint a committee at this time to arrange the financial end of the matter. That is the sticking point, of course, and I presume the National Council would help us out to a certain extent. We might be able to receive donations from some large companies who are interested, or from individuals, as some of the other Sections are doing. We would like to have the suggestion of any one who feels interested in this matter. I might add, the officers of this Section are usually men who are busy. If we had a man whose business it was to work all the time for the interests of this Section, getting new members, working up local meetings in various sections of the country, we could get every mining company of any importance in the United States into the organization. We have not those companies now.

MR. POLLOCK: I make a motion that this committee be appointed by the chairman, to do what it may think is right. It will cost between \$7,000 and \$10,000 a year to handle such a thing and finance the whole proposition anyway.

(The motion was seconded and properly carried.)

MR. HODGSON: I would like to suggest that the present chairman be a member of that committee.

MR. POLLOCK: He ought to be chairman of that committee.

CHAIRMAN YATES: We will now have a paper presented by Mr. H. C. Henrie of the Phelps-Dodge Corporation.

EMPLOYEES' REPRESENTATION AT THE COPPER QUEEN BRANCH OF THE PHELPS DODGE CORPORATION AND THE RELATION OF INDUSTRIAL REPRESENTATION TO THE SAFETY MOVEMENT

H. C. Henrie, Manager, Labor Department, Copper Queen Branch,
Phelps Dodge Corporation, Bisbee, Ariz.

Employees' Representation, which has been designated as "a method of settling peacefully and by joint action all matters that mutually concern employees and management," is no longer an experiment. Recent statistics indicate that over 800 American industrial concerns employing one million workmen are now operating under some plan of representation.

My purpose in presenting this paper is to outline the Employees' Representation Plan of the Copper Queen Branch of the Phelps Dodge

Corporation, its method of development, and to discuss the relation of Industrial Representation to Safety and Accident Prevention Work.

The mining and milling operations of the company are located in the Bisbee District and consist of the underground mine, which produces direct smelting copper and lead ores; the Sacramento Hill open pit operations, which produce concentrating and leaching ores; the Concentrating Mills and Leaching Operations, as well as the mechanical shops, power plants and other service departments. These operations furnish employment to approximately 2,000 workers.

Labor Conditions

The company has been operating in the Bisbee district since 1881. During these 45 years labor disputes have been rare and an organization more permanent than is usually found in mining operations has been developed. At present 92.1 per cent of the underground employees are American citizens. Mexicans are employed for unskilled surface labor and constitute 18.5 per cent of the total force. Exclusive of Mexican labor, 95.1 per cent of the total employees are citizens. Sixty per cent of the employees are married and have their families residing in the district.

The inauguration of Employees' Representation at the Copper Queen was a natural step in the development of satisfactory relations between management and the employees; since various employees' committees had been functioning with limited authority since 1910. At intervals since that date the employees' committee, known as the "Grievance Committee," has been enlarged to provide for additional representation and the scope of its activities broadened.

In 1920 the employees' committee requested the management to outline to that committee its powers and authority. This request not only emphasized the need of a workable plan which would define the powers and authority of the employees' representatives and provide machinery for administration, but also afforded the management an opportunity to correct certain unsatisfactory conditions which had developed, due to expansion of operations. The management advised the employees' committee to appoint from its membership a special committee to investigate the question of employees' representation, and to make recommendations.

This committee after a period of six months' study of various plans in effect throughout the country, recommended a plan which, except for minor changes, was approved by the directors of the company with the proviso that it must first be ratified by two-thirds of the employees before becoming effective.

At a special election held for this purpose 90 per cent of the underground employees and 82 per cent of all employees voted in favor of its adoption.

The plan was inaugurated under extremely favorable conditions, namely; the previous policy of the company had developed an unusual feeling of good will and loyalty; the organization was composed largely

of employees who had long service with the company; the majority of the employees were English speaking and American citizens; the plan was not adopted as an emergency measure, but was inaugurated at a time when there was no labor agitation; and finally, the plan was drafted and sold to the employees by representatives elected by them, only after the employees had been trained for a number of years in committee work.

The Representation Plan

The representation plan is modeled after our Federal Constitution and provides for three departments: legislative, executive and judicial.

The legislative department consists of a House of Representatives and a Senate.

The House is composed of representatives, one-half of whom are chosen every six months at elections conducted by the employees, to serve a term of one year. Electoral divisions, based on the natural divisions of operations and arranged so that every department is represented, were created. The various electoral divisions are allowed representation on the basis of one representative for each 100 employees or major fraction thereof, provided, however, that each division shall have at least one representative.

Foremen, bosses or other employees whose duties are of a supervisory nature can not vote for or serve as a representative.

The House of Representatives assembles at least once every month and special sessions may be called by the manager. The House elects its own officers, appoints its own committees, adopts its own rules of procedure and through its election committee, conducts all elections.

After organization, the House created the following standing committees: election committee, rules and procedure committee, wage and bonus committee, safety and working conditions committee, employees' magazine committee, and a recreation committee. Matters coming before the House which require investigation and study are referred to one of these committees for recommendation.

The Senate is composed of members chosen by and from among the foremen and bosses. The method of organization and election is practically the same as that followed by the House of Representatives.

The purpose and object of the plan is stated in the preamble which reads as follows:

"The employees and officials of the Phelps Dodge Corporation, Copper Queen Branch, in order to promote closer relations between employees, the management and the stockholders, to insure a square deal to every employee, official and the company, to encourage loyalty, cooperation and efficiency, to promote our mutual welfare and insure the blessings of industrial peace to ourselves and to this community, do hereby adopt and establish this Constitution of the Employees' Representation Plan for the Copper Queen Branch."

The Constitution provides that:

"The employees of the company shall have a voice in the adoption

of the rules and regulations governing their work and the conditions of their employment through representatives chosen from among themselves by secret ballot."

"No legislation shall become effective until it has passed both Houses of Congress and has been approved by the manager of the Copper Queen Branch. If a measure does not meet with the approval of the manager, he shall return it with his objection to the House in which it originated, who, after noting the objections, may proceed to re-consider it or revise it, but any measure may be passed over the manager's vote and become effective by a two-thirds vote of the members elected to each House."

In addition to the general powers and authority granted, following are some of the specific powers embodied in the Constitution:

Congress shall have the power:

1. To enact a code of Safety Rules and provide for the enforcement thereof.
2. To enact a code of rules for the employment and discharge of employees and provide for the enforcement thereof.
3. To pass such measures as may be necessary to establish a Benefit Association and maintain a fund, to be contributed jointly by the employees and the company, from which sickness and accident benefits may be paid to employees.
4. To pass such measures as may be necessary to establish an Apprentice Plan whereby the young men of the community may be given a chance to learn a trade under proper supervision.
5. To pass such measures as may be necessary to provide for Bonus Plans, whereby there is an equitable division between the employees and the company of any saving in the cost of operations as a result of increased labor efficiency when compared with a fair standard of efficiency for the same.
6. To pass such measures as may be necessary for the peaceful settlement of all differences arising between the employees and the company.

In order to provide against possible discrimination or curbing of activity, employees' representatives are guaranteed protection by a clause in the plan which reads as follows:

"No Senator or Representative shall ever be penalized by the company or the officials thereof for any speech, debate or activity in the performance of his duties as representative."

Method Provided for Settlement of Grievances

The expansion of operations had made it necessary to delegate considerable authority to the supervisory staff, who had not been held accountable to any great extent for proper use of that authority. Consequently, it was often abused, favoritism was not unusual, men were subject to the whims of bosses and unfairly treated, discharge without just cause was common, and no means had been provided whereby these

conditions and grievances could be easily reviewed and adjusted. One of the most difficult problems which the management had to contend with was the settlement of minor grievances, and since there was no satisfactory method for placing before the employees the facts relating to specific grievances, agitators and malcontents had unlimited opportunity to present their own versions of these matters and employees rarely ascertained the real facts in a given case.

To provide a means for promptly investigating and settling individual grievances of employees, a "Grievance Committee" was established. The powers of this committee are defined as follows:

"Congress shall have the power to appoint a standing committee to consist of three members from the House of Representatives and two members from the Senate to be known as a 'Grievance Committee.' It shall be the duty of this committee to hear grievances of employees and to decide upon settlement of same. Decisions made by this committee shall be submitted in writing to the manager. If he concurs, he shall see that the decision is promptly enforced. If he does not concur, he shall promptly call the committee in conference for further consideration of the grievance. If a majority of the committee and the manager fail to reach an agreement as to settlement, the grievance shall be submitted to the Supreme Court for final decision, and if the employee submitting the grievance is not satisfied with the settlement of his grievance, he may appeal his case to the Supreme Court."

The Executive Department

The executive powers of the organization are vested in the executives of the company. The Constitution provides that the executive department shall consider all measures passed by Congress and shall, through the manager, approve or disapprove the same within ten days after presentation to it. The manager may attend the meeting of either House at any time and may participate in a discussion of any measure before either House, but shall have no vote.

The judicial powers of the organization are vested in the Supreme Court which is composed of three judges appointed by the manager by and with the consent of Congress.

The Supreme Court has original jurisdiction in all cases where the constitutionality of a measure is in question and has appellate jurisdiction in all cases arising out of grievances between employees and those in authority.

Appointments to the Supreme Court are made as follows:

One member is a representative of the employees, one represents the company, and the third is a well-known citizen of the community who has no connection with the company.

The procedure in handling matters coming before the employees' Congress can best be illustrated by sketching several actions of this body.

Shortly after the inauguration of the plan, several representatives requested that a definite code of rules concerning the employment and

discharge of employees be enacted. After discussion of this matter in the House, this was referred to the safety and working conditions committee for investigation and recommendation. This committee drafted and presented to the House our present code of "Employment and Discharge Rules," which was passed by the House of Representatives, the Senate, and approved by the management without amendment.

In the consideration of this legislation, the rules of the company relating to employment, furloughs and transfers were accepted without question and the principal effort of the committee was confined to formulating rules for insuring fair treatment to employees by those in authority. This legislation had the effect of establishing a definite policy and eliminating subsequent discussion concerning physical examination, open shop and similar controversial questions. The following specific rules of this measure may be of interest:

Specific Rules Insuring Fair Treatment

"Before obtaining employment, all applicants shall be required to pass a satisfactory physical examination."

"The right of the company to select its employees shall not be questioned."

"Ten offenses were specified for which an employee may be suspended or dismissed from the service without further notice."

"For other offenses not included in the list, an employee shall not be discharged without first having been notified that a repetition of the offense will make him liable to dismissal. Such notice shall be given by the foreman or boss in charge of the work and a written copy thereof forwarded immediately to the labor department."

"Any employee who feels that he has been unjustly treated, subjected to any unfair condition, unjustly discharged, or has a grievance of any nature may appeal his case to the Grievance Committee."

The procedure in the event that the management desires to make certain changes in policy or present for consideration a specific condition is illustrated by the following action of the employees' Congress:

In August, 1922, the manager met with the House of Representatives and stated that the wage schedule of the company needed revision in order to correct certain discrepancies and iron out all points of difference. It was pointed out that this revision might increase certain occupational rates and possibly reduce other rates, but when the revision was completed we should have a wage schedule which would be satisfactory for some time to come, and thereby avoid the necessity of discussing minor adjustments in certain occupational rates every few months.

This matter was referred to the wage and bonus committee of the House, who met with representatives of the management and assisted in the revision. As a result, a new wage schedule was recommended, passed by the House and Senate, approved by the management, and accepted by the employees.

This legislation has proven very beneficial in settling minor wage questions. The House of Representatives, in handling requests involving an increase in the wage rate emanating from individuals, particular crafts or other small groups, has taken the position that, "Unless it can be established that the wage now paid is not in accordance with the established wage schedule or does not apply to the particular class of work being performed, the House of Representatives will not recommend an increase in the established wage schedule for any one individual, craft or group unless all occupations and departments are considered."

Individual grievances of employees which are not satisfactorily adjusted by the foreman or the labor department are settled by the Grievance Committee.

This committee consists of three workmen appointed by the speaker of the House of Representatives from among the members of that body, and two members of the supervisory staff appointed by the president of the Senate. This committee holds office for six months. The frequent change in personnel of the committee has brought a number of employees, both workmen and foremen, into contact with the work, thus eliminating criticism to the effect that the committee was dominated by the company.

Naturally, the great majority of cases involving a legitimate grievance are settled before reaching this committee. Since the inauguration of the plan, 33 hearings have been conducted by the Grievance Committee. In one instance the case was dismissed because of lack of jurisdiction. Twenty-three cases were decided against the employee presenting the grievance, and in nine instances the decision was in favor of the employee.

The Supreme Court has held six hearings to consider cases appealed. The court sustained the decision of the Grievance Committee in four of the cases and reversed the decision of the committee in two cases.

The decisions of the Grievance Committee and the Supreme Court have been accepted as fair by the employees and management. Many of the foremen have stated that the plan of adjusting grievances was an aid to discipline and of assistance to the supervisory staff, since the employees now ascertain all the facts regarding a given case. As a result, malcontents receive little consideration other than being told by their fellow workmen to present their complaint to the Grievance Committee where they can obtain a fair hearing.

Copper Queen Bulletin

The employees obtain complete information concerning the business transacted by the employees' Congress through publication of the *Copper Queen Bulletin*, which is issued each month. The minutes of the House and Senate meetings, committee reports, decisions rendered by the Grievance Committee and Supreme Court, as well as minutes of the various departmental safety committee meetings are published. This

publication also affords an opportunity for the management to discuss specific conditions, outline company policies, and thus maintain a contact with the employees.

Regarding Results

The plan has not been changed since its inauguration and during the five year period over 500 matters bearing on questions of wages, efficiency bonus standards and payments, working conditions, and safety have been investigated, discussed and settled.

That the plan is popular with the employees is apparent from the fact that at a recent election held for the purpose of selecting employees' representatives, 86.5 per cent of the men working that date voted.

We believe the employees have grasped the idea that the interest of the employer and the employee are mutual and experience thus far indicates that when the complete facts in a given case are presented to the representatives, they can be depended upon to reach a logical, just and sane decision.

When the plan was inaugurated, there was considerable doubt regarding the possible effect on the supervisory staff and plant discipline. It was evident that certain foremen and bosses of the "old school" would be unable to adjust themselves to a labor policy of this type. It has been necessary to make some changes in the supervisory staff, but the result is a more efficient, broader minded and higher calibered foreman and boss. Since members of the supervisory force have an opportunity to present their views on all questions coming before the employees' Congress, through representatives elected by them to the Senate, little or no criticism of the actions of this body is heard.

As there has been no labor agitation since the inauguration of the plan, we cannot say how it would function in the event of a general labor disturbance. Our principal interest has been in its day by day operation where problems arising have been settled satisfactorily to all concerned.

Need of Better Relations in Industry

When the idea of employees' representation first attracted the attention of industrial managers, the dominant note was the development of a plan to insure industrial peace. With growth and development has come the realization that by creating a spirit of confidence and cooperation, industrial representation is more than a means of preventing labor disputes; it is also an important factor in securing better safety and production results.

There are many who question whether American industry, as at present organized, affords an opportunity for industrial cooperation between employer and employee and hold that there is an inherent antagonism between the two groups which will prevent development of mutual confidences and genuine cooperation. It is perhaps difficult for

those committed to the policy of "Organized Employers" versus "Organized Employees" to realize that while there may be certain conflicting interests between employers and employees, there are also many activities in which their interests are mutual. Industrial representation places emphasis upon the mutual rather than the conflicting interests, upon cooperation rather than conflict.

It has been said that the viewpoint of the average employee, his mental attitude toward his job, is the most neglected asset in American business today. This thought is not new, yet we have been slow to recognize its truth and importance. Since the physical and mental accomplishments of a man depend a great deal upon his state of mind and the environment in which he does his work, a workman who is convinced that a policy of fair dealing exists in his organization is not only a better workman, but will generally cooperate on matters of mutual interest. Industrial representation, by developing a cooperative rather than a combative spirit in the organization, is changing the viewpoint of many workmen toward their jobs and industry in general.

There is also an economic side to this question. With keener competition in business from Europe and at home, the increasingly higher standard of living of the American workman, together with the prospect of a comparative dearth of labor, due to our restrictive immigration law, we face an era of competition in American business which will touch the labor problem very closely during the next few years. We are coming to realize that our safety and industrial relations work must tie in more closely with the whole production process. If, through proper methods, we can change the viewpoint of the average employee by providing right environment and necessary education on industrial problems, it will materially aid us in meeting the competitive problem with which we are faced.

At the Copper Queen the labor efficiency has increased in recent years. The production costs have been good, due in a large measure to this improvement in labor efficiency. Just how much of this increased labor efficiency is due to the improved relations with our employees and how much is due to improvements in our production processes is difficult to determine. We do know that we have had no difficulty in securing sufficient American labor and that our labor turnover for the past year has been the lowest in the history of the company.

Satisfactory Industrial Relations Necessary for Effective Safety Work

One of the important by-products of the safety movement has been its tendency to bring about better industrial relations. Mr. Arthur Morey, past president of the National Safety Council, has said, "The Safety Movement was the beginning of a necessary better day, a closer understanding and relationship between worker and employer. The safety movement was the entering wedge for the present better industrial relations situation in this country."

It is natural that a close relationship should exist between our safety

and industrial relations work, since the success or failure of the safety movement is largely dependent on the degree of cooperation existing between employer and employee. The inauguration of proper safety methods, together with the necessary mechanical guarding will, when administered by an effective safety organization, enable a company to decrease materially its accident rates, but it is extremely doubtful if any company can secure satisfactory safety results without the cooperation of its employees. Most certainly genuine cooperation can not be developed in an atmosphere of discontent and abnormal labor turnover.

The importance of satisfactory relations is illustrated by the problem confronting a manager of a large coal company, who recently discussed with me conditions existing at his property. Due to the lack of a constructive labor policy, competent workmen are avoiding the camp. The labor efficiency has decreased and turnover is abnormal, resulting in a serious economic problem. The plan of safety organization and the general conduct of safety work at this property are based on sound practice; however, the accident rate is bad and, due to the heavy labor turnover, little progress in safety education can be made.

Safety Work at the Copper Queen

Safety work was first inaugurated at the Copper Queen Branch in 1913, when a definite safety policy was formulated, a safety department organized, and a safety inspector employed. While there had been an appreciable reduction in the accident rate during the 12 year period, 1913-1924 inclusive, it was evident that we were not securing maximum results and that expenditures for compensation on account of personal injuries were excessive. There was a pronounced inclination on the part of the members of the supervisory staff to allow the safety inspector to carry the whole burden. The workmen, while interested in having safe working conditions, were inclined to view our accidents as "an act of God," and one of the risks incidental to the occupation of mining.

In order to correct these conditions, the safety and accident prevention work of the Phelps Dodge Corporation was reorganized in January, 1925, and the committee form of organization was inaugurated. The manager of each branch or subsidiary company of the corporation was made responsible for the safety work of his branch. Operating superintendents and department heads were made responsible for the proper conduct of safety work in their respective departments. The essential features of the organization plan are as follows:

A. Corporation Safety Committee:

The vice-president and general manager of the corporation is chairman and each branch manager a member of this committee. This committee has general supervision of the safety work of the corporation.

B. Branch Safety Committee:

Each branch or subsidiary has established a general safety

committee of which the branch manager is chairman. This committee is composed of the various superintendents, department heads, and representatives elected by the workmen, and has supervision of the safety work of the branch.

C. Departmental Safety Committee:

Departmental safety committees of which the departmental superintendent is chairman were established in each department of the branch. These committees are composed of equal representatives from the foremen and bosses and representatives of the workmen employed in the department, and supervises the safety work of the department.

This form of organization was adopted in order to secure the cooperation of managers, superintendents, foremen, bosses and workmen, and to bring them into direct contact with the safety problem. The delegation of definite responsibility and the interest and cooperation of all concerned have resulted in a marked decrease in the accident rate. The results secured afford a striking illustration of the importance of proper organization, sincerity of purpose, strict enforcement of the safety policy by the management and the value of sound industrial relations as an aid in securing the interest and cooperation of the employees in the safety movement.

COMPARATIVE ACCIDENT STATISTICS

Years 1924—1925				
All Departments			Underground Mining Operations	
Year	Number Lost Time Accidents	Accident Rate Per 1000 Shifts Worked	Number Lost Time Accidents	Accident Rate Per 1000 Shifts Worked
1924	710	1.04	268	1.18
1925	330	.56	170	.70

Year 1926 to Date				
All Departments			Underground Mining Operations	
Year 1926	Number Lost Time Accidents	Accident Rate Per 1000 Shifts Worked	Number Lost Time Accidents	Accident Rate Per 1000 Shifts Worked
January	23	.452	8	.343
February	14	.308	10	.482
March	12	.235	8	.339
April	14	.293	7	.310
May	10	.213	5	.235
June	5	.108	3	.142
July	1	.023	0	.000
Totals to Date....	79	.24	41	.27

It has been especially gratifying to note the interest and cooperation prevalent in the departmental safety committee meetings. The various safety problems are discussed in a frank manner. Employee committeemen express themselves freely without fear of intimidation or retalia-

tion by their foremen and bosses, and no difficulty is experienced in securing safety suggestions from the men.

While this discussion of the safety and accident prevention work is necessarily brief, I believe it is evident from the results obtained that industrial representation, when administered with sincerity of purpose, does assure the cooperation of employees in safety work, as well as in other activities of mutual interest to employees and employers. The labor conditions prevailing at the Copper Queen were not brought about over night, but are the result of a gradual development and the strict enforcement of our labor and safety policies by the management.

In view of the general labor conditions likely to prevail during the next few years, it is probable that the largest contribution to profits in industry will come from a more perfect adjustment of relations between employer and employee. I believe that an understanding of the economic benefits to be gained will do more than any one thing to bring about this better understanding and relationship.

Discussion Following Mr. Henrie's Paper

CHAIRMAN YATES: I presume a number of men here would like to discuss this paper, and if so, this is your meeting.

MR. HALL: I would like to know whether this has been adopted by the Phelps-Dodge Corporation in Dawson, New Mexico.

MR. HENRIE: It has not, Mr. Hall. Our Morenci branch is strictly a Mexican camp and Dawson, also. They are not ready for a plan of that type yet at Dawson, although some improvements have been made there.

MR. CONIBEAR: You mentioned a committee on wages and bonuses. Will you please explain your bonus system?

MR. HENRIE: I am afraid I can not do that this morning. It is a rather complicated system. We have a production bonus whereby miners underground secure a bonus if they exceed better than the average performance. The bonus plan differs from those usually in effect in that it was taken from the records compiled over a number of years together with time studies; it is rather complicated and it would be entirely beyond me to explain that in our limited time.

CHAIRMAN YATES: I would like to ask you when these different bodies meet, the legislative body for instance? Do they meet at a special time outside of their working hours, or during the working hours, and are the men paid for their time when engaged in legislative work?

MR. HENRIE: The men at present have 20 representatives in the various departments. They meet on the second Wednesday of each month at 1:30 in the afternoon. The men come up at noon, change, they are paid their regular shift, that is they are allowed time for attending the meeting. There is no separate cash payment made. They meet by themselves and conduct their own business, but the regular meeting date is set the second Wednesday in each month.

MR. KERR: After this plan was adopted was there a change of labor to the extent of drawing more American laborers to the plant?

MR. HENRIE: We have always been an American camp there. I think at the time the plan was inaugurated 85 per cent or 88 per cent of our underground employees were American citizens. At present 99.2 are Americans. It has always been practically an American camp, outside of a few aliens who are old timers.

MR. KERR: I wondered if you had a larger percentage of foreign labor, whether the plan could be used?

MR. HENRIE: I have my doubts whether such a plan could be used in a strictly Mexican plant. Your men would have to become sufficiently Americanized and have a sufficient degree of intelligence to work properly under such a plan.

MR. CONIBEAR: You stated that any law passed by the Congress and vetoed by the general manager can be passed over his veto by the Congress. Is that true regarding the wages and bonuses?

MR. HENRY: There is no restriction on that at all. That question has never come up. It is rather difficult (although there is a possibility of course), to foresee where such an action would be taken. I have discussed that with the manager a number of times. You see your Senate is composed of your supervisory staff. The House is composed of the men. We take the position that if he can not go in front of those two bodies with sufficient facts and argument to convince them that he is right and they are wrong they are probably right and it would have to stand.

Most Grievances Are Settled by the Foreman

C. A. McDOWELL (Manager Industrial Relations Department, Davis Coal & Coke Company, Thomas, West Virginia): What is the procedure of a grievance, Mr. Henrie? Does your employee take his grievance directly to the committee who in turn takes it to the legislative body?

MR. HENRIE: The ordinary grievance of course the man takes up with his immediate boss and foreman. Of course 90 per cent are settled right there. If there is difficulty he will generally see the employees' representative in his division. The representative then will take it up with the boss. Now the great majority of grievances which get beyond the foreman and boss are questions on which the foreman himself may be a little bit dubious as to his authority or the policy of the company. In that case the representative would then come to the Labor Department and see me. Again, the great majority of those matters are settled right there. We do, however, have cases where a man feels he has a legitimate grievance and nobody can satisfy him.

I may tell him, for instance, so far as you are concerned, you have had four or five trials; you are through; we have nothing more to offer you. He decides he would like to take the case to the grievance committee. All right, it is arranged. There are three workmen and two foremen on this committee. The man appears and states his case. They ask him any questions they want to ask and get to the facts as near as they can. They also have power to subpoena any employee of the company. They have asked the individual foreman to come in on numerous occasions.

The foreman simply tells his side of the case. There may be essential witnesses and they may be called in. This committee then renders a decision. Generally it is accepted.

I think without question the men look upon the committee as being fair. They may think they did not get all the facts sometimes, but they regard the decision of the committee as fair. Even then, some men are not satisfied, and they can appeal their case to the Supreme Court, which you might say is really a board of arbitration, having one member of the company, one working man and an outsider. This court of course will review the grievance committee case, talk to the man and anybody else they may require, and that decision is final.

Grievances Handled by a Mutuality Committee

MR. GRABOWSKY: We have no industrial relationship committees such as Mr. Henrie has outlined in his very excellent paper. We do have what is termed a mutual committee, the chairman of which is appointed by the president of the company. He selects from a list given him by the heads of the different underground and open pit operations a committee known as the mutuality committee. The grievances can be handed to the committee or the chairman of the board. Those grievances are considered, the chairman having power of accepting witnesses for both sides and that committee renders its decision in any case. If the decision handed to the general superintendent is agreed as all right the action is taken by the committee. If not agreed upon it is returned to the chairman of the mutuality committee and the man has a right of appeal to the general manager, but the same action is taken one way or another, and if the committee have recommendations not concurred in by him the man has a final right to appeal to the president of the company whose decision is final.

We have had decisions rendered both ways. I do not know of a case that has gone to the top for final decision. We generally settle them before they get to the top. I do not know what effect that has had upon the dealings of the organization. In our particular district we are operating about 1,800 men and have about 29 nationalities involved. I do not know what Mr. Henrie refers to as an American citizen, whether he refers to what might be called a white man and a Mexican.

MR. HENRIE: No, these are citizenship statistics as listed.

MR. HODGSON: From 1912 to 1926 I was superintendent in general charge of operations at the property of the Copper Queen Branch, Phelps-Dodge Corporation, and inaugurated the original safety work which in general gave very satisfactory results but not as satisfactory as are being obtained today. I have been manager of the Morenci branch since 1918. The labor of my branch comprises about 56 per cent Mexican labor, the balance mixed nationalities and Americans. I have very carefully watched the working of the representative plan at the Copper Queen because I am a great believer in cooperation between management and employees.

I watched it critically, if you please, but I have not yet been able to

see where in an organization such as I have, comprising miners, millers, smelters and industrial railroads, and with the type of labor that I have, that we are ready for this plan yet. However, we have welfare committees, our general safety committees, we have our departmental safety committees, and we are working year by year in an effort first to obtain the full confidence of our men in the management and in the company, with the view that in the future we may extend our plan along the general line of that in operation at the Copper Queen branch, because I consider that plan is working out very satisfactorily there. But we must bear in mind that, as Mr. Henrie says, they have there over 90 per cent American citizens, a high class of labor, men who have been in the employ of the company for a large number of years, and that it is one example that is very hard to duplicate. It can not be duplicated in any other mining property in the southwest—I mean in the general labor conditions. However, I think the plan has succeeded admirably.

CHAIRMAN YATES: We have with us a representative of a manufacturing establishment making machinery for mines. I wonder what kind of a plan they have in the Cleveland Rock Drill organization, Mr. Hall?

GEORGE H. HALL (Sales Manager, Cleveland Rock Drill Company, Cleveland, Ohio): We have a varied industry, because we have both a manufacturing plant making machinery and a large drop forge establishment with 52 drop hammers. In the machine shop our accidents are very minor, mostly confined to cuts and small bruises. We have a first aid man always on hand and a doctor coming into the plant about 8:30 every morning. Every man is invited to visit the doctor at any time.

We have no regular organization outside of the first aid kit and two or three well trained men under the doctor. However, in the forge shop we have quite different accidents and very serious when we do have them. We have no system of grievance or working out any proposition of complaint the man may have other than going directly to the management.

CHAIRMAN YATES: The next paper, upon the "Value of Rock Dusting as a Safety Measure in Preventing Coal Mine Explosions," is by Mr. J. S. Jones, Safety Engineer, Old Ben Corporation, West Frankfort, Illinois. Mr. Jones is not with us and his paper will be read by Mr. J. T. Ryan.

THE VALUE OF ROCK DUSTING AS A SAFETY MEASURE IN PREVENTING COAL MINE EXPLOSIONS

J. S. Jones, Safety Engineer, Old Ben Corporation, West Frankfort, Ill.

Personal safety is one of the most important problems of the present generation. This is especially true in the coal industry. It becomes of greater importance as hazards increase with the more difficult winning of deeper seams and the consequent development of bigger mines, requiring the employment of larger numbers of men in each mine. As depths to coal seams increase the tendency is to greater gaseousness and dryer conditions, necessitating greater precautions against hazard of explosions.

Explosion disasters are the result usually of two distinct phases or actions. First is the primary explosion resulting generally from the ignition of gas by open flame; and second, the propagation of the explosion by coal dust. Safety measures to prevent the initial explosion are many, their chief weakness being that so much depends upon the human equation. A thoughtless action or mistake by one person may result in this initial explosion which may develop into a disaster if the natural or artificial conditions of the mine are not such as to compel the initial explosion to spend itself and not be propagated by coal dust.

Our mining industry has been concerned since quite early in its existence in preventing the small explosion from developing into a big one. It fully realizes the weakness of the human element as an absolute prevention against the initial explosion. This is manifest in the frequent explosions that do occur, and occasionally under what are termed the best of regulated conditions. An opened flame lamp, a bad shot or blast and an electric arc each adds percentage of hazard to the usual cause of ignition by an open light.

Our problem then, with rock dusting, is to stop this second phase or action of the explosion. Rock dusting is not concerned in preventing the initial explosion for this comes under other safety measures. Its duty is to reduce the human equation of the hazard so as to eliminate it insofar as possible and make the resultant mine dust inexplusive. The use of rock dust is to prevent a mistake from developing into a disaster.

The value of a proposed safety measure can be theorized upon and an estimate ascertained as to its worth. The true value, however, can only be determined by what it has done in actual operation. There has been considerable theorizing about the value of rock dusting as a safety measure, largely because of insufficient performance, but we have now progressed sufficiently to determine its value from actual experience and to foretell what may rightfully be expected from complete installations of this safety measure in our coal mines.

Demonstrations of Efficiency of Rock Dusting

The value of rock dusting as a safety measure in preventing coal mine explosions under actual operating conditions has been demonstrated to me upon more than eleven occasions. The brief facts of each I will narrate here in their order:

(1) A coal dust explosion from gas ignited by an open light in a mine employing 600 men on the day shift. Explosion occurred at night killing all working on the night shift, 17 in number. The flame penetrated into every corner of this mine except two small sections which were unintentionally rock dusted. This rock dusting was from grading into the floors of the entries, resulting in a high ash content of mine dust at these locations. Additional ash content was supplied by accumulation of sand used on the steep haulage at these grades.

(2) A gas explosion; ignition by open light in a mine employing 450 men on the day shift. Explosion occurred while mine was operat-

ing and three men were killed. Mine was rock dusted by the barrier system and troughs were overturned and dense cloud of shale dust thrown into suspension ready for flame had it reached the barrier location.

(3) A gas explosion probably developing into a coal dust explosion, ignition by open light in a mine employing 530 men on the day shift. Explosion occurred while mine was operating. There were no fatalities. Mine was rockdusted by the barrier system, the origin of explosion being less than 100 feet from the barriers. The flame was extinguished by the rock dust.

(4) A gas explosion which developed into a small coal dust explosion which was extinguished because of expansion due to large open territory. Ignition by open light. Mine employed 500 men on the day shift and explosion occurred while mine was operating. There were no fatalities. Mine was rock dusted by the barrier system and coating of roof and ribs by hand in the vicinity of barriers. The barriers operated and dense clouds of shale dust were in suspension ready for flame had it reached the barrier location.

(5) A coal dust explosion from black powder shot, killing two shot-firers. The propagation of the explosion was stopped when it reached the older workings where the soft roof shale had fallen giving the mine a natural rock dusted condition.

Flame Extinguished by Clouds of Shale Dust

(6) A coal dust explosion from gas ignited by a match in enclosed light mine. Explosion occurred at night when 41 men were working. This explosion occurred on the haulage entry between two shale dust zones, the mine being dusted by the barrier system and coating of ribs and roof by hand in the vicinity of the barriers. Two fatalities resulted to men who were at the origin of the explosion. Flame was extinguished by the dense clouds of shale dust at the first barriers reached in both directions.

(7) A gas explosion of terrific violence in a shale dust zone on an idle day when 30 men were in the mine. Gas ignited by electric arc. Dust troughs were demolished and I-beam was blown down but flame did not get out of dusted zone. No fatalities.

(8) A coal dust explosion, the coal dust ignited from dynamite charges on top of coal bench. Explosion occurred on idle day when 37 men were in the mine. There was one fatality. The mine was dusted by the barrier system and coated by hand in vicinity of barriers. The distance from origin of explosion to barriers was 700 feet, permitting the explosion to develop into one of terrific violence and flame. The evidence of flame disappeared before it had penetrated ten feet into the shale dusted zone.

(9) Two gas explosions on different days in a mine that was operating with about 550 men on the day shift. The gas was ignited by open lights, the origin of the explosions being in shale dust zones. The flame did not get out of the zones. There were no fatalities.

(10) A gas explosion on an operating day; ignition by open light in a mine employing nearly 600 men on the day shift. The origin of explosion was in a shale dust zone and flame did not get out of the zone. There was one fatality.

(11) A coal dust explosion from gas ignited by an open light on an operating day in a mine employing about 300 men. The mine was not rock dusted. The explosion came out of a panel and had three directions in which it could travel. It took but one of these directions, omitting the other two. The ash content of the two omitted was high because the floor had been graded and the locations unintentionally rock dusted. Twenty-one lives were lost.

(12) A gas and coal dust explosion, gas ignited from attempting to relight flame safety lamp with match near face of entry. Mine rock dusted by coating method to within 250 feet of face. The mine was operating and there were 1079 men in the mine. The flame penetrated into the rock dusted area a distance of about 25 feet and was extinguished by the rock dust. Five men were killed.

Approximately 165,000,000 tons of coal have been produced in Franklin county, Illinois, since the beginning of the industry there in 1903. There have been 228 deaths due directly to explosions. Two hundred eighteen of these occurred in the production of the first half of this tonnage, or the first 82,500,000 tons of coal and 10 occurred in the production of the second half. We are not justified in attributing this great improvement entirely to the use of rock dust but rock dust and enclosed lights unquestionably have been important factors in this reduction of explosion fatalities. At the present time nine-tenths of the coal production in Franklin county is obtained from mines that are rock dusted and operated on an enclosed light basis.

The value of rock dusting has been shown in press reports of mine explosions occurring in other parts of the nation. These reports have been given wide circulation and need no further comment here.

Further value of rock dusting is the unlimited quantity of acceptable rock for pulverizing in almost every mining community. Shales, lime-rock or adobe are in abundance near all mining locations, making the possibilities of rock dust supply a simple problem.

Redusting Required One to Three Times a Year

Another important value of rock dust is its stability. It does not evaporate and only a very small part of it is blown away. Redusting is required only after spalling has caused it to fall and to be covered or when it has been coated to such an extent with coal dust as to make the resultant mine dust too high in combustible content to guarantee a sufficient factor of safety to prevent the propagation of an explosion. Redusting from one to three times per year will fulfill the rock dust requirements of almost any coal mine. This value of rock dust is reflected in the small cost per ton of coal production for this important safety measure, this cost varying from a quarter to three-quarters of a cent per ton of coal produced when considered upon a yearly basis. The

cost varies of course with the size of the mine and the amount of coal produced.

Important factors in the value of rock dusting are the ease and simplicity of its application. Where track is installed it is a simple matter to rock dust the mine surface of the haulage ways and nearby passage ways by mechanical rock dust distributors. Good distributors are being manufactured and may be obtained at reasonable prices. Where such rock dusting can not be effectively applied in each mine the entrances and exits to such territories can be protected with rock dust barriers, these being so designed and constructed that dense clouds of dust will be easily thrown into suspension in the event of an explosion.

The value of rock dusting is acknowledged by insurance companies and compensation bureaus, as shown by charges made for explosion hazard in mines not rock dusted and credits given for mines that are rock dusted.

Rock Dust Can Not Protect by Name Only

Rock dust, when properly applied is a real safety measure. Like all other safety measures it can not protect by name only. There possibly will be a time when a so-called rock dusted mine will have a coal dust explosion. It seems to be human nature to try to "get by," and getting by with rock dusting may not be an exception. Fortunately the application of the dust to assure a big factor of safety is of no great labor cost and of but slight increase in material cost. The chief concern is to rock dust at sufficiently short intervals of time to insure that the dusted territories are kept sufficiently high in ash content and that the newly developed territories are not permitted to go too far without rock dust protection.

In conclusion I wish to emphasize the value of the peace of mind to the workers and those in authority because of the reliability of this safety measure in a well dusted mine. None but those who have experienced the dread of an explosion disaster can fully appreciate this value. May we by education, discipline, courtesy and example spread the knowledge of the value of this and other safety measures and hasten the day when human and mechanical hazards will be reduced to a minimum.

CHAIRMAN YATES: I would like to ask, is there any more dust formed in undercutting with machinery than formerly by hand?

MR. RYAN: Yes, there is; that is, more fine dust. Mr. Davidson in his paper yesterday pointed out the way in which they are very effectively overcoming the dust hazard, the dust that is developed at the face in the cutting operations, and that is by putting water on the cutter bar.

MR. GRABOWSKY: We have no dust hazard or gas hazard; this is a matter of information only. You spoke of rock dusting in periods of one to six months. Does that apply to the adits or does it apply to the working face as well?

MR. RYAN: That applies more particularly to the adits or entries.

Rock dusting the immediate face is not being done except in a very few mines. I will put it this way, that 85 per cent of your explosion hazard is in your narrow workings; the 15 per cent of your hazard is in your rooms—what we term our wide workings. Now the illustration I painted here of this large room for studying dust explosion is a very remote possibility because there is so much room for expansion here that it would be difficult to throw the dust in a thick enough cloud for the flame to pass through it.

If this room was sufficiently narrow the chance of building up the pressure is much greater and in addition to that we are more liable to find our gas in the narrow advance workings than in the rooms, so our hazard is 85 per cent in our narrow workings, and we do try to keep the dust of those up to what we term the last break through. They are not dusting in the rooms because the cost of keeping the dust up to the working face of the room is greater than dusting the rest of your mine, so the expense of taking care of that 15 per cent of the hazard has kept the most of them from doing it. Some of them do it, as explained by Mr. Correll yesterday, by keeping the dust at the working face and having the men distribute it.

Dust Hazards Also Found in Metal Mines

I want to answer your other question. You say in the metal mines you do not have dust hazard. I want to surprise you by telling you that you do have a dust hazard, and some of you are going to have a dust explosion in the metal mines. It is almost unbelievable the dust that will explode, if you get a high sulphide dust, get it ground, have it pulverized enough, and have the other elements as we have in the coal mine. You know we do not always have to have gas. I pointed out the picture of getting the explosion started from gas; that is the way 85 per cent start; but 15 per cent start direct. You can ignite the dust from an arc without any gas present—and there are certain sulphide dusts that will explode, and if you have them scattered along as we have in the coal mines they will propagate. That is only a prediction, but it is possible to find, and there are some dusts in the metal mines that are just on the danger zone.

GEORGE FORDHAM (Gulf Smokeless Coal Company, Wyco, West Virginia): Mr. Ryan remarked that 85 per cent of the hazard existed at the face—am I not right?

MR. RYAN: Eighty-five per cent of our hazard is in what we term our narrow workings, the haulageways, entries and the advance working. I include haulage entries because that is where you have your electric wires which are considerable hazard.

MR. FORDHAM: It seems to me rather than considering the safety end of it they are looking more to the cost of it. Our costs are much higher than the figures we note in the records, but we are working successfully, I believe, and I consider the hazard at the face. We have the mining machinery at the face, the rooms are filled with coal dust, the entries are full of coal dust, and if coal dust is a hazard, why not have the rock

cost varies of course with the size of the mine and the amount of coal produced.

Important factors in the value of rock dusting are the ease and simplicity of its application. Where track is installed it is a simple matter to rock dust the mine surface of the haulage ways and nearby passage ways by mechanical rock dust distributors. Good distributors are being manufactured and may be obtained at reasonable prices. Where such rock dusting can not be effectively applied in each mine the entrances and exits to such territories can be protected with rock dust barriers, these being so designed and constructed that dense clouds of dust will be readily thrown into suspension in the event of an explosion.

The value of rock dusting is acknowledged by insurance companies and compensation bureaus, as shown by charges made for explosion hazard in mines not rock dusted and credits given for mines that are rock dusted.

Rock Dust Can Not Protect by Name Only

Rock dust, when properly applied is a real safety measure. Like all other safety measures it can not protect by name only. There possibly will be a time when a so-called rock dusted mine will have a coal dust explosion. It seems to be human nature to try to "get by," and getting by with rock dusting may not be an exception. Fortunately the application of the dust to assure a big factor of safety is of no great labor cost and of but slight increase in material cost. The chief concern is to rock dust at sufficiently short intervals of time to insure that the dusted territories are kept sufficiently high in ash content and that the newly developed territories are not permitted to go too far without rock dust protection.

In conclusion I wish to emphasize the value of the peace of mind to the workers and those in authority because of the reliability of this safety measure in a well dusted mine. None but those who have experienced the dread of an explosion disaster can fully appreciate this value. May we by education, discipline, courtesy and example spread the knowledge of the value of this and other safety measures and hasten the day when human and mechanical hazards will be reduced to a minimum.

CHAIRMAN YATES: I would like to ask, is there any more dust formed in undercutting with machinery than formerly by hand?

MR. RYAN: Yes, there is; that is, more fine dust. Mr. Davidson in his paper yesterday pointed out the way in which they are very effectively overcoming the dust hazard, the dust that is developed at the face in the cutting operations, and that is by putting water on the cutter bar.

MR. GRABOWSKY: We have no dust hazard or gas hazard; this is a matter of information only. You spoke of rock dusting in periods of one to six months. Does that apply to the adits or does it apply to the working face as well?

MR. RYAN: That applies more particularly to the adits or entries.

Rock dusting the immediate face is not being done except in a very few mines. I will put it this way, that 85 per cent of your explosion hazard is in your narrow workings; the 15 per cent of your hazard is in your rooms—what we term our wide workings. Now the illustration I painted here of this large room for studying dust explosion is a very remote possibility because there is so much room for expansion here that it would be difficult to throw the dust in a thick enough cloud for the flame to pass through it.

If this room was sufficiently narrow the chance of building up the pressure is much greater and in addition to that we are more liable to find our gas in the narrow advance workings than in the rooms, so our hazard is 85 per cent in our narrow workings, and we do try to keep the dust of those up to what we term the last break through. They are not dusting in the rooms because the cost of keeping the dust up to the working face of the room is greater than dusting the rest of your mine, so the expense of taking care of that 15 per cent of the hazard has kept the most of them from doing it. Some of them do it, as explained by Mr. Correll yesterday, by keeping the dust at the working face and having the men distribute it.

Dust Hazards Also Found in Metal Mines

I want to answer your other question. You say in the metal mines you do not have dust hazard. I want to surprise you by telling you that you do have a dust hazard, and some of you are going to have a dust explosion in the metal mines. It is almost unbelievable the dust that will explode, if you get a high sulphide dust, get it ground, have it pulverized enough, and have the other elements as we have in the coal mine. You know we do not always have to have gas. I pointed out the picture of getting the explosion started from gas; that is the way 85 per cent start; but 15 per cent start direct. You can ignite the dust from an arc without any gas present—and there are certain sulphide dusts that will explode, and if you have them scattered along as we have in the coal mines they will propagate. That is only a prediction, but it is possible to find, and there are some dusts in the metal mines that are just on the danger zone.

GEORGE FORDHAM (Gulf Smokeless Coal Company, Wyco, West Virginia): Mr. Ryan remarked that 85 per cent of the hazard existed at the face—am I not right?

MR. RYAN: Eighty-five per cent of our hazard is in what we term our narrow workings, the haulageways, entries and the advance working. I include haulage entries because that is where you have your electric wires which are considerable hazard.

MR. FORDHAM: It seems to me rather than considering the safety end of it they are looking more to the cost of it. Our costs are much higher than the figures we note in the records, but we are working successfully, I believe, and I consider the hazard at the face. We have the mining machinery at the face, the rooms are filled with coal dust, the entries are full of coal dust, and if coal dust is a hazard, why not have the rock

dusted face? For my part I am unable to see where the danger exists at the mouth of the mine entrance and of course while it is necessary to rock dust along the haulageway, I believe the main point of the place is the working face. We have the dust there—the dust is in suspension and there is where you should have the rock dust.

I fear many of us are holding back on account of the costs. We are trying to get away from that and look to the safety of it, and are rock dusting the room workings, and at the present time we are going over the mine not only four times a year but continually rock dusting the workings every night, and it amounts to something.

MR. SMITH: I had occasion to inspect the Superior Smokeless that blew up last month and make recommendation on it and I want to know if I overlooked anything. They are going on closed lights, adjusting and putting in their barriers, and we recommended they put water on the bar and wet the cars. What else can we do?

Rock Dusting Unavoidably Whitens the Coal

MR. RYAN: I do not think you missed very much. If they do all those things effectively, I think you have practically eliminated the danger.

Another thing I want to emphasize particularly in anything to do with coal mining hazards, "Watch the ventilation."

MR. SMITH: You perhaps are familiar with the Oklahoma situation on that.

CHAIRMAN YATES: Have you been doing this before?

MR. SMITH: Yes, this mine was rock dusted before it blew up.

MR. RYAN: I did not mention that particular mine that just blew up about six weeks ago. The vice-president of the company told me there were 16 killed and 141 in the mine. He said he was quite convinced that if the mine had not been rock dusted they would have lost all those 141 men.

MR. SMITH: There is no doubt of it.

MR. HALL: I think one of the difficulties of rock dusting at the face, the coal has to be sold and it is very hard to sell coal that is white instead of black, and that is one thing that interferes very largely with those people in the commercial business. Those people who are mining coal for coke are washing the coal before they put it out, and may possibly manage to get away with coal which has been covered with rock dust, and they can well afford to rock dust their narrow entries and in that way attain a very large degree of protection. They have in some cases, however, rooms that are only 15 feet wide, and in those cases there is considerable danger because the places are narrow; at the same time the coal that would be rock dusted would have to be sold, and they might have some trouble with it. The public in the United States is very particular about having black coal. They are not so particular in Germany. I understand that in Germany they throw on the tops of their railroad cars a body of lime, slaked lime, and in that way if anybody steals the coal they will be found guilty of having stolen it, and apparently the public is willing to accept that coal.

A second objection to rock dusting coal from a commercial point of view is, even in a metallurgical mine, you can not tell whether the miner is putting out dirt or not if he is going to make his coal white so you can not satisfactorily see the coal. It is unfortunate we are not doing more rock dusting than we are in the rooms. In some cases it is being done. I understand there are about 12 cases near Pittsburgh.

I was going to say a few words about Mr. Ryan's remarks about the Old Ben Corporation being the first one in this country to rock dust. I presume Mr. Ryan had reference to the first company to rock dust in the present successful rock dust effort. Prior to that there had been some work done by several people, the Victor American Fuel Company, after their explosion and fire, and Delagua had put rock dust barriers along the sides of their roadways. The Gallatin Mine, I believe, of the Pittsburgh Coal Company was rock dusted a little about the same time. A rock dust machine was introduced by McMurray of the Victor American Fuel Company and the Reliance Mine of the Union Pacific Coal Company was dusted with adobe dust.

That was way back in about 1912; and then for some reason or another the practice was dropped. I understand the Victor American Fuel Company dropped the practice during the war because they were anxious to get out the coal and had no trouble and so ceased to rock dust any more. But it was Mr. Jones' working at the Old Ben Coal Corporation which reinaugurated this practice of rock dusting coal mines.

Gas Explosions Also Occur in Metal Mines

O. N. WAMPLER (Safety Engineer, Eagle Picher Lead Company, Picher, Oklahoma): Mr. Ryan made the statement that some of the metal mines might expect a dust explosion some day and most of us smiled. If he had told me three years ago we would have a worry from gas I would have smiled the same way; but last December we had a gas explosion in one of our mines, some eight or 10 men were injured at the time and one fatality. We have two mines now where we have to use safety lamps, and since that time we have had one other explosion where two were injured; this is close to the coal section of Kansas and also a few gas wells further on. We have some open water course caves we strike in the ground and I would judge this gas has accumulated in these caves, so we now have the gas troubles along with the coal men.

MR. GRABOWSKY: I might say the smile originated with those who are in the iron mining game.

CHAIRMAN YATES: I might say I smiled also as a gold miner.

MR. HURTER: Mr. Grabowsky, I investigated a few years ago where two men in the Chapin mine got singed by gas accumulated in a raise, that came from decaying timber.

MR. AGETON: Mr. Harrington went out to a mine in Dubuque in 1915, where six men had been injured from methane explosion, two of them fatally. We had a 1,250 foot shaft, about 1,000 feet full of timber, a mine filled with water and the shaft filled with muck and dirt. There was an accumulation of methane from this decaying timber under the water,

and when they were cleaning out the shaft and got down to the 1,050 foot level and one man working over the skip pocket with his carbide lamp, the whole thing blew up; so it is possible to have a methane explosion in nearly any kind of mine. Mr. Wampler neglected to say this was a zinc mine where this methane explosion occurred.

MR. DAVIDSON: I have one other suggestion that might be valuable to Mr. Smith as recommended for that mine. Some of our people are rock dusting the old workings 500 feet back from the live workings and main entry, and reinforcing that with rock dust barriers at all openings from the old works into the live workings, and we think that is a very great safeguard against explosions originating in old workings. The miners will go in there in spite of the prohibition against it and strike matches and smoke and are liable to set off gas. It is a very good precaution to take. As to rock dusting your rooms, if you have your entries and narrow working thoroughly rock dusted and then rock dust the gob and ribs and floor and roof of the rooms reasonably close to the working face you have a fair degree of security.

The Human Element a Big Factor to Contend With

H. T. BANNISTER (General Safety Inspector, Madison Coal Corporation, Chicago, Illinois): We fellows in southern Illinois have the human element to contend with as much as anyone else, and the explosion Mr. Ryan referred to a short time ago is one where a man was working with a closed light and had a flame testing safety lamp with him and he lit a match and lit the gas. There would have been a repetition in mine No. 11 had it not been for the rock dust. At the Orient mine a year ago a mine examiner was sent in to remove the gas. There were over 1,200 men in the mine at that time. The mine examiner's lamp went out for some unknown reason and he took a match and lit it, and the explosion killed him and his crew, but the mine was well rock dusted and it confined it to a very small area. Those are the things we have had to go up against in southern Illinois.

Mr. Jones and I have been working together for a number of years, and he made a trip east with Mr. Ryan in 1915, and when he came back he was very enthusiastic over rock dusting. On Thanksgiving night, 1917, No. 11 mine of the Old Ben Corporation blew up. Mr. Ryan said there were 18 men—there were 22 men in the mine and they were all killed. It would have been impossible for anyone to live in that mine, and Mr. Jones at that time converted Mr. Buchanan to the view that rock dusting was the thing; and in our opinion we have saved a lot of lives by that in southern Illinois.

MR. FORDHAM: I would like to ask the gentleman in regard to the health of men that are continually exposed to rock dust. Have you noticed any increase in the sick rate?

MR. BANNISTER: We think it improves their health. We have found no ill effects in our examination or tests of the men employed.

MR. AGETON: In answer to the gentleman's question, I noticed Mr. Ryan specifically said "Limestone and other dusts without silica content or

low on that." The main causes of respiratory diseases among miners is inhalation of fine particles of siliceous dust and not inhalation of limestone dust. It is the sharp edges of silica after being inhaled into the lungs that cause the trouble; furthermore the dust causing the greatest trouble is dust less than one-tenth of a micron in diameter, and that one ten-thousandth of an inch, so it has to be pretty fine dust to cause the trouble. So I do not think your adobe dust having no silica content will cause any trouble.

MR. HURTER: The Pittsburgh Limestone Company has some large underground operations getting out limestone and I do not think there has been a case of silica poison in the history of the company.

CHAIRMAN YATES: This is all very interesting and the time is rapidly going. We have with us Miss Marion Telford, Field Secretary of the National Safety Council, who will talk to us on safety work in the schools.

An Interesting Trip Across the Mesaba

MISS MARION TELFORD (Field Secretary, Education Division, National Safety Council, New York City): I hope I am right in assuming you want details, and since this is the Mining Section, I want to tell you about a trip I had across the Mesaba a few weeks ago. Due to the interest of Mr. Pollock, of the Oliver Mining Company, we were asked to go up there to make some suggestions as to what might be done in the way of safety education in the range schools. We had two thoughts in mind; the first is to decrease the actual accidents occurring to all children themselves. Our child fatalities last year, you know, amounted to over 23,000. We were to decrease the accidents and fatalities occurring to children; and, second, to influence that child when he gets on up as an individual, a motorist, pedestrian, miner or whatever his job, so that safety will be something in which he is interested.

In the various districts of the Mesaba Range schools and in the independent school districts, consisting of a city like Eveleth, Hibbing or outlying locations, the superintendent has been asked to cooperate by appointing a safety supervisor, not suggesting that he add a paid person to the existing staff, but some good, live, practical, interesting sort of person already on the staff to become supervisor of the safety work. When introducing a new thing in schools the matter of personality is extremely important, and that is something to keep in mind when you say to the superintendent of schools, "Can we have some one to be responsible for the introduction of safety education in the school system?" I have seen in some schools where the thing has gone across because of the personality of the person that introduced it, and vice versa.

When suggesting plans for that supervisor, one is the safe direction of child activities, in the organization of student councils, the safe conduct on the street, health patrols, publicity patrols and things of that sort; and to introduce class room instruction, by issuing bulletins, by making suggestions to teachers, by presenting statistics for the teachers, by getting current information to them, to keep wherever possible a record of the accidents occurring to children. The Mesaba Range is doing one

of the finest pieces of work of this type with which I am familiar. They are contributing to us actual information concerning the accidents to their children. One school I visited in Minnesota recently, where 1,883 children were enrolled in the nine months of the last school year, they reported 92 broken bones. That may not look serious to you if you are talking in terms of fatalities; but think what that means, 92 broken bones of one type or another in a school enrollment as small as that!

What we want to ask you to do, wherever it is possible, is to follow that general scheme of things—get a supervisor, have the supervisor get a picture of existing conditions and then give to the teachers material that they can use. The Education Division of the Council can help you out there somewhat, and I think Mr. Pollock would tell you that in his Range schools it has been of value and importance for many for us to offer certain publications; and so I want to call to your attention a manual for the teachers, with an introduction by Harold Rugg. The Education Division is reached at 120 W. Forty-second Street, New York City. I also call your attention to a Junior Safety Council hand book which tells the story of child activities and a monthly publication which we have, "*Safety Education*," printed the 10 months of the school year, dealing with child activities, a play, stories and current material a teacher can use.

Where the School Safety Problem is Rough Play

We are glad to come into your communities and make suggestions as to the proper procedure, talk it over with your school people, and we make available certain publications. Mr. Pollock's experience on the iron range is of extreme importance. I think it indicates, first of all, something must be and can be done. In these communities where such various elements of population are collected, where your children represent probably every type of nationality you can think of, in communities of that sort the play is rough. The outstanding impression I got of the school safety problem on the range was rough play, and it sometimes has disastrous results. Not only that, but there is a question of being able to do something through the schools located in the small towns.

This problem of safety is not limited to our large centers of population. The people of North and South Dakota may sit back and say: "Yes, your traffic problem is limited to large centers of population and also your safety problem:" but such is not the case as shown by statistics, that is in proportion to the population.

CHAIRMAN YATES: How do you connect up this work of the school children with the work of the child as it grows up and goes out into the field of industry?

MISS TELFORD: Education is founded on the conviction that the instruction of the child as to morals, safety, health and on down the line, all child instruction influences the conduct of the adult. One of the best ways to fight the automobile problem, our traffic problem, is to influence your child. have him be a traffic patrol and get an attitude of mind that will make him conscious of that part he has. We admit it is intangible;

we admit there is a break between the majority of the safety work now carried on in our schools, in the first six or eight grades—there is a break between that and the same boy coming into your plants. But the whole scheme, the whole safety educational scheme, is based on the firm conviction that there is a relationship between the direction of the child activities and child thought and his conduct as an adult.

MR. POLLOCK: It is a sort of selfish measure on our part that we got the safety education in the schools. You go through and talk to the miners like I have at many safety meetings and they will tell you what their children told them about blasting caps and other things. I do not know whether the boys here realize this service of the National Safety Council Education Division is free. Miss Telford is sent wherever she is asked for and has time to go. I think the insurance companies are paying expenses.

MISS TELFORD: It takes interest on your part to get this thing started. If the people in the local community do not try to put this thing across our efforts are not going to help you out a bit.

Accident Rate High in the Upper Peninsula

MR. TRESTRAIL: I want to support one fact Miss Telford brought out. A lot of us living in the small districts of population believe the majority of accidents occur in the large centers of population. I was asked to give a talk before a Rotary Club and I had to get some facts to sustain my arguments. I wrote to the Secretary of State of Michigan and received a comprehensive statement from him. They have their accidents, automobile and other public accidents tabulated according to the districts in which they occurred, and I was surprised to find in the upper peninsula there were more accidents per thousand than in the city of Detroit; so if we think we have not a problem we are badly mistaken.

D. W. DANIEL (Safety Supervisor, U. S. Gypsum Company, Chicago, Illinois): Until this summer I was in school work myself and I know it can be done. I have worked around some of the smaller coal mining regions in southwestern Virginia. I am now with the U. S. Gypsum people in safety work. I started in September at safety work and there is not a child in that vicinity that is not a booster. I never go through the Gypsum mine but what some miner tells me something I said over at the school that his child has brought home to him. They are the biggest boosters to put the safety education over at school.

MR. HALL: I thought it might be well if Miss Telford would put us right on how the appropriations are made for her employment. We may think the National Safety Council is using money for general educational purposes, and that they might help us a great deal more if they spent more on our own Section.

MISS TELFORD: I am glad to clear up that question. The Education Division of the National Safety Council is very distinct from the other part of the Council. It is supported primarily by the National Bureau of Casualty & Surety Underwriters; Mr. Albert W. Whitney of New York is the Vice-President in charge of education. My traveling expense,

my salary, etc., are paid indirectly by the National Bureau of Casualty & Surety Underwriters. It means they pay into the treasury of the Council every year the money necessary to cover the operating expenses of the Education Division, with the specific understanding that the money that Bureau contributes to the Council shall be used for the maintenance of that Division.

If some one else says they will give money to study traffic problems, it will be used for that purpose. This arrangement is made because of Mr. Whitney's interest in education, I believe, and his very firm conviction of the value of this thing. Mr. Whitney was formerly Professor of Mathematics at the University of California. Naturally he should think of safety work as it should be worked out in a school, and naturally he should consider what the school people can contribute to the movement.

I am the only Field Secretary who travels all the time. We arrange the itinerary by suggestions, indications and requests from various school people, chambers of commerce, local safety councils and industrial members who write to us and ask us to come down and make suggestions to their school people. We can not always arrive on the date we are asked, but in so far as we possibly can our itinerary is arranged so it will fit the plans of the people who are interested in the work. Incidentally, we do not know whether you are interested or not in this particular angle of the problem in your community unless you indicate it, take the initiative in letting us know. We can not send letters to every one asking if they are interested, but we make every possible effort to accommodate the people who take the initiative in letting us know they are interested.

CHAIRMAN YATES: Our next paper is by Mr. Daniel Harrington, Consulting Engineer, Salt Lake City, Utah, but now with the Bureau of Mines. This paper will be abstracted by Mr. R. V. Ageton.

MR. AGETON: Mr. Harrington has asked that it be made absolutely plain that this paper was written by him as a Consulting Engineer in Salt Lake City, and at a time when he was not in the employ of the United States Bureau of Mines, and the statements and ideas presented in this paper are his own personal ideas, and are not the authorized ideas of suggestions from the Bureau of Mines.

SAFEGUARDING ELECTRICAL EQUIPMENT IN MINES

Daniel Harrington, Consulting Mining Engineer, Salt Lake City, Utah

During the past 18 years I have had an opportunity to make examination of 21 coal mines after explosions resulting in loss of over 800 lives, and it was fairly definitely determined that the original ignition in nine of these explosions was due to electricity, causing the loss of over 300 lives.

The igniting agencies in these nine explosions were trolley locomotive arc and gas, trolley locomotive arc and dust, electric hoist and gas, electric under-cutting machine and gas, electric over-cutting machine and gas, ruptured pick proof electric cable and dust, electrically-driven

booster fan and gas, electric shot firing and gas or dust, and electric pump and gas. In several of the other 12 explosions electricity was blamed at one time or other but finally the cause was placed elsewhere.

During the above-mentioned 18 years, eight serious fires in coal mines and nine in metal mines were studied at first hand; four of the coal mine fires were of electrical origin with property loss of several million dollars and loss of life of five persons; five of the nine metal mine fires were directly or indirectly of electrical origin, the loss of life being approximately 250, and property loss much more than one million dollars. The four costly coal mine fires of electrical origin were all caused by electric wires, two in contact with timber and two under coal falls; of the five serious metal mine fires caused by electricity one was due to an electrically-driven fan, one to an electric cable, one to an open type electric switch, one to an electrical junction box, and one to an electrically-operated pump (at least it occurred in the neighborhood of the pump).

Many Disasters Charged Against Electricity

Hence of the 38 disasters with which I had close contact, practically 50 per cent were charged to electricity. This fact together with the knowledge that at nearly every mine disaster in either coal or metal mine which I attended, electricity has been tentatively given the blame by nearly all those interested, until or unless other cause was definitely placed, has convinced me that electricity is now one of the most distrusted agencies in mining, and deservedly so, notwithstanding the fact that present day mining demands an increased use of electricity and that in general electrical installations in mines continue to be carelessly placed and even more carelessly maintained.

Available statistics charge electricity with 75 to 100 lives out of a total of 2000 to 2500 lost annually in our coal mines, this including only those killed by direct contact with electrical devices and not including those deaths brought about by explosions or fires of electrical origin. A tabulation of 100 coal mine disasters from 1915 to 1924 (all but 18 having occurred since 1915) on pages 22 and 23 of Bureau of Mines Bulletin No. 251 gives a total loss of 4770 lives and of these over 1500 were from disasters known or suspected to have been of electrical origin. Hence it is conservative to place average annual deaths in our coal mines from electricity at 200 or over.

Of 10 major explosions in the coal mines of the United States in 1924 with total loss of 459 lives at least five with death list of 97 were of electrical origin. In one incomplete list of 10 major explosions in 1925, six were held to be of electrical origin, deaths numbering about 106. Hence during 1924 and 1925, 11 major explosions out of a total of 20 were of electrical origin. In other words, electricity caused more than 50 per cent of our coal mine disasters during those two years.

I have spent much of the past 26 years underground in coal or metal mines averaging from 50 to 75 days annually, and the one outstanding

impression as to possible personal injury while underground is in connection with electricity; I always give electric wires or equipment in mines as wide a berth as possible.

Underground workers have been killed by coming in contact with 110 volt light wires; by touching bare or poorly insulated, hence "leaky" 220 or 440 volt A. C., 250 or 500 volt D. C. wires; many workers have been burned, several have been electrocuted in attaching or detaching the "nips" of mining machine trailing cable to bared places on power lines 250 or 500 volt D. C., 220 or 440 volt A. C.; contact with 250 or 500 volt trolley lines has killed many; even bare signalling lines have caused several deaths due to power-line short circuits; and burnings or electrocutions at various kinds of underground electrical equipment, such as switches, fans, pumps, mining machines, locomotives, etc., while not extremely numerous are by no means rare. Explosions have been started by arc from ruptured "pick proof" power cable and dust; by trolley line arc and dust; by trolley line arc and gas; by arc from electric light wires and gas or dust; by incandescent globe and gas; by mining machines and gas or dust (both top-cutting and bottom-cutting types and away from the face as well as at the face); by arc from nips and gas; by trailing cable and gas; by pump motor and gas; by hoist motor and gas; by electrical drill and gas; by trolley line, black powder and dust; by stray currents and electric detonator; by electric shooting wires and gas or dust or both; by storage battery locomotive and gas; in fact almost every kind of electrical equipment used in mines has taken its toll of life both by explosions and by burnings or electrocutions by contact.

Mine Fires Are Ignited in Many Ways

The mine fire menace in mines in the past was largely from use of open lights and black powder blasting in coal mines and from use of candles in metal mines; electricity has largely superseded these in present day mines as the cause of fires, and an increasingly large percentage of present day fires in both coal and metal mines is chargeable to electricity. The ignition method is of great variety. Open types of electrical switches attached to timber, with leading wires in direct contact with timber, have caused many destructive fires in both coal and metal mines; abuse of safety devices, such as locking circuit breakers, or no voltage release devices on fan or pump motors, has been a fruitful source of fires; misplaced or poorly devised or constructed but unattended safety devices (to cut operating costs) have caused expensive fires; rupture of power cables in shafts due to abrasion by falling material or to shaft movement has caused fires; falls of coal or rock or timber on power cables are a frequent source of mine fire; trolley wire contact with timber cap has caused several fires and seems especially dangerous when the timber is damp; defective rail bonds or lack of sufficient bonding undoubtedly causes fires (and very likely some fires and explosions of "mysterious origin" are due to poor

bonding condition); power lines passing through timber or cloth brattices have caused fires which have resulted in loss amounting to hundreds of thousands of dollars, and power lines insulated or uninsulated allowed in contact with coal roof or rib or timber cap or leg or fastened to timbers with wooden cleat or with track spike, or with nail or with piece of wire or hemp rope (all more or less prevalent practices) are likely to cause fires; and fires originating in both coal and metal mines at underground places which house electrically-operated equipment such as hoists, pumps, fans, compressors, motor generators, etc. are only too numerous and have cost many lives and property loss aggregating millions of dollars. Mine fires of electrical origin are of almost daily occurrence, usually resulting only in property loss, but the terror from the cry of fire in a mine is but little less than exists among those who have survived an explosion.

Safety Suggestions Based Upon Personal Experience

There is absolutely no question that the tendency of the times is toward the more extensive electrification of mines and while the above skeleton outline of some of the deaths and disasters due to electricity in mines indicates that electricity is potentially of much danger in mine workings, those dangers can be greatly lessened if reasonable precautions are taken in connection with installation, use and maintenance of mine electrical equipment. Many mining men as well as makers and salesmen of electrical machinery appear not to realize the potential dangers of electricity in mines, or at least they seem to be determined to minimize the possible dangers and even to decry or censure those who call attention to those possible troubles. This is the wrong attitude and much better ultimate headway would be made with electricity in mining if all concerned would strive to ascertain the facts as to the dangers and when they were learned take the necessary steps to prevent loss of limb or life, on the one hand, or of property on the other hand. I am not an electrician nor an electrical engineer, nor am I particularly well informed as to electricity, and the following suggestions are largely personal conclusions as a mining engineer after more than 25 years of observation in and around coal and metal mines. Many if not most of the suggestions may not be in accord with the ideas of most mining men as well as of most electrical engineers, yet all of the suggestions have behind them some specific occurrence or condition, recurrence of which it is aimed to avoid.

Power lines should be heavily insulated, preferably with lead and steel armor, and if possible, held on intake airways, preferable buried in a trench or cement box on the floor. Bare cables for power lines are dangerous and poorly insulated ones are but little safer; the widespread practice of using bare stranded cables as feeders for trolley lines is anything but safe. Power lines, unless extremely well insulated, should not be allowed to touch coal or timber and should be held by efficient insulators instead of wooden cleats, or spikes, nails or wire.

Power lines should not be taken into rooms or beyond the last cross cut in entries in gassy mines, and power to the face for pumps, mining machines, etc., should be passed through well insulated types of trailing cable. It is unsafe and unfair to have power lines in manways unless they are well insulated cables so located that men or animals will not come in contact with them; especially is it unsafe to have power lines in manways which are damp or wet unless those lines are very well protected. In passing power wires from one rib or side of a mine opening to the other, it should be done in such manner that men or animals are not forced to crawl through or under or over those lines, a good method being to use a trench either in the roof or the floor.

Where high voltage (2300, 4000 etc. volts) cables are brought into a mine if at all feasible it should be done through a bore hole. Bare wires are necessary for signal lines but voltage should be held as low as possible and every possible care taken that there shall be no short circuiting of high-power cables and signal lines by falls or wrecks; it is of decided importance that bare signal lines on haulage slopes or shafts have minimum voltage, since haulage wrecks may stir up clouds of fine dust which may be ignited by electric arcs from wrecked signal wires if high voltage is present. Weather-proof wires are not suitable for underground purposes and the protection afforded by this sort of insulation in comparatively short time is of little real value.

Power lines, including trolley lines, should be sectionalized by switches at intervals of about 1200 feet, and preferably each cross entry or panel should be capable of having its electrical current cut off by a switch at the entrance to the cross entry or panel. Power should be cut out of a mine or of any part of it when men are not working in it; it is dangerous to have pump or other electrical equipment running without attendance either constant or at least periodical, and many fires have been caused by falls upon power lines in unworked or untravelled parts of mines.

Trailing Cable and Incandescent Globe Hazards

The practice of securing transfer of current from power lines to the trailing cable of mining machines by attaching bare metallic hooks or other bare metallic devices, called nips, to bare places on the power lines is decidedly dangerous, both as to possible contact burnings or electrocutions and as to possible explosions. There are now available enclosed connectors which give assurance of safety in connecting and disconnecting the trailing cable and power lines. Where system of bare places on power lines and open hook or other "nip" continues in use, the bared places on power lines should be dropped to a point approximately one foot above the floor, hence in case of arc in connecting or disconnecting the nip there will be less danger of igniting gas than if the bared places were close to the roof. The trailing cable of mining machines should be high-grade rubber insulated concentric cables and

there should always be two men to a mining machine, otherwise arcing will very frequently take place with trailing cable in detaching it, running over it by cars, etc.

A distinct electrical hazard which is becoming increasingly prevalent is the use of incandescent globe electric lighting, now being introduced into the face regions in connection with the new so-called intensive systems of mining. There is danger of explosion from these lights even on intake haulage roads in case of wrecks or falls causing dust cloud and electric arc; the hazard is much greater at the face as there is greater likelihood of falls or of being struck, and not only dust but explosive gas may be involved. The hazard is readily apparent but the remedy is not so readily found. Until some permissible flood lighting device is at hand similar to the permissible electric cap lamp, the best precautions seem to be that the installations shall be carefully made to prevent the involvement of the wires or lamps in falls or wrecks; there should be extra precautions as to ventilation and the lights should be protected by guards and be located where there is minimum chance of them being broken by flying coal or by men or material during working operations. This system of lighting should not be allowed where much explosive gas occurs; a better system would be to have at "strategic" points extra lamps of the permissible electric cap lamp variety.

The Individual Employee Lamp Question

Permissible electric cap lamps are now in use by more than one-third of our coal miners and to date have not been responsible for loss of a single life (so far as I am informed) nor have they started a single mine fire, while the open carbide lamp has caused numerous explosions and fires with heavy loss of life and property in coal mines. The open carbide lamp is one of the greatest hazards as to fires in metal mines and users of this lamp have been asphyxiated by gases in both coal and metal mines. The permissible electric cap lamp is by far the safest and most efficient miner's lamp now in use; it is far safer than the flame safety lamp, which has taken toll of hundreds of lives in our coal mines. While our metal mines turn a deaf ear to even the slightest hint that the electric cap lamp should be used in metal mines, the fact of the matter is that the up-to-date permissible electric cap lamp gives a better light, a cheaper light, and by far a safer and more efficient light than the open, hand acetylene lamps to which the metal mining fraternity clings so religiously and tenaciously. Progressive conscientious "up-and-coming" coal miners now use the permissible electric cap lamps and find them far safer and more efficient than the open type of lamps. It is my opinion that all mines, coal and metal, should be required by law to use permissible electric cap lamps exclusively for miners' light.

Trolley lines should not be placed in return air courses nor should they be located in intake entries which have open workings which give

off explosive gas or out of which gas may be forced in case of fall or cave. Trolley wire less than six and one-half feet above track rail should be protected by box or other means to prevent men who walk on the haulage road from coming in contact with the wire. While this boxing is particularly desirable with high voltages such as 500, 550, etc., it should be done even where voltage is around 250 and the boxing should extend wherever the wire extends, not be confined merely to crossings or partings. Any entry which has a trolley line or any mine workings into which trolley locomotive or combination trolley-reel locomotive goes should be kept securely rock dusted at all times, inasmuch as the combination of coal dust on haulage ways plus electric arc which is likely to occur in case of haulage, wreck, or fall of roof or timber on trolley line, may cause an explosion. It also is anything but safe to utilize the reel type of electric locomotives to gather cars at gaseous faces and one frequently sees reel locomotives going to faces where line brattices are held necessary, this being a decidedly unsafe situation.

All trolley locomotive track should be securely bonded and bonds kept in good condition. While expensive, all joints should be bonded (by welding, if feasible) and there should be cross bonding at frequent intervals, possibly every 400 or 500 feet. Poor bonding is a fruitful cause of stray electrical currents which may "put off" blasting charges prematurely; also poor bonding or bonding in poor repair may cause fires or explosions or burnings or other electrical injury to men or animals.

Electrical Blasting the Safest Method

Electrical blasting is undoubtedly the safest of present-day methods of bringing down coal or rock, yet it has its possible dangers. The danger from stray currents is ever present and the loose ends of the detonator wires should be twisted together on the surface before being taken into the mine and kept twisted together until ready to fire, and great care should be taken to prevent the loose ends of the lead wires from touching coal, rock or track rail at any time. Preferably the charging as well as blasting of holes electrically should all be done when electric current has been cut out of the mine. Shot firing batteries which fire more than one shot at a time are capable of igniting methane, hence the only "permissible" shot-firing battery fires but one shot at a time. I firmly believe that the safest system of coal mine blasting in the United States is the one in which all shots are fired by electricity from the surface after all persons, including the shot firers, are out of the mine, all explosive having been excluded from the mine during the working shift and all loading having been done after all persons but the shot firers were out of the mine and all electric power had been cut out of the mine during the loading period. Where feasible, explosives should not be taken into a mine when electricity is in use there; if this is not possible, explosives should be placed in specially constructed, thoroughly insulated cars and, if possible, the explosive should be

removed from these special cars in some place free of electric current or open lights.

The present day mine telephones may ignite methane, hence care should be taken to install mine telephones in intake circulating air. At any rate, it would be dangerous to place a telephone at any point where there is likelihood or even remote probability of having an accumulation of methane. The danger of gas ignition at a telephone is present while ringing from a distant point as well as when ringing at the phone in question.

Hazards of the Electrically Driven Fan

The mine fan in general is now being driven by electricity and this entails numerous dangers: In very gassy mines an exhaust fan may be dangerous if the return air passes a sparking motor or an arcing open-type switch, hence care should be taken first to prevent the arcing or sparking and secondly to locate or ventilate the region of motor, switch, etc., in such manner that mine return air will not come in contact with the electrical equipment. Very gassy mines should have an auxiliary fan or a fan drive separate from the usual one and in some instances this is a steam, gas or oil engine readily connected to the fan. It is very desirable that the power line to operate the fan be separate from the mine power line in order to prevent fan interruption when there is power-line trouble in the mine, and especially to insure that the fan can be kept operating in case of mine explosions or fire, which would partially or wholly destroy the underground wiring system.

Some very gassy mines now have automatic cutting of electric power from the mine when the fan stops. I am decidedly opposed to the use of so-called booster fans or to any kind of auxiliary fan underground in coal mines, even when the fan is operated by steam or compressed air. When electricity is used for underground fan drive such installations are absolutely out of place in coal mines. Where used in metal mines these auxiliary fans driven by electricity should always be in thoroughly fire-proofed housing and there should be available fire extinguishers, water and sand for emergencies wherever these electrically-driven fans are placed, even if the use at any point is but for a few days.

One of the most serious problems confronting present-day coal mining is what is the best way to insure safe use of electric coal cutting machines in mines which "make" explosive gas. When electric coal cutting machines are used at faces which give off any methane, only permissible types should be used and they should be kept in permissible condition; the precautions as to nips heretofore given should be taken, there should be at least two men to a machine, the faces cut by machine or region through which a machine must pass should be well ventilated and water should be used on the cutting chain while cutting. Places in which machines are expected to cut should be examined for gas imme-

diately prior to entering the place, the examination to be made by fire boss or some person fully qualified to make the examination safely and efficiently, and under no circumstances should the machine be allowed to enter the place if explosive gas is found, even if the cutting machine is of the permissible type. In this connection it should always be borne in mind that "permissible" equipment is not designed for continuous service in a gaseous atmosphere, but merely with the idea that unexpected or occasional occurrences of methane will not be ignited; mines which have continuously gassy air at faces, or mines subject to heavy outbursts of methane, should not use electric cutting or other electric equipment where such gas condition is found.

Electrically operated pumps and hoists are frequently seen in mines in unventilated places, an extremely dangerous situation, especially since the motors are almost invariably of open, non-permissible type. Where it is at all feasible this class of equipment should be held in circulating intake air, and placing such equipment in the return in gassy mines is essentially as dangerous as if they had no air circulating around them. Lack of numerous gas ignitions from pump motors in our coal mines is much more a matter of good luck than good practice in installation or operation.

Intensive Systems of Mining Increase the Hazards

The newer so-called intensive systems or methods of mining involving loaders, scrapers, conveyors, etc., nearly all of which are electrically operated, offer new hazards to our coal mines and there is much probability that they will increase rather than decrease the sum total of mine hazards, notwithstanding claims to the contrary. However, if our mining men will take common-sense precautions there is no real necessity for any increased hazard due to the new methods. Instead of calmly (one almost might say cold bloodedly) ignoring the dangers of placing at gassy or dusty or both gassy and dusty faces a multiplicity of electrical equipment and devices, such as uninsulated or poorly insulated wiring, incandescent globes, open switches, non-permissible electric motors of various kinds, operating fans, hoists, conveyors, scrapers, and loaders, also open fuse boxes or fuses, starting boxes, etc., generally with attendant neglect of ventilation, rock dusting, fire proofing or sprinkling—if, on the other hand, these new methods were planned and operated with due regard to safety there is no good reason why the newer methods can not be made safe.

It should be kept in mind that with the concentrated methods there is also concentration of personnel, and a gas or dust ignition which under old hand methods in room and pillar workings might burn or possibly kill the one or two men at the face region affected, a similar ignition under concentrated mining might involve a score or more persons.

For these new methods wiring should be very carefully installed; motors should be of permissible type where such are available; water

should be used around or on mining machines, conveyors and loaders to prevent dust from flying into the air; loading of blasting holes or shooting should not be done with the shift in the mine; single entries should not be driven; electric or other auxiliary fans should not be allowed and ample circulating air should be furnished by ordinary ventilating methods; in fact, there should be extra safety precautions taken instead of this actual existing relaxation of safety precautions.

Fire-Proof the Stationary Electrical Equipment Underground

Underground stationary electrical equipment, such as hoists, pumps, motor generator sets, switch boards, switches, etc., are a fruitful source of fires, explosions, burnings, and electrocutions, chiefly because of slipshod methods of installation and maintenance. All places which house this stationary electrical equipment even if only for a few weeks should be well fire-proofed by gunnite, rock dust, cement or rock walls or other good method. These places should be well ventilated; should have fire proof doors which when closed isolate this equipment. The vicinity of such equipment should be held free of inflammable material, such as oil, oily waste, papers, brattice or canvas or other loose flammable material; wiring should be attached to efficient insulators and held free of timber or coal; the equipment should be thoroughly grounded and guarded with plenty of room around rotating parts or bare "live" metal parts; foundations should be of solid, fire proof material; there should be ample provision for prompt fighting of fire, such as fire extinguishers, sand or rock dust or hose and water located preferably just outside the electrical station on the intake air side.

While direct current is generally supposed to be more dangerous than alternating current at like voltages as to ignitions of gas or dust and less dangerous as to shock, the evidence as to relative danger is not very definite either as regards physical contact or ignitions of gas or dust. The greater number of "permissible" certificates appear to apply to direct current motors, on the other hand alternating current is becoming much the more popular for use in mines. It is my opinion that voltage above 250 should not be allowed on movable machines which operate at or near faces, this to include pumps, cutting machines, drills, conveyors, loaders, hoists, etc. Where the higher voltages 500, 2300, 4000, etc. are used in cables, pumps, motor generator sets, etc., extra care should be taken to make grounding and other precautions thoroughly effective and practically fool proof.

One of the most difficult features in connection with electrical equipment in mines is to keep safe the safety features installed surrounding or inherently placed in the equipment; fuses are replaced by heavy wire bridging, circuit breakers are locked, no voltage release devices are locked into starting position, etc., and these very dangerous practices are "winked at," even engineered in many instances by the local operating officials and many disasters have been initiated by these practices. The remedy is not readily at hand, especially where mine oper-

ating officials are so indifferent to the safety of their men and of the mine placed under their jurisdiction.

Competent Electrical Inspection Is Badly Needed

One of the greatest "wants" in our mines (coal and metal) at this time is competent electrical inspection and supervision. Electrical installations are usually planned by copying after some other mine, the conditions frequently being entirely different; very often an electrical engineer plans the installation on paper but never goes underground to see whether or not the underground installation is safe, complete or effective. Few mines have inspectors of underground electrical practice or equipment and in most instances the inspections which are made are of the most cursory nature and by men incapable of making a real electrical inspection. Very few state inspectors, safety engineers, mining engineers, company inspectors, or operating mining men know enough of the theory of electricity or of up-to-date methods of safe electrical practice to realize what is an unsafe method, installation or practice when they encounter one.

Each state should have at least a sufficient number of inspectors well grounded in the safest, up-to-date methods of electrical usage to make at least an electrical inspection of all mines in the state once annually; every company should have a man who is up-to-date in safe use of electricity and who makes at least one thorough inspection of all electrical equipment in every mine at least once every three months, and his report should go to the highest operating official of the company with copies to local operating officials; local mine officials should be acquainted with safe as well as warned against unsafe practices and conditions with electrical equipment; and underground workers who persist in unsafe practices as to electricity should be given the strictest discipline available.

Underground workers should be taught not to work on live power lines or to come in contact with them even where voltage is low; men who must work around electrical equipment should be carefully instructed as to their duties and as to the possible dangers in the work, with suggestions as to what to do to avoid those dangers; where feasible, underground workers should be excluded from electrical stations, entries having electrical power lines, etc., except when engaged in work on the electrical equipment; workers should not tamper with electrical equipment in such ways as bridging fuses, locking circuit breakers, etc.; all electrical equipment, but more especially permissable electrical equipment, should not be repaired by face workers and repairs should be made only by a competent mechanic who has a full knowledge of safety in connection with electricity; playing jokes with electricity is so inherently dangerous that anyone caught doing it should be discharged and if feasible prosecuted.

Whether electricity should be used in gassy mines is a much-debated question; if used, all available precautions, including those heretofore

described, as well as any others to be found, certainly should be taken and it appears that one of the probable solutions to the question is the application of the permissible storage battery to the various activities in mines, including locomotives, cutting machines, pumps, drilling machines, etc. The storage battery of permissible variety appears to have very great possibilities as to both safety and efficiency, and it now seems as if future safety in application of electricity to mining will tend largely to broaden the use of the storage battery which now is so very successful in application to individual lighting in mines.

The Safest Electrical Machinery Is None Too Safe

"Passing the buck" seems to be the order of the day as to safety in connection with the use of electricity in mines. Machinery manufacturers make electrically operated machines known to be unsafe in gas or dust, others which are fairly safe and others which are as safe as present day knowledge goes; however, they seldom hesitate to sell a machine even if they know that the place in which it is to be used is very likely to have conditions which make the machine unsafe. Mining machine salesmen cold bloodedly admit that their business is to sell and don't hesitate to invoke the Latin phrase "caveat emptor," let the buyer beware. Usually the mining company buyer has only a distant association with the mine and if he can save a few hundred dollars by purchasing one kind of electrical equipment as against another, he will almost invariably purchase the cheaper, provided it is essentially as efficient as the more expensive and irrespective of the fact that the more expensive one is probably more expensive because it has been made more safe.

Safety in electricity in mining will not be attained until it is realized and recognized that present practice is by no means good and that the safest available is none too safe; this to include equipment as well as practice. The use of electricity in mines is increasing much more rapidly than is our knowledge of safety in its use and it certainly is time that due thought should be given the matter of safety, before disasters from electricity arouse the public to a demand that our mines be operated without it.

CHAIRMAN YATES: The paper is now open for discussion. I might say one way to get away from electrical haulage underground is to use compressed air. It costs a little more money but I believe in the long run it is safer. Our electrical equipment consists of pumps and lighting. All of our cables going down to the shaft are armored; all of our lighting wires are well supported and a matter which may not be of so much interest to you gentlemen, but we have a practical electrical engineer who does go underground and inspects, and not only inspects but sees that things are in proper shape.

MR. DAVIDSON: I make this observation, too, that if the mine is properly ventilated, a gaseous mine is properly ventilated in the manner in which it should be to permit open lights, you will eliminate a great deal

of danger from electrical equipment, and in addition to that in the use of electrical cap lamps it should not be forgotten that you can not depend on the electrical cap lamp as the whole safeguard. You have to continue to ventilate your mine the same as if you were going to use open lights.

MR. SMITH: I would like to know if you consider it safe to use mining machinery in a very gaseous mine, where they use enclosed lights? Do you think the ventilation can be kept up to the point where it is safe to use them?

MR. DAVIDSON: That would depend upon the conditions of that particular mine. If you are able to ventilate your mine where the gas content is not dangerous it would be safe.

MR. SMITH: This one is so hot you can hear it all the time, and you can see it coming up through the water.

Adequate Inspection of Electrical Equipment

MR. DAVIDSON: I doubt whether you can ventilate it to make it safe.

MR. READ: I believe Mr. Smith's question could be answered from an electrical point of view rather easily, that the development along storage battery equipment, application of storage battery tanks to the handling of mining machinery, also pumping propositions and gathering the motors, will take care of a gaseous mine just as well as your safety lamps do, as far as the electrical hazard is concerned; but whether any friction type of mining machinery can be used in a gaseous mine is entirely different from the electrical part of it.

MR. POLLOCK: I worked in two mine fires in our own mines in the last two years, caused by defective wiring, short circuits. That is in an iron mine.

MR. HURTER: I do not know whether it is applicable to mention a certain piece of apparatus standardized on the Benjamin proved vapor lamp number 601, to be used in dangerous places or its equivalent.

MR. AGETON: Discussing Mr. Harrington's paper, the big thing I find in there is the insistence on adequate inspection of electrical equipment. Too often I found the electrical man is under the direction of the surface superintendent or boss or whatever you call him, and your mine foreman or mine boss is unable to tell him anything. He has to go to the surface man. In Butte, in 1916, 1917 and 1918, we got away from that by putting in what we call the mine electrician who was responsible to the mine foreman only. I have seen similar arrangements worked out in coal mines. It seems to me that is the very important factor and that a very efficient method of solving it is to have at least one mine electrician under the mine foreman so he can tell him where to go and what to do and be sure it will be done.

MR. MARTINSON: This is not in connection with this paper, but as long as we are talking about fires I want to report an incident which may be of benefit to some men. This is a new way of starting a fire underground. A short time ago we had a fire that was caused by the taking into the mine of an acetylene torch to cut out some steel plates and chute

in the repair of it. The men went away thinking the job was done, and the next morning we found the mine full of smoke caused by the heat generated in the wood under the steel plate.

CHAS. F. HASELTON (Safety Engineer, Pickands, Mather & Company, Cleveland, Ohio): I find it seems to be a general opinion among the operating men and also some electricians as to the danger from taking lights off trolley, for instance. Take the power off the trolley and ground the other leg. They seem to think the ground wire does not make any difference where it grounds; they do not take any particular pains to insulate the ground leg; they say it grounds anyway.

MR. CONIBEAR: I would like to ask what hazard there is in the open light carbide lamp in metal mines containing no gas and having high humidity?

CHAIRMAN YATES: We have had two very serious fires in the Homestake Mine caused by burning timbers; of course gas formed afterward to drive the men out of the mine. I think both of them undoubtedly were caused by explosives, either burning fuse or burning dynamite. The explosion occurred, ordinary blast, in such a position that it was not accessible after the blast; in other words, it brought down old cave country and covered up the fire so it could not be reached, and the fires kept on burning. I do not think we have ever had a fire start from a carbide light. Mr. Ross could either correct that or substantiate it, and we have used the carbide lamp for years.

MR. ROSS: I do not know of a fire started from the use of carbide in our mine, but it is a constant source of worry that some day a man cleaning his lamp or recharging it will dump the contents, containing more or less escaping gas, against the timbers, in spite of the fact that we have cans placed in position for them to dump the old carbide. You know yourself they will dump it any place. Some day a man is going to be careless and I am afraid that the partly used carbide will become ignited. The first thing a man will do will be to throw more water on the carbide and I think that will start a fire.

ADJOURNMENT

THURSDAY MORNING SESSION,

October 28, 1926

The third session of the Mining Section of the National Safety Council, held at the Tuller Hotel, Detroit, Michigan, convened at 9:30 o'clock, Mr. B. C. Yates presiding.

CHAIRMAN YATES: I am sorry that our new chairman is not present this morning, as I would be very glad to give up the chair to him. Inasmuch as he is not present I will try and preside at the last meeting.

The first paper on the program is by Clyde McDowell, Manager Department of Industrial Relations, Davis Coal and Coke Company, Thomas, West Virginia.

GENERAL SAFETY IN AND ABOUT THE MINES

**C. A. McDowell, Manager, Industrial Relations Department,
The Davis Coal & Coke Company, Thomas, W. Va.**

This extremely interesting subject has so many different angles that it is difficult to write a paper on the general phases of safety. We are covering considerable ground when using the word "Safety," but will endeavor to do so in a manner that may be clearly understood. Our interpretation of the increasing phases of safety problems must be fairly correct and conform to the ever increasing worldly intelligence and probably the over increasing speed of our industrial activities, which means, that those following this accident prevention work must actually be a little ahead in progressive thought of the industrial problems of today.

We realize that all accidents are expensive to somebody and for that reason should be absolutely avoided. The human element must be considered and therefore it is a duty of all mankind. Accidents will disorganize a mine force, cost money, run up the compensation-insurance rates, may take life and leave orphans, or produce cripples for stated periods. Therefore, the first requisite in prevention of accidents is the saving of life and suffering.

Our first thought of safety can possibly be exemplified by the three "A's"—Accidents Are Avoidable. We see this slogan portrayed daily by the automobiles whose radiator emblems glisten with these three letters representing the Automobile Association of America. It might be a good symbol for any industry to adopt by linking these three letters together, with but one objective—Accidents Are Avoidable. You will contend, however, that this would not literally be true or stand a 100 percent test, but neither will the so called pure oxygen used in a self-contained oxygen breathing apparatus.

We read of wonderful safety results accomplished by some industrial

enterprise, but upon inquiry learn authoritatively that such bold type proclamations were the results of a short campaign of activity, probably the first six months or year of such work within this industry. Or we may learn of the wonderful results obtained through a short campaign of a week or a month by an industry which has had a so-called safety organization for years. Again we are reminded by a picture and beautiful caption of some special achievement in this safety movement, which is one small phase of what the word safety means. I contend, however, that the above is meaningless in one sense. I am not belittling the value of these minor accomplishments but my idea is that unique comparisons should only be accepted in their places, and accomplishments of such industries along industrial relations activities should be compared through a long time period in measuring their success.

It is true that an organization with safety committees has accomplished excellent results but not without the ever changing of personnel and the inspirational new ideas put behind such committees by wide-awake safety leaders. Safety and community gatherings have produced their good work but not without the constant changing of programs and the discontinuance of same for stated periods. New ideas must be gathered from outside sources, from attendance at meetings of this type, from the different mining institutes, first aid contests, and the like.

First Enthusiasms In Safety Effort Seldom Last

The inspiration garnered from an epochal effort in eliminating accidents is truly wonderful and the immeasurable results generally obtained over the first birthday anniversary of such an undertaking are exemplified by startling figures; but results noted after many years of anniversary birthdays in this work, in many instances reveals the fact that the good work has not progressed and is not even holding its own in comparison with the first year's record.

What's the trouble? The interest manifested at the beginning seems to have waned as the years rolled by. Why? The point of contact seems to have lost its spark. The dynamo of energy is run down, so to speak. What's the answer?

The answer is not difficult. If an industry desires to establish industrial relations activities which include more than the word "Safety" implies, it should bear in mind that an organization is necessary which will function actively over a long period of time.

By an organization, I mean literally an active human being, as it were, that really has life and not merely a name; an organization that has more than a luke-warm feeling for activities, but a being with a seventy-two well balanced pulse, always strong and at times an overabundance of energy. Such an organization has complete cooperation from the president to the most humble laborer.

The first problem in this kind of an organization, if the word means

anything, is an understanding between the president and his officials. These are the back bone of any worth-while organization, no matter what any one says. These are the men who study the problems of the day and should first receive the information gathered from time to time by the organization. These are the men who are always meeting the employees and know without contradiction just what they are doing. They are the key to our personal contact. A passing word of good cheer to the men means much, while an "I don't care attitude," or an "I don't have time" talk means little. An understanding between the president and these men that they must do their part as an example for those employed for the company, means the beginning of a complete success.

The industrial relation activities should then be under the constant supervision of a leader who has the unqualified support and cooperation of the industrial organization. But a man of this type means more than the mere word "Safety" implies. To be a success, he must be a man possessed with knowledge of the industry in which he is a part and know the characteristics of the men and their families in that industry. His knowledge of compensation, relief and insurance matters is an asset. His understanding of labor turnover and the statistics of same is worth while. Accident and other statistical records must be made and be part of his study. He must be able to make inspections of mines and other parts of the industry for safety and efficiency. His knowledge and experience of first aid and rescue training and contests is imperative. He must be able to grasp new ideas for helping the officials and men to keep keyed to activity at all times. He must be active in community welfare.

Compare Safety Results Over Long Periods

Our organization for industrial relations activities was effected in the latter part of 1917 and, therefore, we are in our ninth year of safety work. We feel that we have been successful. We have had unequaled results in certain phases of the activities and set backs in other ways. Short periods of so called campaign activities have shown wonderful results, but we like to compare or think of our activities on a basis of what has been accomplished over the entire period.

Personal contact, we have found, is the most satisfactory manner of cooperation. This is brought about in many ways; superintendents' meetings, meetings of superintendents, foremen and assistants, occupational meetings, advanced rescue trained meetings, employees meetings, and first aid classes. To all of these we present statistics and have discussion of what has happened and what may happen. We have found that a great deal is accomplished by our cooperation with the employees' committee of each mine who are elected through our working agreement between the company and its employees. These committees are instrumental in various ways in putting across our cooperative programs. We find that we have had excellent results through these programs and especially through the personal contact of this

department and other officials with the employees themselves at their place of work.

We have stated meetings at the different plants for the employees and endeavor to have a program that will be educational and instructive. A Baloptician picture machine is used to portray various charts and other information relative to working conditions, safety and general activities. Moving pictures are shown. We also distribute pamphlets to employees at such meetings. For example, we were recently favored by the United States Bureau of Mines with a demonstration of the explosibility of coal dust in a glass gallery at all plants, at which time the Bureau of Mines pamphlet No. 27, "Causes and Prevention of Fires and Explosions in Bituminous Coal Mines," and Bureau of Mines pamphlet No. 25, "Erection of Barricades During Mine Fires or After Explosions," were distributed.

In the matter of statistics, our accident records for each year are compiled in 17 forms as follows: Accident Analysis, Summary of Accidents, Nationalities of Employees, Summary Classification of Nationalities of Employees, Accident Analysis by Plants, Causes of Fatal and Non-Fatal Accidents, Ages of Employees, Terms of Experience of Employees, Fatal and Non-Fatal Accidents as to Hours of Occurrence, Percentum of Accidents by Hours Through Actual Producing Periods, Percentum of all Accidents as to Severity and Natural Deaths, Inside and Outside Accidents, Comparisons of the Fatality Rates of the United States, State of Pennsylvania, Bituminous field of Pennsylvania, State of West Virginia and our Company, Number of Weeks lost per Non-Fatal Accident by plants, Fatal and Non-Fatal Accidents by days of Week, First Aid Analysis, Comparison as to Frequency and Severity Rates. On each of these reports we show the record for the current year as compared with the previous year and also the compiled record of the same information for the entire period of our activities. This is all shown in a percentum basis.

The Procedure in Case of Accidental Injury

Under statistics we also run a chart for each mine, one page of which portrays three years, showing the number of fatal and non-fatal accidents by months. Other charts showing four year periods of hours of occurrence, frequency rate and severity rate. Also charts showing fatality rate per one million tons and fatality rate per one thousand employees. Labor turnover charts are also compiled.

A brief outline of the procedure in case of accidental injury may be of interest. The safety department is called immediately and a preliminary telephone report made. The department investigates most of our accidents. Probably a drawing is attached to the report of the accident sent to the head officials and recommendations are made with this report. These reports are used in our occupational meetings. Naturally, an accident report is made by the foreman for all accidents no matter how slight the injury. Our accident records are absolutely correct, inasmuch as we record every accidental injury case where the

employee loses any time beyond the day of accident. We have many accidents in our records yearly for which no compensation is paid. Our frequency rate, therefore, may seem high when compared with many companies who do not report accidental injuries for which no compensation is paid. Last year we reported to the Compensation Commissioner and the State Department of Mines, 28 accidental injuries to employees, each of whom lost less than a week's time and naturally received no compensation. No accident statistics are correct unless these are recorded.

For any accident where no time is lost, an injury card showing first aid treatment is sent in to our department. Of course, a card is also sent in if treatment is given to a lost time accident. A follow-up is made of all lost time accidents by our department in the matter of compensation and relief, and when an injured employee is able to resume work, the question of occupation is considered for his physical welfare. Our physicians cooperate wonderfully in this follow-up work. In fact our physicians are to be commended at all times for their cooperation in any success that we may achieve in safety work.

Upon investigation of an accident, we usually find that the injured man, or someone else, did not observe our rules; or if we observe any employee, whether official or others, disobeying the Mining Law or our established safety regulations, we immediately make up an "Always be Careful" card showing the mine number, check number, name, place of accident or observation, a description of what happened or was observed and what the result was or may have been. This card is signed by this department and placed in his envelope on the next pay day. Our employees endeavor to keep these out of their pay envelopes.

A monthly accident report is compiled with a description of each accident showing the mine where it happened, name of person injured, date, age, nationality, time of accident, cause, result, loss of time and remarks, which are exceptionally plain. This report reaches every superintendent, foreman and physician and can be studied as to what and how accidents are happening at the other plants. A summary is attached showing many interesting phases for study. A monthly report of compensation paid for accidental injuries also reaches these officials.

First Aid Men Have Helped Materially in the Program

Our first aid training has been a successful help in our program. Since 1920, we have had approximately 75 percent of our employees trained and holding United States Bureau of Mines and company First Aid certificates. It was only last year we adopted the plan of 100 percent first aid training. Every employee, when he completes this training, receives our special "First Aid Pocket Packet" which was our own make-up and has been used extensively by other companies. This packet belongs to the individual, and through our personal contact and injury cards received, we learn that he treats injuries in the mine, on the street, in the home and elsewhere. We often get letters from former employees with cards attached asking for assistance to get the

packets refilled. We gladly send material and record the injury treated.

With such a percentum of first aid trained men at all times, we know that they have helped materially in our excellent record. The same accident cards are placed in our cabinets in first aid stations, both inside and outside of mines, and in the schools. Last year 70 percent of our lost time accidents received first aid treatments. It is interesting to note that 278 of our employees rendered 574 first aid treatments last year. We also received 146 injury cards from 63 school children. Company, state and international first aid contests have no doubt contributed to our progress. Boys' and Girls' first aid teams have been appreciated by the employees, and recognized as part of a definite program by many other mining organizations.

Mine First Aid Stations Are Taken to the Injured

In the mines our stations are of the moveable type; that is, we cut a standard size opening in the rib in a certain section in which is placed a wooden platform, install lights and hang on two hooks a large canister containing a stretcher, two blankets (rubber and woolen), a complete set of splints and a small cabinet containing first aid material. This canister, which is really the station, may be carried or transported upon a motor, and thereby we literally can take the station to the injured man which really is where you need it. Then we bring the injured man to the outside where an ambulance owned by the community transports him to the hospital or home.

Our first aid training in two of our high schools has been noteworthy. We have trained three of the largest classes on record and they have received American Red Cross certificates and small first aid pocket packets; but these classes were not so large that they could not be handled efficiently by the excellent help at our command.

Rescue apparatus training has helped considerable in our work. We always have more than 10 percent of the total number of employees at each plant trained and holding United States Bureau of Mines Rescue certificates. We maintain two well equipped rescue stations which contain Gibbs breathing apparatus, Burrell All-Service gas masks, M-S-A self-rescuers, inhalator with electric pads, Burrell methane detector, carbon monoxide detector, life line and reel, safety lamps, Orsat apparatus for gas analysis and the pyrotannic acid method of determining carbon monoxide in blood and air. An emergency box containing hatchets, axes, saws, chalk, buckets, nails, hemp rope, flame safety lamps, flash lights, trowels, hammers, shovels, picks, and copper hammers, is also part of the equipment. All officials carry M-S-A self-rescuers.

We have 59 of our employees holding United States Bureau of Mines certificates for advanced training in recovery operations. We have printed and posted at all mines, a mine fire or explosion procedure which shows the equipment and general directions in case of a mine fire or explosion, and also a definite schedule of procedure in case of a mine fire or explosion. In addition, we have a chart showing the

employees designated for specific duties at the respective mines in case of mine fire or explosion. These charts were originated and posted before we received this advanced training.

We are firm believers in rock dusting and have therefore established this safety measure in our program. We have two machines and at present have two mines completely rock dusted.

Periodical inspections of all mines are held and a report form compiled for each inspection. These are distributed to all superintendents. In addition to this, periodical inspections of the mines are made for safety and efficiency.

A great deal of interest is noted in the safety reminders, or small cards, placed in the pay envelopes. The National Safety Council and other posters, placed in well lighted conspicuous safety bulletin boards, are appreciated. Our new safety bulletin printed on the 15th and last day of each month has brought out considerable comment. These bulletins show each accident by mine, name, cause and extent of injury and the circumstances of each. They also give striking, snappy safety reminders as to what we should and should not do. Our employees stood 100 percent in signing the safety pledge cards put out by the West Virginia Department of Mines.

The Annual "Safety Congress Trip Contest"

We established a National Safety Council Trip Contest, planned in September, 1924, which was very successful the first year and is progressing nicely so far this year. A superintendent, a foreman and an employee, other than an official, are awarded a trip to the Annual Safety Congress each year. The superintendent with the lowest severity rate, the foreman with the lowest frequency rate, the employee who received the highest number of points for meritorious first aid work and safety suggestions are selected. Each injury card must have the O. K. of the superintendent or physician and points are given in accordance with a scale of credits awarded by a committee of three, the chief medical director, the employees' commissiomer, and the manager of the industrial relations department. Points are awarded for safety suggestions by the same committee, if they are accepted.

Our fatality rate per 1000 employees has been reduced from the high peak of 6.35 in 1918 to 1.38. The fatality rate per one million tons of coal produced has been reduced from the high peak of 6.45 to 1.65. The severity rate (days lost per one thousand hours worked) has been reduced from the high peak of 25.8 to 10.5. The frequency rate (number of accidents per one million hours worked) has been reduced from the high peak of 83.1 to 51.1.

H. W. GIESING (Safety Engineer, Commerce Mining & Royalty Company, Miami, Oklahoma): In Mr. McDowell's paper he states the injury is posted, the nature of the injury, the name of the man and various other items; does his company ever have any unfavorable reactions for the reason that they post the man's name that has been injured, especially if it becomes necessary to discharge that man?

MR. McDOWELL: That would really go back to one other part of my paper, which was brought out yesterday by one of the other members of this Section. We have what is called a working agreement and the workers themselves elect a committee of three to each mine, one a year, and they serve for a year. The chairmen of these committees meet once a year and elect their commissioner and this commissioner is their boss. We have nothing at all to do with that man. He handles all their problems.

Procedure in Handling Men's Grievances

As to small grievances or large grievances, disputes or cases, I might give you an outline procedure while we are on that subject. The man who has this grievance takes it to the foreman; if not satisfied he takes it to the superintendent; if he is still not satisfied he takes it to his committee; this committee meets with the foreman and superintendent, and if possible irons out and makes a disposition of the grievance. If it is not settled at that point, the committee takes this grievance to their commissioner, while the superintendent takes the same grievance to the employer's commissioner (and in this case I am employer's commissioner). The two commissioners then endeavor to settle the grievance by meeting with the party concerned and any witnesses, the committee foreman and superintendent. If it is not settled at that point (of course it is written up when the commissioners get hold of it), it goes to the general manager.

But I might say here, we can settle that grievance. The two commissioners have absolute authority to settle that grievance, but if they can not agree it goes to the general manager. If it is agreed upon, then it is settled. If not, it goes to a board of review. A board of review is composed of six employees, three of whom are selected from the committee (that is the committeemen, and the other three by the vice-president and general manager. Those six men sit on that case. The commissioners present their side the same as lawyers do. But this grievance can be settled there and whatever the decision is it is final. I might say though, here, that that decision must be unanimous. For instance, we have the unit vote—the employees have one vote, the employers one vote—so it must be unanimous.

But if the question is not settled it is then presented to an umpire. If the board of review can decide on an umpire it is perfectly satisfactory and his decision is absolutely accepted by both sides. If they can not decide, the senior Federal Judge in our district acts, or he appoints a man to act, and that decision is final.

Now, in answering Mr. Giessing's question, if this man feels that he is not justly dealt with in this way or any other, he goes through that procedure.

CHAIRMAN YATES: Is there any further discussion on this paper?

Yesterday you voted that the Chair should appoint a committee to arrange if possible for a paid secretary for the Mining Section. That committee will consist of Mr. Dan Harrington, the new secretary of the

Section; Mr. J. P. Hodgson, and Mr. W. H. Cameron of the official staff, Managing Director of the National Safety-Council. The other members of the committee might talk with Mr. Cameron before they leave, if possible, and arrange a meeting, or the work might be done by correspondence.

CHAIRMAN YATES: It has been suggested that all the men who signed up cards in the Mining Section are to receive the *Monthly Bulletin*. How many are in favor of that? (Unanimous.)

MR. POLLOCK: I do not know how many of you have seen a series of cards which Mr. Forbes got out at my request, showing number killed in coal and metal mines.

The Record of Fatalities in Metal and Coal Mines

I wondered whether safety was getting anywhere in our mines. It does not look as if we were getting far. The card for metal mines shows that in 1920 3.2 men were killed per thousand men; 1915, 3.5 men killed per thousand men. It does not look like we are getting very far in the last five or six years. Of course back in 1911, the record is 4.4 men. I suppose that was when the Bureau of Mines started working. Another card for 1911 shows men killed in mine fires, 4.08 men killed per thousand men employed.

Here is the record for coal miners: 1920, 3.8 men killed per thousand men employed; 1924, nearly five men killed per thousand men employed. Are we getting anywhere? It does not look like it. It seems we are getting worse. In 1911, 1.5 men killed; and in 1924, practically 4.8.

M. H. HUNTER (Safety Director, U. S. Gypsum Company, Fort Dodge, Iowa): How does that compare with production?

MR. POLLOCK: Production has probably gone up but this is on the basis of men employed.

The reason I got this out was to satisfy myself that we were not getting very far yet, and maybe that would be a good reason for us to have a paid secretary to round up these people that are not practicing safety.

MR. TRESTRAIL: I think you will find the production in the iron mines in the last three or four years practically doubled. Naturally, while we do not like to admit it, there has been an increase as far as our accidents are concerned.

MR. POLLOCK: The metal mines are probably a little better, but the coal mines are not.

MR. WARDROP: Since we have made such an extensive study in our accident severity rate and frequency rate I think there are more accidents being reported in the last three years than were ever reported before, and for that particular reason the curve chart may not be right.

MR. POLLOCK: These are fatalities. You can not get away from a fatality.

MR. DAVIDSON: I think the point is in your last remarks; we are getting somewhere with the mines that are doing the things they should do; and I think that by far more mines are taking safety measures now than they did two years ago and very many more than 10 years ago.

We are making great progress, in my opinion, if you will base your figures on the number of mines and the record for a particular mine rather than the total production and total number of men employed. I think that is really a fair way to get at it to see if we are getting anywhere. Just think of what the result would be if Mr. McDowell and others were not doing the things in the management of their mines they are doing to protect their men. The death rate would be appalling.

MR. HALL: I do not think people realize our mines are getting more dangerous, our coal mines, every year, getting further underground, and consequently developing a lot more gas than they used to. That is making a considerable difference. Then there is a risk in a very large mine. If you have 1,000 men in a mine there are 1,000 risks and there are 1,000 people exposed to those risks, and so it varies as to the number of men in the mines. Very large mines, consequently, unless very carefully managed, are a greater hazard than the small mines, because there are more people to make the hazard with gas or dust and there are more men exposed to that hazard; therefore it varies, as I have always said, although I could never get people to agree with me, as the square of the number of men who are employed.

CHAIRMAN YATES: I think Mr. Forbes is ready now and we will postpone the rest of this discussion until Mr. Forbes has finished.

J. J. FORBES: In the first place, I want to thank members of the Institute and those companies that contributed "Safety Kinks" that made possible this collection. About eight months ago Mr. Read, who was then Secretary of the Institute, asked me if I would act as a kind of clearing house for safety kinks. I agreed, but I have had some difficulty in getting the fellows to send in kinks. I have done the best I could under the circumstances; some are very good, others not so good. I think we have a sufficient number here to bring out a pretty good discussion.

SYLLABUS ON SAFETY KINKS IN MINING

J. J. Forbes, Supervising Engineer, Instruction Section, U. S. Bureau of Mines, Pittsburgh, Pa.

(Editorial Note: This "Syllabus" by Mr. Forbes comprised one of the most interesting and valuable features of the Mining Section program; but, due to the peculiar nature of the matter presented, it is impossible to reproduce all of it in these published Transactions.

(The pictures shown alone numbered 108, each of them presenting some safety device in practical use to lower the accident possibilities in the mines. Mr. Forbes accompanied each of these pictures (as thrown on the screen by lantern slide) with brief descriptive sentences and a running commentary upon safety appliances. It is valuable to note that all of these pictures were taken from the records of the Bureau of Mines, and that they, together with a multitude of other pictures and descriptive matter on safety appliances, are available in the Bureau for reference and examination by all who may be interested.

Figure I. A guard for end of trolley wire.

(It has been very difficult to select from this mass of material a moderate number of the pictures for reproduction in these Transactions. The editors have used their best judgment, in view of the fact that all Sectional activities of the National Safety Council in the Annual Congress are so very voluminous, and have sought by a presentation of a selected group of the pictures to indicate the wide range and importance of the whole program feature.)

Figure I, as shown here, was No. 22 in the Syllabus, "A Guard for End

Figure II. Guards on motor bumper.

of Trolley Wire." The Consolidated Coal Company of West Virginia uses a box, open on top and held in place by wood pins to protect the end of the trolley wire in an entry. The box is easily moved forward when additional wire is put up and it prevents the possibility of workmen being injured by end of the wire protruding from last hanger.

Figure II, which was No. 23 in the Syllabus, shows "Guards on a Motor Bumper to Keep the Cars from Jumping on Deck." This practice is followed in its coal mines by the Consolidated Coal Company, of Fairmount, West Virginia.

Figure III. Automatic cut-off for rope haulage—open position.

Figure III, which was No. 31 of the Syllabus, illustrates an "Automatic Cut-off for Rope Haulage—Open Position." The Consolidated Coal Company of West Virginia uses an automatic cut-off on slopes for rope haulage. The automatic cut-off is arranged so that it opens when slack is made in the rope by the haulage engineer, but will remain closed as long as there is the slightest pull on the rope. The view shows the automatic cut-off in the open position and gives a good idea of its construction. The device has been in use for about six years and has proved to be a very safe and effective device for uncoupling trips at the tippie.

Figure IV, which was No. 34 in the Syllabus, shows an "Interlocking Door Lock for Heading Air Lock." The Bethlehem Mines Corporation of Pennsylvania uses interlocking doors on heading air locks. By using

a device of this kind it is impossible to open both doors of the air lock at the same time, thereby preventing short circuit of the air.

Figure V, which was No. 35 in the Syllabus, shows an "Insulated Coupling for Mine Cars." This device is also employed by the Bethlehem

Figure IV. Interlocking door lock for heading air lock

Mines Corporation of Pennsylvania, and is used on cars of all man trips and explosive cars. The view shows the coupling attached to a car.

Figure VI, which was No. 49 in the Syllabus, illustrates a "Mine Car Safety Coupling for Hoisting on Slope." This is a view of a safety coupling used by the Wilkes-Barre Colliery Company of Pennsylvania.

Figure VII, which was No. 56 in the Syllabus, shows a "Safety Coupling for Man Trips." This close-up view of the man trip coupling shows the

clevis pins, hoist coupling and safety rope. The rope passes along the bottom of each car and is clevised to main hoisting rope. This device is used on the man-trips of the Woodward Iron Company and other coal mining companies in Alabama.

Figure VIII, which was No. 59 in the Syllabus, shows a "Carrying Case for Capped Fuses." The Penn Iron Mining Company, Vulcan, Michigan, uses a special carrying case for capped fuses. This case was devised for miners who have to carry their capped fuses or primers through raises or small openings. The general practice is to coil the fuse in a roll and stick it over the forearm. Where a steep ladder is to be

Figure V. Insulated coupling for mine cars.

climbed there is danger of bringing the primers in contact with the miner's lamp or of striking them against some piece of rock or metal. This carrying case is made of heavy galvanized iron, is nine inches in diameter and three inches deep, with a flange one inch deep around the top and it has a hinged cover which is also one inch deep. The entire case is lined with heavy felt and a soft rubber band is placed around the inside edge of the flange. In this way there is no metal exposed which the caps can touch during transportation. The case is carried over the shoulder by means of a strap and does not impede the progress of a person climbing ladders.

Figure IX, which was No. 67 of the Syllabus, shows a "Lock for Trolley Wire Switch." The Oliver Iron Mining Company of Minnesota uses such a lock on the trolley wire switches. It consists of a heavy leather strap of sufficient length to go around a standard switch. To this strap is

Figure VI. Mine car safety coupling for hoisting on slope.

fastened a padlock. This device is used when doing repair work or connecting blasting wires.

Figure X, which was No. 78 in the Syllabus, shows a "Swinging Chute Lip—Closed Position." The Homestake Mining Company of South Dakota uses a swinging extension chute lip at loading stations which allows the cars to be loaded without danger of spilling. This view shows the extension chute lip in the closed position. The lip as shown can be raised out of the way of motor haulage or of men passing in the drift. Counterweights hold the lip in position.

Figure VII. A safety coupling for man trips.

Figure XI, which was No. 80 in the Syllabus, shows a "Safety Handle for Coupling Cars." The Homestake Mining Company, South Dakota, uses this safety handle on its cars. The photograph shows a simple lever device of flat wrought iron fastened to the end of the ore car and

Figure VIII. Carrying case for capped fuses.

operating the pins of the link pin couplers. With this device it is not necessary for the brakeman to get any part of his body between the cars when coupling or uncoupling.

Figure XII, which was No. 91 of the Syllabus, shows "Safety Lugs on Ore Cars." Mines in the Tri-State Zinc and Lead Ore District use such

a safety lug on buckets or cans. The lugs are so constructed that the bail can not fall on the rim of the can, and thus prevents workmen from having fingers and hands injured in this manner.

Figure XIII, which was No. 94 of the Syllabus, shows a "Guard Over Fan Motor for Small Booster Fan in Place." This guard is made of sheet steel and forms an effective position against spreading of fire,

Figure IX. A lock for trolley wire switch.

should the motor burn out. It also protects the motor from dirt dropping from above. Note the all-steel box to which the installation is bolted, making it convenient to move and affording good fire protection. This device is used by Pickands, Mather & Company, Mesabe Range, Minnesota.

Figure XIV, which was No. 99 of the Syllabus, shows "Grizzly for Top of Ore Raises." The Pickands-Mather Company, of Michigan, uses grizzlies to protect tops of open raises. The grizzly is made of 20-pound rail throughout, fastened with one-half inch rivets so constructed that the whole will partially collapse. The framework fastens by spikes or lag screws to the timber bearing pieces of each end of the raises. It has a nine inch drop below the bearers in order to allow more dump room.

MR. FORBES: In connection with these kinks, this is the first attempt we have made in this Section, and I want to thank these members that have sent in material. I think it is a subject that should be continued.

MR. TRESTRAIL: Is it possible to have those in the report of the meeting?

MR. FORBES: The Bureau has the negative in its possession for the kinks. Any member desiring the positive or print of it can have it by writing in to me and I will take care of you. The whole business will cost you about \$8.50. That will have to be done outside the Bureau. I am going to furnish the N. S. C. with the photographs in connection with my paper.

CHAIRMAN YATES: I think we owe Mr. Forbes the thanks of this Section for what he has done in this matter. I know he has had difficulty in getting these subjects. It is a start and in the right direction, and I think as he said, we should continue this next year. I think we should appoint Mr. Forbes right now to receive these.

MR. HALL: I feel very much indebted to Mr. Forbes for getting this material. I suggested the collection of it for about four years and they tried to get me to do it.

MR. FORBES: If the men would send them in, there are outstanding devices at most any mine. I went to Mr. Bannister and he said, "We don't have any." I said, "Let us take a trip underground," and in half

Figure X. Swinging chute lip in the closed position.

an hour we had picked out 10. The stuff is second nature to you fellows, you see it every day, but it would be very valuable to the other men. I think the next fellow that undertakes a paper of this character will be helped considerably.

CHAIRMAN YATES: Now I do not understand the difference between this Mine Safety Devices and the Round Table Discussion of Mine Safety Stunts. I think we have had our stunts. We are now ready to receive the report of the Committee on Resolutions from Mr. Ageton, chairman.

Figure XI. Safety handle for coupling cars.

MR. AGTON: I wrote down the resolutions and passed them to the other members of the committee. The first is:

WHEREAS, The U. S. Bureau of Mines, Department of Commerce, has been very active in furthering matters pertaining to the safety of the men in the mining industry; and

WHEREAS, It is our opinion that this Bureau has not had sufficient funds appropriated them to carry on this work during the past year, proportionate to the growth of the industry throughout the country;

Figure XII. Safety lugs on ore cans.

BE IT HEREBY RESOLVED, That it is the sense of the Mining Section of the National Safety Council that the Congress of the United States should appropriate more money to the use of the Bureau of Mines in order that this very necessary work may be expanded in the various mining industries in the United States;

IT IS FURTHER RESOLVED, That a copy of this resolution be for-

Figure XIII. Guard over fan motor for small booster fan.

warded to the Honorable Herbert Hoover, Secretary of Commerce, by the secretary of the National Safety Council.

I move the adoption of this resolution.

(The motion was seconded and duly carried.)

MR. AGETON: The second resolution reads:

WHEREAS, It has been noted that other Sections of the National Safety Council have very successfully conducted Section luncheons and dinners;

BE IT HEREBY RESOLVED, That the officers of the Mining Section, for the next year, be requested to arrange either a luncheon or a dinner for the Mining Section.

I move the adoption of that resolution.

(The motion was seconded and carried.)

MR. HALL: These luncheons have their disadvantage. They set them for a special time, and we have overrun our time every day. It would spoil our meeting.

CHAIRMAN YATES: We have no time to end these sessions. We start at 9:30.

MR. HALL: I think it would be a very good thing if we could arrange to carry on the papers after our luncheon, provided the luncheon cuts off short in the middle of our discussion.

MR. HODGSON: Make it a dinner. Work night shift.

MR. AGTON: Resolution number three is:

Figure XIV. Grizzly for top of ore raises.

WHEREAS, The success of the present meeting of the Mining Section has been due largely to the effort of our present chairman, Mr. B. C. Yates, and his associates;

BE IT HEREBY RESOLVED, That a standing vote of thanks be extended to Mr. Yates and all of those assisting him in the conduct of these meetings.

I move this be adopted.

CHAIRMAN YATES: Put the motion.

(The motion was carried unanimously by rising vote.)

CHAIRMAN YATES: I wish to thank you for the expression of your appreciation, and I wish to thank all the members of the committees who aided me during the year. It is largely their efforts and your attendance that make this meeting a success, and by your readiness to take part in the discussions.

Has anyone prepared a speech along the lines of Mine Safety Stunts or anything of that kind?

H. F. WEBB (General Safety Director, Allegheny Pittsburgh Coal Company and Windsor Power House Coal Company, Pittsburgh, Pennsylvania): I can not make a speech but one of my inspectors came in from the Pittsburgh coal region last Saturday and brought back a piece of poetry written by a ten-year old boy who was the son of a man who lost his life in a mine explosion along with the lives of 43 of his fellows. I am not going to mention the name of the mine. Without a doubt it is one of the most remarkable pieces of poetry I have ever come across, and I want to take a few minutes to read it to you men because I believe

you will be much interested. All the schools in that section are causing the pupils to commit it to memory.

Daddy, Please Come Back

May he rest in peace,
My Daddy, dear:
His voice again I'll never hear;
His smiles again I'll never see;
In dreams alone his face I'll see.
Oh! Daddy, please come back to me!

Mamma cries and sister, too,
Oh! Daddy, dear, what shall I do?
I'd like to work like other men,
But Mamma says I'm only ten:
And Mamma will not let me go
Into the mines so far below.

But Daddy only smiles to me
Across the wild eternal sea;
With tear-stained cheeks, he's kneeling there.
His pale eyes move with silent prayer.
He's praying to come home, I know.
Oh! dearest Lord, please let him go!

Mamma's sick and times are bad,
Now's the time we need our Dad;
I'll go to church and pray and pray,
So that he will come back some day.
If he returns, what joy it would be!
Oh! Daddy, please come back to me!

Oh! Daddy, Daddy, please come back
To our humble shack;
We'll need you more day after day,
As the long hours roll away,
I'll always pray on bended knee,
Oh! Daddy, please come back to me!

(This remarkable original and pathetic poem was written by the ten year son of a miner who lost his life along with 43 fellow workers in a recent mine explosion.)

CHAIRMAN YATES: Does anyone else have anything to add? I am wondering if you will permit me to read something I had prepared. I can not speak off-hand very well, and I wanted to read it. This touches on several things we have mentioned in this Section. Will you kindly permit me? The general subject is Mine Safety Stunts. I took that from

the last number on the program, and my assertion is that an operating organization with a unified safety mind is the best safety stunt.

AN OPERATING ORGANIZATION WITH A UNIFIED SAFETY MIND

B. C. Yates, Superintendent, Homestake Mining Company, Lead, S. D.

From the viewpoint of the executive, the best "Safety Stunt" is to have a working organization thinking safety as a unit. It matters little how efficient a safety engineer may be, one man in the organization whose mind is not in tune with the accident prevention idea will hinder the work just to the extent of the man's importance in the organization.

W. W. Adams, statistician of the Bureau of Mines, says that the causes of accidents are 20 per cent mechanical and 75 per cent human. If we can control this human element do we not at the same time control the mechanical? In other words, when every person in an industrial organization is working for accident prevention, mechanical safeguarding will follow.

At the Homestake we have our local safety committees, we put on special safety campaigns, and we give our underground shift bosses a monthly and yearly bonus provided their accident records are below a certain average. We reward our mine employees who have worked throughout the year without a lost time accident. We distribute National Safety Council calendars to all employees and furnish the *National Safety News* to all members of our safety committee. What is it we hope to accomplish by this? Nothing more nor less than to get accident prevention firmly fixed in the mind of every person in the organization.

Many writers on the subject contend that accident prevention is a matter of education. It is more than that, it is the application of such education to our daily living so that safe thinking becomes a part of our subconscious thought. Guarding and inspecting machinery, protecting workmen from falling objects and instruction in safe methods of doing work naturally follow such applied education.

It is necessary to educate not only the workmen, but the shift bosses, the foreman, the superintendent, the general manager, the directors and even the stockholders as well. When we have reached this stage in the education of industrial organizations we will have nearly reached the goal for which our National organization is striving, and the money now spent by industry to pay for dead and broken men will be available for a better use.

Before leaving the subject permit me to say that this education must begin with the child in the home and the school. It has been said that Germany trained her soldiers at their mother's knee. If children can be taught to be instruments of destruction they can be taught to be instruments of preservation.

MR. AGETON: Four or five men have asked me to explain some of the flags and things around this meeting room. The flag is the safety emblem

in our district. About two years ago, that is in 1925, we started a contest among the 185 mines of the Tri-State Zinc District, to see if we could not get a few mines to go a few weeks without having time lost accidents. During the month of January three mine foremen (we call them ground bosses) turned in complete records showing no time lost accidents. All three of those foremen were immediately voted as being the biggest liars in the Tri-State District. Everybody could prove that they had had accidents of that nature. Now we figured that they were correct and that we ought to recognize that work, so we developed four flags to fly above the shaft house of the different mines.

The Pete flag is a small flag showing the picture of our guardian angel, "Accident Prevention Pete," and is given for two months or 2,000 man shifts without a time lost accident. At the present time 69 mines out of the 185 fly that flag. The Star flag is given for four months, or for 7,500 man shifts, without a time lost accident, and at the present time 24 mines are flying that flag. The New Broom flag was given for six months or 10,000 men shifts without a time lost accident. We adopted the new broom, following Benjamin Franklin's saying that a new broom sweeps clean. Any ground boss that runs his force for six months or 10,000 shifts without a time loss accident cleans up on accidents. Fourteen mines are now flying that flag.

Mr. McNeil of the Federal Mining Company is just a whole lot of bother down there; he keeps winning prizes and more prizes, so finally we had to adopt the combination flag for 20,000 mine shifts without a time lost accident. That has Pete, the broom and the star. I am up against it again because Mac has a mine now that has gone over 33,000 man shifts without a time lost accident. He is insisting I give him something else.

The point I want to make is this—our stunt is like that used in lots of other places, but traveling around on the street cars in the districts there you will find the "rustlers," as we call them, candidates, are looking for jobs in the mines that are flying these flags. We have only been in there three years now, but I think these figures will be indicative of improvement. In 1924 our severity record was 19.7 man shifts loss due to accidents per 1,000 man shifts working; in 1925 it was 16.9; the first six months of 1926 it was 10.1. All that we can do is hope that we can have the energy to stay in there and keep them going down. But the stunt of awarding the mine as a whole, I think is a good stunt. The Federal Company and the Commerce Company and the Eagle-Picher Company, all whose representatives are here, have the different bonuses for the ground bosses and for their men, and anything that recognizes the good work of the foremen and the men themselves is a good safety stunt.

ADJOURNMENT

Packers and Tanners Section

New Officers of the Section

CHAIRMAN: WILLIAM C. COREY

Delaware Leather Co., Wilmington, Del.

VICE-CHAIRMAN: WILLIAM CAMPBELL

Graton & Knight Co., Worcester, Mass.

SECRETARY: O. C. STERN

October 26, 1926

OLIVER F. W. CROMWELL, Chairman

Safety Engineer, Central Leather Co., Ridgway, Pa.

THE first session of the Packers and Tanners Section, Fifteenth Annual Safety Congress, National Safety Council, was called to order at 9:45 o'clock, in Parlor A, Book-Cadillac Hotel, Detroit, Mich., Chairman Oliver F. W. Cromwell presiding.

CHAIRMAN CROMWELL: The first paper on the program this morning is by Wm. C. Corey, President, Delaware Leather Co., Wilmington, Delaware.

THE PRACTICAL APPLICATION OF SAFETY AMONG LEATHER WORKERS

William C. Corey, President, Delaware Leather Co., Wilmington, Del.

The facts and figures that I shall read to you are mainly from my own experiences as the chief executive of a small plant which employs about 120 hands. I think, however, that those things which are practiced with success in a small plant can be practiced with the same success in a larger plant.

The physical condition of a tannery is liable to cause many injuries which would rarely occur in a plant where the work is carried on under different conditions. I refer particularly to the wet floors and small pieces of fleshings of the banana peel variety, all of which bring about conditions not encountered in plants where the work is done on dry floors. Every individual industry, however, has its own particular hazards. We are all rather prone to think that our industry is more difficult than that of our neighbors; but perhaps if we knew as much about their business as we do about our own, we would see that they also have their difficulties to contend with.

One of the first things necessary for successful safety work in a plant of any kind is the personal cooperation and interest of all official heads; or, in other words, "they must," as the saying is, "be sold on safety." How can an executive expect to interest his employees in any subject unless he is interested in it himself? To obtain any objective we must start with the head of the company and work down through the foreman to the worker himself. You will agree with me that it is quite impossible for a teacher to be successful unless he is interested in the subject he is teaching. Therefore, since our employees are only grown-up children, we employers should be the interested teachers. It has been my experience that if the head of the concern is interested, it is not very difficult to get your workers interested also.

A clean, well-kept plant should be had at all times. If you are clean, your worker will be clean. Machinery must be kept in repair; guards placed where needed. If you are careful, your worker will be careful. Well-kept machinery shows good care. If you visited a plant and saw machinery in poor condition, what would it indicate? I need not answer.

Guarding machinery and belts has always been our practice, more so since the advent of safety. Of course, there are some machines for which no practical guards have yet been devised. I have in mind roller fleshing machines, shaving machines, staking machines, and side glazing machines. We do guard belts and moving parts and engineers in our industry are working on the design of operating guards that will not interfere with production.

One of the principal hazards that have to be guarded against in tanneries, especially those tanneries making leather from imported hides and skins, is that of anthrax. Many foreign skins carry this germ and

precautions against infection have to be taken. The workman is generally infected through an open cut or from picking off a scab or pimple. The symptoms of this disease are in most cases unmistakable and the infected workman should be taken to a physician at once. In most tannery centers there are generally one or more physicians who have studied the treatment of anthrax and know the symptoms. It is to a physician of this training that the patient must be taken. I have heard of cases where a man was infected and failed to report his trouble to the factory dispensary or other responsible authorities at the tannery, but went to his family physician and was treated for swollen glands, and died. Some states have passed certain rules concerning the sanitary measures to be used in those tanneries and a study of these is recommended. In short, the following rules should suffice:

1. Allow no one to work in those departments in which an infection from anthrax may occur who has an open wound or scab exposed. A mere bandage about the wound or scab will not suffice.
2. In case of a cut send the workman to the dispensary at once. (As in all accident cases).

Four General Rules for Safety Conduct

3. In the raw stock department workmen must wear gloves and in handling dusty hides or skins respirators should also be worn. In the raw stock and bean house the men should wash the hands in bi-chloride of mercury solution at the end of working periods.

4. At the first sign of infection, take the man to a physician skilled in the treatment of anthrax. It only takes anthrax from two to five days to prove fatal.

Permanent notices, painted where the worker can see them while he works, are desirable; also bulletin boards placed in conspicuous places on which are displayed weekly posters; these are furnished by liability insurance companies and the National Safety Council. These bulletins, I find, are very useful; but do not put up too many at one time! I find many of my employees looking for the new posters each week.

Mass meetings should be held at least twice a year. These meetings should be opened by the president himself with appropriate remarks. He will introduce the speaker who should give a talk on safety. Most of the liability companies now furnish this service. But, by all means, the head of the concern should open these meetings and there should be present with him his executive staff. I have addressed my workers many times, and the interest that they have shown has given me much pleasure and many a thrill. The speaker furnished by our insurance company, has often told me that it was inspiring to talk to our workers, they were so attentive and interested!

I have heard of a president whose excuse for not being present and speaking at a safety meeting was that he was too busy, and did not have the time. How about that afternoon golf? A stereopticon, or, better, a moving picture illustrating safety and the dangers of careless-

ness are fine adjuncts to these meetings. A lesson can often be taught much better through the eye than through the ear!

A safety organization should be formed consisting of safety committees; in a small plant, say of 100 to 125 hands, one committee of four or five, I consider enough; in larger plants there should be departmental committees, with a central or main committee having at least one executive.

Our practice is to listen to suggestions from employees pertaining to safety; and several times we have carried out these suggestions, when they were not as practical as they might seem to be. We consider it worth while to do this in order to keep our employees' interest and encourage further suggestions which might be practical.

We investigate all accidents, try to determine the cause and see what can be done to prevent them happening again. To illustrate, one of our men slipped on a wet incline and strained his back, and we put up hand rails on both sides of this incline. Another time, a man slipped in a passageway near a drum, and we immediately guarded this place. The reward is that the worker sees our real interest in him and he becomes interested in us.

On several occasions I have worn a long linen duster, a common habit of many of us, and I have been approached two or three different times by my men, suggesting that I do not wear such a garment as it could easily get caught in running machinery and cause me injury.

The Small Company Executive Has an Advantage

I think that the president of a small company has a better opportunity to carry on successful safety work than one employing a large number of hands. To illustrate, I know personally the names, residences, and something about the family of every foreman in my employ; and, furthermore, I know the names of many of the other workers, so that with this personal touch it is much easier for me to interest my 125 workers than it would be if we had five or six times that number.

How close a personal touch has the head of a concern employing 800 or 1000 hands—or perhaps twice that number? You see, we small fellows do have some advantages, after all!

I doubt if any of us today will live to see the real benefits of safety teaching. None of us ever heard of safety when we were school children; but some of our grandchildren who are now being taught safety are going to grow up to be safety workers; although I expect the hazards will be greater then, as they now are compared with those when we were children.

I have heard it said recently that "the safe plant is the efficient plant." I cannot agree with this! I think that it should be "the efficient plant is the safe plant." Efficiency is made up of several elements, and safety is one of them. The progressive executive will have his plant as efficient as he can make it. If he hears of improvement whereby he can improve his product or lower costs, he will install the

device; so the progressive executive installs safety as an element of efficiency.

I would like here to give you a few figures showing our accident records as compared with some of our neighbors. Our record proves, I think, that safety teaching pays. Our lost time accident frequency per 100 employees per year for 1925 was 2.05 per cent; one of our neighbors, 4.56 per cent, more than twice as much. Another, 2.45 per cent or 25 per cent greater. Our loss ratio for four years averaged 6 per cent; our neighbors', 20 per cent and 49 per cent respectively. The longest time that we operated without a lost time accident was one year and four months; this was for the whole plant. Our staking machine department has operated nine years, our beam house five years, and our tan cellar five years, without a lost time accident.

In the last eight years, since the advent of compulsory liability insurance and safety teachings, we have had only ten lost time accidents, none of which has caused permanent injury of any kind nor the loss of any part of the body. Our most serious accident in our 23 years of manufacturing life was the loss of a hand, and that was 18 years ago, before we thought much about safety teaching. So, after all, safety teaching is worth while and pays big dividends, although we will never know how many accidents we prevent.

Let me add that "interested executives make interested employees!"

An Organization with More than Average Intelligence

CHAIRMAN CROMWELL: If anyone has any questions to ask I am sure Mr. Corey will be glad to answer them.

FRED SCHWARZE (Pfister-Vogel Leather Co., Milwaukee, Wis.): I should like to ask Mr. Corey regarding the type of help he has in his plant?

MR. COREY: My foremen are men who have been with me ever since I started in business. I don't think there is one foreman who has been with me less than 12 to 15 years. We have 25 or 30 girls. About half are American and half Polish girls. We have some colored help, about 15 or 20 per cent colored. We do not employ a great deal of foreign help and I do not believe we have an employee who can not understand English. The intelligence of our help today is much higher than it was 15 to 18 years ago, and it is not so difficult to get them interested.

N. L. BRAINARD (Swift & Co., Chicago, Ill.): Do you fumigate all your hides and all of your raw stock?

MR. COREY: We do not fumigate all of them. Some of the skins come from foreign countries where it is necessary that they get a consular certificate of health, in which it says that they are free from hoof and mouth disease. There are others that come to this country where we can not get the certificate of health and we have to fumigate them ourselves.

From my experience, I don't believe that goat skins are quite as liable to have hoof and mouth disease as sheep skins and others, although we have two or three neighbors who have had several cases.

I can not tell anything about goat skins by looking at them as to whether they are all right or not, so I usually have them fumigated. I can not get my men to put on gloves when examining them unless I do so myself.

We have one doctor in my part of the country who is very good on these diseases. He has cured several. Most doctors are prone to commit themselves on these diseases.

I might add while I am on my feet, that when I get back to Wilmington I am going to have a mass meeting and I may read part of this paper to my help. It will help to pep them up a little. Mass meetings should be held at least twice a year. These meetings should be opened by the head of the firm himself. He should have a speaker who will give a talk on safety. I have addressed my workers many times and the interest that they have shown has given me much pleasure. The speaker furnished by our liability insurance company has often told me that it was inspiring to talk to our workers, they were so attentive and interested.

Successful Treatment in Cases of Anthrax

CHAIRMAN CROMWELL: I know of a Dr. Bouhr who has never lost a case of anthrax. He is a specialist along that line, and we have shipped him all kinds of cases and he has never lost one.

The way we do if we have a case of anthrax, or if we even suspect it is a case of anthrax, we put him right in a car and ship him over to Dr. Bouhr and let him take care of the man.

Wm. CAMPBELL (The Graton and Knight Mfg. Co., Worcester, Mass.): We fumigate all hides that come from foreign countries before they come out of the car. I think it is a good way to keep away from anthrax to do it right in the car before they go into soak.

CHAIRMAN CROMWELL: Our company practices the same thing. All foreign hides must be sterilized before they are taken out of the car. We have a special man to do this if the state can not do it.

MR. COREY: We are always watching accidents and when there is one we try to safeguard against a recurrence. One of our girls tripped over a truck handle which was laying on the floor. We immediately had all the truck handles painted white and there has not been an accident of this nature since.

CHAIRMAN CROMWELL: Our truck handles are such that they can be turned around under the body of the truck. This prevents a lot of tripping accidents.

MR. COREY: Our employees are supposed to do that but they don't always do it.

CHAIRMAN CROMWELL: Last year we had quite a few accidents where the employees got their feet pinched under the floor wheel trucks. We have put a shield around the truck wheels. This comes about half an inch from the floor. The shield does not interfere in any way with the movement of the truck.

There is another point I should like to bring up and that is a system

we tried out in our different departments. We gave to the foreman of each department going three months without a doctor bill a gold medal. This medal consisted of a two-dollar-and-a-half gold piece with the foreman's name engraved on it. This made quite a hit with the employees.

DEAN MONEYMAKER (International Shoe Co., St. Louis, Mo.): Do you have any trouble with your sheridan presses in guarding them and keeping people from getting their hands caught in them?

MR. COREY: We do not have any of that kind of presses in our factory.

MR. FRED SCHWARZE: We have a guard for these machines. I won't say that it is 100 per cent safe, but I should be glad to give you specifications.

CHAIRMAN CROMWELL: I might say that our company uses the same guard that Mr. Schwarze does. I am sure you can get any information you want from Mr. Schwarze.

If there are no other questions we will proceed to the next speaker. Mr. Al Kroes, Director of Safety Education, Employers Mutual Liability Insurance Co., Milwaukee, Wis., will talk to us.

HOW TO SELL SAFETY TO THE WORKER

Al Kroes, Director of Safety Education, Employers Mutual Liability Insurance Company, Wausau, Wisconsin.

Whenever I find myself addressing a group of safety workers my first thought is of gratitude for the opportunity and the chance of perhaps planting a bit of seed here and there, which will advance the great cause of safety for which we all are giving our time.

"How to Sell Safety to the Worker" is a task, a real problem, and it would take a lot more time than we can give it here to do justice to it. We shall, therefore, pick out the most important phases, and you will readily agree with me that the best man in all the world to sell safety to the men, is the foreman.

Oh, yes, there may be a safety director in your plant, and all hail to the real outstanding ones, who are a credit to that profession; but even in those plants that have one and in the smallest shops too small to support one, the foreman is the real captain of the ship. On him depends the safe conduct of the men in his charge, the frequency of infrequency of accidents and a lot of other things which contribute to the smooth running of things in his department. All this has a tremendous effect on the production sheet and makes the foreman who knows the intricate combination. But my subject is nothing so far as effect to the foreman.

Salesmanship, the real kind that gets the work done, depends upon that great essential, "enthusiasm," and enthusiasm can not be sold by a foreman or safety man of whatever kind, who has not in him that divine spark of enthusiasm necessary to get over any successful sale.

In the first place, you must have something to sell. Present the real thing. Don't try to pass off to these fellows that safe-work substitute familiarly known as "something just as good," for they can quickly detect

the "near beer quality" of your proposition. The average fellow in the shop is willing to be sold on the genuine article but resents just as quickly the imitation that is handed out in some of the industrial plants.

Safety today is not what it was in 1910 or thereabouts, when almost every foreman thought he had done a hundred per cent job by guarding a few belts, pulleys, shafts and gears. Of course, this had to be done in the same way as building the foundation of a house, but the upperstructure of safety has more and more to do with the guarding of the human machine than ever before. And here we come to the line of demarcation, the question whether you are just a guard-foreman or a safety man who can reach out to the human side of accident prevention and get at the man on the job. When we have gone that far the real selling begins.

And, before we get out our book and start to sell, let us here and now pause for a moment and consider what a splendid thing it is to be instrumental in this wonderful work of eliminating the sorrow which always goes with every accident. What a chance to be a part in this worthwhile proposition to make dad a safe worker so that the boys and girls may have a chance, and the home may be spared from disruption, and happiness may reign instead of grief and despair. That is the heritage of being a leader of men.

Expect a Comeback of Some Kind in Selling Safety

Refreshed by this thought of our responsibility and pepped up by the inspiration of our work, we will now consider how best to reach our fellow worker and sell to him what he surely needs, but which many of them so indifferently or even suspiciously reject. And never forget the fact that the sale is not made until you have gone all the way. Naturally, you can not sell all of these men your proposition direct. You can hardly expect them to sign your bill of sale unconditionally and without some kind of a comeback.

Oh, indeed, a few of them take it willingly. They not only are one hundred per cent sold on it, but actually become your agent and enthusiastically sell it to their pals and shopmates. However, many of the others will have to be sold on the installment plan, and you have a regular time to follow them up for monthly payments and "interest." Some of the crowd are unwilling to seriously consider your best plan. They are sure that you are trying to slip something over, and they start broadcasting over station U.N.R.E.S.T., which is a serious menace to both safety and shop efficiency.

The last two groups of men are your problem. There is the test. You may as well stand up and be counted. You either are a born salesman or you belong to the class commonly known as ordertakers. We all have some different idea of how best to sell the safety idea to the great mass of workers, but we also have come to some definite conclusion.

The National Safety Council's Annual Congresses have long been known as the clearing house for these ideas, and the good they have done in the national field can not be disputed. Carelessness, thoughtlessness and indifference have cursed humanity for ages. The great waste of

human material in the workshops of America has been somewhat cut down since safety came into its own, and it is to the everlasting credit of thousands of superintendents, foremen, safety supervisors, safety committees, and the fellows on the job that much has been accomplished.

Just what has done or will do the most good depends on the size and conditions of each individual shop. But, whatever is done, must have in its inception the willingness of the man in the ranks to do his part and the capability of the foreman to put his men in a frame of mind where safety willingly becomes a part of the daily routine.

To have a man become a safety enthusiast willingly can only be accomplished by great and persistent effort on the part of the foreman or safety director, plus the earnestness and enthusiasm he puts in the work. The contrary-minded and "I-dont-give-a-damn" fellows should be talked to privately. To bawl them out when they violate a strict shop rule and especially at the spot and in the presence of fellow mates is the worst kind of a blunder and leads to nothing but trouble. A heart to heart talk in your private sanctum and an appeal to their good judgment and sense of justice will have amazing results, which will even surprise yourself. It will create good will and harmony, two essentials in the safety campaign. And, put this down, that these heart to heart talks are worth more than a box car full of printed stuff.

Close contact with the men you have called on the carpet not only makes for a better understanding between the party of the first part and the party of the second part, but it makes the party of the second part a missionary for good and your safety work has welded another link in the chain that eventually will become endless.

Successful Foremen Have Faith in Their Men

Such a process is slow and tries your very patience but it also puts you in a position where the leaders are. It's hard but it is not without compensation. To be a part in the great scheme of accident elimination to add your mite to the happiness of the many homes of your workers ought to make you feel proud and give you that peace of mind which nothing else can give.

Think what it means to put over a sale like that. No loud boasts or soap box oratory, but quietly and surely reach into the hearts of your men and find fellowship. And, above all, have faith. The really great foremen, the most successful safety supervisors, are those who have faith in their men. And, then, be human, you're dealing with men. Talk to them in their language—don't be too technical. Don't try to put over the Einstein theory. Don't forget that you are talking to Joe Kalinsky and not to President Coolidge. They're not hard to meet if you meet them on their own ground.

There are many more things that enter into a real campaign of selling safety. Important among these is a live wire safety committee, including an inspector, who not only knows his business but is a mixer. He must have that much-needed asset, personality, and the ability to radiate the safety spirit when he makes his rounds. Only a safety com-

mittee which includes the men on the job is worth while. Very few committees or councils composed only of executives are doing real good work. They are apt to become paper organizations and exist in name only. They certainly can not have the full endorsement of the men for they have not been considered as a part of it. Human nature is much the same in every station of life and when you ignore a man, and then expect his cooperation in the safety game, your efforts will end in failure.

During my 15 years of safety work I can look back with pride upon some safety organization bands of earnest men who have sold safety for many years and are still on the job. All honor to them. They deserve it. It's all work and no pay.

Bulletin boards sell safety just as surely as newspapers sell politics. It's a slow job but all advertising is slow work. The most attractive ads catch your eye first, and with bulletin boards it is no different. Then it is not only the right board and the right material on it, but above all the right location that counts. Good safety bulletins should be augmented by some news material of interest to the average men. Some of you may say that they don't read it. It depends a great deal what you mean by "it." Try it; just put a two-by-three-inch notice on the board that after November 15 all piecework will be raised fifteen cents a hundred and you will have a riot at the old bulletin board by noon. Keep the bulletin board up to the minute. The most enthusiastic newsboy can't sell a yesterday's paper. Today is what interests us. Yesterday is under the roses.

The Individual Plant Safety Campaign

Another stimulant that sells safety to the men is earnestly conducted individual plant safety campaigns. They call for everybody's help. They act like a primer to your old bus. These campaigns brush away the cob webs and put ginger into a lagging safety movement. They call for pep and point and put every man on his toes to get through the month without a mishap. Departments vie with each other with good natured jealousy to come through clean. These campaigns sell our old friend safety in a new garb and it is marvelous to watch the place in spic-span-safe attire after a concentrated effort. The old dark gloomy corners where old man carelessness has lived and grown fat for years will take on new life and the whole shop become a safety worth while place to work in. These campaigns arouse the competitive spirit born in all of us and write the word "efficiency" on every machine even though you can not see it.

Yes, safety can be sold to the worker, but the sale must be a real sale, made by real methods and by a real salesman. It means work, you must keep everlastingly at it, but you'll win out with a little patience.

At no time has accident reduction been more important than it is now. Always putting in the foreground the humanitarian aspect of this great work, it has a salutary effect on the bank book of both the employer and the men. The same fellow at station U. N. R. E. S. T. will tell you or some other close friend that all this safety work means a

lot of money to the boss. Pick 'em out and tell him frankly that he is right. Also tell him that the small sum the boss saves is nothing compared with the benefit to him in saving a hand, a leg, or an eye. Be honest with him and you'll make a sale. The primary assets of safety are a better work place, an ever increasing better atmosphere, a better understanding, and, therefore, better men, all of which means more efficiency, production, health and happiness. They are the four aces in the deck. It's a great game.

When safety supervision in the shop goes on the hummer and things go by default, accidents become epidemic and everybody joins the trouble club. Work for harmony. Put the oil where the squeak is. A noted piano manufacturer in this country is a great sticker for harmony in his plant. He truly said "There can not be real harmony in my pianos unless we have it in the factory."

Accidents Are the Growing Pains of Safety

Gentlemen, your work has many angles. It has all the high ideals of a profession. Yours is the noble missionary zeal of the enthusiast. What a God given opportunity to be a leader of these industrial masses and teach them to walk into the channels of safety. Safety furnishes a common meeting ground on a lot of questions, having a bearing on sound industrial relations. Sell real safety. Do it now—you can't put it over by putting it off. In the safety dictionary there are just two words "HOW" and "NOW."

Accidents and the attending toll of suffering are the growing pains of safety. Thousands upon thousands of fair minded workers are beginning to hate these unnecessary preventable accidents. They are looking for guidance and leadership.

In closing, I would say that on the glorious foundation of kindness to our fellow men the safety movement stands like a rock.

It stands there to the everlasting credit of the thousands of earnest superintendents and foremen who have unselfishly given of their time and efforts to shield their fellow workers from untimely death or serious injury.

It stands there to the glory of the thousands of "Unknown Soldiers" who without much praise but wholeheartedly gave all they could give to the great cause of safety so that their comrades may remain on duty and unhurt.

It stands there because safety is built on service and the brotherhood of men.

Gird on your sword, you men of safety. Your task is not without trouble, but it is a great work.

Make a brand new resolution today. Return to your desk with a new vision, a new slogan:—

"Quell your quarrels and sell your stuff."

CHAIRMAN CROMWELL: I am sure we all appreciated Mr. Kroes' paper. Mr. Kroes is an authority on this thing. Is there anything you want to ask him about putting over safety talks in the plant to your workers?

MR. KROES: Is it ever done in your plants? Do you give any talks of this kind or any other kind?

MR. MONEYMAKER: We do on occasions, getting the foremen together and giving them a talk.

MR. KROES: I mean, talk to the men particularly.

MR. MONEYMAKER: Occasionally we do, probably once every month or six weeks. Of course, that isn't done in all of the plants, just certain of our plants.

MR. COREY: We have mass meetings twice a year for every employee. We have them during the noon hour. We believe in taking our time instead of their time. We shut down for lunch about 11.00 o'clock and give them a chance to eat and then from 12:15 to 12:45 we have our meeting. Everyone in the plant is there. We have no difficulty in getting them there. I have seen some meetings where they were so interested you could hear a pin drop. We get our speakers from the liability insurance companies. Mr. Kroes knows something about that.

I want to have a moving picture made. The only difficulty is to have the room dark enough at noon to make the picture show up.

MR. CAMPBELL: We get all the insurance companies to send men, like yourself, who are posted on this sort of thing to come up and talk to our men. We are going to do that for eight weeks and the men will ask questions. At the end of eight weeks we will award diplomas.

MR. KROES: It is kind of a school.

MR. COREY: Our local safety council still runs some sort of a foremen's school, which is very good.

LOUIS BARR (Armour & Co., Kansas City, Kansas): I should like to ask Mr. Kroes a question. Do you think that the greatest benefits can be derived from employees' safety rallies, or do you think that the greatest benefits can be derived from performance meetings?

Meetings of Employees with Foremen Beneficial

MR. KROES: I should think, from my experience, that meetings where all the employees and all the foremen attend are very beneficial. We have held meetings in plants where we have never been before. We did not know the conditions there. When it was time for the meeting, the timekeeper was told to get the fellows together. The timekeeper is not the man to get the employees together for a meeting of this sort. He is all right to get them together in a certain way. When he got them together they did not know exactly what it was all about, so there was no interest.

We then had meetings for the foremen and they were very much interested. We asked them about having a meeting for all the employees. They thought it would be a fine thing and they went among their men and told them about the fine meetings they had been having and asked them to be there. The meeting was set for 1:00 o'clock as they wanted it to be held on the company's time if possible. The foremen got all their men together and it was a real meeting.

MR. BARR: You have the same idea that I have. I have been carrying on that sort of work for a number of years. We have meetings for the foremen and they take the message and pass it on to the employees.

However, I am a great deal like you, I think the combination meetings are the best, where all the employees attend. They get their inspiration from the meeting, not secondhand, and we do not have to depend upon the foremen to take the message to them.

F. M. SINGER (U. S. Gypsum Co., Gypsum, Ohio): We have had considerable experience in the safety line. We find that you must continually keep after the foremen in order to keep them interested in the subject of safety. Our meetings are in the form of training classes for the foremen. We find that you can discuss topics with the foremen at these meetings that you would not want put out to the men in the shop.

CHAIRMAN CROMWELL: I want to add a word. You can not get along without having the foremen and men meet together. You can talk to the foremen until you are blue in the face and you will not get very far. You must talk to the men themselves in order to get the desired effect.

A Foreman's School Graduated Two Thousand

MR. SCHWARZE: We have a foremen's school under the guidance of our local safety council. Over 2,000 graduated from that safety school last year. In our company we believe that the foreman is the key to the situation. We believe that the foremen can lead the men in safety work by example and courtesy.

We are confronted by this problem. We have a variety of languages prevailing in every single department. We have about 12 different languages. How will you solve this problem? We admit that a great deal can be done by example and leadership. How can we get this message of safety to them when there is such a variety of languages?

MR. COREY: Moving pictures will help some. In other words, put it through the eye. Of course you will have to have a moving picture that is especially adapted to illustrating without any words, but that is something that could be worked out.

MR. KROES: That is the only answer to that question except one more. The Illinois Steel Co., years ago got out a little book showing all the different hazards of the plant, and rules of conduct. All of these things were in this little book in 10 different languages. Every new employee got a book and at the end of four weeks they had an examination. If they could not answer three or four questions out of that book they had to take it home and read it over. Usually the man will be attracted to the book which is printed in his own language. He doesn't see that every day. He might get an old country newspaper, but most of them don't do that, so this little book is very attractive to them in that way.

If these foreign employees could answer three or four questions in this book, as a recognition of that, the firm would give them a little button. That little button was certainly a feature. If some of those new fellows

had a button on, and the other fellow didn't have one, they knew that he surely was a dumb-bell. When they had a button, it raised them up into a better class. If they could pass the examination, it showed conclusively that they had been reading. When a new man was employed they gave him a book and told him to read it and in a few weeks they would ask him some questions, and if he answered them, they would give him a button. These fellows were proud of those buttons and classes were created in that line.

MR. SCHWARZE: Has anyone here had experience in making moving pictures that could be adapted to use in their own plants?

MR. KROES: I happened to be on the Motion Picture Committee of the National Safety Council. There are many very good motion pictures which teach safety in an effective way. Of course, there is no single film which might cover the hazards in all industries, nor is there yet a film picture depicting the hazards of each industry. The production of motion pictures teaching safety is yet to be developed; but many of the pictures that have been produced and shown in industrial plants have been very influential.

The ideal film would, of course, depict scenes and hazards in the individual plant for the individual employee organization. But this would entail prohibitive expense and a great deal of time and difficulty.

MR. CAMPBELL: We had a motion picture company come into the factory where I worked and make a picture. It was a fine picture after it was finished. It showed the various hazards of the plant. I think the moving picture company paid for getting into the plant.

The Safety Committee Pulled a Stunt

MR. BARR: Our Safety Committee pulled a little stunt which I thought was pretty good. We made a moving picture of accidents that had happened. We had a general meeting of all the employees after working hours and it was surprising to see 400 men turn out. We produced a scene in tableau form, showing a man looking over an elevator gate and the elevator coming down from above. Next we showed that man lying out on the operating table, and in the other rooms there were the wife and two small children.

We then showed a scene of a man working at the grinding machine with his goggles hanging around his neck and not over his eyes. The next scene showed him with dark glasses being led around by a little boy.

In another scene we showed a man going down stairs with his hands in his pockets. He stumbles and falls on his head. That gave them a kick. It was surprising how they enjoyed that picture. They went out into the factory and told the fellows who didn't show up about it. When I went out in the plant, many of them had suggestions to make and a lot of them said, "Come over here, I want to show you a bad place."

MR. KROES: I have had something on my mind for some years and I have never mentioned it. I might just as well do it now.

Your scheme is fine. I think it would be a fine thing to have a film of scenes like a man walking down stairs with his hands in his pockets, and

then have your employees write a story in their own languages of what they have seen and give prizes for the best story. That would interest them a great deal. A watch fob makes a good prize. That costs money, but at the same time the fellow will say, "I am going to see what is going on." It will keep them interested.

J. J. JULSEN (Jacob E. Decker & Sons, Mason City, Iowa): I don't know if this is just exactly in order, but the gentleman from Kansas City mentioned the elevator pit accident in the factory. We have had posters that showed the elevator hazard and the man with his head over the elevator pit. My company is putting in two new elevators which can not be raised or lowered until the gates are closed. The contact is in the gate of the elevator. To have this safety device installed, it does not cost so much, and the elevator can not be raised or lowered until the contact is made when the gate is closed. Of course that does away with that one particular hazard.

CHAIRMAN CROMWELL: Don't most states require that elevators be equipped with that safety device?

MR. BARR: I just want to say that in lots of plants you will find that the elevators are built according to conditions and they will have gates about six feet six inches high, which is the standard height. In some factories a gate that size will not clear sufficiently for some loads that have to go on the elevators. In a case like that it is necessary that they have a gate of several sections.

Where this accident happened, there was just the ordinary slotted gate and the man looked over the gate to see where the elevator was.

MR. COREY: We have such a condition as that in the basement of one of our buildings where we have put in two gates, one above the other. They both shove up together. On the bottom of the gate we have small ropes tied to it so that when a man sticks his head too close to the elevator it will tickle his face.

CHAIRMAN CROMWELL: Our time is getting short. The next paper will be by Mr. F. R. Jensen, Chief Engineer, Armour & Co., Chicago, Ill., on the subject of "Safety From the Viewpoint of the Chief Engineer."

Mr. Jensen was unable to get here and Mr. W. F. McClellan of the same company will read his paper.

ACCIDENT PREVENTION FROM THE VIEWPOINT OF A CHIEF ENGINEER

F. R. Jensen, Chief Engineer, Armour & Company, Chicago, Ill.

The student of safety and accident prevention, and in fact all of those who are engaged in the field of conserving industrial life and limb, have reason to be well satisfied with the steady progress that the safety movement has attained during the last few years.

Not so very many years ago, if one advocated safety in an industrial plant, that person was not regarded very seriously. But now, "The Safety Movement" is not a mere slogan nor a meaningless phrase—it is an important and vital part of industry.

The company with which I have the privilege of being associated, realized long ago that it was an absolute necessity to its progress to maintain safe and sanitary working conditions in all of its plants throughout the country, and it insists at all times that the premises and equipment must be in such a condition that every employee may enjoy the greatest measure of safety and protection in his work. As there is no nobler or more worthy aim than the conquest of accidents and the prevention of human suffering, it is the duty of everyone to participate in this conquest and try, at all times, to eliminate accidents and thus make this world a better place to live in.

When accidents happen, the workmen and their families are the ones who suffer most, and the financial burden of the employee is far greater than that of the employer. In no case does the amount of compensation equal that of the income lost, to say nothing of the pain and suffering necessitated by the accident. The word "compensation" is a misnomer when applied in reference to serious accidents, and in reality should be supplanted by the phrase "*partial compensation*." This, for the reason that money, in any amount, is a poor substitute for lost eyesight, lost limbs, etc., for they can not in reality be compensated for; they are lost forever.

As there are no short cuts nor secrets about accident prevention, the problem of prevention comes down to a very simple formula of education.

The chief engineer of an industrial organization, aside from his manifold duties, has today an obligation to fulfill that is as important as the rest of his duties, and that is to be a leader in the safety movement. He must see that the premises and equipment under him are at all times in safe working condition. Mechanical guards and protection devices such as safety goggles, gas masks, shields and knife guards, high voltage danger signs and safety campaigns, have reduced the number of accidents to a remarkable degree.

Man-Failure the Big Cause of Accidents

But when one realizes that more than 75 per cent of all accidents are due to "man failure," and not directly to machinery, it can be seen that a great majority of accidents can be prevented *only* through education, that is, to educate *the workmen themselves* as to the hazards of their occupations and the importance of playing the game safely.

Psychology, the great science of the human mind and its operation, plays a very important role in this safety education. You have all heard the maxim, "As a man thinketh so is he." If you can lead a man to "think" safety, then he will also "act" safely. This man should be *led* to think, and not *driven*.

Someone, in a safety discussion, made the remark that it was not so much the men who should be educated, but rather, the bosses. There is considerable truth in that remark, because if the foremen or "straw-bosses" are not "sold" on the safety idea, then the workmen will not be apt to consider it seriously.

The chief engineer, therefore, must first of all be sure that the supervisory force directly under him are all "sold" on the subject, and by their conduct set an example to their workers. The supervisory force should instruct the men in their duties and point out to them the hazards of the job and give them specific instructions as to working with safety. New men should receive more attention than the older employees. The chief engineer should at all times make use of the safety engineer, and every accident, no matter how small, should be given the greatest publicity, so as to study it with a view of preventing similar accidents in the future. Inspection of the departments by the safety engineer, regularly, and daily watchfulness, should be insisted upon. Every dangerous place and practice should be pointed out and particular attention given to these.

The importance of the safety engineer, in every industrial organization, is being more and more recognized, and the chief engineer should work hand in hand with the safety engineer, in order to devise ways and means of accident prevention. The safety engineer is of great importance in educational campaigns, as he specializes in this work and has more opportunities than the supervisory force to observe accident causes.

A great progress has been made in the industrial plant, but the surface is barely touched; as we are in an age of speed, no one knows what the future has in store for us.

Discussion Following Mr. Jensen's Paper

CHAIRMAN CROMWELL: I would like to thank Mr. McClellan for reading that paper.

Is there any discussion of the paper?

MR. BARR: There is one point I wish to bring out. I find in my plant, and no doubt most of you find it is true in your plants, that when you sell safety to your employees, you are naturally going to sell some of it, but when he goes back into his department and the foreman is not sold and takes that "I don't give a damn" attitude, what kind of an attitude do you expect the man to take? If the foremen are not interested, the men will not report any bad conditions or unsafe practices that exist in the plant.

I think the question is to sell the foremen. A lot of our foremen are overburdened with the production end of the plant, in fact some of them have more than they can handle. The safety engineer can work with the foreman and get him lined up. He can tell him what is causing his accidents. The safety engineer studies the conditions in his department and he can encourage the foreman to encourage the men to keep safety uppermost in their minds, in that way, if we all work with that point in view, we can accomplish more than has been accomplished in the past.

MR. COREY: Of course I wouldn't have the difficulties in a small plant that some of you gentlemen would experience in a large plant where there are several thousand employees.

Safety is a hard problem to teach the employees, but I can recognize the fact that you have to sell your foremen first. If you don't sell your

foremen, it will be impossible to get very many employees interested. The same principle applies to the head of a small company like my own. I am sold on safety and I can get my employees interested. That is the problem that we have to contend with, but it is interesting to see how the employees will take hold of the idea when the man above them is interested in the subject.

MR. BRAINARD: I think that brings us to a phase of the work in connection with accident prevention that has not been touched upon this morning. It is the value of statistics. Our foremen are great men to study figures. They figure the cost of labor and other operating expenses. It is just as essential that they should have figures on what accidents are costing the company. We have to pay for casualty insurance.

The foreman should know that the cost of insurance in his department or the superintendent should know that the cost of his plant is based upon his actual expenses, and I think we should utilize that information by giving it to the foreman and impress upon him the cost in connection with accidents.

It always appeals to the foremen to know what the accidents are costing them, and that means that we should analyze accidents as to causes and for frequency; we should always put before them what these accidents are costing and this should be based upon the actual experiences in each department.

CHAIRMAN CROMWELL: I would like to ask Mr. Brainard, are those statistics gotten out every month?

Monthly Statistics Tell the Accident Story

MR. BRAINARD: I think monthly is the most logical way to get them out. Show him how much his department is costing him, and the foreman, as a business man, is quick to catch the idea. Show him comparative figures from other plants. Show him the cold facts in figures and impress upon him that your plant is not as efficient in safety measures as perhaps some of the other plants.

CHAIRMAN CROMWELL: The trouble we have had in comparing statistics is that almost in every state of the Union the compensation law, and the cost of insurance, are different. We finally agreed last year that the only way we could arrive at a fair comparison would be to figure the number of accidents and figure the time lost.

MR. COREY: You gentlemen who are with companies which have plants in different parts of the country have an excellent opportunity to put your different plants on a competitive basis. Put one plant up against another and figure their lost time accidents, and offer a prize to the plant that has the lowest lost time rating.

CHAIRMAN CROMWELL: About three years ago we started a campaign by giving a first prize in money and a second prize in money to the foremen of the plant which came out ahead with fewer accidents. That materially reduced our accidents. In one plant they dropped over 85 per cent. You can readily see that that means a lot of money to us.

MR. COREY: We have a poster in each department reading like this:

"The last accident in this department was on, a certain day. Who is going to spill the beans next?" Once in a while we have to change that poster when they have an accident, but it is a factor in keeping the subject of safety foremost in their minds.

HUBERT L. CLOVER (International Shoe Co., St. Louis, Mo.): I am a new man on this safety work. This is my first year to attend the Congress and I am here to get the safety kinks from the rest of you. Probably next year we can offer something.

MR. SINGER: I want to say this for the Packers' and Tanners' Section, that this has been a very interesting meeting. I have been coming to these meetings for the last five years and I don't know when I have gotten more inspiration than I have here this morning.

CHAIRMAN CROMWELL: I am glad that you have. I hope you will come back again.

Accidents Last Month in the Sheridan Presses

MR. MONEYMAKER: We have quite a number of problems. During the last six months we have had three people lose fingers or the complete hand in the sheridan presses. It is a pretty big problem that is confronting us, and we haven't been able to work out a guard or a system as yet to overcome it.

We did work out a guard, but about a month after it was installed another party got his hand taken off, so that brought up the question again.

CHAIRMAN CROMWELL: Do you use a stick to straighten out your leather?

MR. MONEYMAKER: We should, but occasionally the employees don't.

MR. CAMPBELL: We have tried several kinds of guards for the sheridan presses. We put a platform on each machine. It is impossible for them to put their hand into the machine with the platform in that position.

MR. MONEYMAKER: This guard that we manufactured was the same proposition as yours, but we had girls operating that machine. We had to do overtime work and the men came in and used the machine. A man's reach was longer than the girl's and he would reach his hand into the machine while the guard was still out and so he got his hand taken off. It was probably the foreman's fault for not readjusting it for the man.

MR. JULSEN: Isn't it compulsory in the other plants that men who carry their cutting knives around with them, carry them in pouches? I find it is an every day occurrence that the men go around with their knives sticking out in front of them and they hurt themselves or hurt others. We have had several accidents of that sort. I wonder how the other packers handle that situation?

MR. MCCLELLAN: It is compulsory so far as our trimming floor is concerned. We furnish them knives and pouches free. On the killing floor we sell these pouches to the men for just what they cost us. When a man is seen running around without a pouch, the superintendent gets after him and tries to make him buy a pouch, and in this way we have elim-

inated quite a lot of running around without pouches. In fact, all our government men have bought pouches.

We can't get the hog killing department to use them. That is the only department where we are bucking into any trouble. The sheep killing department uses the pouches. We do not make it compulsory, but we sell the pouches to them at cost.

MR. COREY: Why do you charge the men for the pouches?

MR. McCLELLAN: They take better care of them when we sell the pouches to them. We tried giving the pouches to them at first, but we found that we could not keep enough of them in stock. I don't know what they were doing with them. The first thing you knew you would not see any of the boys with them on, so finally we started to put a little charge on them. They take better care of them now.

MR. COREY: How about their knives?

MR. McCLELLAN: They buy their own knives. Of course, if a new man comes in we furnish him with a knife. After that he has to furnish his own knife. We find by putting a little charge on it, he takes a great deal better care of it. He doesn't throw it around and let some one steal it.

The Problem of Supplies for the Workers

CHAIRMAN CROMWELL: We had six new pairs of rubber boots disappear one morning from a department.

MR. McCLELLAN: We had that trouble in the cutting department. It got so we could not keep gloves there. We finally had to keep them in the storeroom and in order for a man to get a pair, he would have to leave his check number. If they didn't have them when they left, they were docked for them.

MR. CAMPBELL: We furnish rubber boots at half cost, although we give them aprons free.

MR. COREY: In our company it is customary for the men to furnish their own rubber boots.

MR. SCHWARZE: I would like to ask Mr. McClellan if all the things that the men take out are charged to them, or just the initial cost borne by them?

MR. McCLELLAN: Just the initial cost. When a man comes to work he is given everything that is necessary, and we charge him for them. If anything wears out, he takes it to the foreman and gets another pair free. When he leaves our employ he turns in all of the stuff that has been issued to him, and we refund his deposit.

MR. SCHWARZE: How far should the safety engineer go in regard to retaining foremen who can not be sold on the idea of safety? It is my idea that the man who can not be sold on safety should not be retained by the company. Are there any definite rules for that?

MR. SINGER: A case like that will usually take care of itself. The foreman who can not see the relationship between safety problems and cost of production is a poor manager. His deficiencies are liable to crop out to such an extent that he will be replaced. I have seen that work out three times in the past year.

MR. SCHWARZ: That hasn't proven true in our organization.

MR. MONEYMAKER: The men higher up must be sold on the idea of safety, but if you have a man (I have one particular man in mind) who hasn't been sold definitely on safety, but is one of the best production men in the organization, he is still on the job and is likely to be for some time. Of course, if he falls down in production or on some other phase of the work, he may get the gate, but that problem hasn't been worked out to my satisfaction in our own organization. It is a problem that is confronting me as a safety man and the instructions that we have are to go and sell him. If you sell him, he is a safety booster, but if you force him, he won't be.

MR. SINGER: I am a safety engineer myself. We have discussions with our foremen and we give a reward for good records. I am going to admit a few of my own faults now and point out some of the faults the safety engineer is liable to have. He is likely to pass the buck to the foremen just a little too much, and in judging accidents he is a little too apt to say that it is the foreman's fault. Your sales methods may be just a little bit at fault.

MR. MONEYMAKER: I will admit what the speaker just said, but when you run up against the management which is not absolutely sold, of course you are reflecting back on the safety man and his inability to sell the idea.

MR. SINGER: This may be a radical statement, but if I worked for a company that did not back me up, I would have a new job in four or five months.

MR. MONEYMAKER: I am going to sell the proposition. I am comparatively new in the game. I have never given up the hope of selling them the proposition.

Representatives of the Small Packers Welcomed

MR. McCLELLAN: In looking over the registration cards I see that there are a few men here from some small packers. There are also a few boys here from our leather industries. I am glad to welcome you in behalf of our chairman.

I would like for you, Mr. Chairman, to appoint a committee of three to see if we can not get together with the American Institute of Packers and see if we can not build this Section up. Year after year we have to dig and scrape around to get somebody to fill out our program. Why not make up a program of the small packers so that they can not say that the big five always dominate this meeting? We tried to get them to serve this year but they all declined.

Every year has been a duplicate of the past year. Mr. Campbell, Mr. Brainard and some of the older heads have always met and taken part in the programs. I think we should have some of the boys who are new here today, serve on this program. Some of the boys from the small packers and from the leather industries. If your companies are not members of the National Safety Council, go back and try to get them to join, and attend these meetings regularly.

CHAIRMAN CROMWELL: That is right; it has been an awfully hard job to get people out to these meetings. Mr. McClellan, Mr. Campbell and Mr. Brainard have always been in on the programs and we want new faces. I see a lot of new faces here for the first time.

MR. BRAINARD: Mac referred to me as one of the old ones here, but I want to say to those who are here today for the first time, that I have always gone back to my work with a lot of inspiration and help from these meetings. I always get a lot of benefit out of these round table discussions. The talk that Mr. Kroes gave us was one of the best safety talks I have ever heard, and I think all of us can go back with a lot of new ideas.

I want to say a word to the new men. Come in and take an active part in the work of this Section. Make some contribution so that we may all profit by it. We are coming here every year and we learn every time we come, and we want to profit from the experience that most of you have had. Bring it in the form of a paper so that we may discuss it here, and it will help those who are working along similar lines. I assure you, if you will do that, we can build this Section up and we will all benefit by it.

MR. COREY: I think this meeting today has been very helpful. I am going back with a lot of new ideas and new thoughts, and that is what we have to get in order to keep this safety movement going. We have to get something new all the time from these meetings and take it back to our plants.

MR. CAMPBELL: If this was the Leather Workers' Council instead of the tanners, we would have more of an audience here. The Leather Workers' Council have meetings all over the country in bigger rooms than this.

MR. BRAINARD: There are a great many problems that are of mutual importance to both the packers and tanners, while the leather workers might bring in something which we don't come in touch with in our industries.

Mr. Corey's paper this morning was of interest to us all and it all bears on safety. I think that the two industries are better united, at least for the present.

CHAIRMAN CROMWELL: I would like to make a suggestion that the incoming officers try to hold more meetings this year. I have tried to hold meetings on the outside, and I would suggest that they hold meetings around where we could get to them. I think we should get together more than just once a year at the annual meeting of the Safety Council.

J. A. FONRO (Elliott Service Co., Chicago, Ill.): I am a new member of the organization here, and I enjoyed the meeting very much.

ADJOURNMENT

WEDNESDAY MORNING SESSION

October 27, 1926

The meeting of the Packers and Tanners Section was called to order at 9:30 o'clock, Chairman Oliver F. W. Cromwell, presiding.

CHAIRMAN CROMWELL: We will have the report of the Nominating Committee.

H. W. SCHILDT (Plankinton Packing Co., Milwaukee, Wis.): The Nominating Committee recommends the selection of the following officers:

Chairman, H. W. Schildt, Plankinton Packing Co., Milwaukee, Wis.

Vice-Chairman, Wm. C. Corey, Delaware Leather Co., Wilmington, Del.

Vice-Chairman, Wm. C. Campbell, The Grafton & Knight Mfg. Co., Worcester, Mass.

Secretary, O. C. Stern, Plankinton Packing Co., Milwaukee, Wis.

Chairman Membership Committee, F. L. Schwarze, Pfister-Vogel Leather Co., Milwaukee, Wis.

Chairman Program Committee, Oliver F. W. Cromwell, Central Leather Co., Ridgway, Pa.

Chairman Bulletin Committee, Dean Moneymaker, International Shoe Co., St. Louis, Mo.

Chairman Publicity Committee, C. Boneholt, Hammond Standish & Co., Detroit, Mich.

Engineering Representative, F. R. Jensen, Armour & Co., Chicago, Ill.

A motion was made, seconded, and regularly carried that the officers as recommended by the Nominating Committee be declared elected for the ensuing year.

CHAIRMAN CROMWELL: Mr. Schildt, I will turn over the meeting to you and wish you all kinds of success for the coming year.

Mr. H. W. Schildt took the chair as the new chairman.

CHAIRMAN SCHILDT: Our next order of business is a paper by Mr. Frank Morris, Assistant Chief Engineer, Liberty Mutual Insurance Co., Boston, Mass.

SAFETY KINKS IN THE LEATHER WORKING INDUSTRY

Frank E. Morris, Assistant Chief Engineer, Liberty Mutual Insurance Co., Boston, Mass.

The question of who tanned the first skin so as to make it at once pliable and imputrescible is as unsolvable as the question "Where did Cain's wife come from?" Fig leaves were sufficient for a covering while in the Garden of Eden but just as soon as they began to travel the first female demanded from her spouse a fur coat.

Because we men of our day know how imperious this demand for a fur coat can be we are all willing to agree that in all probability Adam

was the first tanner. He had some trouble in obtaining the leopard skin in the first place but it was not much of a problem to dry it to prevent putrefaction. Eve complained, however, that the garment was too stiff and poor Adam was in desperate straits. After trying everything he could think of he finally gave up the idea of ever making the coat fit Eve as snugly as it had clung to its first inhabitant and in a forlorn attempt to please his wife he lined it with leaves, because in the garden she had never complained about the fit of the fig leaves.

As we all know, Eve flew into a rage and threw Adam's labor of love into a corner of the hut where it lay during the several ensuing weeks of the argument. Manhood finally asserted itself. Adam determined to make her try the coat on. He tied his recalcitrant wife to a bed post, rushed to the corner where the leopard skin lined with leaves had lain for many days, picked it up and discovered with great glee that it was as soft and as pliable as it was on the day he removed it from its original owner. Thus was revealed the secret of the curative properties of certain leaves, twigs, and bark, and ever since that day men have known how to tan leather by the vegetable process—and women have continued to demand fur coats.

Tanning Is One of the Oldest Domestic Trades

Two weeks ago Dr. George Grant MacCurdy, of Yale University, returned from Europe aboard the steamship "Belgenland" bringing with him specimens of domestic tools used by the Neanderthal man, about 60,000 years ago. Mr. MacCurdy, who is a member of the American School of Prehistoric Research, visited five countries during the four years he was abroad, and made excavations in France and Czechoslovakia. The domestic tools included a combination knife and scraper, of pure rock crystal, used by the Neanderthals to skin, as well as clean the skin of reindeer and other game animals.

How do we know that there were reindeer? Because in the caves that were the homes of these prehistoric people we today find pictures of reindeer carved on the walls. We know quite a bit about these people of 60,000 years or more ago, and we can feel certain that they knew how to tan hides and skins even before they learned the art of softening metal by fire.

Mr. Paul Warburg says, "The remarkable feature of the industry, even now, remains the fact that it rests primarily on an empirical basis, far more so than any other of our primary industries."

In the state of Massachusetts we have 11,000 workers employed in tanning and finishing leather in 125 different plants, or an average of 88 workers to the plant. In all of our safety conferences such as this, we naturally think in terms of the large plant, the plant that has a safety department, nurse, safety committee and so on, and of course most of us here assembled come from plants of that size. One of the big problems of the National Safety Council is to reach the small plant, for we must remember that 92 per cent of the manufacturing industries of the country have less than 100 employees and obviously such a plant can not employ

a full time safety man, and moreover there may be serious doubt about the value of a safety committee in a plant of that size.

A few months ago the Engineering Section of the National Safety Council undertook to stir up interest that would culminate in a regional safety conference in Boston of men from tanneries and leather finishing plants in New England. The reason such a conference was not held has already been given—the average plant in Massachusetts has but 88 employees and I doubt if you could dig up a half a dozen full time safety engineers among the 125 plants.

A study of the accident experience of these plants reveals that they have an accident frequency hazard that is slightly lower than the aver-

TABLE No. I

**Accident Experience of Three Plants, 650 Employees Each,
1920-1924 Inclusive**

	Plant No. 1	Plant No. 2	Plant No. 3	Total
Infections	72	41	35	148 Accidents
	1,572	1,315	875	3,762 Days lost
Strains—lifting	54	51	28	133 Accidents
	1,845	2,400	1,675	5,920 Days lost
Slips—floor	21	27	11	59 Accidents
	840	875	241	1,956 Days lost
Non-mechanical totals.....	222	219	173	614 Accidents
	6,990	7,100	4,440	18,530 Days lost
Mechanical totals	12	35	47	94 Accidents
	471	1,956	2,415	4,842 Days lost
Total lost days.....				23,372
Days losts to infections, strains and slips.....				11,638

age industry in the state but the insurance rate is about 30 per cent higher than the average rate, due in some measure to the occupational disease hazard which is compensable under the Act in Massachusetts and due in part to the higher than average cost of the non-mechanical accidents.

Over a period of five years the non-mechanical accidents in Massachusetts averaged 67 lost days and the same class of accidents reported in tanneries averaged but 64 lost days; but, as I will show, the percentage of the more costly accidents in tanneries is much higher than in the average plant. I refer to "strains," "slips and falls on floor level," and "infections."

Let us view the experience of three plants each having 650 employees over a five-year spread. They had a total of 708 reported accidents, 94 of them being mechanical and 614 non-mechanical. Of these 614, over 50 per cent, or 330, were due to the three above causes. I will analyze mechanical accidents later but for the moment let's talk about these three causes in these three plants. (See table I.)

Plants No. 1 and No. 3 handle hides and Plant No. 2 handles sheep skins. In the sheep skin plant we have 27 slips on the floor level, com-

permits of a finger getting in danger. One plant in our state has such a guard all made up but they will not put it on until they have an accident. They claim that they have yet to have a serious jack accident and they have been in business 47 years. The moving parts on a jack look terrifying to the uninitiated but the hazard here is often over-emphasized.

On buffing drums we had but one partial disability with an exposure of 55,000 men years. The fire hazard under the bench here, however, does demand attention and of course this can be obviated with a sprinkler head at each drum.

TABLE No. II

Summary of Machine Accidents in Tanneries in Massachusetts,
1920-1924, Inclusive; Average Employees, 11,000

	Tabulatable	Permanent Partial Disability	Death
Fleshing, Shaving, Skiving Machines.....	135	12	0
Jacks, Glassing, Rolling, etc.....	99	9	0
Buffing Drums	54	1	0
Splitting	52	8	0
Presses and Baling Machines.....	33	8	0

Setting Out	11	1	0
Extractors (centrifugal)	8	2	0
Unhairing	8	0	0
Drums (not buffing) and Paddle Vats.....	7	0	1
Miscellaneous	435	46	1
Totals	856	84	2

Splitters are bad actors. One fellow who was very fond of golf, in fact, he was a golf professional on Sundays, got his fingers in a splitter several months ago and he may play golf again some day and he may not, but certainly not for several months. This man agrees that splitters should be guarded. If a bar guard is not practical here why not at least insist on using a small block with a handle for smoothing out the skin?

On presses we have several guards on the market but a wide table and a short armed feeder make that side safe, providing the workman always uses his flat stick when necessary. In one plant the short armed feeder was sick one day and a long armed man was substituted, with a distressing result. On the take-off side a guard that will come up with the ram and push the take away man out of danger is simple and practical.

The rest of the machines on this list do not appear hazardous enough to worry much about. Note that during these five years one man was killed on a tanning drum. If the belt is locked in the "off" position with a spring lock that takes two hands to operate, and so located that to start the drum one would step on a worker who had his head in the drum, I believe this problem is adequately provided for.

Tanning of leather has not changed remarkably in processes during several hundred years and that is one difficulty in accident prevention work in this business. We often hear the story, "We've been in business 47 years and no one was ever hurt in that way or by that machine, so why worry?" The real truth may be that accidents are so infrequent that the employer really believes that he hasn't had a serious accident in 47 years; but the probabilities are that his father and his grandfather never worried about the accidents, so why should he?

Discussion Following Mr. Morris' Paper

CHAIRMAN SCHILDT: Are there any questions that you would like to ask Mr. Morris?

MR. CROMWELL: Mr. Chairman, in speaking of an arrangement for making a drum safe, I would like to draw Mr. Morris' attention to the one which the Eberle Tanning Co. has. It has an electric contact safety device and I believe it is one of the best I have ever seen. You have to throw a series of levers before you can start the drum, and everything must be in position.

MR. COREY: I should like to ask Mr. Morris if he can get me a sketch of the drum used by the Letts Co? We have a device that one of our men built some time ago, but instead of putting the pin back of the lever, he has a lock arrangement with the pin sticking out. That keeps the spring holding the latch so that you can not start it without taking hold and pulling it down.

MR. CROMWELL: Mr. Campbell has one of the best safety devices that I know of for a side loading drum. I am sure Mr. Campbell would be glad to furnish you with a blue print.

MR. COREY: We use a stave loading drum.

MR. McCLELLAN: I would like to ask Mr. Morris if he knows of a good practical guard for a fleshing machine?

MR. MORRIS: No, I can't say that I do.

MR. COREY: I don't see how you could operate it with a guard. We have fleshing machines and I have operated them myself and I don't see how you can put a guard on them that would be practical.

MR. McCLELLAN: I did not ask that question to embarrass you. I thought maybe that in your travels and experiences you might know of one.

MR. MORRIS: It doesn't embarrass me a bit. Up to the present time there hasn't been a guard developed for those machines that is practical.

MR. COREY: Are there so many accidents on those fleshing machines?

MR. McCLELLAN: There are not so many accidents but when you do have one it takes the arm right off. Our company also uses these machines for another purpose. In the hog cutting room they take the fat off the skin with them. The skins are not always the same size and in getting the small skins into place the men sometimes have an accident. When they do it usually means an arm.

MR. CROMWELL: Last year we had an accident in one of our plants.

The man had his arms inside the machine and in some way kicked the starting lever and caught the arms at the wrists. That has been the only bad accident we have had in years. To overcome that I have put a board over the treadle. It is about four inches over the treadle and extends out about two inches beyond the edge of the treadle. This prevents anyone from kicking the treadle by accident.

MR. MORRIS: I would like to say that in studying the experiences in those two plants, the one with the lowest number of accidents was not the best guarded plant. We found why this was true in spite of poor plant conditions. We found that the manager of that plant was right on the job. He believed in accident prevention and kept his people lined up. I have been in Mr. Corey's plant and I have seen how close he is to his people and how he is after that accident proposition all the time.

I am absolutely sold on the fact that accident prevention is a managerial proposition. In our larger plants we have safety experts, but if the boss at the top will pass the word down the line and see that all the men are sold on this same idea that we are not going to have needless accidents in this plant, that plant is going to have a good accident experience.

Executive Influence Important in Teaching Men

Take a tannery that guards all the machines and the employees think that they are the bunk, and then take another tannery that is not so well guarded but the boss and all the employees think safety while they are on the job, that plant will have the best safety record.

That is the conclusion that I am sure of now because of the large percentage of non-mechanical accidents such as infections, strains, slips and falls on floor level, etc. These non-mechanical accidents cause more than three times the number of lost days than mechanical accidents do.

MR. CROMWELL: If you will talk to your foremen about taking care of accidents immediately after they happen, it will eliminate your infection hazards. We have practically eliminated them in our plants. We had one bad case of where a man's arm was infected. He has been to the hospital three times to have his arm cut and drained. He will probably lose the use of it.

MR. SCHWARZE: I am heartily in accord with Mr. Cromwell. I think you should treat a wound, no matter if only a scratch, immediately to guard against infection. We have our employees pretty well educated up to that idea.

Mr. Morris mentioned the possibility of guarding a splitting machine. We have guards which we think are very effective. They are subject, of course, to improvement like all these guards, but these are the result of getting the men who operate these machines to express their ideas. If anybody would be interested in these guards, I would be glad to give them the drawings.

H. B. BENJAMIN (Haynes Stellite Co., Kokomo, Ind.): I may be a little out of place here. But I saw a few topics that I wanted to hear dis-

cussed, and while I don't belong to the Packers and Tanners Section, I came in this morning to take away what I could.

A gentleman was talking about the management being behind the safety movement. The biggest problem in most plants is to get the management to cooperate with the safety man. That does not mean that the management will have to get out in the plant and run around every place. If the management will get behind the safety man, give him a 15 minute talk occasionally, it will give the safety man a chance to go out and put it over with the men. You can not fool those men.

In one plant by agitating among the workers we reduced the accidents 66 per cent in one year. All the manager said was, "Go out there and put it over. If there is anything you want or if there is any way I can help you, let me know." I did not have to call on him much.

The following year, under another superintendent, he told me, "We want safety, put it over. I have heard all about you. Keep it up. It is a wonderful thing." However, certain little things have come up out there that need correcting. I did not have the authority to correct them. I would go over and tell him about it so that it would be stopped, but he didn't appoint anyone to stop it and he didn't give me the authority to stop it. The accidents got so frequent that I quit the job.

I have been offered two or three other jobs, and I am going to one of them, but I am going to know that the management is behind the safety movement before I take the job of promoting safety among the workers.

CHAIRMAN SCHILDT: I want to thank Mr. Morris for his interesting paper.

The next item on the program is by Mr. N. L. Brainard, Industrial Relations Department, Swift and Company, U. S. Yards, Chicago, Ill.

NO-ACCIDENT CAMPAIGNS

**N. L. Brainard, Industrial Relations Department, Swift & Company,
Chicago**

To the end that the whole plant shall work together for safety, organization is necessary. The plant manager, superintendent, foreman, and workman, each have a determinate and distinct responsibility and each is answerable for the effectiveness with which definite phases of the problem are met. They are jointly accountable for the promotion of safety as an enterprise embracing the whole plant, the success of which requires that their forces shall be unified. The effective agency for this co-ordination is the Plant Safety Committee.

The story of our accident prevention campaigns can not be told without a description of this safety committee. Eighteen of our packing houses have a plan of employee representation known as the "Assembly." A general description of the plan contains the following:

"The Assembly discusses and makes recommendations on all questions referred to it or raised by it, relating to the joint interest of the company and its employees, and to working conditions in particular, such as wages, hours, safety, sanitation, and like matters."

A consistent adherence to the purposes of the plan as declared in the foregoing statement, requires that the safety work of the plant shall be linked to the Assembly. For that reason the safety committee is one of the major committees of the Assembly. In making up the safety committee provision is made for including in its membership someone standing for each of the groups we have named as sharing the burden of maintaining safety.

The plant foreman, as an appointed representative, is the delegate of the management in all affairs coming within the scope of the assembly and through him the management has a voice in the activities of the committee. But it is in his own sphere as foreman that his presence on the safety committee is especially needful. The foreman's attitude toward the safety projects instituted in the plant is the most important factor of any. He brings to the committee a fund of valuable knowledge which, in his place as a leader of the men, he alone acquires. His experience in operating and production problems, of which safe working is a recognized item, is needed to fully equip the safety committee.

Elected Representatives Zealous in Safety Matters

The elected representative, standing as he does for the workmen, is zealous in all matters affecting their interests. It may be that when he first becomes a member of the safety committee he does not fully appreciate what a large contribution safe working conditions and safe practices make to the welfare of his constituents. He quickly becomes imbued with the importance of this subject and he not only gets an education in safety work, but his influence is invaluable in educating the men of his division along the lines of thinking and practicing safety.

The plant safety supervisor is also, ex-officio, a member of the safety committee. He devotes a large portion of his time to safety work and gives the committee the benefit of his technical knowledge and his information on safety standards relating to machinery and equipment. He follows up general lines of outstanding safety work and frequently brings to the committee ideas which suggest to them new lines to work on. Discussion of these suggestions adds to the interest of the meetings and prompts the committee to check up and deviate their methods when it is found desirable to do so.

The committee has broad powers and large prerogatives. The management gives it the support necessary to maintain its prestige. Recommendations made by the committee usually need only the formality of an official order to make them plant rules.

The appointments to membership on the committee are confirmed by regular assembly action, and membership, with the exception of chairman, alternates regularly. Records are kept of all meetings. The meetings are held regularly, and reports are made to the meetings of the assembly. At the committee meetings all lines of safety work are reviewed and plans for future activities discussed. Inspections of the plant are made by a sub-committee of which the plant safety supervisor is always a member. Reports of their findings are made to the main

committee. Should anything of special importance, such as an unusual hazard or a notoriously bad practice, be brought to light or any suggestion of value to the plant as a whole develop in the discussions in the committee, it is taken before the entire assembly and made a part of the published minutes. By that means information about what the safety committee is doing is spread wide. I am outlining these methods at length as the accident prevention campaigns and no-accident contests which I shall describe originated in the safety committee and were sponsored by the plant assembly.

In the inter-plant campaign the local committee devised means for sustaining the interest as well as maintaining the enthusiasm by formulating plans for inter-department contests.

A notable project which had its origin in the safety committee of one of the larger assemblies, was that of awarding various divisions of the plant operating one or more months without a lost time accident, a "Certificate of Merit." This certificate is signed by the president or vice-president of the company, or in case of plants at a distance from the general office, by the plant manager, the plant superintendent, the chairman of the plant assembly, the chairman of the safety committee, and the safety supervisor.

Certificates of Merit are Valued

A certificate bearing a seal and a white ribbon is given for one month; a red ribbon certificate for three months, and a blue ribbon certificate for six consecutive months without a lost time accident in the division. After adoption of the plan at the plant where it originated, it was presented to the assemblies of all the other 17 plants and acted upon favorably in every instance. The plan was also presented to the smaller plants and allied concerns without assemblies. The support of the plant manager, superintendent, division superintendents and foremen were enlisted in promoting the plan. It was presented to the workmen, however, through the plant assembly and was featured in the plant publications as well as on the bulletin boards.

When awarded to a division, the certificate is carried in a suitable frame, covered with glass, and displayed in a conspicuous place. This idea appealed to the assembly as a means of recognizing division efforts as well as the individual efforts of division representatives. There was considerable rivalry between different divisions to secure the first blue ribbon certificate. Some unusual records have been reported and the divisions evinced a good degree of pride in obtaining the certificates.

The safety committee at some of the plants asked and were given permission to modify this plan in minor details. One of the larger plants made the goal necessary for the attainment of the certificate of merit a 50 per cent reduction in lost time accidents. At another plant certificates were awarded to departments instead of divisions. At the Chicago plant, where some of the divisions are quite large, it was found that certain departments were penalized by the performance of others in the same division and there was danger of their saying: "What's the use of making a big effort to win a certificate. Other departments of the

division will fall down and our good work will not be noticed." So it was arranged that smaller certificates should be awarded to each department on its record. Any record made during inter-plant or inter-department contests counted also in securing for the division or department the "Certificate of Merit."

In the month of December, 1924, an inter-plant contest was held in the Chicago plant with the idea of creating inter-department rivalry and stimulating interest in reducing accidents. This contest took the form of a "Cross Country Run." The 18 divisions of the plant were represented by cars of distinctive color and the position of each car during the days of the race was shown on a large map of the United States, on which the course of the run was marked. This course took the cars through cities and towns in which the company has packing houses. The division superintendent appeared on the list of entries as driver of the car, and the employee representative as the mechanic. Cars were handicapped on the basis of the previous record of the department, the handicap carrying from 60 miles to 1,395 miles. Each day in which a division had no lost time accidents, that division's entry advanced 450 miles along the route. Every lost time accident caused the division to lose 150 miles.

Names of the entries, drivers, mechanics, and departments represented and officials of the race were posted and in naming the entries there was considerable ingenuity displayed in finding names suggestive of the department—"Premium Frank" for Sausage Department, "Maxine Elliott" for Soap Department, "Stick Tite" for Glue Department, etc. While no notable records were made in the way of no accidents, this campaign stirred up foremen, division and plant superintendents, as well as the men in the gangs with the result that before the cars were far on their way the spirit of competition was having its effect and those who were indifferent at the start, somewhat laggard or perhaps overconfident, realized they were going to be put to shame by the contestants who had worked energetically not only from the start but for some weeks prior thereto. The big thing learned from this race was that it could be done.

A Second Campaign Better Than the First

The fact that nearly every division made a substantial reduction was conclusive that all, with organized effort, should do just as well or better. Before the race was finished, plans were under way for another contest for the next month. Some of the scoffers were waking up, and the next contest saw divisions that had been tail-enders in a complete reversal. Several departments low on the list in the first contest came through in top position. The results of this second campaign were even more convincing of the value of the contest as a method of developing leaders and making converts.

These campaigns inspired the Chicago assembly to seek new worlds to conquer and in their monthly meeting of January, 1925, on the recommendation of the safety committee, they voted to issue a challenge to

all plants for an inter-plant campaign. The challenge with the plan of the campaign was formally presented to the various plants through their assemblies.

The plan submitted was that each plant should contend against all other plants by competing against its own lost time accident record for the fiscal year, 1924. The plant showing the best percentage of reduction in its lost time accidents for March against its 1924 average was to be considered the winner. All of the plants with employees numbering from 400 to 6,000 and a total of 22,000 accepted through their plant assemblies the challenge of the Chicago plant. Several of the plants ran inter-department contests concurrent with the inter-plant race.

The device for posting the standing of the plants each day was a thermometer on which 56°, or temperate, was its 1924 average accident rate per day of 100 employees. Each one per cent cumulative increase, or decrease of one per cent, from the average rate resulted in a decrease or increase of one degree in temperature at that plant. In this way the greater the reduction of accidents the higher the temperature and vice-versa. The 15 plants went into the campaign with a wonderful spirit. The various plant assembly committees were enthusiastic and the interest did not slacken while the campaign was on. Bulletins were wired each day showing the standing, or temperature, at each plant at the close of the preceding day. The interest in the standing from day to day extended throughout the whole body of workmen, foremen, division men, superintendents, as well as to other executives in touch with plant operations. Several of the plants ran very close from the start. Some remarkable records were made and the contest was a wonderful demonstration of what organized spirited effort and determination can do.

True Sportsmanship Prevailed in the Contests

Just prior to the day upon which this contest began, a letter was sent to the manager of each of the plants intimating that each plant would be expected to observe a spirit of true sportsmanship. They were asked to make sure that in the ardor of the contest and as a result of the eagerness to win, there should be no deviation from the usual practice in handling accident cases. They were urged to see that every accident, however slight, should be reported and given medical attention. The attention of the managers was called to the risk there was of harm resulting from the campaign rather than good if minor injuries were not reported. They were asked to check any tendency there might be to getting injured men back on the job too soon and to impress upon the plant doctors their responsibility in giving first thought to the safety of the patient. No injured employee was to resume work of any kind if there was a chance that the work would cause discomfort or hinder recovery. As a result of these precautions the showing of each plant at the close of the contest was considered a fair summary of what had been done in actually preventing accidents rather than the ability of the organization to get injured men back and keep them on a job.

At the conclusion of the four weeks of this campaign Denver and Cleve-

land were tied for first place, having had no lost time accidents during the period and their temperatures were shown as 156°; Omaha, St. Joseph, Kansas City, and St. Paul showed over 90 per cent improvement and the average for all competing plants was 66.8 per cent. Cleveland and Denver plants by agreement continued the campaign for another five weeks. At the end of that time Denver had recorded against it two lost time accidents, an improvement of 49 per cent, while Cleveland, showing an improvement of 77 per cent with four accidents, and temperature 133°, was declared the winner. A silk banner was awarded the Cleveland plant in recognition of their finishing the race in first position.

As a result of this campaign all phases of accident prevention work were greatly stimulated. Inter-department plant contests were held during and after the inter-plant campaign and when comparative figures were made up at the end of the fiscal year they showed a reduction of 12 per cent in lost time accidents for the year on the basis of million hours worked.

The Loser Challenged All Plants to Another Contest

The Denver plant assembly was inclined to question the final decision, as it seemed inconsistent that the plant having fewer accidents should have to take second place. However, they were reminded of the terms of the contest which provided that the determining factor should be the percentage of reduction and accepted their defeat graciously. They were game, however, and at a meeting of their plant assembly in March, 1926, the Denver plant challenged the plants that had taken part in the 1925 contest to a contest in May, 1926. This challenge was accepted by all the plants. The contest was for five weeks and on the same basis as that of the preceding one.

Each plant was to compete against its own record of lost time accidents for the preceding year and the plant showing the greatest reduction was to be declared the winner. This took the form of an archery or arrow shooting contest.

A target was used for showing the position of the various plants. The percentage of improvement was indicated on the target by means of arrows, colored and lettered to represent each of the plants; 100 per cent improvement (or no lost time accidents) placed the arrow in the bull's eye, while each per cent less than 100 placed the arrow toward the outer edge. The last ring from the center represented the 1925 accident rate or zero. An increase in the accident rate placed the arrow outside the target proper.

After the contest had continued five weeks, as originally planned, five plants had come through without a lost time accident, each showing an improvement of 100 per cent and standing equal in the contest. Of the remaining plants, one plant with one accident showed 95 per cent improvement and one with two accidents had a standing of 94 per cent. All plants combined registered 63 per cent improvement over the previous year.

The five plants having a perfect score agreed to continue indefinitely

and the plant which continued longest without a lost time accident was declared the winner. The first of these remaining five plants to drop out of the race continued until June 17; the next, July 1, and third, July 31, leaving two plants neck and neck. Their battle continued until September 17 with a remarkable record of 105 days without a disabling accident. The Omaha Packing Company was the survivor and winner of the campaign with 89,804 man days at that plant without a lost time accident. They were awarded a silk banner suitably worded in recognition of this achievement.

At the Chicago plant an inter-department contest was run concurrent with the 1926 inter-plant race. This contest was in the form of an election for the safety mayor of "Swifttown." The plant was platted into precincts, one for each assembly representative. The employee representative whose precinct gave him the greatest number of votes during the period of the contest was declared elected mayor of "Swifttown." Each day in which the voting division did not have a lost time accident, one vote was recorded for the representative of that division. The representative who received the most votes—i. e., the division continuing the greatest number of days without a lost time accident—was elected and was inaugurated as mayor at the next meeting of the plant assembly, to hold office for the six months to follow.

The Position of Mayor One of Considerable Honor

The candidate elected was the representative of one of the mechanical divisions, usually considered one of the most hazardous, his constituents being carpenters, masons, tractor drivers, and tractor repair men. The successful candidate was a carpenter. His ward had a previous accident rate of six and three-quarters lost time accidents per month. He secured the interest and earnest support of his constituents and avoided lost time accidents entirely.

This position of mayor was not one of empty honor. Since his election he has been an important factor in the safety enterprises of the plant, having taken on a number of special commissions to check up divisions which seemed to be laggard and act as adviser and consultant in difficult divisions.

With the inauguration of Mr. Gustafson as "Safety Mayor of Swifttown," the election of his successor was immediately under way. During the six months following conclusion of the first election each day that a voting division goes without a single lost time accident is to count as one vote for the employee representative from that voting division as next mayor of Swifttown. Reports are posted twice a month and show the standing of each candidate up to the time of posting. Notice is sent daily to the employee representative in whose division an accident has occurred, giving him the details of the accident, so that he can investigate and remove the cause.

The methods used in preparation for these contests and for keeping up the enthusiasm while they lasted, probably do not offer anything new. There were group meetings held with inspirational talks, slogans were posted and the plant publications got out special editions, devoted

wholly to the campaign. We must have special concern to convert what we learn in planning, organizing, and training leaders and workmen, into something permanent. We recognize that the greatest value of special, intensive safety drives for a week or a month is found in demonstrating what can be done by organized effort. We lose the value of the campaign if we relax at its close and fail to conserve what the experience of these weeks of special attention to promoting safety brings to us. Here is a big field of effort for the safety organization. Looking ahead, the safety committee should begin well before the conclusion of the campaign to lay their plans and be getting pointers which will indicate ways best calculated to continue the work.

In preparing for and carrying on such a campaign we enlist every agency in accident prevention and utilize every factor necessary to its success. The safety committee must be brought to full strength in organization and personnel. A definite program of activities must be mapped and the efficiency of those already laid down gone over. Plant inspections, maintaining safeguards, proper use of accident reports, the cooperation of the doctor's office in determining the extent of the injury and getting the injured man back to work, are all important considerations. Securing and maintaining the interest of the management, superintendent, foremen, and workers, providing programs and speakers for mass meetings, material for bulletin boards, instructing the new workmen, preparation of printed matter, distribution of rule books, etc., must all be arranged for.

Campaigns Were Kept Before the Management

We kept our campaigns before the management, not only the plant managers, but the directors, by sending each of them at regular intervals a mimeographed report showing the standing of the plant. At the conclusion of the 1925 campaign Mr. Louis F. Swift, president of our company, wrote a letter to each of the plant managers as follows:

"We are pleased with the spirit shown at your plant in organizing and carrying on the Accident Contest during March. The good work done by your Assembly, Safety Committee, foremen, and employees, resulting in an improvement of 100 per cent and first place for Cleveland, should be a source of satisfaction to you, as it is to us.

"We note that you had no accidents during the month, and that the saving in money is quite an item, and these are important considerations, but not as important as the avoidance of injury. Swift & Company is deeply concerned to avoid all accidents and to preserve the lives and limbs of its employees.

"Very often there is a letting down after a campaign like this. Real progress is made only by continuous and consistent effort, and I hope that we may have an improving record of accident prevention for the benefit of the employees and the company."

This letter was signed by the president personally.

Four months after the close of the campaign a comparative statement

was sent to each manager showing the lost time accident frequency prior to the campaign and for each month subsequent, with the five months average, putting before him how his plant was reacting to the special drive. This report showed improvements over the period of four months prior to the campaign of all the way from one per cent to 60 per cent. The letter as well as the statement were passed on to the superintendents, and by them to the plant assembly and the safety committee.

The report demonstrated the value of statistics. Placing before a plant manager at such a time a statement showing his plant far down on the list could not help but stir him to action. He knew the figures were also going before the officers and directors and that they were showing a special interest in the safety work at every plant as a result of the campaign. The plants with a poor record were spurred to do intensive research into causes and analyze the record by divisions and departments. The poor showing of certain plants, which led to a closer analysis by divisions and causes, usually disclosed that someone—foreman or straw boss—was not thoroughly sold on accident prevention as an economic or humanitarian proposition. Laggard plants and laggard superintendents and foremen have been stirred into consistent safety boosters.

The Plant with the Poorest Showing Spurred Ahead

A result of this closer scrutiny of their methods during and after the intensive campaigns has been that some plants have shown a complete reversal in a period of a year. The plant with the poorest showing in the 1925 campaign was one of the five that came through without a lost time accident during the five weeks of the campaign of 1926. They have found the sore spots in their organization. Every plant, as a result of focusing so much attention upon safety, has given more attention than heretofore to all phases of the problem. They are doing more than ever to study the causes of accidents, to properly report and treat all injuries, and to see that each case is followed so that the injured employee is influenced to get back to work as soon as possible.

The various plants were asked to report on their impressions of the campaign, what benefits had come to them, and what plans for the future had resulted. Here is what one plant wrote, on investigating and following up of cases. This is a striking example of what can be learned by diligent investigation of a case where there is only the injured man's statement.

"We had two lost time accidents which happened off the plant:

"The first was a man in yard cleaning department who on his way home stumbled while getting off of street car, fell to the ground and caused contusion and bursitis of right knee. He first claimed it happened in plant, stating that he stepped in a hole, but on being questioned the second time he admitted that it did not occur in the plant. When questioned why he made a false statement, he stated that he thought he would not draw E. B. A. benefits if the accident had not happened in the plant.

"The second case was a man trucking the same as usual. He worked for several days when he hit his wrist against the wall very lightly and had not the wrist been sore it would not have caused even the slightest injury. He laid off from work three days and upon his return stated that he did it by scraping his hand along the brick wall while trucking a heavy load. After digging into the case a little deeper he admitted that the injury occurred at home and that he merely hit his wrist a light tap breaking the skin which, of course, was very tender. This man is a Mexican and hard to understand. When questioned about the false statement he stated that he didn't think it made any difference where or how it occurred.

"With these two cases in mind we believe we have learned a point which will be a great benefit to us in checking up cases in the future. We feel that this campaign has been a lot of benefit from the fact that the standings on the thermometer from day to day caused great interest among our employees, especially the assembly members, and consequently they became interested in safety first work.

Plant Managers Were Enthusiastic

"The assembly members figured a big part in this campaign as they were all determined not to be the first to go down. The determination together with the cooperation of the division men and workmen's safety committee saw us through the first 13 days before we had our first lost time accident.

"However, during this campaign we had 148 accidents as against 137 for March, 1924. This is accounted for by the doctor's office explaining that the employees are being more educated to the point where they are reporting to the doctor's office in every little case regardless of how small the injury might be. This was probably the reason for more infections and consequently more lost time accidents in 1924.

"As a result of this campaign, a feeling has been created among the employees which we believe will eliminate a great deal of lost time in minor cases. They seemingly realize that lost time accidents are a loss both to the company and the employee.

"With the intensive effort for the past month and the 'Certificate of Merit' campaign being pushed now, we believe we will be able to show a decided decrease in lost time accidents on our monthly report during the present campaign."

Another plant manager wrote as follows:

"We attach statement showing the results of our March campaign by divisions; also comments of our General Safety Committee. We are pleased to inform you that to date, during the month of April, we have had only one lost time accident, which indicates that the spirit of the March campaign is still being maintained, and we feel that the distribution of the Certificates of Merit will help us in still further maintaining this interest."

And still another plant wrote as follows:

"We have decided to continue on a competitive basis at Fort Worth plant by showing the assembly divisions in daily and weekly comparison with one another. We will use different methods as may be decided upon from time to time to keep SAFETY constantly before our employees, and we are confident we will show a good decrease for the year as compared with 1924. We are enclosing a copy of *Safety Hints* put out to all employees April 1st."

And here is letter from the Omaha Packing Company:

"We are rather disappointed in not showing up better in this accident campaign but the reason is due to the small amount of accidents March last year. Also case of employees not reporting to the doctor's office on small scratches and cuts.

"We believe this campaign is working out very good at this plant, and we are arranging to put up a blackboard made up with a thermometer for each division which will show their standing.

"I am attaching hereto analysis of each accident that occurred during this campaign. You will notice that six of the seven accidents which occurred were due to carelessness on the part of the employees."

You will note the explanation and apology for the poor showing. This plant was the winner of the next campaign.

Not the least of the benefits we have derived from these campaigns is the stimulus and vigor imparted to our safety committees. As a result of their prominence in the campaign and bringing them to the front as an important cog in the plant machinery, membership on this committee has a new meaning. Placing this committee and their accomplishments before the entire plant force as an agency with large responsibility and the opportunity revealed of a chance to deal with a big problem, makes it attractive. The man in the parable while digging in his hard, stoney field came upon a rare and hidden treasure. We never know what talent may be lying dormant, what genius for planning new methods of reaching the careless workman.

Men are quick to respond when they are asked to compete. There is an appeal to pride in the division, if it is an inter-department contest, and an equal call to their pride as well as their loyalty in an inter-plant contest. This and the unique devices used to stir up interest frequently provide just the touch needed to supplement the everyday efforts of foreman, representative, and safety supervisor in winning a man for safety.

Better Safety Conditions Mean Better Production

CHAIRMAN SCHILDT: Is the production affected in all of these campaigns?

MR. BRAINARD: The question of production, while we know it is a factor, is rather indeterminate with us. I think as a general proposition that if you have better safety conditions, you will have better production. I don't think there was any slowing up of production in any of our plants. Our men are working under a wage incentive plan in practically all of these plants that were in the contest and you may be sure that when they are working under such a plan, they are not going to allow produc-

tion to slacken; and our experience has been that we have pretty good evidence from superintendents and foremen that when working under the incentive plan, there is no tendency to increase accidents, because when the production of the man or gang is affected by lost time accidents, it is brought home to them in the loss of earnings.

MR. MORRIS: How do you keep your plant managers informed of the money saving?

MR. BRAINARD: Largely by casualty insurance. That will bring it home to them quicker than anything else. They can tell from that in a general way. I think we have statistics at all plants showing just what the average cost is.

MR. BENJAMIN: In looking at it from a business standpoint, that is a thing I have had to do because I have had to be in a small plant. We have found that by taking suggestions from the employees it will help us. Those men bring up things that improve the efficiency of the production, which you could not expect them to bring up, and we let them go ahead and give them credit for those suggestions. Later on, if there is a promotion in sight, we look to see who is turning in those suggestions.

One Department with a Lengthy Safety Record

We have one department which has a safety record of having gone 21 months without a lost time accident. They increased production 22 per cent and reduced the cost 17 per cent. I think every man in that department received a raise in wages during that period. That one department proved that safety is a financial proposition. I know of one suggestion which was just a chance remark. It developed into enough saving of production cost to pay for our safety movement in that department for a year.

MR. SCHWARZE: Does your lost time accident record include any disability as a result of disease hazards?

MR. BRAINARD: If there are any, they are very rare. We have very few occupational diseases in our business. They do not enter into the final figures. Sometimes in our paint shop there are little hazards in the use of sprays and in the use of lead paints.

MR. BARR: I would like to ask Mr. Brainard, who draws up the plans for these contests? Are they submitted from the other plants outside of Chicago or do you have to be devising these plans all of the time?

MR. BRAINARD: No, these plans have originated at the various plants. Not one of our safety supervisors has made suggestions in reference to these plans. Of course we encourage them to do so when we do get a suggestion. We do have some men in executive positions on the plant assemblies who have a place on the Safety Committee and it usually was with some of those men that the plans originated.

MR. BARR: In your assembly, does that include the various divisions in the plant or do you subdivide any assembly in another town?

MR. BRAINARD: We have the main divisions of which there are about thirty in the Chicago plant and as few as eight in some of the other plants, but there is no subdivision of the main divisions.

MR. BARR: How are the men selected?

MR. BRAINARD: They are elected by the Safety Committee, or appointed by the chairman of the assembly.

MR. BARR: They are not selected by employee representatives of the assembly?

MR. BRAINARD: No, sir. The chairman of the assembly is appointed, but they keep a record of the representatives who have had positions on the safety committee and they alternate the appointments so that in the course of the year or 18 months each employee representative has had a place on the Assembly Safety Committee.

MR. BARR: The chairman of the Safety Committee, is he a general manager representative or an employee representative?

MR. BRAINARD: As a general thing he is a manager representative.

MR. BARR: As a general rule, does the safety supervisor sit in at the safety meeting?

MR. BRAINARD: Yes, but at most plants he does not act as chairman.

T. R. BICKFORD (Flint-Kote Co., Rutherford, N. J.): I do not belong to this Section, but I should like to ask Mr. Brainard a question. In your campaigns, do you count minor accidents that may never have been reported, I mean such injuries as slight scratches?

More Accidents Usually Mean Fewer Lost Time Accidents

MR. BRAINARD: Our campaigns had reference to lost time accidents, meaning the time lost beyond the shift in which the injury occurred. We have not taken into consideration accidents which might have made it necessary for the man to lose a little time on the shift where he was working, but would be back on the job again the next day. We do keep for statistical purposes the record of all accidents as well as lost time accidents. Our statistics show that the plants which have the greatest number of accidents reporting to the doctor's office, show the smallest percentage of lost time accidents. It shows conclusively that the better attention given to all injuries, the smaller the rate of lost time accidents will be. If minor injuries are given attention promptly and frequently, it will in a lot of cases prevent a lost time accident, but if not attended to it might run into a lost time accident.

We had a case not so long ago. A man working in the press room hurt his finger about 10 minutes before quitting time. Instead of going directly to the doctor's office he stopped to change his clothes and wash up. By the time he got to the doctor's office there was no one there, and his injury did not receive attention. He reported to the doctor the next morning in pretty bad shape, but it had progressed so far that four days later that man died.

That is what I want to bring out. The plants that had the greatest number of accidents reported to the doctor's office, have the best lost time accident records.

Of course, we all must recognize that in the time of campaigns the employees are going to bend every effort to keep the accident rate down.

If there is any evil connected with campaigns, that is it. You have to give them awfully close supervision.

MR. SCHWARZE: Have you had any unfair competition during your campaigns?

MR. BRAINARD: No, sir.

MR. COREY: I think the fellows have to be good sports like in any other contest of any kind. There is that definite appeal of sportsmanship to the contestant, as the plants are scattered over quite a range of territory.

MR. CAMPBELL: How many employees have you in the plant that won the battle?

MR. BRAINARD: About 124 employees.

MR. CAMPBELL: How long did the contest run?

MR. BRAINARD: About 112 days.

MR. MCCLELLAN: Did you start out by counting the frequency of accidents and totalling them all, and then later on change to counting the lost time accidents?

MR. BRAINARD: We have never counted anything but the lost time accidents. Counting the total number of accidents has never been a factor in our campaigns.

CHAIRMAN SCHILDT: The next item on the program is a paper by Mr. Wm. Campbell, Safety Inspector, The Graton & Knight Mfg. Co., Worcester, Mass.

HOW TO MAKE A PRACTICAL SAFETY INSPECTION

William Campbell, Safety Inspector, Graton & Knight Mfg. Company,
Worcester, Mass.

In carrying on an accident prevention campaign the organization of a local inspection service within the plant is of the greatest value. This is effective not only from the standpoint of eliminating accident hazards, but also from that of educating the personnel of the working forces along accident prevention lines.

Whether a plant be large or small, it is very desirable to have a definite organization with a regular time allotted for making inspections; otherwise, the work is likely to be done in a haphazard, inefficient manner, and the interest of the men will soon lag.

In our plant we have a general safety committee which consists of our general manager, master mechanic, superintendent, and assistant superintendent. They make inspections regularly, but are really "on the job" all the time as they travel about the plant—thus assuring themselves that all are working in harmony, and keeping in mind the welfare and safety of our employees.

The safety inspector is on the job all the time, and he makes a general inspection every Friday, so that he can fill out the superintendent's report for the week ending Saturday. On Monday morning he rings the sprinkler alarms which are on the top floors of all our buildings, the area of our floor space being twelve acres. To fulfill the requirements

of our master mechanic, Mr. Dahlin, the safety inspector must make an inspection once every week or he will soon be told he is slipping. The general manager, Mr. F. H. Willard, is sold on safety, and he holds his organization responsible for the welfare and safety of the employees. Everything possible is done to make the factory a safe place in which to work.

We now employ about 1,200 hands. Our labor turnover is very small, not exceeding two and one-half per cent per month, which indicates that a large number of our employees have been with us for many years. I myself have been with the company over 40 years. The general manager and general superintendent are both old employees, having started in the factory as errand boys.

The personal qualifications of a safety inspector are very important. He should have a good knowledge of machinery, and resourcefulness in solving the safety problems which arise. Above all, he should be able to work with the other employees and secure their cooperation without arousing antagonism; otherwise, safety recommendations are likely to be considered as a form of criticism by those to whom they are made, and it is essential that controversies and disagreements be avoided if this work is to be carried on successfully. It must be considered mutually advantageous by all, and for all, with the entire organization working together toward a common end—namely, safety.

The foreman is the logical safety executive for his department, and should be held accountable for any accidents of whatever nature happening in his department; also for the education of his employees, in the safety work. The safety engineer and safety committees can do little or nothing without the cooperation of the foreman and employees, and must depend upon the foreman for the education of the workmen.

The entire organization must be "sold" on the idea that accidents are an additional cost to production, as well as a cost in the living expenses of the employees. Accidents are just as much an additional cost of production as waste in material, break-down of machinery, or unnecessary waste of time, and much more important in relation to the efficiency of the employees, because a well safeguarded employee will be free from any sense of danger, and will turn out much better work than one working in a plant where safety has not been thoroughly sold to the organization.

The Safety Committee Checks Careless Practices

CHAIRMAN SCHILDT: Is there any discussion on Mr. Campbells' paper? There should be some questions and discussion.

MR. MORRIS: What does the safety committee do to check up on careless practices? The reason I ask this question is that I believe if every safety committee that is functioning today would forget machine guards entirely and go out through the plant and study careless practices and do nothing else for the next few months, we would see a great deal of improvement in the accident rate.

MR. CAMPBELL: We have made an organized effort in that direction. The State Labor Department and the insurance companies are all interested. The people who are making the machines are putting on the guards now and the safety committee can forget the mechanical side and study careless practices.

MR. BRAINARD: I think that is also true of the supervisors. They are on the job all of the time and could do a great deal to correct bad practices. In our organization the safety supervisor brings into the meetings of the safety committee a report of bad practices which he has noted. Sometimes he can correct them while on the job, while at other times he reports them to the safety committee, which meets twice a month. They are made a matter of record and they then are reported to the general meeting of the assembly; and always those matters are brought to the attention of the plant superintendent who is instructed on them. I think we all agree that what you say about careless practices is the most important thing right now.

Most Plants Are Believed to Have Modern Safeguards

MR. COREY: It was not uncommon a number of years ago to see machines unguarded, belts and different moving parts were exposed, and the first thing that was done was to guard those moving parts. Now, in all modern plants the machines are guarded with the latest types of guards, but with our machines all guarded we still have accidents. Most of them are, I believe, of a non-mechanical nature. The idea then would be to investigate why we have these accidents. In other words, we have to get away from the guarding of machines, and we have to think of something else that comes ahead of the guarded machine and that is careless practice, and I think that there is a big field to develop in that line.

MR. JULSEN: Mr. Corey just mentioned that we do not operate a machine without having it properly guarded. I don't know how the other packing plants work, but we have never been able to guard the head splitting machine. We have had one or two serious accidents on that machine and I would like to hear from some of these men as to whether there is a guard for this machine.

MR. COREY: When I spoke of proper guarding, I meant where you can practically guard a machine. We have machines that we have never found a practical way to guard as yet, but where we can guard a machine, we do.

MR. MCCLELLAN: I will try to answer Mr. Julsen's question. I have traveled through almost every packing house in the United States and I can truthfully say that there is no practical guard for the head splitting machine. The only way we will ever be able to guard them will be to change the design of the machine which is a very costly operation. The boys in the packing industries who operate the head splitting machines, split the head open in two halves so you can pick out the brains, but the machine is so constructed that you must get your hands in danger. There is no other way this can be done unless the design of the machine

is changed. Some day we will have to change. We do not have many accidents on that machine. In all my experience I do not recall but one accident in our plant. The head slipped a little in the machine and the man got his thumb taken off. The heads are not all uniform in size.

CHAIRMAN SCHILDT: I have a little note here which I think strikes the sentiment of the Packers and Tanners Section entitled, "Pass it along."

No matter how much accident prevention is discussed in committee meetings, unless the information is passed along to the man on the job, little will be accomplished. The objective, therefore, of the safety committee should be the purpose of disseminating safety and educational data to employees in organizing for the prevention of accidents.

We are apt to forget that the foreman is the one man responsible for the safety of his department and that the safety organization composed of the safety department and all committees simply represents a Service Department to assist the foreman in meeting his greatest obligation, that of the conservation of human life and limb.

Carelessness is a matter of habit and if you are going to get rid of it you must replace it with another habit, carefulness.

MR. McCLELLAN: Just before you adjourn I want to take the privilege of thanking the speakers for their papers. They were splendid and I think we all got some wonderful inspiration from them.

MR. CROMWELL: Before the meeting breaks up I would like to ask every one in behalf of our new chairman to give him all the cooperation during the coming year that you possibly can. It was awfully hard to get members out to this meeting and to other meetings. We want to get some new material into this Section.

Two Final Resolutions by the Section

MR. SCHWARZE: I would like to offer the following resolution:

RESOLVED, That we, as members of the Packers and Tanners Section, appreciate the remarkable services of the retiring officers for the past year. It has been very helpful to us all.

A motion was made, seconded, and regularly carried that the resolution be adopted.

MR. McCLELLAN: Here is a resolution that I want to appear in the minutes of this meeting:

RESOLVED, That we, as members of the Packers and Tanners' Section, request that the National Safety Council bend every effort this coming year to help the Packers and Tanners build up their Section and not to leave it to one or two people to do all the work. We want them to appoint a member to work with us.

(A motion was made, seconded, and regularly carried that the resolution be adopted.)

ADJOURNMENT

Paper and Pulp Section

New Officers of the Section

CHAIRMAN: W. J. PEACOCK

Northern Paper Mills, Green Bay, Wis.

VICE-CHAIRMAN: M. G. HOYMAN

Kimberly-Clark Company, Neenah, Wis.

SECRETARY AND NEWS-LETTER EDITOR: AMEIL UMBERHAM

Fort Howard Paper Co., Green Bay, Wis.

Committees

PROGRAM: M. G. HOYMAN, Chairman

Kimberly-Clark Co., Neenah, Wis.

ENGINEERING REPRESENTATIVE: A. P. COSTIGANE

Ontario Pulp & Paper Makers' Safety Assn., Ont., Canada.

REGIONAL DIRECTORS OF CONFERENCES, CONTESTS, MEMBERSHIP AND POSTERS:

ALVIN RECORD

International Paper Co., Chisholm, Me.

N. F. BARTLETT

Hollingsworth & Vose Co., Boston, Mass.

W. A. GLEASON

Hammermill Paper Co., Erie, Pa.

G. W. PHILLIPS

The Champion Fibre Co., Canton, O.

WALTER L. MEAD

Consolidated Water Power & Paper Co., Wisconsin Rapids, Wis.

ERNEST AUGUSTUS

Mead Pulp & Paper Co., Chillicothe, O.

R. S. TURNER

West Virginia Pulp & Paper Co., Mechanicsville, N. Y.

JAMES M. MURRAY

International Paper Co., Gatineau, Quebec, Canada.

October 26, 1926

W. J. PEACOCK, Chairman

Head, Department of Personnel, Northern Paper Mills, Green Bay, Wis.

THE opening session of the Paper and Pulp Section of the National Safety Council convened at 9:30 o'clock at the Book-Cadillac Hotel, Detroit, Michigan, Mr. W. J. Peacock, Head, Department of Personnel, Northern Paper Mills, Green Bay, Wisconsin, presiding.

CHAIRMAN PEACOCK: Gentlemen, I am going to suggest a form of getting acquainted before we go to reports or program. Let us have a general self-introduction. I would suggest first of all that you rise, one gentleman from each mill, tell who you are, then introduce the rest of the representatives from your mills.

(The members then followed this suggestion.)

DELEGATES IN ATTENDANCE AT CONGRESS

Adams Bag Co.—J. F. Grazer, Chagrin Falls, Ohio; Alton Box Board & Paper Co.—C. G. Patterson, H. C. Sackett, Alton, Ill.; American Zinc Co. of Tenn.—P. M. Arthur, Mascot, Tenn.

The Beveridge Paper Co.—O. E. Blanford, Indianapolis, Ind.; Bryant Paper Co.—Mrs. M. Buckingham, Kalamazoo, Mich.

Casualty Engineer—C. J. Strobel, Philadelphia; Champion Coated Paper Co.—Kenneth L. Faist, Hamilton, Ohio; The Champion Fibre Co.—T. L. Jamison, G. W. Phillip, S. W. Plott, Bob Varner, C. N. Wright, Canton, N. C.; Chief Sanitary Inspector—Alex R. White, Toronto, Ont., Can.; Consolidated Water Power and Paper Co.—Leo J. Barrett, C. E. Jackson, Walter L. Mead, J. J. Plzak, Wisconsin Rapids, Wis.

Detroit Sulphite Pulp & Paper Co.—Ernst Gaschwender, Detroit, Mich.; Director Safety Dept. The Celotex Co.—H. T. Bond, Marrero, La.

Esleeck Mfg. Co.—John L. Gibson, Stuart Winch, Turners Falls, Mass. Falls Mfg. Co.—Wm. Benninghaus, Hugo Boldt, H. A. Korth, Oconto Falls, Wis.; Fort Howard Paper Co.—Amell Ueberham, Green Bay, Wis.

Robert Gaylord, Inc.—Ed. Ahrenhoerster, St. Louis, Mo.; Great Western Paper Co.—E. A. Kennedy, Ladysmith, Wis.; Hammermill Paper Co.—W. A. Gleason, Jacob B. Lind, J. J. Little, Walter Packard, Erie, Pa.; Hercules Powder Co.—M. G. Milliken, Parlin, New Jersey; Hollingsworth & Vose Co.—Mat F. Bartlett, Boston.

Indemnity Ins. Co. of North America—S. J. Steinmann, L. G. Wood, Philadelphia; Industrial Laboratories, Ltd.—T. Linsey Crossley, Toronto, Ont., Can.; Interlake Tissue Mills Co.—C. Nelson Gain, Merritton, Ont., Can.; International Paper Co.—Daniel T. Meady, John Lundrigan, New York City.

Kimberly-Clark Co.—Edw. J. Goodman, M. G. Hoyman, A. W. Redlin, Neenah, Wis.; Arthur W. Hoffmann, Niagara, Wis.; F. A. Robinson, Niagara Falls, N. Y.

Lincoln Pulp and Paper Co., Ltd.—J. R. Leslie, Merritton, Ont., Canada. Marinette & Menominee Paper Co.—L. Larson, Marinette, Wis.; Mead Pulp & Paper Co.—L. O. Bonner, J. E. Collins, Chillicothe, O.; Michigan Mutual Liability Co.—Ed. H. Vaniere, Detroit.

National Carbon Co., Inc.—A. J. Herrin, Niagara Falls, N. Y.; Nekoosa-Edwards Paper Co.—F. H. Rosebush, Port Edwards, Wis.; Northern Paper Mills—W. J. Peacock, Green Bay, Wis.

Ontario Pulp & Paper Maker's Safety Assoc.—A. P. Costigane, Toronto, Ont., Canada.

The Paper Industry—A. Scott Dowd, Chicago, Ill.; Peerless Div.-Mead Pulp and Paper Co.—C. W. Twitchell, Dayton, Ohio; Port Huron Sulphite and Paper Co.—James J. Hastings, Port Huron, Mich.; Provincial Paper Mills, Ltd.—F. M. H. Cushing, Thorold, Ont., Canada.

The Richardson Co.—Wm. A. Hellemann, Melrose Park, Ill.

Sec., Safety Committee—Ben Wahl, Detroit, Mich.; Scott Paper Co.—Edward J. Gayner, 3rd, Chester, Pa.; Sorg-Oglesby-Smith Paper Co.—H. H. Faries, D. D. Thirkield, Middletown, Ohio; Standard Accident Ins. Co.—Edward W. Bidigare, C. R. Blackburn, Detroit, Mich.; Herbert A. Raseh, Milwaukee, Wis.; L. C. Long, Watertown, N. Y.; E. S. Shartzler, Utica, N. Y.

Tennessee Copper Co.—H. T. Harper, Copperhill, Tenn.; Travelers Ins. Co.—C. Fred Wolf, Hartford, Conn.

Union Bag & Paper Corp'n.—Stuart H. Brown, New York, N. Y.; United States Casualty Co.—O. J. Smith, New York City, N. Y.

West Virginia Pulp and Paper Co.—Walter D. Bauer, Tyrone, Pa.; R. S. Turner, Mechanicville, N. Y.

REPORT FOR OFFICERS AND COMMITTEES

CHAIRMAN PEACOCK: The first item on the program is the report of officers and committees.

May I speak a word informally for the officers? I do this, less in the nature of a report to the meeting than as a means of getting a record. I find that in the records of the meetings of the Section in past days a great deal has failed of historic note. What I have to say is for the use of future officers.

Following the meeting at Cleveland last year there was an informal gathering, a kind of committee of the whole, at which we canvassed the question of programs, contests, and Sectional activities, and after that there was a meeting of the officers of the Section. Thus the year's activities began before we left Cleveland.

The activities of the year that have occupied the attention of the chairman in the main might be listed under the head of program service with Mr. F. W. Ashe and the other officers. The program was built with Mr. Ashe as chairman.

Another activity occupying attention during the year was a voluminous correspondence.

First of all are the news letters. These news letters have been made as personal as possible and have built up friendships and contacts that have been valuable. A great number of personal letters have been written.

Another activity that has occupied the attention of the chairman has been the executive sessions of the National Safety Council. I have attended eight such meetings in Chicago and other places. Also, there has been a major activity which I would call Regional Conferences. Naturally our opportunity to set these things up has been at home in

the state of Wisconsin. Two such conferences have been held, and we were able to advise in a third conference centered in Erie, Pennsylvania. So we must include in the activities of the year not simply the Congress, but three other conferences that have been engineered from within this Section.

Try to get some idea of how many mills were represented in each conference. At the Green Bay conference, December, 1925, there were about 200 representatives of paper mills, foremen and others. At the Appleton conference held in September of this year there were 300 representatives of paper and pulp mills.

My conception of the chief problem of the Section, as it has been in my mind throughout the year, is the formation of a group spirit, a consciousness in the Section, if you please. We have tried to get you gentlemen to feel throughout the year that you belong to one of the major activities of the National Safety Council.

The news letters sent out by Mr. Umberhan have been very valuable toward this end. And with this problem of the formation of a group spirit in mind we have been majoring through the year on the safety contest. It has developed interest in safety in your mills, but above all things, I hope it has helped to increase this spirit of the group.

Part of the task of the Section is to get every mill present at a regional conference or at the annual meeting. At another time we are going to have presented to us the value of regional conferences in which the spirit, the speakers, exhibits and methods of the National Safety Council are brought to your own safety committees, and to your own foreman.

Will you keep these things in mind throughout the three sessions we are to have, and participate as much as possible in the building of a group feeling inside the Section?

We are to have reports from two committees at this time. A report from our Program Committee. Mr. Ashe isn't present. I am afraid he is confined at home on account of sickness.

We will have the report of the Poster Committee, by Mr. Gleason.

REPORT OF W. A. GLEASON, CHAIRMAN, POSTER COMMITTEE

W. A. GLEASON (Hammermill Paper Co., Erie, Pa.): Your Poster Committee had the power to collect the bulletins. (I say power because power was needed.) We were able to furnish the Section with 15 posters during the past year.

I want to appeal to you gentlemen, especially those of you who are in the contest, to send on your ideas to the Poster Committee so that we may get a number of Sectional posters. You all know the value of having posters particularly adapted to your industry, and I want to tell you, gentlemen, if you can place in your mill a poster which has at the bottom the notation, "Donated by Hammermill Paper Co.," or whatever company you are connected with, it will have much more effect than a poster made by some steel company.

One of the members yesterday cited the case of a man in his mill, a boss machine tender, who had worked in the mill at the trade for 37 years without an accident. That would make a great poster, not only for his own company, but for the rest of our companies. Post that in your machine room and you get a wonderful kick out of it. This year I hope that you will cooperate very greatly with the chairman of the Poster Committee, because we need more posters, at least three a month. We fell down on furnishing half that number this year.

CHAIRMAN PEACOCK: This year has seen the completion of a real contribution on the part of the Paper and Pulp Section to the literature of safety engineering, the Paper and Pulp Safety Code. I think you will want to meet members of the committee that had this matter in charge. Mr. Altman was chairman, he isn't present; Mr. Costigane is present. Let's get a good look at you on your feet, Mr. Costigane.

Personally I feel that these gentlemen have put the Section on the map. Certainly the government has recognized what has been done by them.

I am going to take the liberty of turning the meeting over to the vice-president of the Section, Mr. F. H. Rosebush, who will announce the speakers.

(Vice-Chairman Rosebush took the chair.)

CHAIRMAN ROSEBUSH: It is a matter of principal comment to have so many representatives of paper mills here this morning. It certainly is the earnest and sincere desire of your committee to make this Section so worthwhile that not only will you men return but you will also bring members of other mills to these sessions.

The first speaker of the morning is Mr. G. W. Phillips, of Canton, N. C.

THE A B C OF PAPER MILL SAFETY ORGANIZATION

G. W. Phillips, Champion Fibre Company, Canton, N. C.

When we speak of the A B C of Paper Mill Safety Organization, we mean of course, the fundamentals of organization or the best way to begin. Although I may not be able to tell you the best way, I shall endeavor to give you a few suggestions which seem to me are very important in organizing for accident prevention, and should be given consideration.

You understand, of course that conditions vary somewhat in different plants, therefore no set rule can be laid down or followed.

It is generally conceded, I believe, that the accident problem involves three essential activities: safeguarding, education, and engineering adjustments. To secure the best results, it is necessary, of course, that the highest measure of cooperation exist between the management and the worker.

The management must be thoroughly "sold" on the value of safety work in the plant. In other words, safety must have an equal place along with production, financing, etc. Don't make it a kind of "side issue," a welfare

proposition. Every employee must understand that it is a business proposition; that safety is as much a part of their job as any other duties. If the management is not in earnest, the workers will not be.

In organizing for safety, it is absolutely necessary that one man should direct all of the safety activities. The departmental superintendent and foreman are interested primarily in production. Therefore if the safety of the plant is left entirely to them it is apt to be neglected in the interest of production.

We have long since learned that to accomplish the best results in any enterprise, especially in accident prevention, a certain amount of organization is necessary. Now, I do not mean, of course, that there should be a lot of unnecessary "red tape stuff," but with the right kind of organization I am sure that a better spirit of cooperation can be developed.

There should be at least two committees, an executive and a shop committee. The executive committee should be composed of the manager and superintendents from each department of the plant, together with the safety director. This committee should meet once a week to discuss and act upon all safety problems over which the shop safety committee does not have jurisdiction, and consider safety suggestions and recommendations for the prevention of injuries. In other words, this committee should act as a clearing house for all safety ideas and activities and follow them until disposed of.

This committee should also decide all questions of operating methods which affect the safety of the workers; decide on standards for guarding machinery and equipment, standard operating policies, safety rules, and so on.

The safety engineer should submit to this committee a report of each injury causing lost time, together with a suggestion for the prevention of a recurrence of a similar accident.

Shop Committee

A shop safety committee should be composed of either foremen or workmen from the various departments of the plant. This committee should consist of at least five members and should meet each week. The duties of the shop safety committee should be:

1. To make inspections of the plant for unsafe conditions and practices, and submit a report to the safety engineer.
2. Help create a safety "atmosphere" in the plant.
3. Instruct the workmen in safe methods of doing their work and discourage unsafe practices.
4. To investigate all serious accidents and near accidents and make a report with recommendations.
5. Help to encourage the cooperative spirit between the management and the workers.

The size of this committee will depend upon the size of the plant, but should of course consist of enough members to insure a variety of ideas and opinions; however, not so many that all members will not have a

chance to express themselves in the short space of time allotted for the meeting, which should not be more than one hour each week.

As to the election or selection of this committee there is a wide difference of opinion. Personally, I favor appointment by the superintendents of the various departments. When the committee members are chosen by the elective method, there is danger of the wrong men being chosen. Members who are not enthusiastic for safety, or who do not harmonize in a safety committee, will be a hindrance rather than a help. All members of this committee should be selected with a view of rendering the best service. It is a good idea to change the members at regular intervals.

Experience has shown that the most productive field now open to development is that of education—that is creating and maintaining interest in safety.

A Definite and Concrete Program Essential

To accomplish worthwhile results in safety education, I believe that a definite, concrete program is absolutely essential. I do not mean merely posting bulletins, placing danger signs or formulating a lot of safety rules, all of which are of course more or less necessary; but there should be a program of instruction covering the hazards of each particular job, followed by a convincing argument why employees should make safety their first consideration.

All dangerous places and equipment should be guarded and made reasonably safe, but we should always bear in mind that "a careful employee is the best safeguard."

I am convinced that in the plant where men are taught to play safe, there will be less accidents without mechanical safeguards, than there will be in the plant where all machines and dangerous places are well guarded and the employees disregard safe practices.

Remember, careful workmen are not born, they must be taught to observe the rule of safety. The most effective method perhaps is "precept upon precept, line upon line, here a little there a little," or in other words a constant and everlasting repetition of the message of caution. It may require the patience of Job, the wisdom of Solomon and the persistence of a book agent, but remember that life and time are at stake and we should put forth every effort possible to prevent injuries.

Department superintendents must be convinced that supervision plays an important part in the elimination of accidents, that they are responsible to a large extent for accidents in their departments, just as they are held accountable for production, and that the safety of their men is a real part of their operating problems. The foreman and workman must also be "sold" on safety. All of which can better be accomplished through the medium of an organization.

All safety committees have an educational value, especially for the men who are appointed to membership. Committee service is the best and sometimes the only means of arousing and holding the interest of the men in safety and thus securing from each the necessary cooperation in his own department. Such interest is absolutely essential for maximum

success and can be secured only when each man is completely sold on the safety idea.

In closing, I want to emphasize the fact that you will be disappointed with results if the safety program is not wholeheartedly and enthusiastically supported by the general manager and superintendents. Half-hearted interest will mean failure, therefore remember you can not fool the workers. If the management and members of the safety committees are not in earnest and enthusiastic you can not expect the workmen to be.

The Connection Between Safety and Production

CHAIRMAN ROSEBUSH: Mr. Phillips has given us some fine things to think about and discuss. The first thing for your consideration is Mr. Phillip's point of safety and production. I wonder if there aren't some mill managers here or members of the management of some companies who would talk on safety and production.

The question is this: Do you men really believe that there is a connection between safety and production, and what is that connection?

H. C. SACKETT (Alton Box Board & Paper Co., Alton, Ill.): The part, I take it, that safety plays in production is keeping an organized force on the job all the time. Of course, aside from your general turnover, an organization that can go along with the minimum amount of accidents actually receives a greater production due to the fact that they have the same organization on the job day in and day out.

M. G. HOYMAN (Kimberly-Clark Co., Neenah, Wis.): That question as a rule many times applies to what effect safety campaigns have on production. I remember one time when we had a contest (which we have nearly all the time), taking men out to put on various stunts from the departments; and the question arose as to what effect that had on production, putting so much time on the campaigns. I inquired from some of our production heads and found two different plants, which at the time were putting the most intense effort on safety and taking a great many men off the job to help on safety committees and on the programs, yet they had their greatest production and broke all records during this safety drive at those plants.

H. T. BOND (Celotex Co., New Orleans): We have had our safety campaign on for about two years. The point we have found of greatest value is that the men work with better spirit and are more contented, more eager to make good on the job. That helped out considerably, better morale, better discipline. It was easier to enforce discipline among the men after the safety campaign started. Production has increased some, too, and we lay it to the safety organization.

CHAIRMAN ROSEBUSH: I would like to suggest this question: Do you believe that the teaching of safety brings direct results in production? Do you realize that if you teach men safety you are teaching them those characteristics of carefulness, precision and attention to business that not only make a good safety man but that have a direct result in getting out more tons of paper?

We will pass to the next paper, which will be delivered by Mr. E. A. Kennedy, of the Great Western Paper Company.

APPLYING SAFETY ORGANIZATION TO THE SMALL PLANT

E. A. Kennedy, Great Western Paper Company, Ladysmith, Wis.

So much has been said and written relative to organizing for safety that anything I can tell you will be merely a repetition of what has been said and done. Mr. Phillips in his paper covered thoroughly the reasons for organizing and how to organize.

Another thing we have to offer is a very excellent pamphlet entitled, "An Industrial Safety Program to Fit Your Needs," put out by the National Safety Council, something that covers every foot of ground relative to organization.

The question arises: Can these points of organization be applied to a small plant? Why not? I could pick 11 men in this room and call them a football team but that would be rather flattering; they would not be a football team until they had some sort of organization.

The same thing applies to a small plant as to a large plant. Your large plant, I might say, is Kimberly-Clark with a central organization. They have a number of mills, but, as I understand it, each mill is an organization within itself. Mr. Hoyman this morning said they had one mill with 27 men. Has that mill an organization within itself? There is one example of what an organization can do within a small plant. They look after their own safety.

The dictionary defines "organization" as "a number of individuals systematically united." Organization deals with men rather than with things. In its relation to accident prevention, organization has been symbolized as a three-legged stool in which the management, operating executives and workers represent the three legs, each being dependent on the other two to perform their functions. Any two legs are useless without the cooperation of the third. The safety director is the block that retains the legs in a normal cooperative and working position, and gives the whole stability.

Incidentally I might add that the safety director serves as the block on which everybody sits.

It is not so many years ago that paper mills were dumping practically all their white water into the river. Shrinkage was something we knew about but paid very little attention to. Nowadays the mill which has a large shrinkage is a back number. So with safety work. I can recall just 15 years ago when we used to go to a man when he got hurt, before he left the mill, and find out how he got hurt. We would do that because we had to turn in the report to the Industrial Commission. Now safety organization is not guess work. It has been perfected in any number of plants. Safety organization is necessary and it is just as necessary in a small plant as a large one.

Mr. Phillips brought out the fact that one man should be picked as a safety director. If you leave safety work to anybody and everybody, it is nobody's business. One man should direct the safety work in every plant, regardless of its size. (The larger the industry, the greater is the need for a safety director trained in the personal and technical problems of accident prevention. In a small plant this man may have other duties also.)

Our plant employs in the neighborhood of 250 men. We have a safety organization, based on this pamphlet issued by the National Safety Council. We have no full-time safety director, but he has a great deal of other work to take care of.

Here is a short outline of what our organization consists of:

Details of a Safety Organization

We have the safety director and we have what we call our foremen's club. It is practically the same as what you call a general committee. It includes all the foremen throughout the plant; we have 19 foremen. Every man in that foremen's club considers himself a safety director of his own department. Within this foremen's club we have an executive committee made up of the officers, that is, president, vice-president, secretary and three members of the inspection committee, which makes an executive committee of six. The president of the club appoints this inspection committee from members of the foremen's club.

Within each department a foreman appoints an inspection committee for his department. This inspection committee, the department inspection committee, makes an inspection once a week. They post their report in their department. The inspection is gone over by the foreman; he endeavors to remedy all suggestions made by the inspection committee and crosses them out as they are made. The safety director, when he goes through these departments, looks at these slips and when he finds something has not been taken care of he can take it up with the foreman. The inspection committee makes an inspection once a month, and foremen directors make an inspection once a month. We have monthly meetings of the foremen's club, but at their last meeting they decided that once a month was not enough. They are going to have a meeting every two weeks.

A year ago we organized for safety work. Prior to that we did not know what it was to have a month without a lost time accident, but since organizing we have had four months this year without a lost time accident, and in other months we have cut it down to where we had one minor accident. We have had one fatality this year.

N. F. BARTLETT (Hollingsworth & Vose Co., Boston, Mass.): Do these inspection committees look after their own departments? You wouldn't have a member of the finishing room go into the machine room to make inspection of their reports?

MR. KENNEDY: We have tried sending men from one department to another to make inspection. Now we send men to different portions of

their own department. A machine tender will inspect another machine besides his own.

I will mention an instance along that line. On our number three machine they had a roller cooler. The bottom of that platform had been missing. It was a very dangerous thing, and I waited for the inspection committee to make a report, but the members of this crew never reported that step missing. They had always stepped over to miss that last step. But when the man from number two machine went over it, one of the first things he noticed was that the step was gone and he reported it. A short while later we had it remedied.

EDWARD J. GAYNOR (Scott Paper Co., Chester, Pa.): Is it the tendency, Mr. Kennedy, for your inspection committees, to recommend the guarding of machines and the spending of the company's money, or is it their tendency to push the education idea?

MR. KENNEDY: These inspection ideas, when we started out, were to give the men in the department something to do. I think you have found that if you want to get a man interested in safety work, or any other work, you should give him a job. It was an educational proposition in the first place. But we find they make suggestions for guarding and they talk it up. It has aroused more interest in the department. They suggest guards, but if their suggestions are not feasible, the foreman will explain to them why the suggestions are not feasible. There is no suggestion ignored; we try to explain to him why his proposition is not feasible.

Departmental Inspections One Hour Each Week

KENNETH L. FAIST (Champion Coated Paper Co., Hamilton, Ohio): Do you allow the departmental inspection committee a certain amount of time each week?

MR. KENNEDY: We allow them an hour during the week.

A. W. HOFFMANN (Kimberly-Clark Co., Niagara Falls, N. Y.): I would like to know where you draw the line as to who constitutes a foreman?

MR. KENNEDY: A foreman is any man in charge of the department. That is a ticklish question, I grant you.

MR. HOFFMANN: Do you consider a machine tender a foreman, or a head grinder a foreman, in this club you have at Ladysmith?

MR. KENNEDY: We have three pulp mills; one at Ladysmith, one six miles farther down the river in charge of one man, another 12 miles down the river in charge of another man. There are three men in charge of those three pulp mills. They are members of our foremen's club, but every time we have a meeting the foremen of the two lower mills bring the two machine tenders that are not on tour with them to the meeting. These wet machine tenders are not members of the club, but they are brought to the meeting to instill in them safety organization because they really are foremen in absence of the first foreman. You might say the first foreman is the first sergeant, the other two are under sergeants.

MR. HOFFMANN: I think that is a good idea.

MR. KENNEDY: They have no vote nor power, but they attend the meetings of the foremen's club.

CHAIRMAN ROSEBUSH: Do you have present any members of the management, or is it confined to foremen?

MR. KENNEDY: The safety director represents the management at all meetings and no members of the management attend the foremen's club unless they are invited by the club.

CHAIRMAN ROSEBUSH: Why do you exclude members of the management?

MR. KENNEDY: In the first place, we have found that in the presence of the superintendent and managers, the foreman would hold back, he would not express himself. We have gotten a number of things the men would not have brought out if their own particular boss was on the job at the time.

A. P. COSTIGANE (Ontario Pulp and Paper Makers' Safety Association, Toronto, Ontario): What discussion takes place in that club?

MR. KENNEDY: The discussions become public property. Whatever they say at that meeting, the manager and superintendent gets a copy of; each member of the foremen's club gets a copy.

Committee Members Are Rotated Regularly

MR. STORLE (Philadelphia, Pa.): Do you rotate your safety inspector every three months?

MR. KENNEDY: The general inspection committee serves one year and the committees within each department change every three months. New members are appointed on the general inspection committee by the new officers.

W. A. GLEASON (Hammermill Paper Co., Erie, Pa.): I would like to have you bring out the point that you mentioned to me yesterday, that when you make your inspection the foreman sends three men with you to make repairs, etc.

MR. KENNEDY: In one department we have a superintendent who lost a leg in the mill. He was caught in a pulley and was just thrown around and his leg caught on a concrete pier and was shorn off. We have a fine support for safety in this superintendent. When they make an inspection of the mill, the foreman and superintendent know I am going to make an inspection within that week. I start out to make that inspection and this superintendent has three men of his repair crew to follow me around. It is not my suggestion, however. The minute I make a recommendation regarding anything in the plant, one man drops off and that is fixed. By the time I have dropped the third man, the first man is back on my trail again. I never lose him. I have had the finest sort of cooperation from that superintendent.

JAMES J. HASTINGS (Port Huron Sulphite & Paper Co., Port Huron, Mich.): Are your safety directions carried out on recommendation of the foreman, or the committee men? Does he see that the work is carried on or merely see that it is crossed off the recommendation?

MR. KENNEDY: The inspector himself sees that it is carried out.

MR. HASTINGS: The reason I asked that, I have found that a committee man would recommend a thing, the foreman would cross it off, and say the thing was not necessary.

MR. KENNEDY: We have the safety inspector because we do not want the foreman to slight anything. If a man is dissatisfied with the way he has been treated relative to a suggestion, we want to find it out and set him right, because the dissatisfied man is going to ruin everything for you in a short while.

CHAIRMAN ROSEBUSH: Is your safety director responsible to see that the work is done after it has been recommended?

MR. KENNEDY: Yes, if it is feasible.

CHAIRMAN ROSEBUSH: Is your safety repair man under your safety inspector?

MR. KENNEDY: No, that is done by the millwright's or master mechanic's crew, and carried out.

STUART H. BROWN (Union Bag & Paper Corporation, New York, N. Y.): Mr. Kennedy, I was very much impressed by your reference to the fact that the minutes or recommendations of the safety committee are posted in the department of the foreman to have his attention and be crossed off at the time they are finished. That is rather a new one on me and I think it is a very splendid thing. Does that safety inspector make a report to you of these various items that have been completed?

MR. KENNEDY: No; at first we had them send these written reports in to the safety director, but the safety director in our plant has other work to do. We found he was swamped with these inspection reports, so we finally decided they should be posted in a place where everybody could see them, and the safety director makes it a point to go through the plant to look over all these reports.

Safety Education is Emphasized

MR. BROWN: Another thought occurs to me as to whether or not the matter of safe practices, or the abolishment of bad habits, takes any part in your committee discussions.

Some committees I have seen recommend guards for this and guards for something else, and everything they see must be guarded, and it runs into a lot of what I consider unnecessary expense, and they lose sight more or less of the fact that the modern view of eliminating accidents is largely a matter of safety education, and under that heading I was moved to ask the question if the matter of preventing accidents by safer practices or the elimination of bad habits of doing things, forms any part in your discussion.

MR. KENNEDY: Yes, each accident of the previous month is brought out at these foremen's club meetings and the accident is discussed, and in the course of discussion one or more men make the remark, "We still have accidents. My suggestion is that every man when he punches the clock, put on his own particular guards." That brings out the thought that safety education is something we have to stress.

Our paper machines were a source of accidents. We had any number of

them prior to our organization, but we have not had an accident on any of our paper machines since organizing, that is, in the last nine months.

Now we find that men bring up things during the month. The foreman usually makes a note of it and it is brought out and discussed at the foremen's meeting. In that way we have eliminated a number of unsafe practices which were current before.

EDWARD J. GAYNOR (Scott Paper Co., Chester, Pa.): Is your foremen's club interested in anything else besides safety work?

MR. KENNEDY: We take up matters of safety and fire prevention.

J. R. LESLIE (Lincoln Pulp & Paper Co., Merritton, Ontario): What is the limit of authority vested in your safety director to carry out suggestions made by your safety committee regarding expense?

MR. KENNEDY: The management, from the first meeting of the foremen's club, stated right from the shoulder that it was absolutely behind the foremen's club. Any suggestion they make that can not be approved calls for an explanation as to why, either by the safety director or by the management.

MR. LESLIE: You mean by that you would refer suggestions to the management before they were carried out?

MR. KENNEDY: Yes, sir.

MR. PEACOCK: Referring back to Mr. Gaynor's question, Mr. Hoyman might have something to say regarding other matters being considered by foremen. Your foremen's club takes up matters of waste, economy, etc.?

Safety and Production Discussed in Meetings

M. G. HOYMAN (Kimberly-Clark Co., Neenah, Wis.): Yes, we have enlarged our plan. For two years, every Friday, at 11 o'clock we meet. Our Kimberly mill has about 1,000 people. All the foremen, superintendents and department heads meet on safety. That works very well now, because the men know things that ought to be corrected. The superintendent who has the power to correct it is there, and anything that comes up is supposed to be handled the next week.

But I started to say we have since worked in production and other things. Twenty minutes or half an hour is allotted to safety and then we discuss production or any other pertinent matters in this same meeting.

MR. KENNEDY: That is the spirit I carried back with me at Cleveland last year after talking with Mr. Hoyman and other Kimberly-Clark men at the meeting. We had a case before the Industrial Commission, a case of hernia, a man in our plant claiming to have hernia. We had seven men who reported to the office that they wanted to go on the stand as witnesses to the fact that this man had not been hurt in the plant. That was something unheard of before we started safety work. It just goes to show how far the safety spirit has got down to the rank and file through our safety organization.

MR. WOLFE (Travelers Insurance Co.): There is one thing I don't quite understand, that is about the management injecting their influence

in this organization. As I understand it now, the head man is really the safety director.

MR. KENNEDY: Yes, and then you have the foremen's club to discuss these different problems.

MR. WOLFE: I can see very well that you have your foremen interested and with all that cooperation you are going to have success, but let's assume another case.

I was taken to a plant last week where they have a somewhat similar arrangement. They have a safety director and they have the foremen's committee. As I understand it, most of the foremen in this committee razz each other when they get together. Sometimes when a foreman criticizes or points out that he was sort of responsible for an accident he comes back with a slam. While the safety director has authority to order improvements, he doesn't seem to govern this situation that has arisen between the foremen. What would you do in that case if it arose in your plant?

The Management Not Actively Interested in Safety

MR. KENNEDY: Is the management of that plant in favor of safety?

MR. WOLFE: He is in a way, but he seems to be so busy he leaves it to the safety director and foremen.

MR. KENNEDY: I think there is your answer.

MR. WOLFE: I appreciate that, but I was wondering what you would do?

MR. KENNEDY: I don't think any foreman, if he knew the management was in favor of safety, would deliberately get up in a foremen's meeting and razz, as you say, some other man because the other man made a suggestion he didn't like.

MR. WOLFE: Is this safety director a man of authority?

MR. KENNEDY: I don't know. I happen to be the safety director.

MR. WOLFE: If you found a foreman that wasn't interested, would you discharge him?

MR. KENNEDY: No, sir, I would not; I would take it up with the superintendent. The safety director has no authority to discharge any man.

G. W. PHILLIPS (The Champion Fiber Co., Canton, N. C.): I seem to have had a very similar experience to that the previous gentleman spoke about. I know when we first formed the safety committee we had several foremen on the committee. We found that practically all they did on the committee was to razz each other. After two meetings I formed a new committee with very few foremen and some workers, and then just let these foremen slide for a while, gradually educating them to the safety habit. Recently I put two of these foremen back on the committee and I find they are right with me now.

L. J. BARRETT (Consolidated Water Power & Paper Co., Wisconsin Rapids, Wis.): I wonder if the seven men who volunteered to witness in the case of hernia, knew this man had been ruptured.

MR. KENNEDY: Two of them testified that he had been ruptured before he entered the employ. Others testified that the man never worked hard enough to get hurt. At the time he claimed he got hurt these men volun-

tarily offered to testify to the fact that there was nothing there at the time that could have hurt the man.

MR. PEACOCK: What was stimulating their interest in offering to testify this way?

MR. KENNEDY: The safety idea had gotten to these men. A lost time accident would hurt their department, and the men felt that this chap was trying to slip something over on the company.

MR. BARRETT: Would it be a fair question to ask what the decision was by the Industrial Commission?

MR. KENNEDY: It was thrown out.

KENNETH L. FAIST (Champion Coated Paper Co., Hamilton, Ohio): Do you have a physical examination of your employees when they enter the service?

MR. KENNEDY: No, sir, we do not.

MR. FAIST: I wonder if that would not have eliminated that case in the first place.

MR. KENNEDY: It undoubtedly would have, but at the present time we have no physical examination.

CHAIRMAN ROSEBUSH: The last speaker on the program this morning is to talk on "The Value of Medical Examinations." It is quite a problem for the small mills, and you are all interested in it. I know you all feel the need of having medical examinations. Perhaps how that can be handled will be touched upon by Mr. Robinson, Kimberly-Clark, Niagara Falls, N. Y.

THE VALUE OF PHYSICAL EXAMINATIONS IN INDUSTRY

F. A. Robinson, Employment Secretary, Kimberly-Clark Company,
Niagara Falls, N. Y.

The time is at hand when the modern industrial plant must conserve all waste in order to live, and if we let our "human machine" run down are we not overlooking the possibility of a big saving?

The "human machine" costs us more than any mechanical mechanism we have. I have been informed that the wages paid to industrial workers, in the average plant over a period of four years, equals the cost of the plant. Just think of that!—in the short period of four years the average plant pays out to the "human machine" the equivalent in money of the entire building and machinery. We go on painting, repairing and inspecting the building, but our "human machine," which costs us the most, is neglected. After the four years the factory still stands and the machinery keeps on operating for years to come, thus making the cost of the mechanical machine considerably less than the "human machine," but the "human machine" gets the least attention.

I think you will agree with me that the general tendency of industry today is to develop men for tomorrow and that the progressive, alert, keen, ambitious worker of today is the foreman of tomorrow and the executive of the future. But can we develop men to such a degree if

they are not in the best of health? In most cases the answer is "no," and in others, "it is possible but improbable," for a healthy mind lives only in a healthy body.

The only way to know whether this body is in good physical condition is to have a thorough check-up made by a competent physician. If we go into our development program without such health service, we are gambling our money; for we may be spending considerable money and time trying to develop men to the high degree of proficiency at which we have aimed, and suddenly find out that the individual has to leave us for a sanitarium, or for a climate more suitable to his health, a condition which should have been known years ago.

Companies are judged by acts of individuals and individuals by their own acts. Do individuals act normally when the body is not in A-1 physical condition? No, is the answer, and you know it to be true. Then it is to the advantage of both company and employee to have medical service.

Build Leadership in Men With Healthy Bodies

You will grant me, I am sure, that the best promotion policy is to fill all vacancies from within the organization, whenever possible, but if a man is ailing, or slow, or not steady, due to physical trouble, he will not qualify; and here again medical service would have eliminated him in the first place from employment, or helped him to correct his trouble and thus made him a desirable candidate for promotion.

If you desire leadership tomorrow, you must build it today in men of healthy bodies. When a man is ailing in any way his mind is not on his work; it is divided between the two.

It is only fair to industry in these days of liberal compensation laws to know what an employee's physical condition is before he is given work. I have hired men who appeared robust and looked every bit the men for the job, yet the doctor found them to be afflicted with "T. B," "high blood pressure," "heart trouble," and other defects that disqualified them. These are cases where the company and our Mutual Benefit Association were saved the taking of an unjust chance.

I can quote you one case where a man upon entering our employ had defective sight in one eye. He was later injured by receiving a blow on the forehead just over the eye and he later claimed defective eyesight as a result of this blow. His doctor found defective sight and stated that it could have resulted from such a blow, but we were able to prove through the record of his examination at entering our employ that the defective sight was present at that time and the case was dismissed, with a saving to the company of about \$600. I could quote a number of similar cases, as can anyone having to deal with compensation cases where there is physical examination upon entering the employ of the company, where the company has been saved a considerable sum of money.

The employee benefits by such medical service also. Whenever we

make an examination the doctor gives the employee, or prospective employee, a card stating thereon his ailments and advising him to consult his own physician, or a specialist, as the case may be. Many of our employees have used this service to their advantage by having their defects corrected. As you know, good eyesight is a necessity in the paper industry to distinguish the various colors, etc., and a color-blind man, or one with poor eyesight, would soon get the company in bad as well as himself and thus retard his promotion.

Much emphasis has been placed in the past upon safeguarding all hazardous machinery, equipment and conditions. The importance of this factor in accident prevention can not be overestimated. But let us bear in mind that when a plant has been 100 per cent guarded we have only insured against the occurrence of 10 per cent of the preventable accidents. We are not safety boosters when we put men to work with any ailment that might be the means of causing an accident. It is not just to the man or the company, and the only way we are going to find these defects is through physical examinations. I do not say that we should never employ people who are not 100 per cent physically fit; but I do say that if his trouble can be corrected and he is willing to have it corrected, then he should be given a chance.

It might be well, here, to consider some of the objectives of physical examinations, which are:

Six Objectives of Physical Examination

1. To ascertain the exact physical condition of employees at time of hiring.
2. To prevent contagious diseases from getting into the factory and being spread among the present force.
3. To place workers in jobs for which they are physically fitted.
4. To prevent workers in poor physical condition from entering the factory, where they would be a danger to themselves, others, and property.
5. To use the information learned through the examination for future follow-up to better his physical condition and make better material for promotion.
6. To prevent workers being transferred to jobs for which they are not physically fitted.

A close study of these six objectives will convince you that physical examinations at entry and periodical re-examinations are of mutual benefit to employee and employer alike.

At the Niagara Falls factory of the Kimberly-Clark Co., we have such examinations and we do not reject every prospective employee because of some minor ailment. Our medical examiner classes them as follows:

"A"—Those physically fitted for any employment.

"B"—Those fitted for any employment, but who have minor defects.

"C"—Those having more important physical defects which would permit them to work in only certain occupations.

"D"—Those physically unfit for any employment.

To get the best results from such service the employee should have just as much privacy as he would have should he go to the doctor's office. The service department should follow up all employees hired with a view of having their physical defects corrected. In our particular case any employee under 50 years of age may become a member of our Mutual Benefit Association, which costs the employee a very small premium in proportion to the wide scope of the policy; and after a six months membership a number of ailments can be corrected, for the cost of which the association will stand from 50 per cent to 90 per cent. The employees appreciate this and make use of it.

Statistics Gathered from the Physical Examinations

Our examination goes into the applicant's past physical condition relative to the diseases he may have had. This information, we find, is of great help to our nurse in keeping close watch on the employees and preventing any recurrence, if possible, while in our employ.

In 1925 we examined only female help, and out of a total of 288 examinations 16 were rejected, or a total of 5.6 per cent. Exactly half of these rejections were conditional, meaning that any time they had their defects corrected they would be employed. The other half were permanent rejections.

In 1926 we examined both male and female applicants. Of the total we found we had 6.3 per cent rejections. Out of the female applicants we had 4.2 per cent rejections and 7 per cent rejections out of the male applicants. One per cent of the total are temporary rejections, leaving a total of 5.3 per cent permanent rejections. It is interesting to note that we had a smaller percentage of rejections among female applicants than we did the male. Further, we found that the average number of defects per man was 2.4 per cent while for the girls it was 2 per cent, which indicates that the female help is in better physical condition than the male. In this connection I might say that we are more strict in our female examinations than we are in the male because of the product they are working on.

We also find that the new employees accepted are in better health than the old employees. In other words, we are building up our organization on a better physical basis. We also find that the female help is more easily sold on the idea of correcting their physical defects.

In 1925 we examined 273 girls and found 119 in "A" class, this being a larger number than usual; but we account for this because of the fact that we had more applicants to choose from at the time of starting up the factory than we have had since. We found 209 defects out of a total of 273 examinations. Through careful check-up by our nurses we succeeded in getting 133 corrections, or 64 per cent of the total defects corrected, which probably put about 100 others in "A" class.

It is interesting to note that out of the total number of examinations, these were the outstanding defects:

35.7 per cent had nose trouble.
93 per cent had teeth trouble.
16 per cent had throat trouble.
12 per cent had skin trouble.
18 per cent had right eye trouble.
16 per cent had left eye trouble.
14 per cent had trouble with arches.

Out of total applicants accepted in 1926, 27 per cent were in "A" class, 67 per cent in "B" class, and 6 per cent in "C" class.

Re-examinations should be made, but just how often depends on the class of workers and the class of industry, as there are factories that have poorer health conditions than others and, naturally, re-examinations should be made more often.

Of course, as it is with safety, production, or any other program, the success of it depends on the management. If they are thoroughly sold it will go over. If they are not, it will not go over.

Health Service Cost is Very Moderate

Health service, generally called medical service in industrial plants, costs employers \$5.14 per employee a year, according to a National Industrial Conference Board survey of 501 plants employing more than a million workers. The report points out that the significant feature of this figure is that it is greater than the annual expenditure of many individuals for medical care and shows that industrial health service is thorough and efficient and, therefore, profitable to all concerned. Public health service is supported by taxation, and so is paid for by those who live under it. Industrial health service is not a tax on the workers whom it benefits. In theory it is a tax on the consumer of the goods produced; since it is a production cost, but in practice it is not even that. As a matter of fact, it pays for itself. Large as the sum of \$5.14 per individual worker may appear, it is quite apparent that an extremely small increase in average worker efficiency would balance the account.

The average book on employment gives the cost of turnover as from \$50 per person up. If we can save one employee to the company we have off-set the cost of medical attention for approximately 10 employees, or entrance examinations only, of 25 people. (Using the National Industrial Conference Board figures.)

The cost of the examinations generally run from \$1 to \$2, depending upon the completeness of the examination and the time consumed in making it.

One of the bulletins of the United States Public Health Service stated that the plant with medical service had an 18 per cent better attendance record than those plants without it, due to less sickness.

There is one big point to take into consideration in selling this service to the management, and that is this: By looking around us we will find plants that have had medical service in the way of entrance examinations alone, or more completely for a number of years, and others just going into this field of work, and what is happening? Just this, the plant

without such service is getting the physically unfit and suffering from it, either consciously or unconsciously, and is not keeping that costly human machine up to standard; while the plant with the service takes the "cream" and builds up its force to the point where production costs them less. In these days of high competition can we afford to be without such service?

For further study on this subject, I will refer you to:

"Medical Care of Industrial Workers," by "National Industrial Conference Board."

"American Management Association's Bulletin No. 19" on "A Manual of Health Supervision," by Dr. R. S. Quinby, of The Hood Rubber Company.

"Health Service in Industry," by Clark.

I must also say I have been very pleased with the attitude shown by some of the older employees who have come back to work recently after operations, as a result of our follow-up work; and their physical condition is certainly improved.

I might say in closing that if you haven't gotten hold of the Industrial Conference Board's report of survey, and you are interested in this subject, you had better get it, because it is a mighty interesting book. The report is complete. I have a few other references here, one of which is the American Association Bulletin Number 19, by Doctor R. S. Quimby of the Hood Rubber Company.

If there are questions I will try to answer them.

Medical Examination with Old Employees Optional

J. R. LESLIE (Lincoln Pulp & Paper Co., Merritton, Ontario): Mr. Robinson, when you first started the medical examination in your plant, did you make it compulsory that your employees take it?

MR. ROBINSON: No, we made it optional.

MR. LESLIE: What about new employees?

MR. ROBINSON: In that case it is compulsory. We don't want them unless they pass it. We are having less rejections now than we had when we started, because some of the fellows who are coming to work now know we have this examination and if they have defects which will eliminate them they don't come.

MR. LESLIE: What was the general attitude of old employees toward the medical examination?

MR. ROBINSON: It was like anything else you start in your plant, it was about fifty-fifty; fifty for and fifty against. But you have to get out and sell it. It will be easier from now on to get the older employees into it because of the follow-up work we have done. The men who have come back from the hospital are so pleased that they are selling agents.

MR. COSTIGANE: Suppose one of your older employees submits to this examination and something is found wrong with him, what do you do?

MR. ROBINSON: He goes under medical care, but if his weakness can not be corrected the man may enter a long period of disability.

MR. COSTIGANE: Who takes care of him?

MR. ROBINSON: We do. Of course, we are more lenient with our old employees than anyone else, but they have all had that chance of coming into our Mutual Benefit Association, which takes care of them, to a certain extent, even to the operating expenses.

MR. COSTIGANE: If they should go to a doctor or hospital and be operated upon and die, who would be responsible?

MR. ROBINSON: I don't know why we are any more responsible for that death than they would be themselves.

MR. COSTIGANE: In the event of a man dying under an anaesthetic that was practically encouraged by his employer, would the employer be responsible for that death, and would he compensate the wife and family?

MR. ROBINSON: No, I don't think so. Whether they go for that operation depends upon the advice the doctor gives them. What that advice would be depends upon the doctor. Mr. Hoyman, can you answer that better than I can?

Clearing the Employee's Mind of Suspicion

M. G. HOYMAN (Kimberly-Clark Co., Neenah, Wis.): One thing we did before starting the physical examinations was to guarantee that it would not interfere with their jobs or their chances with the company. We simply offer them the opportunity, and whether they take advantage of what they find out, is purely optional with them.

MR. COSTIGANE: In the event of a death under an anaesthetic what is the position of the wife and family?

MR. HOYMAN: I don't see the point. To begin with, a man has some disabling ailment or he wouldn't do this.

MR. COSTIGANE: We are assuming that something has been discovered in the medical examination.

MR. HOYMAN: I can't see where anyone would be responsible but himself. If he decides to take advantage of any knowledge gained that way and it should prove unsatisfactory or fatal (which is a long chance under modern surgery), I can't see why the employer would be responsible.

MR. COSTIGANE: Yes, but if due to some inherent weakness he passes out under an anaesthetic, should the man be wholly penalized and his wife and family have no provision to take care of their needs?

KENNETH L. FAIST (Champion Coated Paper Co., Hamilton, Ohio): When we make a recommendation that a man have an operation performed, we recommend that he go and take that up with his own family physician. Therefore, two physicians make the recommendation and one of them is his own physician.

W. A. GLEASON (Hammermill Paper Co., Erie, Pa.): Our plan is not to suggest any doctor to do the work. They can have any doctor they wish. Sometimes they will ask our medical advisor who would be a good man to do it, and he will name over two or three specialists. We have to be very careful not to commit ourselves or the doctor who is handling it, and he will take care not to commit himself. I think Mr. Costigane's question has been very ably taken care of by the position taken by the insurance companies. Some of the big companies offer a

physical examination with the insurance, and examine every two, three or five years and submit the finding of this examination to you, with advice of an operation or of other means of correction. If you pass out during the operation, they lose.

CHAIRMAN ROSEBUSH: Mr. Robinson has brought up some very fine points in his paper and it is open for further discussion.

D. T. MEANY (International Paper Co., New York, N. Y.): I would like to ask Mr. Robinson a question in regard to the Mutual Benefit Association. When you have a man in service who is over 50 years old and he is eligible for insurance after a certain period of employment, I understand from your paper that you don't take him in your group insurance.

MR. ROBINSON: In the case of men over that age in the employ of the company who have not taken the insurance, that is their hard luck. That amendment to the clause was made later.

D. D. THIRKIELD (The Sorg-Oglesby-Smith Paper Co., Middletown, Ohio): I would like to ask if a plant employing 375 employees would justify the employment of a full-time doctor. Can anybody give me an idea as to that?

The Doctor on Duty Four Hours Each Day

MR. GLEASON: At the start of our medical examination we had a full-time doctor who was an older man, sort of on the downward grade. We changed and are now employing a young doctor, a graduate in 1920, for a period of four hours a day, two in the morning and two in the afternoon, 9 to 11, and 3 to 5. That gives him a chance to maintain his own office. We have 1,250 employees and it works out very well.

MR. THIRKIELD: Do you have a full-time nurse?

MR. GLEASON: Yes.

MR. THIRKIELD: Does the doctor come to your office and spend the four hours?

MR. GLEASON: Yes, unless we send him out to make visits at homes, which is never more than once or twice a week. If a man is injured and is not able to come, of course, we send him out.

MR. THIRKIELD: That is the question, how are we going to handle a medical examination? We have never done anything along that line, but we are planning such an activity.

MR. GLEASON: Our doctor makes all the examinations of new employees; we don't require the old employees to undergo that examination. We have had this examination for a period of four or five years and we find the old employees gradually drift in one at a time with some ailment, and at that time the doctor uses very good judgment as to whether they wish to submit to an examination or not.

MR. THIRKIELD: What do you do in case of an accident if the doctor is not at the mill?

MR. GLEASON: If it can not be taken care of by the nurse we send him to the doctor's office. We practically have control of the doctor except from hours 11 to 12 in the morning. We govern his office hours from

3 to 5 at the plant and in the evening any cases are sent to the office. Those, of course, are paid for at the regular medical rates. He is only subject to duty from 9 to 11 and from 3 to 5. We pay for any office calls or anyone sent to his office outside of those hours.

MR. ROBINSON: My information is that when an employee is injured he is obliged to go to the doctor you specify. He can't have his own doctor.

MR. GLEASON: Under the compensation law in Pennsylvania we regulate the doctor. We have other consulting surgeons; we don't require that he submit to ours if it is a surgical case. We have a surgeon whom we have had for about two years and outside of those two doctors we have sent a man to Cleveland in one case, but you have to use judgment. We don't make it arbitrary. He may go to his own physician, but, of course, in that case he must pay his own bill.

J. E. COLLINS (Mead Pulp & Paper Co., Chillicothe, Ohio): Would it be feasible for mills employing the same number of men to get together and hire a doctor for full time?

Employment of a Doctor Full Time Not Advised

MR. GLEASON: We found it wasn't successful, for when you employ a doctor full time he has no other incentive. He doesn't have any outside practice, and the employees sometimes think they are not getting first class medical attention; whereas, if you get a practicing physician from the town, even if you employ him only part time, it has a much better effect.

H. C. SACKETT (Alton Box Board & Paper Co., Alton, Ill.): Our plant, which employs something over 200 men, and the steel plant across the road from us which employs approximately 700 men, employ the same doctor and he takes care of his outside practice just the same, and in a case of an employee being severely injured we have never had any difficulty in getting the doctor down to the plant. I might add that the leading physicians do not care to concentrate on just a few plants, because they feel that they are losing their identity with the public.

L. J. BARRETT (Consolidated Water Power & Paper Co., Wisconsin Rapids, Wis.): Mr. Robinson, what success have you had with your physical examinations, so far as eliminating hernias?

MR. ROBINSON: I should say about three and one-half per cent of rejections are on account of hernia. Those rejections will be less because men who have those ailments don't come to us.

MR. BARRETT: In case of hernia, within a short time some of them get ruptured. What do you do in a case like that?

MR. ROBINSON: We don't take them.

MR. BARRETT: How do you get around it? We don't like to take the responsibility, we want to see our men through. Hernia comes on during a very light task. It is pretty hard to determine who shall take the responsibility of that injury. How can we work that out?

MR. ROBINSON: That is a problem that every one of us has where the compensation laws are as lenient as in New York state. I think it.

requires a very serious thought on the part of the plant that has that question to deal with, to take into consideration the compensation laws. Other plants could answer that question for you better than I can.

MR. BARRETT: It should be interesting to the members from the state of Wisconsin. What are we going to do about it?

MR. SACKETT: I think that the Illinois Compensation Law provides that if hernia comes on a man while he is in the employ of a company, the company must stand behind and pay the medical bill and put the man on his feet, because they claim it is an aggravated condition due to the hazard of his employment.

MR. PEACOCK: The disadvantage under which employers labor in New York was called to the attention of the Section last July by Mr. Samuel Pruyn, of Finch, Pruyn & Co. He stated that all hernias, whether there has been trouble from them before or not, are considered accidents arising out of employment. To a Wisconsin man this is curious from both standpoints, law and medicine. In our state the burden of proof rests on the man.

MR. GLEASON: I would say in Pennsylvania the burden of proof is on the employer, that is the compensation law there. There is nothing we can do. If he develops hernia we have him taken care of. If he doesn't want it, we correct the condition in another manner.

The Question of Hernia in the "Meade Case"

MR. PEACOCK: The situation in Wisconsin is embodied in what is known as the "Meade case," with a decision by the Supreme court of the state. George Meade had appealed from an order of the Industrial Commission dismissing his application for compensation for an injury which he claimed resulted in a hernia. The accident was a fall. Meade took the case to the circuit court, where the Commission was reversed. In the Supreme Court the case was dismissed on grounds that now form the policy of the Commission regarding hernias. The man must show (1) that the hernia was produced by accident; (2) that the accident was such as could produce a hernia; (3) that the hernia appeared immediately after the accident; (4) that it was followed by pain immediately disabling the applicant; and (5) that the applicant gave immediate notice of the injury to his employer.

In our mill I had an excellent man lose out before the Commission, although I took the stand in his behalf fully convinced that he was ruptured on the job. Insurance companies in our state deny responsibility for hernias as a matter of form.

R. S. TURNER (West Virginia Pulp & Paper Co., Mechanicsville, N. Y.): In New York a man can have hernia and if, during the course of his employment, he aggravates the hernia, the employer or the insurance carrier is responsible. I heard a case last Thursday in which the insurance carrier in this particular case was the State Fund, and they argued through the employer that the man had the hernia previous to his taking employment. It was a brick concern and the referee and the insurance carrier both held that the nature of the work the man was doing would not produce or aggravate an existing hernia; and the referee held that a

man might do a job one time and not aggravate or create a hernia, but that he might do it another time and twist himself in a different way or make some movement which would cause the abdominal rings to be more weakened and cause a hernia, and the insurance carrier had to pay.

MR. PEACOCK: This is all very interesting, showing the state of mind in the Commissions in the states. In Wisconsin the Industrial Commission assumes from common knowledge that inguinal hernia is rarely caused by accident, but is generally the result of inherited or acquired weakness. We are given to understand that this is the position now being taken by the medical profession and we are told by our insurance carriers that hernia can not be caused by any sort of accident or strain. We are informed that a man can not make an effort severe enough to produce a hernia.

W. L. MEAD (Consolidated Water Power & Paper Co., Wisconsin Rapids, Wis.): In this same connection not long ago I wrote the Industrial Commission asking for any possible information on hernia, and in addition to the case which Mr. Peacock just gave of the instantaneous hernia, they also said that hernia can be an occupational disease. I think it was in 1919 that there was added to our Industrial Commission Accident Laws the industrial disease element, and that if a man was working in such work that would cause hernia even if not caused at the immediate time, and he didn't go through the intense pain which would come from sudden hernia, still it would be considered industrial accident, which wipes off the map the theory that it has to be sudden or caused by a sudden lifting or jolt.

I wish we knew more about this hernia, gentlemen. I think that medical authorities are divided. Some of them say that hernia has to be inherited or a congenital proposition and others say that it is caused by heavy lifting or a heavy jolt of some sort.

I think many on the Commission say the industry shall stand part of the responsibility, and I am not sure how many. I think the industry stands the hospital bill, and the industry does not pay compensation for the days the man is off.

CHAIRMAN ROSEBUSH: I would like to emphasize one point Mr. Robinson made in his paper regarding the Mutual Benefit Association, which is intended to cover a man's accident or sickness while off duty. I think that is a fine thing and a coming thing, and I can't see much excuse on the part of an employee to whom that is offered, for a come-back on the company if he has the opportunity, in addition to receiving the state compensation which protects him, to take protection in a Mutual Benefit Association.

It is about time for us to close and I am sure the committee would welcome suggestions from you members during the remaining session for points on future programs. I will now turn the meeting over to Mr. Peacock.

(Chairman Peacock took the chair.)

ADJOURNMENT

WEDNESDAY MORNING SESSION

October 27, 1926

The second session of the Paper and Pulp Section of the National Safety Council convened at 9:30 o'clock at the Book-Cadillac Hotel, Detroit, Michigan, Mr. W. J. Peacock, head, Department of Personnel, Northern Paper Mills, Green Bay, Wisconsin, presiding.

CHAIRMAN PEACOCK: The Round Table discussion was put first on the program this morning. I think we will reserve the topic of frequency and severity until certain gentlemen come in who are peculiarly interested in that subject and who have some interesting information on it; and we will go to the topic, (b) Practice versus Theory in Safety Work.

I gave you yesterday what was in the mind of the program chairman regarding this topic. He is asking the question, "What Is the Goal of Our Safety Work?"

Let me ask this question first: "Is it a practical hope that we may some day achieve a condition of no accidents?"

EDWARD J. GAYNOR (Scott Paper Co., Chester, Pa.): I feel that hope for no accidents would be a fine thing, but some accidents seem unavoidable and it will be years and years before we strike the acme of perfection. We shall always have men who are not acquainted with the job and men who are themselves hazards. I would like to go on record and I feel that it is good to hitch your wagon to a star, but we can't hope to attain a perfect record. The nearest we can come is some percentage of imperfection.

CHAIRMAN PEACOCK: Mr. Larson, what do the Marinette and Menominee Paper Mills think?

L. LARSON (Marinette and Menominee Paper Company, Marinette, Wisconsin). As long as we have human nature to deal with we can expect accidents, although that may not be exactly the right attitude to take. Up in our mill we have been a little fortunate and we are hitting the ball just as hard as we possibly can to reduce the accidents by keeping the men informed. The men in the mill are informed what our experience is from month to month and from year to year. We seem to be getting somewhere; we are aiming to reduce and we know we shouldn't have as many accidents as we are now having.

I. G. WOOD (Indemnity Insurance Company of North America): I might say just a word about the American Railway Association. They have established a goal of 30 per cent reduction in accidents by 1930. They haven't established a goal of "no accidents" because they want to establish a practical and workable goal. They say, "We will get five per cent each year," and that is their goal, and if they do that they will certainly have done well, but to believe they can get no accidents is to establish no goal at all.

H. T. BOND (Celotex Company, Marreno, La.): We are trying for longer and longer periods between accidents. I read in the *National Safety News* and journals of other mills that are setting up "no accident" records for increasing lengths of time, and when we accomplished one month without an accident we thought we were doing something. If we accomplish two months we are doing better. We have accomplished four and one-half months as our best record. I think the goal is longer and longer periods between accidents until we get accidents really very scarce.

CHAIRMAN PEACOCK: What does International think about this topic?

DANIEL T. MEANY (International Paper Company, New York City, N. Y.): I was just thinking that it is much better to develop a careful workman than to win the goal of "no accidents." We have one mill that is our oldest division where we employ about 800 to 900 men, and during the past year, so far, we have only had two or three lost time accidents there. That is due first to the manager's interest in safety, to the foremen and the low labor turnover there.

In some of our other mills our accident experience is not so good, and to some extent it is due to the high labor turnover in those mills. If we can get a man when he comes to work to take an interest, teach him safety from the beginning, get him interested in his work, and show him there is an object in view for him in promotion, then we can develop careful men, and that, in my judgment, is the better goal to look for.

Perfection in Safety Should Be Striven For

NAT T. BARTLETT (Hollingsworth & Vose Company, East Walpole, Mass.): We take our separate departments and compare them month by month with the records for the previous month and year and determine in each department the reduction. When you have a "no accident" campaign, an accident discourages everybody.

CHAIRMAN PEACOCK: Kimberly-Clark, what is your goal?

M. G. HOYMAN (Kimberly-Clark Company, Neenah, Wis.): In any endeavor your goal is perfection. Why shouldn't it be in safety? We can strive for it and unless we endeavor to act in that direction we will never reach perfection. In all the ramifications of safety there are many ways to work toward that end. Various contests have been mentioned. There are some objections to these contests. Objectionable features will in time eliminate themselves, but I think we should strive for perfection.

CHAIRMAN PEACOCK: How are you gentlemen who are presenting goals other than "no accident," going to sloganize the thing? How do you keep up the enthusiasm of your men?

L. O. BONNER (Mead Pulp & Paper Company, Chillicothe, Ohio): Give each department head his record for last year in the form of a chart of the total accidents during the year. Get him to keep under that line this year. If you do that I think it is the crux of the whole thing.

MR. BARTLETT: When I came here last year I was a new fellow at this safety work. I am a traffic manager and this safety question is a side

line. I am going to tell you something that has happened in our mill. Last year I had 71 lost time accidents and 570 cases of first aid. At the East Walpole mill, up until the first day of October, I only had 31 accidents. You may say that is still an awful lot of lost time accidents in 280 days, but we cut last year's record in half. My aim is to bring that down every year until we go along without a lost time accident for a whole year.

MR. BONNER: I would like to ask Mr. Bartlett what he does if he has an accident on the last day of the month?

MR. BARTLETT: I have had two or three months without a lost time accident. When I have a lost time accident I write a letter to my safety committee at the mill and they post it up. I say, "Here we have had an accident; let's go to it a little bit harder, see what caused this accident and prevent the next one." I look at it in this way: if you have \$100 and find that \$10 of that amount is counterfeit, you think a lot more of the \$90 that is left. I cherish those days more that are left without accident.

Each Year Should Cut Down the Accidents

CHAIRMAN PEACOCK: You saw the picture last year of last year's prize winner, Mr. Rosebush. Mr. Rosebush is here. What is your goal, Franz?

MR. ROSEBUSH: I am frank to say that I have a dream of no accidents. In 1924 we had 363 accidents. In 1923 we had a larger accident average. In 1924 it was cut to 44. In 1925 it was 39. This year we have had 19. I am going to be disappointed if next year we don't cut 50 per cent of those accidents.

I remember in December, 1921, we tried to go a week without an accident. We felt pretty proud because we did go the week without an accident and later we tried to go a month without an accident and then we tried to go two months.

At Port Edwards mill last year we went five months without any lost time accidents and I hope the time is coming when an accident in our mills will be regarded as a calamity. I can't see any objection to making your goal zero and having no accidents at all.

CHAIRMAN PEACOCK: I will call upon Mr. Augustus.

ERNEST AUGUSTUS (Mead Pulp & Paper Co., Chillicothe, Ohio): Our goal since we started in on organized safety work two years ago has been no accidents. Each month it has been our ambition to go that month without an accident. As a result during the past 23 months we have had 10 of them without any accidents. We have a large sign out in front of the plant showing the number of days we have gone and the number of accidents. I think 730 days with 20 accidents is our showing at the present time, but our goal is to go without any accidents.

CHAIRMAN PEACOCK: Does not the phrase, "no carelessness" sloganize the thing and doesn't it put into the minds of your men that safety measures are entirely practical? "No Carelessness" eventually means "No Accidents."

Let us now take up "Frequency, or Severity?" I am going to call upon Mr. Costigane, to open the discussion for us.

A. P. COSTIGANE (Ontario Pulp & Paper Maker's Safety Division, Toronto, Ontario, Canada): The question you have put is, frequency, versus Severity. Before saying anything at all on this subject I would like first of all to make the statement that any remarks that I make are applicable only to conditions as we have them in Ontario.

The cost of accidents from our point of view is a very vital one because in our province insurance companies have no standing of any kind. The whole accident prevention movement in Ontario is under a government commission. The government commission at the beginning of the year levied what is called a provisional assessment on all the employers in that group and of the actual industries in Ontario divided up into different groups, some groups embracing quite a number of smaller industries.

The pulp and paper industry, as you gentlemen may know, is now becoming one of the largest in Canada and is expanding daily so that now it is large enough to take up a group by itself.

View the Accident Costs Critically

All accident expenses, all accident costs, both for hospital, disability and for nursing expenses are paid direct by the board, so that you can easily see there is a direct and close connection between a government commission and the industry itself. I think you will also see that when the government is assessing direct, one of the chief aims of industry is to view accident prevention not only from the humanitarian side, but that compensation loss must be brought down. In order to do that and to emphasize the necessity for accident prevention, one must show the cost, and in showing the cost give reasons and methods whereby that cost can be brought down and controlled.

From that point of view, I am convinced that as far as our work is concerned we should concentrate on severity and study frequency. I could say something in favor of frequency but it would be entirely from an academic point of view. From a practical point of view in connection with the work that I am engaged in I am convinced after a long period of experience that severity is the goal we should shoot at.

CHAIRMAN PEACOCK: I thank you, Mr. Costigane. What we mean by frequency is the number of accidents. What we mean by severity is the number of days lost in connection with accidents. The subject is open for discussion.

MR. AUGUSTUS: I don't want to start a long argument, but isn't the thing we are shooting at as safety men primarily the elimination of accidents? A man engaged in safety work has one aim, morning, noon and night, the prevention of accidents. He doesn't say, "Now, boys, if you are going to get hurt, don't get hurt very badly"; he says, "Don't get hurt." Therefore, I can't see why frequency isn't the thing we should look at more than severity. We don't want to forget severity

but if we look after frequency properly and do our jobs in the way we should, severity is going to take care of itself.

Personally, if I were in a contest and my mill had a lot of accidents with only two or three days lost for each one of them, and the other fellow had four or five accidents and two or three men killed, I would think he was a darned sight better safety man than I.

It is a matter of chance whether a man is seriously injured, whether it is only a minor injury or whether he is injured at all. You can think of any number of serious cases that would result from a minor injury. Something may hit a man and kill him, it may mash his toe or it may miss him by two inches.

CHAIRMAN PEACOCK: Mr. Burns is promoting this subject as much as anybody. Frequency or severity, Mr. Burns?

An Element of So-Called Luck in "Severity"

MR. BURNS: When I originally wrote to Mr. Peacock on Frequency versus Severity it wasn't with any thought of starting a discussion. That idea originated in the promulgation of national statistics, particularly in the sectional reports that we get out each year.

Mr. Augustus feels the same way that I do, but there is an element of so-called luck in severity. The breadth of a hand may mark the difference between a fatal accident and a minor accident. Possibly somebody else has brought this out, but many times the question comes up in our office. Somebody says, "Well, after a man is hurt and leaves the plant it is entirely beyond our control. It is up to the doctor then. The safety engineer has no control thereafter. But you are rating my mill on the basis of the length of time the patient is in the doctor's charge. If it is frequency, it is within my control. If it is severity, it is not within my control."

CHAIRMAN PEACOCK: I am going to call on Mr. White. I am sure he also has some very clear ideas on this subject of severity and frequency.

ALEXANDER R. WHITE (Chief Sanitary Inspector, Province of Ontario, Toronto, Canada): Mr. Costigane expressed my ideas exactly in his remarks this morning. You have mills operating in settled territory where you have well ordered arrangements, hospitals, doctors and so forth, and little or no labor turnover. Because of that it is possible for you to deal with this question from the standpoint of frequency. But if these things are not factors, if you have a large labor turnover, if you are living in a piece of territory that is not yet settled, you have no hospital and very few doctors, then to study frequency and frequency alone will mean in a very short time the boss will be out of patience with you and you will be out of a job.

As you men study this thing it is quite all right to study frequency but for us to spend our time on frequency to the exclusion of severity would be a fatal mistake.

Now everybody knows that the number of accidents you have depends on labor turnover, the number of new men you take into your plant.

If you have 200 new men coming in each month then how do you expect to keep your frequency rate down. But you may have all the control in the world over your severity.

The fact that the case has gone over into the hands of a doctor does not mean you have lost connection with it. It means you have to study a little more about what the doctor does. Our aim is that this doctor shall become hitched up with the company in a new way. He is not merely going to be a man who sits down and says, "We have a patient down here." You want to begin before that. We want the doctor and you people to join hands and form a copartnership so that each of you will play your part and make a prevention agent out of the doctor as well as a curative agent.

Now that may not interest you people; if you went to Oregon in one of the outlying places of that state and you decided to build up a mill there, you would have to be interested in that thing. You go into the woods, you start to build up a community and it will be 10 years before you get a settlement. It is not frequency you are suffering from. It is costs. It is quite conceivable to suppose 30 per cent or 40 per cent of the open wounds will be infected. That is severity. Are you going to leave that to the doctor? You can attend to it just as nicely as the doctor can.

The Problem When Many Employees Are Old

MR. LARSON: We have a situation up in our mill of having a lot of employees that are 60, 65, or even older. They have worked for the company for 30 or 40 years and the company has changed hands two or three times during their employment.

I have this particularly in mind. One man got hurt. I am positive in my own mind that he is able to go back to work but he gets his compensation and he belongs to some benefit society that pays him a weekly amount, I don't know how much. But along with those two incomes he has his home paid for, and we can't get that fellow back on the job. We have gone to the doctors and insisted that they send him back to work but the fellow makes his case so strong and so good to the doctor that the doctor is puzzled. We have had a half dozen cases like that.

The reason we are stressing severity is because the men out in the mill know much better than I do whether that fellow is bluffing or not. The nurse is watching that man, I am watching him, and two or three of the millwrights are watching him. We are trying to catch him in an unguarded moment when he forgets himself and proves to the fellows that he is laying down on the job and that there is nothing the matter with him.

The insurance company charges a premium based upon experience. He is running up our lost time accidents and he is making our experience look bad.

CHAIRMAN PEACOCK: We want to continue just a moment with another very interesting matter. If you gentlemen will look at a chart

showing the general geographic arrangement of the pulp and paper mills of the United States, you will observe how they follow an irregular line down from Maine and across to Minnesota and on southwest, with a few mills away out on the western coast.

This will picture the difficulty of getting all our Section members together. Is there anyone here from the mills of Maine today? We have a dozen members in that state. We have several hundred mills in the northeast, that we only touch when we get far east with our conventions. I suppose the records will show we are today favoring the territory in the vicinity of Detroit.

Promote the Regional Conferences

That brings out something I want to accent to you, namely, the advisability of promoting Regional Conferences. Your object is to get the method and the thrill, if you please, of the National Safety Council into your own mill. How are you going to do that? The mills in this vicinity can send their foremen and their safety men to the convention, but only once in a half dozen years do the men in the extreme northeast have an opportunity of attending the National Safety Congress.

How are we going to afford that opportunity every year? The answer is by means of regional conferences. The setting up of a regional conference means calling in Mr. Burns, of the National Safety Council, and getting together the representatives of allied interests, men who are promoting safety in their various plants, spending a half day or a day and a luncheon talking over the sort of speeches you want, the sort of discussions you want to promote, then turning over printed matters and the building of the program to Mr. Burns. You go out to do the promotion end of it, to work up the attendance. The expense of the thing is very easily met.

At our first regional conference in Green Bay a year ago two dollars and fifty cents per man paid all our expenses. We started in with the idea that we might have as many as 150 present, and we went at the thing eagerly. Within six weeks the interest promoted an attendance of 640. This year we had over 800 present. We had more paper and pulp men present both years than at the National Safety Congress; 200 a year ago at Green Bay, 300 this year at Appleton.

Our members need the conference idea in Pennsylvania, in Ohio, in Maine and in Massachusetts to cover our constituency every year, and it is a simple matter of organization.

MR. BURNS: If there is a local council anywhere in the region they will gladly handle it for you and take care of all the details.

CHAIRMAN PEACOCK: Mr. Rosebush, will you please take the chair. (Mr. Peacock retired and Mr. Rosebush took the chair.)

CHAIRMAN ROSEBUSH: Suppose we call for a report of the Nominating Committee at this time and get that out of the way. Mr. Gleason is chairman.

W. A. GLEASON (Hammermill Paper Company, Erie, Pa.): The Nominating Committee appointed by the present chairman consisting of

Messrs. Hoyman, Phillips and Gleason, submit to you the following officers for the ensuing year.

For chairman, W. J. Peacock, Northern Paper Mills, who is the present chairman. For secretary, Amell Ueberham, Fort Howard Paper Company, who is the present secretary.

A suggestion was made by the officers of the National Safety Council and by our present chairman that we nominate as vice-presidents of the Section, men geographically located who would act as chairmen in their section of the country and handle the affairs of the pulp and paper section in general. We have taken that into consideration and submit to you the following men: M. G. Hoyman, Kimberly-Clark Company, Neenah, Wisconsin; R. S. Turner, West Virginia Pulp & Paper Company, Mechanicsville, New York; James M. Murphy, International Paper Company, Gatineau, Quebec; G. W. Phillips, The Champion Fiber Company, Canton, North Carolina; Nat F. Bartlett, Hollingsworth & Vose Company, Boston, Massachusetts; Ernest Augustus, Mead Paper & Pulp Company, Chillicothe, Ohio; Alvin Record, International Paper Company, Chisholm, Maine, and W. L. Mead, Consolidated Water Power & Paper Co., Wisconsin Rapids, Wis.

CHAIRMAN ROSEBUSH: Gentlemen, you have heard the recommendation of your Nominating Committee. What will you do with these recommendations? A motion to accept the recommendations with the power of election will be in order. (Mr. John Lundrigan so moved, and the motion was seconded by Kenneth L. Faist. The motion carried unanimously.)

CHAIRMAN ROSEBUSH: The next speaker on our program this morning is Walter A. Gleason of the Hammermill Paper Company, Erie, Pennsylvania.

Mr. Gleason is an old timer in safety work and has been connected with this Section for a good many years. He has been a faithful worker and we are glad he is going to talk to us this morning.

SAFETY AND PLANT MIND

W. A. Gleason, Safety Director, Hammermill Paper Company, Erie, Pa.

In this modern age we hesitate to think that the mind of a plant manager or chief executive is so burdened with problems of financing, manufacturing and marketing that he does not take the time to consider the safety and general well-being of the personnel of his organization. Yet this condition must still exist in the minds of some executives, for one of the common subjects at conventions of this kind is "selling safety to the executive." Factory inspectors for state and insurance companies also tell us that the atmosphere with regard to safety in some plants as compared with others is as different as day and night. When recommendations are made to provide safer conditions in some plants they are frowned upon and complied with only after being deferred as long as possible.

New applicants for employment will sometimes look askance at you when you inquire about the safety conditions and practices in the plants they have just left, as if they never heard of such things. It has often been said that the rank and file of any organization radiates the spirit of its leaders.

If this is so, leaders of industry can not delegate the problems of safety to some individual in the plant, and then make it impossible for him to work these problems out by withdrawing their moral and financial support, without this spirit reaching every person in the organization.

Employees making suggestions which are never carried out, foremen and superintendents receiving no encouragement from the management, will soon recognize the insincerity of the officials and cease to interest themselves in furthering safety.

Most Organizations Earnestly Interested in Safety

I believe, however, that there are few organizations today that are insincere in their efforts to prevent accidents. The history of the safety movement and the results attained during the past 20 or more years have proved that the modern executive is turning his thoughts more and more to the improvement of conditions within his plant, which will tend to provide better and safer conditions for the personnel of his organization.

This was not done from selfish or monetary reasons, although it has been proved in your plant and ours, as well as in some of the other large industries, that safety work actually pays in dollars and cents; but rather because the men who are at the head of these various industries have long ago come to recognize that the personnel of any organization is of far greater importance than its mechanical equipment.

Let us assume then, that "Plant Mind," as created by the officials, holds a priceless value on the human life.

Webster defines the "mind" as "power of remembering, retention in memory, consciousness of thought," and in these I see the reason for accidents occurring. If all of us had minds that functioned 100 per cent perfect, there would be very few accidents. Of course, we can not hope for this, and it remains for us to keep awake that consciousness of thought in our own minds, so that we can act as transmitters and pass the thought to others. This is rather difficult sometimes because in every organization there are many types and conditions of mind.

We see this in the fact that some persons are chosen superintendents and foremen, because their minds function quickly and accurately, and they are able to lead, while others are doing work which requires very little thought.

Among the latter class is the fellow who gets hurt several times during the year, because he fails to realize the conditions he encounters on his job. Then there are others of mature years, whose minds have never developed beyond the stage usually attained by a 16-year-old, and we must be ever alert for new methods of reaching these types of minds

and bringing them to realization that the value of human life can not be measured, but is priceless above every other possession.

Defining "mind" as a transitive verb, Webster gives it as meaning "To remember, to call to mind, to put one in mind of." In the work of preventing accidents this refers directly to the person in charge of safety, the foremen and the superintendents. They have been chosen for their places because they have the power to lead and to remind others of the need of caution, and to encourage them to put their best efforts into the making of the product. Sometimes I feel that a great many accidents occur because the foreman in charge of an operation, whose mind is much clearer as to what is the safe way, fails to consider the minds of the persons who receive his instructions; he takes it for granted that they know the safe way, and this sometimes results in an accident.

The Little Girl Illustrates a Mind Type

By way of illustration, and I hope you will pardon the personal reference, my little girl is just eight years old, and in going to and from school she must cross the main highway between Cleveland and Buffalo. We have cautioned her many times regarding the care she must exercise in crossing this highway, and from checks we have made and what we are told she is mindful of the instructions we have given her. Just recently I noticed her leaving our home (which is just one block away from the highway) and running directly across the street without looking in either direction for traffic. When I called her and asked why she had crossed the street without looking, she replied that I had not cautioned her about this street, but had only told her about the Buffalo road. This illustrates that it is not only necessary for us to call to mind safety practices, but we must be sure that we convey to persons whose minds do not function exactly as ours, the thoughts that we are trying to get across to them.

Repetition, too, is a method we must adopt to impress the mind. A leading advertising agency representative recently told me that one of the best methods of advertising is to repeat constantly the good qualities of a product. The lesson of one safety bulletin may not reach every person, but if various types are posted, each one will make its separate appeal, and will drive its lesson home.

Another type of mind is the one that feels that safety is meant for the other fellow, but it is of no value to him. You see him in the fellow who walks from the other end of the mill to locate you, and tell you there is an unsafe condition which he might have corrected with very little difficulty, or who will tell you that the other fellow is doing something carelessly, and the very next day he does something equally as hazardous.

Another example is the new man whose mind has not had time to grasp all the details and conditions of his work, and is injured before his mind has become accustomed to the existing hazards. Still another type is the man whose mind has never been trained in the simple rudiments of safety, who was in industry before its teachings were taken

up in the schools. The teaching of the fundamental principles of safety in the schools will, I believe, insure us a class of workers in future years who will be less liable to be injured in the first few months in industry. Every safety man whenever possible should devote some of his time to the furthering of this educational work. Again there is the man with a troubled mind who has always been a careful workman, and free from accidents on the job, but through sickness of himself or family, finances or other cause, brings his cares to work with him, and in this state of mind contributes to accident causes.

These and many other types of minds lend themselves to the creation of plant hazards, and it becomes necessary for us to devise ways of eliminating them so far as is humanly possible.

What, then is the best means of bringing to the attention of employees these conditions which are to be guarded against, and get them to realize that their most important duty is the consideration and protection of human life? I believe it is by **DEVELOPING PLANT MIND**.

This is being accomplished by different companies in various ways. The manner in which it is carried on is inconsequential, providing the results are obtained.

I believe safety guards are the first and most important step in developing plant mind, as they are a silent testimonial to the value placed on human life by the officials. When guards are being considered, we have many times strengthened good will among our employees, and at the same time insured the use of the guards, by getting their ideas and suggestions for construction and placement. They are just like you and me—they like to be consulted about the things which are so closely connected with their daily life.

Workmen's Safety Committees Furnish Ideas

Workmen's safety committees, when they function properly, provide many new safety ideas, and represent the point of view of the employees on conditions and safe practices. These committees are very often the cure for carelessness among employees and tend to increase their good will.

Bulletin boards, motion pictures and foreman's safety school lectures afford educational facilities for correcting unsafe conditions and practices and help to acquire right thinking or training of the mind, so necessary in the prevention of accidents.

I very recently learned of one industry that has established a bulletin board reading service where one page of a book is published every day. Continuing this idea with the publishing of the life history of Gene Tunney, Roger Hornsby and other recent heroes of the sport world might be the means of attracting persons to the bulletin boards who now take no interest in them.

Safety contests and first aid meets among departments and different mills provide the means to stimulate keen rivalry, so necessary in setting up long "no accident" records.

Athletic contests between mills or among departments will create

team interest which permeates the whole organization and keeps your plant mind in a very happy state.

Picnics and community safety rallies, wherein the affairs of the town or district are discussed, provide excellent means of entertainment and keen interest in striving for certain goals.

Furnishing employees with safety calendars and educational pay envelope material opens the way to have this taken into their homes where it brings its message to the members of their families.

Employees magazines or house organs, giving information on departmental accidents, progress of safety contests among paper mills, safety services furnished by the National Safety Council, pictures of employees establishing long safety records, general news items pertaining to employees, etc., tend to keep the safety message alive in the mind.

Provide a Suggestion System for the Employee

Suggestion systems so that employees may express their ideas regarding improvements in manufacturing processes and be awarded in proportion to the savings effected by them, is a good way to develop plant mind and keep employees thinking. Very often a suggestion for the improvement in manufacture will correct a condition which has been a troublesome subject to you and contributed to your causes of accidents.

Paid vacations for workers, in order that they may spend some time in recreation with their families without sacrificing wages which they may not be able to afford, encourages them to travel and see other parts of the country and how their fellowmen are living. It will give them a bigger and broader view of life and they will return to work in a happier and more contented frame of mind.

Provide group insurance to relieve the mind of the worries incident to sickness or accident, bringing with it loss of wages and discontented and worried minds.

Establish pension plans to relieve the worries of approaching old age for employees who have been unable to set aside sufficient funds to insure a contented existence.

Arrange for transfers to different departments of employees who through day or night work are prevented from extending their education or maintaining happy minds under the present working hours or home conditions.

Arrange consultations in the first aid or medical department for employees threatened with ill health. In some cases it may be possible to relieve financial difficulties arising from unexpected operations, dentist bills, etc., by establishing credit service which will allow payments to extend over a period of time.

Malingering among employees is reduced to a minimum and "no accident" records established by the discussion of conditions which are causing a troubled mind. In many cases what seems like mountains to the individual may prove to be mole hills when he discusses them with others.

Join with them in the discussion of their hobbies. You can get a better mental picture of them and their problems in doing so.

Finally, have employees share in the management of all of the activities in which they participate. Sometimes I feel that we make things too easy for them, and what is not worth trying for is not worth having. This, then, is the keynote, I believe, in building up plant mind.

It is to establish individual thinking as well as organized plant thinking (team work, if you please), so that employees will do their work in such a cheerful and happy manner that they will forget the cares of home and worries of the job. Plants having reputations of this kind bring favorable comment and attract the right type of employees.

If we, as plant safety leaders, are able to maintain employees' interest, instill in them the need of their cooperation, and bring to them and their families the higher ideals of life, we will make this world a better and safer place to live. Then will we truly have established a plant mind bringing contentment and safety.

Safety has been described as just plain, every day, honest to goodness common sense, and if we are able to couple plant contentment with this we never will have to fear that our employees will believe in any of the existing "isms" or any others that may hereafter arise.

A Management That is Thoroughly Sold on Safety

CHAIRMAN ROSEBUSH: That was a splendid paper. Mr. Gleason has put before you a number of points worthy of discussion and the opportunity is now open for you to discuss the subject if you care to do so.

I would like to introduce to you Mr. Walter Mead. I know the Consolidated mills have been doing extensive work along practical safety lines for a number of years and Mr. Mead is the head of the Department of Personnel in that company.

WALTER L. MEAD (Consolidated Water Power & Paper Company, Wisconsin Rapids, Wisconsin): I have heard a great deal about selling safety to the management and I have wondered what that meant. It seems to me that this idea of safety is sold; I mean by this, that management is already sold.

When the safety movement was first introduced in our plant, the management said, "Do whatever you want to. You can spend what funds you need to spend, you may have all the committees you need and we will do whatever you suggest to prevent accidents in the plant."

At that time we established a safety committee among the men and it worked very well from the start. There were many things that were rather foolish to do and yet we didn't object to them and they went on through. Later on we took safety on as a practical production matter and it was no longer what you might call the convention or party affair.

Every foreman is a member of the safety committee. Every man in the plant is a member of the safety committee. We don't have committees in regard to production. We have a centralized system in regard to production. Therefore, we centralize the safety idea and have it go in the same manner that production does. We have the safety

manager and the plant foreman and every man in the plant working toward the reduction of accidents. I think that is the crux of the whole situation, at least of our situation at Wisconsin Rapids.

We no longer have a large safety organization any more than we have a production organization and we run it along with production. Safety is sold to the management in the same way production was sold. Production was the manager's first thought in the beginning and now safety is on the same plane as production.

An Investigation of the Old Employee Problem

CHAIRMAN ROSEBUSH: Mr. Mead has told a new way in which the safety work has been handled in the Consolidated Mills. I hadn't supposed there was a mill in the United States where the management wasn't sold on safety. Some of you men that have problems of that nature may want to talk about them. Mr. Gleason raised the question of the old man, getting him to take safety steps, and then there comes up the question of how much authority the safety man should have. What should he do when he finds unsafe practices going on? Should he step in at once and stop this or work through the foreman?

MR. BURNS: It might be interesting to know that one of the largest corporations in the country made a study of the old employee versus the new employee, a matter of personal injury, and discovered that over a period of years, 33 per cent of the employees that were hurt had been employed 10 years or more by the company. That was the highest percentage of personal injuries in the entire organization.

I. G. WOOD: I know something of this work. It has been found that when a motorman first goes on the job he has car collisions, and in about six months he gets more experienced and becomes careful; but they do have a great deal of trouble with car collisions among their oldest and most experienced men. They get to a point where they think they know more than they actually do about how to do things.

I want to ask you a question. Mr. Gleason suggested the using of safety material in pay envelopes. There is some little feeling in our company against that. It has a very unfavorable reaction from the point of view of wage payment or anything of that kind.

MR. COSTIGANE: We did something along that line but it was in a limited way because most of the mills in Canada pay by check. We took the safety calendar. We made a group of 12 pledges and put them on the pay envelopes with an illustration, using one each month until all were used. When a man got his pay with that illustration he took it home and the chances are he handed it to the children and they studied the illustration. We did a little along that line in getting safety into the home.

MR. PHILLIPS: We tried this plan for a while. At first it seemed to work fine but after a few months we found that the men, when they learned to expect it each month, just took it out and threw it away. When men are looking for their pay they are more interested in that than any other one thing.

MR. AUGUSTUS: We don't have pay envelopes but we used to give out a little card each pay day, attached to the check. He can't help but read it; he can't throw it away.

MR. BOND: We put a safety news sticker on weekly pay checks for about two years, and at first there was a great deal of interest shown in it, but this died down. We then made it interesting by having an artist make posters, and now we are having a great deal of success. If you can give them something to interest them they will read it and appreciate it, whether it is on the check or in a plant publication.

S. J. STEINMANN (Indemnity Insurance Company of North America, Philadelphia, Pa.): It is the consensus of opinion in the insurance companies that payroll inserts, if properly used, will bring results. You simply have to run around and use the advertising principle. If you put an insert into payroll envelopes every week or every month you are doing the wrong thing. You want to stagger it, as it were, just the same as putting up posters, and then you will get results.

CHAIRMAN ROSEBUSH: If there is no further discussion I would like to call on Mr. Crossley. Mr. Crossley has been connected with the publication of the volumes put out by the Pulp and Paper Technical Association. A number of paper mills are using those books for putting on efficiency school work.

Text Books for Efficiency School Work

T. LINSEY CROSSLEY (Industrial Laboratories, Toronto, Ontario): Mention has been made of the fact that a series of text books was gotten out by the pulp and paper industry and I would like to give you a little idea of the origin of those text books.

We worked for a number of years, sporadically in different mills in the United States and Canada, where we had two committees working to carry on night classes and schools in the mills. We found we had no teachers, no text books and we had different shifts. We had only a very small number of men interested.

Eventually we formed a joint committee for the United States and Canada, which went to the industry and said: "Our greatest need is for text books that shall give authoritative, useful information both for classroom and lecture instruction and for conference work, so that if there is a man or two in the mill who wants a course of study in paper technology or elementary education we can give it to him from the point of view of the paper industry." Eventually the paper industry of the two countries jointly will provide us with \$50,000 to get out this valuable set of text books.

This money comes just about equally from the two countries. We had a little advantage in Canada because our organization made it possible to go into the industry directly and assess them. The Technical Association of Canada is a part of the association; when we brought the matter up they decided to assess the mills on the tonnage basis. Members of the committee in the United States found it a good deal more difficult because the Technical Association of the United States, while

affiliated with the association, is not a member, and therefore they had to get their money by personal solicitation.

However, we got the money and then we had about 100 men working four or five years on these text books. Eventually the text books were published, and two conference schools were organized to carry on this work; one of them in the University of Wisconsin and one at Gardenville, Quebec. The one at Wisconsin was under state direction in the state university, the other one was carried on by a committee representing the various organizations of the industry in the two countries. The Gardenville school to which I now refer, is the one I have possibly put more time in than any other; and partly because of their independence of existence, they were able to place funds at my disposal for getting around the country. The other, being a state organization, hadn't the funds available for that kind of a campaign.

I don't want to go too far into that, but I would like to say that we have somewhere in the neighborhood of 140,000 men in the two countries in the paper industry at the present time, and as far as we can find out, there are probably about 2,000 out of the 140,000 who are in these schools, the University of Maine, the Pulp and Paper schools at the Province of Quebec and the University at Syracuse.

Education Makes the Employee Safer

Suppose we take the men who are working in the universities as being employed, that is, the men who are studying and majoring in pulp and paper. There are about 2,000 men out of the 140,000 who are studying to prepare themselves for life work in the paper industry. As the connection between this work and your work, the slogan was adopted: "An educated man is a safer man." He is a safer man.

There are two developments in the industry today that I thought ought to be brought to your notice. One is that the mechanical equipment of the mills has outstripped the mental development of the men. That is a subject for discussion but it is a moot question. The brightest engineering minds of the country have developed the machinery of the mills and some of the lowest in intelligence are operating that machinery. We can't expect to get 100 per cent production from machinery that is delicate in its adjustments and large in its productive capacity, without seeing that the men who operate those machines have an intelligent conception of the elementary principles on which those machines are operated. That not only applies in production but it applies in the safety factor.

A man should have adequate knowledge of the mechanical equipment that he is working with and that knowledge should not only be how to operate that particular thing, but should be also some idea of its constructive principles.

The second general thought I want to bring before you is that the industry is getting away somewhat from the paternal point of view and is getting into a fraternal organization, so that things that were impossible from a psychological standpoint when the mills were paternal, can be put over when the mills are fraternal.

I think those two points should be considered very carefully by all men who have to handle the safety or educational work in the mills.

Another thing is that cooperation is essential to production and to your own department of the mill operation, which is a matter of production as well, because, of course, an unsafe mill is not an ideally producing mill.

I will tell a little story that illustrates the point: There was a coasting steamer on which the engineer and the captain always had a great squabble as to which had the more important job. Eventually the captain said he would go down in the engine room and show the engineer, and the engineer said he would go to the bridge. The captain went down below, and after a while, wiping the sweat, said, "I can't make the darn thing go."

;"Of course not," said the engineer. "She is aground."

You don't want to teach a man the other man's job, but you do want to teach him enough respect for the other man's job so that each can cooperate with the other, and I believe in our work we can do that. Now, I would like to say right here that the Joint Committee on Vocational Education of the Paper Industry of the United States and Canada (which is its full title), has placed at my disposal a fund so that I can get about more freely among the mills. The school at Gardenville has been taking the burden of this in the last few years, but the committee decided that it would help to broaden my work if some more funds were available, so they have placed at my disposal a fund for travel; and if you gentlemen are interested in the matter of vocational educational work in your mills, I should be very glad to meet you and discuss the matter with your directors.

Safety Should Be Made a Part of Company Policy

I might say that it has been my experience that until you get the directors sold it is very difficult to inaugurate movements in the mills. That was the case, I think, with the safety movement. Twenty-five years ago men who had the vision in safety were working to bring this matter about, but until the directors made it a part of the company policy it was difficult to get the thing organized on a proper basis and the same is true of education, and, of course, education and safety are the two hand-maidens of industry that tend to increase production and the lowering of wages.

We have had so many discussions about various aspects of these questions that we are likely to get the point of the old story of Dean Swift's "Gulliver's Travels." You remember Gulliver reached a place at which there was a big war going on, and the cause of the war was that one army was supporting the big end of the egg as being the most important and the other army was supporting the small end of the egg as being the most important; and they forgot altogether that the most important thing was the egg. It didn't matter particularly which end of the egg was concerned but it was the egg itself.

In industry we have to consider, as Mr. Gleason brought up, that the personnel of the industry is more important than the mechanical equipment. We have a long way to go before we reach that point.

CHAIRMAN ROSEBUSH: I am sure we express thanks to Mr. Crossley for this fine talk and for the point he made about stressing men more than machinery.

The next paper on our program is "The Old and the New in Paper Mill Safety." Mr. Kindleberger was to have given that but it was impossible for him to be here and at the last moment another speaker was secured.

Mr. Jackson of the Consolidated Mills at Wisconsin Rapids, as late as last Friday, consented to appear on the program. Mr. Jackson is not new to this section of the Pulp and Paper Industry because for a number of years he was safety director in charge of the safety work at the Consolidated Mills and graduated from that job to become mill manager.

THE OLD AND THE NEW IN PAPER MILL SAFETY

C. E. Jackson, Mill Manager, Consolidated Water Power and Paper Company, Wisconsin Rapids, Wis.

I have no other mission than to discuss the things which you already know. Alexander Pope once said, "What is so tedious as a twice told tale?" It is my hope, therefore, to inject at least one or two new thoughts into this conference, if I can do so without appearing to depart from principles and ideals which have proven worthy and which have been generally accepted. We are surely in accord with the great movement to prevent unnecessary suffering and death, yet there may be certain minor details of application which cause people to differ in their opinions: but as Ralph Waldo Emerson said, "Whoso would be a man must be a non-conformist."

I would like to have you feel that I am here to expound certain theories and philosophies which are practiced in the mills of Consolidated Water Power & Paper Company. The thoughts and methods of other people and other groups may be somewhat at variance in minor details but I am sure that it is our desire to gather together and absorb the experiences of all, thus enabling us to weigh the merits of things broadly and pass judicious judgment.

My subject implies a radical comparison between old and new safety methods in the paper industry. Perhaps we are apt to look back at the old era and call it a benighted age. Personally, I am inclined to be an optimist, as far as the past is concerned, and I actually believe that the old time methods were not as reprehensible as they are pictured. I do not like pessimists anyway, and I am reminded of a definition I recently heard. "A pessimist is one who, when given his choice between two evils, chooses both of them." Let us therefore cheer ourselves with the thought that our fathers in the paper game were in many respects very knowing and reasonably progressive. There is a tree in California still bearing leaves which has stood since the year 2,000 B. C. A living thing

of that age must certainly laugh in contemptuous amusement when it hears men referring to 20 years ago as the "dark past."

We modern people in a spirit of ego complex are prone to regard ourselves as leaders in new and better things and we like to indulge in the thought that in this great safety movement, we are guiding the industry out of stagnation and ignorance. To dispel such a thought we could look back in history and smile at the self-confidence exhibited by men who thought they were doing something new, but were merely copying and duplicating. Christopher Columbus is spoken of by many as the first man who ever ventured the thought that the earth is round. Surely he must have known that 350 years before Christ the library and museum at Alexandria contained 700,000 volumes and was full of studies in astronomy and mathematics. Eratosthenes produced manifold writings on specific gravities, the rotundity of the earth, the polar circles and the distribution of climates. The Alexandrian Museum contained more globes than can now be found in the average state university.

We are apt to regard the steam engine as a comparatively modern item of equipment but Hero, the Greek mechanic, constructed a two-cylinder steam engine long before the days of Julius Caesar. We think we know something about architecture, yet we wonder how the Egyptians built the Pyramids.

Tracing the Development of Safety Ideas

In the realm of safety we must not deceive ourselves with the false assurance that we, in the last decade, are the only people who have revered bodily perfection. A thousand years before Christ a band of conquerors descended upon southern Greece and established three kingdoms, one of which was Sparta. Read the history of the Spartans and their ideals of physical supremacy. You will be interested in the fact that sickness, injury, imbecility, old age and other infirmities were punishable by death. In the Holy Bible, Christ many times spoke of the human body as God's holy temple, not to be defiled or destroyed. Twenty years ago, in the paper industry, was really only yesterday. It is true they had no compensation laws to serve as an impetus for intensive, scientific accident prevention, but in the interests of self-preservation they possessed many of the fundamental things. Safety valves on boilers, spiked feet on ladders, gear guards, trip valves, and stair railings were not at all uncommon.

To get an intelligent and authentic viewpoint, I took pains to interview a member of our organization who is regarded as an expert mechanic and a wise counsellor in the field of machinery. I should also add that he is an enthusiastic supporter of everything which has to do with the prevention of injuries in our mills. His experience in paper making goes back 40 years or more. In the course of the conversation he made what seemed to me a very wise reflection as follows: "One of the principal reasons why paper mills are safer today than they were years ago is because the improvement and perfection of machinery from the standpoint of higher production and efficiency carries with it a safer condition for operators."

I was greatly impressed by the truth of this statement for it is surely

an obvious truth that mechanical efficiency carries safety with it. The modern, up-to-date type of paper mill equipment, even though higher speed is a feature, contains protection for workmen which machinery of former days did not have. I am referring now to improvements which were *not* planned specifically in the interests of accident prevention. The locomotive crane has done away with hand unloading and has incidentally eliminated many of the accidents which were formerly a common occurrence in log yards. I might also mention at random the oil switches on power house switch boards, circuit breakers, concrete flooring, automatic stokers and the well known drum barker which supplants the old knife barker which took such extensive toll.

On paper machines, the operator shoots the paper from the wire to the reel by air and in the present age we see very few calender fingers. The drum reel is rapidly driving out the old stack reels which caused injury and death to paper makers. Twenty years ago paper mill machinery was driven by line shafting, belts and pulleys, and we can recall many tragedies. Today the up-to-date mill machinery is driven direct from motors. There is no shafting and there are no pulleys to threaten human lives. High speed paper machines today have separate individual motors on each press, on each section of dryers and on the calender stack. These motors are synchronized, giving uniform speed. The modern paper machine is a picture of convenience and safety. We have no right to say that the elimination of line shafting was prompted solely by a desire to prevent accidents, but the result is obvious and we are happy to recognize it.

Accident Prevention Is an Institution

Beyond these there are countless things which offer further contrast between the old days and the new—things which are the result of deliberate premeditated safety action. They constitute impregnable proof that accident prevention is an institution, a tangible science and the product of trained minds—pulmotors, goggles, square D switches, rubber gloves, double hand control, illumination, standards, gear guards, belt guards, saw guards, elevator gates, railings, runways, toe boards, distant control of blow-off valves, winder guards, cleanliness, sanitation, and finally safety habit and safety discipline.

When we speak of the psychological aspect of safety we are brought to a major point which warrants our most thoughtful analysis. If there is a correct way to handle the human element, what is it? I would like to quote a familiar adage: "Business is business," and apply it to industrial relations.

Modern business has reached an appalling state of complexity. We look back 150 years and find the one-man factory. One man made a pair of shoes, and now hundreds are involved in the process. Perhaps a single apprentice was in the shop, but he worked six years at no stipend to learn the trade.

Along came the industrial revolution at about the same time, and

equally important with our American Revolution. Hand work was ruthlessly thrown to discard, and machinery, the curse of civilization, took its place. Individuality was placed on the scaffold. The creative instinct was ready to be suppressed.

The trouble started in England and the weavers got the first jolt. Agriculture was next invaded. Oliver Goldsmith said, "Ill fares the land to hastening ills a prey, where wealth accumulates, and men decay." The epidemic spread to the United States. In 1815 there were 200 patents recorded. In 1860 there were 5,000. Children were sold to factories by the parish clergy and made to work from dawn until dark. Gloomy, poorly ventilated factories, harsh employers, rickety tenements, pale anemic faces—these were the marks of American industry.

Today there are ten million wage earners in this country. One-fifth of this number are working in groups of 1,000 or more.

The Golden Rule Is a Workable Principle

A certain gospel has come to the front. The Golden Rule has become a workable principle. I have a Rotary code of ethics hanging on my wall which sets up a high standard of conduct for business. Contracts must be held sacred, employers must be fair, competition must be honest, and business as a whole must be straight and upright. I would like to attribute this great transformation to a higher moral stamina, but I am anxious to go farther than that and say that business actually is doomed to fail unless it is honest. In our present day, material success is impossible unless founded upon a high sense of morality.

The relationship between employer and employee is a business relationship. Paternalism is passe. The worker sells his services; the employer buys them; and each should give value received.

The safety movement should be treated as an immensely practical matter. There has been too much college spirit. In a great many cases safety has been made a travesty rather than a factor in production. It should be treated in a hard boiled, business-like manner, on the same basis as boiler evaporation, stock hydration and Mullen test. It is no wonder that the safety man has been looked at suspiciously by the old timers, and hailed with jeers as a busybody, a reformer and a tenderfoot. Men do not want to be children. They do not want community singing in the interests of safety anymore than in the interests of boiler house efficiency.

I do not believe in selling the "Safety Gospel" to a foreman any more than I believe in selling him the idea of paper quality. If he has not learned that the prevention of mutual losses through injury are just as much a part of his job as to keep machinery from going to pieces, he never should have been made a foreman. A good foreman is not a man who gets low production, low quality, or kills off his men. Business is business.

How about contests? Perhaps the proof of the pudding is in the eating, and the results might be evidence of a correctness of theory. Very likely a safety contest is a good stimulant for the employer; on the other hand,

in some cases it might serve as a temptation to keep unfit men at work. Undoubtedly if a man breaks his neck during a safety contest, the stigma attached to it is greater than if he had postponed the incident until after the race was over. Personally I feel that a contest brings safety into an unreal, intangible realm.

Safety is an essential factor in operation and production. Effective management with its force of discipline, and its business transactions with employees will demand safety as a feature of good service. Accidents are inexcusable economic losses. A concern which kills and maims its men can not survive with a competitor who avoids it.

I am not attempting to exclude the humanitarian aspect of this question. That side of the situation needs no discussion. I am merely pointing out the fact that the employer loses profits every time an injury occurs, regardless of his own negligence. Therefore, he rightfully demands that each man in the plant be awake to his individual responsibility.

In our mills, we negotiate wage contracts and working conditions with representatives of the employees. Our dealings with organized labor have never prevented the introduction of progressive labor policies. We have never been deterred from eliminating incompetent help. Our mill rules are adopted mutually, discipline is enforced by common consent and I want to say that infraction of safety rules is a serious offense in the eyes of management and men.

Routine in the Event of an Accident

For your interest I will state that our routine method of accident prevention is somewhat the same as that which you hear about in other mills. We have regular periodic inspections by competent men. Reports are turned in and the work followed up. In the event of an accident, rigid inquiry is made as to the cause. A conference is held attended by the personnel manager, mill manager, employment manager, foreman, and if possible by the injured man himself. Those who witnessed the accident are brought in. This tends to prevent a recurrence of that particular type of injury.

It is apparent that industry has taken the lead in the preservation of life and health. It is in the industrial world, whether the motive be sordid or humane, that safety has taken on its scientific color and produced the most potent results. Let me cite some figures to prove this.

Automobile deaths in the United States amounted to 14.9 per 100,000 population in 1923. In 1924 this figure increased to 15.7 and in 1925 to 17.2. In July, 1925, there were 58 fatalities per day, and in July, 1926, there were 59. In the year 1913 there were 3,822 people killed in the United States by automobiles. In 1924 there were 17,566. The city of Pittsburgh last year and this year conducted investigations to determine the number of automobiles having defective brakes. Last year's test showed 68.9 per cent, and this year, 69.5 per cent. We are forced to look upon automobile death records with considerable pessimism.

The number of people killed in home accidents does not increase mate-

rially from year to year. In 30 cities, totaling 12,000,000 population, there were 120 home fatalities in July, 1926. This, of course, included falling out of windows, falling down stairs, suffocation, asphyxiation, burns, etc. An examination of statistics does not show a material decrease in accidental deaths at home.

In spite of the increase in the number of automobile deaths, the actual number of all kinds of accidental deaths in the United States has shown an improved condition from year to year. In 1913, 82,500 people were killed. In 1924, there were 85,549. This means in round numbers that 100,000 lives have been saved during that period.

The dynamic effort put forth in the industries of the United States is at the bottom of all this. Every branch of manufacture has shown radical improvement from year to year. The paper industry ranks high among them all. I have talked recently with paper mill representatives and they all tell the same story. The Nekoosa Edwards Paper Company, our neighboring mills, have shown radical improvement. The mills of Consolidated have experienced a reduced number of accidents and a reduced number of days lost every year for the past six years. In 1925, we decreased the number of lost time injuries by 30 per cent and the number of days lost by 40 per cent. So far this year, the number of days lost is about 50 per cent of last year's total.

Prohibition has furthered industrial safety. I do not know much about the politics of prohibition. It is possible that the jails are more crowded. Perhaps young people are drinking more than before. On the other hand, we must not take anti-prohibition propaganda too seriously. One thing is indisputable—industry is better off; workmen are more prosperous; their hands are steadier and their heads clearer. I know that there is less drinking among paper makers and the result is a higher and more intelligent type of man. In the old days, whiskey and accidents walked hand in hand.

The paper industry with its logging operations, its high pressure boiler houses, high voltage power lines and fast running machines, should be proud of its success in this great and laudable activity. I hope that we may continue to go forward, remembering that the inevitable results are greater efficiency, higher quality and the unqualified respect of those hundreds of men whose skill and toil are indispensable and who have a right to demand good management.

CHAIRMAN ROSEBUSH: I am sure you gentlemen have heard Mr. Jackson with a good deal of interest. He has presented these safety ideas, which may be different from some of yours, in a very clear and consistent manner. I am sure he deserves the thanks of this Section for undertaking to take part in this program on such short notice.

You have heard the suggestion made by Mr. Peacock that Mr. Gleason also be included as a regional vice chairman. Will someone second that motion?

(Mr. Augustus seconded the motion. The motion was then carried unanimously.)

ADJOURNMENT

LUNCHEON SESSION.

Wednesday, October 27, 1926

The Luncheon Session of the Paper and Pulp Section of the National Safety Council was held at the Oriental Cafe, Detroit, Michigan, at 12:30 o'clock, W. J. Peacock, presiding.

CHAIRMAN PEACOCK: Let us have some music while we are waiting to be served. Mr. Al Kroes, president of the On Wisconsin Association, is our song leader. Mr. Fred Braun is at the piano. Both of the gentlemen are well known to you.

(Singing, led by Mr. Kroes, was then followed by roll call of mills, by Secretary Ameil Ueberham.)

CHAIRMAN PEACOCK: I want to introduce Mr. Scott Dowd, Editor, The Paper Industry, Chicago, Illinois.

MR. DOWD: Mr. Chairman and gentlemen of the Paper and Pulp Section. The zero hour has arrived and I know you feel just as glad as I do that we are going to get rid of this job. I also know that a good many of you know who is the winner of the cup; nevertheless it has been pretty hard to keep. At the regional conference at Appleton it was hard to stem the tide and not make the announcement there, but I feel an association of this kind should have the real enthusiasm of its members aroused and the winning of this cup has surely kept enthusiasm at high tide.

Edward B. Fritz, who is the donor of awards on our paper, regrets his inability to be here and to make this presentation. He has asked me to extend his congratulations to the officers of the Paper and Pulp Section and to the mills which entered into this contest for their interest and remarkable accomplishments.

In 1925 a suggestion came from one of our field men that a contest be put on because it would be an excellent medium for encouraging more activity in safety work in the industry and would be a means of enabling the Paper and Pulp Section to make a name for itself in National Safety Congress activities.

I wish at this time to express appreciation and give a great deal of credit, as we see it from the viewpoint of publishers, to the officers of the Section. I want to express our appreciation to your chairman, W. J. Peacock, and to your secretary, A. M. Ueberham, for those inspiring news letters gotten out every month which we are sure was the means of keeping up the interest in the contest.

Though we are at distant points of the country, nevertheless the personal expressions in those letters keep us going, keep us together and keep us working towards the same end. They have certainly done remarkable good in preserving and keeping up this contest.

Great credit is also due to George Burns for his untiring efforts in

looking after the details of this contest, and I wish to thank him personally for his great help and assistance in this work.

The mill that has won this beautiful cup has gone for more than one whole year without an accident.

I now have the pleasure of asking Edward J. Goodman, Millwright of the Neenah, Wisconsin, mill of Kimberly-Clark Company, to approach the front. (*Applause.*)

Mr. Goodman, on behalf of the paper industry we extend our congratulations for the winning of this cup and the fact that your mill has performed such a remarkable record and by that performance is the rightful winner of this cup.

We want to say before we give you an opportunity to say a word in response that, while we are largely an outsider and observer in the contest, it seems to us great credit is due the teacher represented by the directors, the man who stages these things, who educates his crew to do the job, who directs the whole job, yet the performance of which is in the hands of the crew, and to them is due the overwhelming credit for their great performance, and that crew, Mr. Goodman, is represented in you and for that reason we are very proud to present this cup to you. (*Applause.*)

MR. GOODMAN: Gentlemen, I am no orator, but I want to thank you in behalf of the employees who sent me down here to receive this cup. I thank you.

Presentation of Certificates of Merit

MR. DOWD: I now have the pleasure of presenting these certificates to the various mills which have won them, and in doing so I will call the name of the mill and their ranking number, starting with number two.

We will give the first certificate to the first mill, which happens to be Spruce Falls, Limited, a subsidiary of Kimberly-Clark, Ontario, Canada.

There is no representative of the Spruce Falls, Limited, here in this meeting today and on consultation with Mr. Hoyman we thought it would be very proper to ask our good friend, Mr. Costigane, Safety Engineer of the Ontario Pulp & Paper Makers' organization, Toronto, Canada, to take the certificate of merit to the Spruce Falls mill when he is in that territory and present it to them with our congratulations.

A. P. Costigane: Perhaps some of you gentlemen know that in Ontario we work in the group system, and the Spruce Falls mill is one of the mills that had entered the contest, but I did not myself know how they stood in the contest. I have learned that fact today and it gives me great pleasure indeed to know that one of the Canadian mills has risen to second place in this list and I am hopeful that the result of the contest next year will be that a Canadian mill will head the list, and from that point of view I am going to make a great deal of use of this certificate that has been handed me today on behalf of the Spruce Falls Company. I am going to take this certificate to every mill within the jurisdiction of our organization and I am going to show it to them and tell them that they, as well as the Spruce Falls mill, can occupy a high

position in any contest that takes place national or internationally. (*Applause.*)

MR. DOWD: Gentlemen, if I might be permitted to make this suggestion, I think it would be a great thing to insert the inscription on this cup right into the record and if you will permit I will read it at this time. The inscription on the cup reads as follows:

"Awarded to the Neenah, Wisconsin mill, Kimberly-Clark Company, winner accident prevention contest among seventy-two paper and pulp mills, members National Safety Council, for perfect No-Accident record January 1 to August 31, 1926, by The Paper Industry, Chicago, Illinois."

The Certificate Inscription in Full

MR. DOWD: And this is the certificate wording:

"The Paper Industry of Chicago in conjunction with the National Safety Council, Certificate of Merit, awarded to Spruce Falls, Limited, Ontario, Canada, subsidiary of the Kimberly-Clark Company. This certificate is awarded as a deserved expression of appreciation of this mill's accident record for the period of eight months, January 1 to August 31, 1926, during which period but ten days were lost out of 535,369 man-hours worked for an average severity rate of .01.

"In witness whereof, the Publisher of The Paper Industry and the Managing Director of the National Safety Council have hereunto affixed their signatures this 27th day of October, 1926. Signed Edward B. Fritz, Editor, *The Paper Industry*, Chicago; Countersigned, W. H. Cameron, Managing Director, National Safety Council."

MR. DOWD: Seventy-two mills were engaged in this contest, the Spruce Falls, Limited, holding the final rank of second.

The next mill, the mill to rank third and which receives the next certificate, is the Badger-Globe mill of Kimberly-Clark, Neenah, Wisconsin. I will ask Mr. A. W. Redlin, Superintendent of the Neenah mills, to approach the front and receive the certificate.

MR. REDLIN: Gentlemen of the convention, and Editor of *The Paper Industry*. I have not the honor of working at this particular mill, but I take great pleasure in being the bearer of this certificate to that mill. I think it is quite an honor to take it back with me. (*Applause.*)

MR. DOWD: Number Four certificate is awarded to the combined mills of Nekoosa-Edwards Paper Company, represented here by Mr. Rosebush, of Port Edwards, Wisconsin.

Mr. Rosebush, as we all know, won the cup trophy for the 1925 contest and it certainly gives me great pleasure to be able to present him a certificate for the second contest to take back to his mill to show they are still in the running. (*Applause.*)

MR. ROSEBUSH: Mr. Chairman and gentlemen, I certainly shall be proud to take this home. I think the Neenah mill is to be congratu-

lated and I want to extend our congratulations to them for the splendid showing they have made and this is going to be an added incentive to our men at home, to the management, to all of us to keep on with this safety work.

Mr. Down: Number Five certificate goes to the Phillipsdale mill, R. I. Bird & Son, Incorporated, Phillipsdale, R. I. This mill lost 32 days out of 299,007 man-hours worked. Severity rate, .107. We are sorry that company has no representative here to accept this certificate from us, but we will see that they receive a letter congratulating them on the part of the Section as well as *The Paper Industry*.

Number Six goes to Kimberly-Clark again. This goes to the Niagara Falls mill. This mill lost 134 days out of 93,473 man-hours for an average severity, .134, and F. A. Robinson is present and represents that mill.

F. A. ROBINSON: Mr. Chairman and gentlemen, the speaker just said it wasn't quite so good to have so many of these prizes coming to the Kimberly-Clark Company. Well, I think it is and I am going to have some photostatic copies made of this certificate and the original is going to stay in the manager's office and every time he holds a meeting in there and I happen to be present his attention is going to be called to that certificate. (*Applause.*)

Two Rooms in the Mill Had a Perfect Score

Mr. Down: The next award goes to the Upson Company, Lockport, New York, and in this connection it is interesting to know the Upson Company was among the leaders until the last month when they dropped, but they are still remaining in the first class. As they do not have a representative it is regretted that we are not able to congratulate them for staying in the contest, but we will see that they get a letter telling them how proud we are that they stayed with the job.

Mr. Burns: We sent telegrams to a few companies, representatives from which we thought might not be present because of distance. Among them was the Upson Company. On October 20th we received a letter from them which reads:

"We certainly appreciate your telegram of October 14th, advising us that you will award us a certificate of merit for our efforts in the recent safety contest. However, we are very sorry we can not have a representative present at the Detroit Congress. There is no one in the place at present we can send and we will surely miss a lot of useful ideas along the safety work line which are sure to be presented at the Detroit Congress. Our heater room and machine room carried a perfect score in this contest. We trust this year's Safety Congress will be the 'biggest ever.'"

Mr. Down: That is the kind of spirit that promotes this contest. The next certificate is awarded to the Paraffin Paper Company, of California, and they haven't a representative present. They lost 41 days out of 260,552 man-hours worked for an average severity .156.

The next certificate goes to the Marinette and Menominee Paper

Company, Marinette, Wisconsin, and since Mr. Larson is present I will ask him to come forward.

L. LARSON: Mr. Chairman and gentlemen, I wish to thank you on behalf of the Safety Committee and the employees of the Marinette-Menominee Paper Company, for this certificate. We are going to try to be at the top for next year. (*Applause.*)

CHAIRMAN PEACOCK: Mr. Larson, may I ask you to read the record on your certificate?

MR. LARSON: Number of days lost, 86, out of 529,028 man-hours worked; average severity, .163. This is certificate Number Nine.

MR. DOWD: The Laurentide Company, Limited, Gardner, Quebec, Canada, gets the last certificate, Number Ten. They had at least 1,000 employees and refuted the idea there was no chance for the big mill. They made a splendid effort to get the prize in this contest. They lost only 323 days out of 3,864,815 man-hours worked, averaging .173 severity.

I am going to ask Mr. Costigane to carry this certificate to that mill, as it is about 30 miles from his place.

I now want to call on M. G. Hoyman, whose official title is Superintendent of Service of Kimberly-Clark, and ask him to give us a few words.

Fine Cooperation Was Enjoyed in the Contest

MR. HOYMAN: It will be just a few words. One thing I take delight in mentioning, however, is the unqualified and whole-hearted cooperation and backing of our management, without which, of course, no safety movement would be successful. To that feature we can lay a great deal of whatever small success has attended our efforts, and then we go right down the line and point to the greatest cooperation from our personnel, and I want to say I am proud of our men.

I am proud of the managers and I am very, very proud indeed of our company.

MR. DOWD: Thank you for those inspiring remarks, Mr. Hoyman.

We had a conference on this matter of contest and I will outline it to some extent. While it is a fact that the severity rate, or the number of days lost per thousand hours worked, is a fair rating, because no matter whether it is 100 people working or 1,000 people working, it is the number of days lost per thousand hours worked, there is in the minds of many a feeling that there is an inequality between the mills in a contest. Both those with a small number of employees and those with a great number feel that they have an unequal opportunity to win this cup, and as it is the desire of the Section to get as many people interested in this contest as possible, these ideas must be brought out, we must have this contest satisfactory to all of the members of the Section.

For that reason it was decided to divide the membership into three groups: the (a) group consisting of 501 employees and up; the (b) group to consist of 201 to 500 employees; and the (c) group to have 200 and less. For each of these groups a trophy will be awarded so that each group

will have something to strive for and at the finish they can say that they made the best record in their particular class.

No one likes to leave an uncertainty in the atmosphere. Everyone likes to see a champion. There is a great human appreciation of one who is called a winner and a champion, and how to determine such a champion has been a problem for the Section officers to decide.

There is no mathematical factor on which to make such a decision. Some claim that severity rates should be taken as a governing factor. Another thinks frequency should govern. So we have finally come to the decision that it becomes a matter of judgment and that a board of judges will have to be appointed, and they should be disinterested judges to decide who among the three winners of the three different groups is entitled to the greatest credit for performance made, and the one the board may select will be named the champion and receive the championship trophy.

Details of the 1927 Contest Plan

For fear you don't understand, a trophy will be awarded to the winner of each group and then from these three winners this board of judges, which will be chosen as a disinterested group, will decide who among those three is entitled to the championship cup.

That will be four trophies to be awarded in the next contest. This contest will be sponsored, as usual, by *The Paper Industry*, to begin January 1, 1927, for a period of six months (as it was this year), with the elimination factor which provides that in the event there is a tie at the end of six months the contest will continue until one mill remains in each group.

Another thing that will be done which was not done in this contest is the publication, in *The Paper Industry* on a certain page of the previous month's record of the mills. That was kept out of the magazine during the last contest because it was thought it would tend to discourage many mills if they saw they didn't have much chance to win the cup. But we have decided to try it this coming year.

I want to read a striking poem to you that seems just to fit the spirit of this meeting. I will give you the author and you may read it for yourselves when you go home. The poem is written by Arthur Wellington and is entitled, "Lift Your Aim."

(Mr. Dowd read the poem.)

CHAIRMAN PEACOCK: I hope Mr. Dowd will see that the poem is published in *The Paper Industry* where we can read it and keep it as an appreciation of the thing we are trying to do in the contest.

My own mill is down the line and yet we are ahead of anything we ever did before and my feeling is that the contest spirit, getting close to the men has done us a world of good and we are going to be very glad to enter this contest.

I notice some very significant things in the final ranking. For instance, the Hammermill Paper Company, 1,282 men, 2,438,119 working hours, and a loss of 6,475 man-hours worked. What represents the real standing of the mill is the 475 lost hours, not the 6,000.

I notice another very significant thing. The Strathmore Paper Company, Mill Number Two, has a loss of 6,012 days. That represents a death and possibly one minor accident of 12 days. Those boys deserve an immense amount of credit for staying in the contest and achieving what they did after they had had the misfortune of a casualty. There are other significant things that should be brought out. Mr. Burns can give you some very interesting figures.

Mr. Burns: We have a score sheet, made up month by month for your information, covering the 72 mills reporting, and this sheet is on file in the library of the National Safety Council, and available for your reference.

I think we have one thing to learn, that is, what constitutes man-hours. Many of us report hours that the mill works rather than man-hours. Some of them seem to think it is a very complicated thing to figure the number of man-hours involved.

To anybody who has asked the question, I usually say, "Take the average number of employees in your plant for the week; if it is 100 and if your plant operates 50 hours a week, multiply it by the 100 and there are your man-hours." That is the easiest way to get at it. To take it off the pay roll is the accurate way to get at it. Many plants depend altogether on the pay roll record.

Prompt Reports Are Requested to Headquarters

One point I want to stress in the coming contest for all mills, and that is the necessity of getting the monthly report into headquarters so that we can publish it. We specify ten days in the usual way, that is, we did in the last contest. If they were 30 days in arrears they were automatically withdrawn from the contest.

I realize that sometimes you have an outstanding case and you don't know how long that particular man will be out. In any event, use the doctor's estimate and then on the following month, if necessary, send in a correction. We will be only too glad to correct one month, two months, or three months back.

I wish to express my appreciation and the appreciation of the staff for such excellent cooperation as we have received from all the mills entered in the contest.

CHAIRMAN PEACOCK: There is one thing for us all to do. We can all express our approval of what has been said today by Mr. Dowd, and I think in our expression we can include our determination to get into the contest and back it up sincerely. Are you all in favor of another contest on the terms that have been outlined, and are you all eager to get in?

Mr. LUNDRIGAN (International Paper Co., New York): Before that is put as a motion I want to say a word which I think I should say in the interest of the manufacturer.

Thereupon, followed by close attention, for nearly two hours Mr. Lundrigan led a discussion regarding the "mythical" scale of time loss which rates death cases at 6,000 days. He explained the refusal of The International Paper Company to participate in Section safety

contests on the ground that they can not agree to have their accurately kept records of losses translated into arbitrary generalities. The 6,000 day penalty, he declared, originated before accurate statistics were available and was adopted by a committee "not one of whom had any particular stake in industry." He urged upon the Section that such widespread publicity as this scale receives in a safety contest of national extent amounts to a suggestion which can be translated into costs and ill-advised legislation. His inquiry among insurance actuaries revealed a general death compensation of \$4,500, which represents 1,000 to 1,200 days. The use of a 6,000 day penalty means that the Section is committing itself to a practice which unwittingly suggests 20 years and \$20,000 in money as the moral and legal obligation industry should assume. This violates all actuarial experience and raises the question whether safety men are capable of representing the interests of the manufacturer in terms of scientific cost accounting. He showed the handicaps incurred by two mills during the 1926 contest. Both have efficient safety organizations and apart from a death penalty achieved records over an eight-months' period far superior to the average, low enough in fact otherwise to have entitled both to honorable mention.

Until, Mr. Lundrigan insisted, The National Conference Board and other agencies committed to service founded upon statistics, can offer to Industry trustworthy guidance in these matters it becomes a serious matter to publish any rating standard. Meanwhile the business-like procedure, fair to employees and manufacturers alike, is to use as a measure in contests the figures that govern actual compensation payment in terms of compensation.

CHAIRMAN PEACOCK: This is an eminently practical matter Mr. Lundrigan has opened up for us. I wish we had a year of time and the freedom of the floor in the Executive Committee in the National Safety Council. However, we have spent practically half of the time of the Section in Detroit, with two protracted periods of the officers' time, in an attempt to discover a satisfactory solution of these matters. If you see fit, I see no reason why the Paper and Pulp Section should not adopt a standard of its own in its own contest. If there is a motion, let's hear it, and we will have further discussion.

Several trial motions were made and discarded. Finally a motion was made in the following form which secured a unanimous vote: Moved:

That the Paper and Pulp Section, in the contest of 1927, adopt a standard penalty of 1,000 days for fatal accidents in place of the present 6,000 days, and that penalties for permanent disabilities be computed on 1,000 days as 100 per cent instead of 6,000 as it now is.

Mr. Burns, of The National Safety Council staff, was asked to prepare and submit the new schedule at the earliest possible date. In addition the chairman was asked to present and explain the stand of the Section to the Executive Committee of the National Safety Council. This he agreed to do, stating that the verbatim report of Mr. Lundrigan's address would be incorporated as "Exhibit A."

ADJOURNMENT

Petroleum Section

New Officers of the Section

CHAIRMAN: V. R. CURRIE
The Texas Company, Houston, Texas.
GENERAL VICE-CHAIRMAN: DR. R. P. ANDERSON
American Petroleum Institute, New York City.
CHAIRMAN, PACIFIC DIVISION: CHARLES M. BUTLER
General Petroleum Corporation, Los Angeles, Calif.
CHAIRMAN, MID-CONTINENT: RAY E. MILLER
Marland Refining Co., Ponca City, Okla.
CHAIRMAN, ATLANTIC DIVISION: THOS. W. WADDINGTON
Standard Oil Company (N. J.), Elizabeth, N. J.
SECRETARY: A. A. NICHOSON
The Texas Company, New York City.

Committees

PROGRAM: F. C. SINGLETON, Chairman
Standard Oil Co. (Ind.), Chicago, Ill.
NEWS-LETTER: A. A. NICHOSON, Chairman
The Texas Co., New York City.
BY-LAWS: DR. R. P. ANDERSON, Chairman
American Petroleum Institute, New York City.
POSTER: D. J. WALLACE, Chairman
Humble Oil & Refining Co., Houston, Texas.
MEMBERSHIP: GEO. F. PRUSSING, Chairman
Union Oil Co., Los Angeles, Calif.
STATISTICAL: J. W. MYERS
Standard Oil Company (N. J.), New York City.
ENGINEERING REPRESENTATIVE: E. J. SENNE
Vacuum Oil Co., New York City.
EXECUTIVE COMMITTEE (The Officers and)
ROY S. BONSIB
Standard Oil Co. (N. J.), New York City.

Tide Water Oil Co., New York City

C. W. SMITH

Standard Oil Co. (Indiana), Chicago, Ill.

October 26, 1926.

E. J. SENNE, Chairman

Safety Supervisor, Vacuum Oil Company, New York City

THE Tuesday Morning Session, October 26th, 1926, of the Petroleum Section convened at 9:45 o'clock at the Tuller Hotel, Detroit, Michigan, Chairman E. J. Senne, Safety Supervisor, Vacuum Oil Company, New York City, presiding.

OPENING ADDRESS

By Chairman E. J. Senne

Friends and fellow-members of the Petroleum Section! It is with much pleasure that I am again privileged to greet you at this, the Fifteenth Safety Congress. A hearty and sincere welcome is extended to all, and I trust that our sessions may be characteristic of the nature and quality of effort that has always been the standard of our industry. To the new members of our Section, for whom this may be an initial visit, we extend a special greeting and invite you to participate fully in our work and deliberations.

Ours is a work of service, not circumscribed by any set rules of procedure, but rather a duty of careful thought towards evolving the best ways and means to protect life and limb, to conserve the manpower of our industry, to avert accidents, to avoid disaster, and, in general, to provide for the safety and security of industrial workers and assist in maintaining orderly progress and to eliminate waste in its various forms.

Injured workmen need not be a by-product of industry. There is no

question that by most of you the word "Safety" has been considered from angles a thousand-fold in the comparatively short time during which the scope of our work has been concentrated. I feel that, although our progress has been somewhat slow, the greatest and most appreciative reward which has come to us is that recognition which is accorded us by the rank and file in our profession and also by the supervising forces connected with the great industry which is represented here today. This, in fact, is a reward worthy of a continued and more intensive effort.

As you all know, the field of our endeavor is among the working people, and whatever success we may achieve is only possible through their cooperation and by their acceptance of the principles which we teach and try to have them practice. Safety fundamentals are the same the world over; but it is through a higher quality of service, combined with a personality which reflects a sincere interest, real friendliness, and a personal regard—all of which are necessary in the make-up of the real, progressive safety man—that efficiency and favorable results are obtained. Any other way may seem to be effective, but will continue only to a moderate degree and for a limited time.

Education the Prime Factor in a Safety Program

Education is the prime factor in successful accomplishment of any safety program. We must follow this education along school lines, from a primary grade upwards to the point where a workman is schooled to the idea of thinking safety and working with that regard so necessary for his own good and for the best interests of his employer. Not until we are satisfied that all workers are careful men will our duties be completed.

Then again, such progress in education will vary considerably. We will find various degrees of intelligence among the workers. Some will readily learn every lesson taught; others must be led through the ABC class of safety; some will always remain in the ABC class; and, strange to say, others may even teach us. Discouragements and a seeming failure of our best efforts will come sometimes and it is in these instances where determination and courage will be needed to overcome the obstacle. Patience, diligence and earnest toil are the requisites of success in your work.

As the spirit of industrial safety work is lofty and ideal, the underlying principle being based on humanitarian impulses, there can be no more convincing evidence of the real worth of the cause to which you have devoted yourselves. The procedure, therefore, as I see it, is not one of a highly technical nature, neither the broadcasting of a maze of theoretical processes, nor the enforcement of some untried or unproven plans; it is rather a modest approach to the subject with a purpose of leadership in a movement of safety and accident prevention, which previously you have analyzed and studied, and for which you can prescribe fair and reasonable remedies, bearing in mind that the support of the employees must be obtained and maintained through

practical and common-sense methods. They will not lean to scientific or speculative practices offered to them in a complex manner; good ordinary judgment and simple advice will reach and stay with them.

Safety work unquestionably is a real part of any plant's existence, and the need was never greater for service and for sincere and competent leaders in this field. The opportunity is here and the duty to grasp it is ours. If we are to carry on this work and keep going forward—and the minute we stand still we commence to go backwards—we must begin today to make a survey of our work, and the forward march will be on.

In conclusion, I wish to acknowledge gratefully the many exceptional courtesies which have been shown to me by all of the officers of the National Safety Council and by all of our own member friends, and for the encouragement and inspiration of my associates which have signalized their support during my two terms as your general chairman. It has been a pleasure and I have considered it a duty to carry on in behalf of this great work, and if my efforts have been instrumental in helping others, or, better still, if I have been able to lessen accidents and injuries among the great army of workers, I consider that I have been amply repaid and that the greatest reward is due to our Petroleum Section for the ideals which it always wants to uphold.

Reports and Standing Committees

We will now proceed with the regular order of the program, the first being a report of officers and committees. If there are any officers or committees here to report, I will be glad to hear from them at this time. Perhaps the chairman of the various divisions are here. Is the chairman of the Atlantic Division present? Is the chairman of the Midcontinent Division present? Mr. Miller, have you any formal report to make?

RAY E. MILLER (Petroleum Safety Council, Tulsa, Oklahoma): No formal report today.

THE CHAIRMAN: I regret to announce the absence of the chairman of the Pacific Division, Mr. Kelly. During the past year Mr. Kelly has found it necessary to sever his relations with the industry, for which we are all indeed very sorry. We have lost a man whom we held in very high esteem and a competent man in every way. He has done a great deal for the Petroleum Section.

I will read the names of the standing committees as they are today:

The Program Committee: C. C. Seals, chairman, Vacuum Oil Co. Mr. S. H. McKenty, of the Atlantic Refining Company. Mr. F. L. Newcomb, of the Standard Oil Co., New Jersey.

Committee on By-Laws: Dr. R. P. Anderson, of the American Petroleum Institute; Mr. W. F. Burt, of the Standard Oil Co. of New York; Mr. Wm. V. Winslow, of the Texas Company.

Committee on News Letter: C. W. Smith, chairman, of the Standard Oil Co. of Indiana; Mr. Roy Bonsib, of the Standard Oil Co., New Jersey; Mr. H. W. Boggess, of the Sinclair Companies; Mr. R. E. Donovan, of the Standard Oil of California.

Poster Committee: Mr. F. A. Epps, of the Tidewater Oil Co.

Safety Codes Committee: Mr. Kelly, Associated Oil; Mr. Prussing, Union Oil; Mr. Timm, Standard Oil Co. of New Jersey; Mr. Roth, Vacuum Oil; Mr. Boggess, Sinclair Oil; and Mr. Miller, Midcontinent Oil and Gas Association.

The next order on the program is the appointment of a Nominating Committee. The Nominating Committee which we have selected through cooperation with the Regional Chairmen is announced as follows:

Chairman of the Nominating Committee: Mr. D. J. Wallace, of the Humble Oil & Refining Co.; Mr. E. A. Timm, of the Standard Oil, New Jersey; Mr. W. F. Burt, Standard Oil of New York; Mr. J. S. Gibson, Prairie Pipe Line Co.; Mr. M. A. Tracy, Louisiana Oil Refining; G. F. Prussing, Union Oil, and Mr. C. M. Butler, General Petroleum Corporation.

Before announcing the name of the first speaker, I just want to outline briefly my ideas of the man.

The gentleman who will first address you is really one of the founders of the Petroleum Section. He has done considerable pioneer work, and that pioneer work has been supplemented by actual physical work, practical planning and continued effort for the best interests of the Section and for the oil industry. He is known by all of the members as a capable and efficient man, a friend of everybody, and a man whom we all enjoy having as company. I am very pleased to present to you Mr. D. J. Wallace, of the Humble Oil & Refining Company.

A Lantern in the Middle of the Road

D. J. WALLACE (Humble Oil & Refining Co., Houston, Texas): That makes it awfully difficult for me, and inasmuch as my voice is weak this morning, I am going to ask everybody to come up here and sit in the front seats. We are not going to work you very hard, but we surely would like to have you in these front seats.

I am sure that everybody thought there was hyperbole in the chairman's remarks. The only reason they put me on the program was to open things up and get going, and we have in the organization an infinitely better can-opener than I am, and I am going to ask Mr. Currie to say a few words to start the thing off and then it will make it easier for me.

V. R. CURRIE (The Texas Co., Houston, Texas): Considering the fact that most of us are more or less strangers in Detroit and that many pitfalls and temptations are likely to cross our way during the next few days, especially due to our proximity to the Canadian border, I thought that perhaps it might be well to call the attention of the members of the Section at the outset of this meeting to a clipping which I cut a few days ago from one of our newspapers. This is dated in San Antonio, Texas, the state that Don Wallace comes from.

"September 18th. A drunken man now sleeping it off in the Barr County jail has proved beyond any reasonable doubt that self-preservation is the first law of nature. Midnight Friday found this self-same

man too much the worse for drink. He knew it and like a whole lot of drunken men he needed sleep badly. The middle of South Almo Street looked fairly safe for sleeping at that time of the night, but before retiring he placed a red lantern at his feet. 'Why the lantern?' a motorcycle officer asked the gentleman after awakening him. 'Well, some of these drunken fellows will run over a fellow if he ain't careful,' was the reply."

Mr. Chairman, I would like to suggest that a committee be appointed to purchase a half a carload of red lanterns to distribute among the employees for their protection during the coming week.

THE CHAIRMAN: The chairman will take note of your recommendation.

EXPERIENCE AND PROSPECT OF SAFETY IN PRODUCING TERRITORY

A Round Table Discussion, Led by D. J. Wallace, Humble Oil and Refining Co., Houston, Texas

I am going to surprise you a little bit.

If I remember rightly, my talk this morning was to be on the "Experience and Prospect of Safety in Producing Territory," and inasmuch as I have not been connected with the producing end of the game for the last couple of years, it left me at a loss to know how to tackle the thing. So I wrote to a friend of mine with the Texas Employers' Insurance Association, and asked him to give me a typical group of accidents which had occurred at any time in the Midcontinental territory, and I have here a group of reports of fatal accidents that he sent to me covering only the state of Texas for a period of about 18 months.

These are the original accident reports in most instances. Sometimes they are copies, but they are all verbatim copies.

What I am going to do—and I certainly hope you will bear with me and cooperate with me in this—I am going to pass these reports out and ask each man who gets one, as it comes his turn, to rise and read "Section D" of this accident report form—what it says about the injury, and then say whatever he will, just give us his own thoughts as to how the accident could have been prevented; and let's have just a very short discussion on each one of these accidents.

That, it seems to me, ought to make it interesting for this meeting. This is a whole bunch of fatal accidents, and they are from the files of only one insurance company out of about seven. So you can see that it really is serious.

Mr. Shaw, will you start the thing off?

MR. SHAW: This accident under "Section D" describes fully how the accident occurred. "Injured party and helper had finished loading six inch bars of round steel onto a wagon and had started to drive away from box car. In making turn, bars of steel which were protruding, fell down, throwing party under left tongue mule, which was thrown down by tongue and whiffletree. As wagon turned over party fell under hindquarters of this mule, receiving crushed skull, dying instantly."

That tells how it happened. The logical follow-up questions, to my

ming, would be: Was the accident avoidable and if so, how could it have been prevented?

In my opinion this accident would have been avoidable because this load evidently was not properly placed on the wagon, and with the protruding bar apparently tripped this mule or cramped the wagon around. That would be carelessness in loading. These fellows evidently weren't watching their job in the loading. That is the primary cause of the injury. What subsequently happened is to be expected with improper loading, and the whole thing, to my mind, shows carelessness on the part of loading. Greater care would have prevented the accident.

MR. WALLACE: Thank you, Mr. Shaw; that is fine.

Mr. Shaw's difficulty in reading the report is the difficulty that we all have in the reports that come in from the field—not carefully made out. They don't show graphically how the accident occurred. Nevertheless, his analysis is very good. Let's confine ourselves to sixty seconds.

T. W. WADDINGTON (Standard Oil Co. of N. J.): This report is of a man who was injured evidently working on a tank on the Humble Pipe Line Company.

"While working on a tank scaffold, standing on bench supported by scaffold, and piling up iron at about 22 feet above ground, the injured man lost his balance, fell backward, dropped to the bottom of the tank."

I do not think you need any comment from me as to what might have prevented this accident. If that man was working on an honest-to-goodness tank erection job and was in a fitting-up cage he could not have fallen backward, because the back of the cage would have prevented this. I do not know what the circumstances were, but if he was standing on a box or an improvised scaffold, that was all wrong. A fitting-up cage would have prevented the accident. Evidently he was fitting up iron.

A Foreman Who Exposed Himself Unnecessarily

F. L. NEWCOMB (Standard Oil of New Jersey): This is a case of a foreman who while overseeing men loading a car was hit by a piece of steel. The foreman should have stayed out of the way; and another thing, I don't think he was supervising the job properly.

MR. WALLACE: There is so much of this that it is going to take us a long while to go over it, and the thought I was trying to get across by asking you to read these was to give you a graphic picture of the production end in the past three or four years. We don't want to take any longer than is absolutely necessary to do. If you don't think the report is fit, it is perfectly all right to say so, but we would like to get the high lights on all of them.

MEMBER: This report says four men tried to lift a barrel and a man got hurt in the side and died afterwards. It shows they should have used a skid.

MR. WALLACE: That we classify as poor judgment. A man is so liable to lift a little bit more than he should. You have got to watch your men when they are enthused.

W. E. MCGRAW (H. H. Robertson Co., Pittsburgh, Pa.): This is a head and shoulder accident resulting in death.

"On a car in which piling was being extended, and was preparing to roll another pile from the car. Men in the car called out, but he failed to get out of the way and the pile struck him and he was immediately rushed to the hospital."

I think there is only one answer to that and that is carelessness.

MEMBER: This seems to be an alleged injury. "Walked out of the way of a locomotive, jumped and fell." Evidently, any stumbling and falling accident is just about the same.

CHAIRMAN SENNE: The report that I have represents one of the most commonplace accidents that we hear of. A man was killed through a fractured skull. His automobile collided with a street car.

The element of control there is in favor of the street car. A street car has only one mode of progress, it runs on a track; it only has one way to go. It is usually under control. It is usually under a speed of less than 10 miles. The automobile average speed is probably 20 to 40 miles. It appears here that this man was entirely at fault because he should have had his car under proper control and avoided a collision with the street car. It is all up to the driver of the car. I should say, the human element of neglect.

Cases of Carelessness and Oversight

MEMBER: This man was caught on a tubing line and caught in the block. It was not a fatal accident but he lost four fingers of his right hand. I think that was a case of carelessness.

MEMBER: "Deceased left bull rope lying idle on the shaft. Deceased attempted to remove bull rope away from the wheel and rope came in contact with the wheel, where either post or rope must break. So post broke, which struck deceased and knocked him in the hole." That was a drilling operation.

Undoubtedly a case of oversight or carelessness on the part of the man in not seeing that his ropes were clear of this revolving wheel before starting the tools down into the hole.

MEMBER: This man left home at midnight to go on duty at the powerhouse and the superintendent found him at the clutch dead at 4:30 in the morning in a badly mangled condition, evidently caught in the clutch.

A man leaving for work at that time of morning might have been a little bit sleepy in operating his clutch, or he should have shut down the gas engine before he went to the clutch.

MEMBER: This man was standing astride of the drilling line. The clamps gave way and injured him. In my opinion, he should not have been standing astride of the drilling line, but to one side and it would not have happened.

MEMBER: A fireman 50 years of age was firing a boiler. "Employee allowed water in the boiler to run low without taking notice of this fact, and turned on the injector, causing terrific steam pressure and causing the man's death."

Very evidently the man was careless in not watching the water gauge, otherwise he would certainly have known how low the water was in his boiler; although the water was in the boiler, the boiler had a blowout which could have been opened and the explosion avoided.

MR. WALLACE: You will find some boiler blowouts in this, and you will notice on almost every one of them that a safeguard is provided to prevent this, and those safety appliances consist of a valve which you can't open with a crow-bar and possibly a water gauge. That is quite typical of the Midcontinent territory, and I presume in most of the other fields. They are runned for safety and they think everything that they can get and they set it up in a boiler and set it up. I have found lots of them.

Let's have about three or four more and the rest of you read them to yourselves.

MEMBER: May I ask if any of the companies have done anything at all in using a water alarm for boilers?

MR. WALLACE: The Fiske Company and we ourselves have tried it out but it has been our experience that they depend too much on the low water alarm rather than on any automatic device. However, that is nothing against the low water alarm.

MEMBER: Company car operated by employee was struck by railroad train causing death. That is obviously carelessness.

Money Lost in Accidents Outside the Plant

MR. WALLACE: How many companies are really losing more money by accidents outside of the plant than they are in the plant? All of them. We are going to find some day that the ramifications of this particular Section go into almost all other Sections, and particularly into the Section on Public Safety. That is our particular problem, to keep the boys from getting killed going and coming from their work.

MEMBER: I have another automobile accident that I don't think I will discuss. In this particular case there isn't anything in this report which will tell you what happened. We have gotten up an auxiliary form that we are sending out with every accident in which, if it isn't a fatal accident, the individual who is injured goes over that report and we have a list of causes—carelessness, wrong methods, poor tools—and ask the injured man to check what he considers caused that accident, sign his name to it and send it in. We find that helps a lot to get down to details. If a report comes in that isn't in sufficient detail to tell what happened, we are returning it, and we tell them it must be in sufficient detail so that the man who reads it knows as much about it as the man who was on the job.

MR. WALLACE: That should be done.

I wonder now if you don't have a reasonably good picture of what the experience has been throughout our part of the country, and I presume it is the same with all of you. The experiences are regrettable, of course, but if we learn by them as we should and profit by them, then there will be at least that much to help us.

As far as prospects are concerned for safety, I feel that if we try to dwell too much on that we will simply be counting our chickens before they are hatched. We all hope for a better record in the future than we have had in the past, and the few years that we have been working together I think have shown a very real development in safety. I know that it has in the Midcontinent territory through our local association there. We have been showing pictures, etc., as you all know, holding foremen's meetings and doing all that we can to get the work down to the man in the field. And that is the problem in the production work because the men in the outlying places are hard to reach and can't be reached very readily by any one company doing it alone with their own men.

However, I believe I am right when I say that there isn't a company in the Midcontinent territory now that isn't really interested in safety work. They are not all bearing their part of the burden; they are all taking a real interest in the work, and that speaks very well for prospects in the future.

I would like to consider this Section here as the real incubator for the ideas that are going to be hatched eventually and the chickens that we can count. I don't want to make any attempt to count them at this time, but I do have a very firm belief that the eggs that are laid here, if we will take them home and incubate them carefully, will hatch into chickens that will really be helpful to us in our work. I only wish that I had the real eggs to leave with you.

The Mental Attitude Necessary in Safety Thought

My experience has convinced me more and more that what we have to do back home, back in our own fields, is simply a shoulder-to-shoulder work with the fellows who are exposed to the hazards, getting as close to them as we can, and developing if possible that mental attitude on their part which in the last analysis is the only thing that is going to protect them. If we can develop the mental attitude that the employees should have, then the ambulances won't have to run near as much and their protection will be just as much with them on their way to work and on their way from work as it is on the job. And that I believe is the best egg that anybody ought to try to incubate and incubate very carefully—that mental attitude on the part of our employees towards their own welfare and towards the welfare of those associated with them.

Just how to do that I don't know, but I have wondered lots of times if it wouldn't be possible in some way to develop some real traditions in the oil fields, some real traditions in our own companies, that would be helpful in developing that mental attitude. You fellows all remember the traditions of the school that you used to fight for so hard before you had to go out to work. If we could develop traditions—not only along the lines of safety, but along all lines of loyalty and real regard for the companies we are working for (which ought not to be hard with any man that is working for a legitimate oil company, because it is the highest

type of industry that we have in the country), if we could develop those traditions and that mental attitude on the part of the men that would make them fight to uphold those traditions as we used to fight to uphold the traditions of our school, then certainly we would have little trouble in our accident work.

THE CHAIRMAN: The next speaker, I am sure, has a subject of more than ordinary interest for us, a subject that I don't recall has ever been discussed or considered in any of our previous sessions, and I know from the nature and experience of our speaker that we will receive information, advice and suggestions of more than ordinary value. He is a man of experience in the oil industry, but I believe his work is also much of an experimental nature and of the nature of research. I know that we shall listen with much interest to the paper by Mr. Newcomb, on "Safety in Connection With Oil Refinery Processes."

SAFETY IN CONNECTION WITH OIL REFINERY PROCESSES

Franklin L. Newcomb, Chief Safety Inspector, General Engineering Department, Standard Oil Company (N. J.), Elizabeth, N. J.

For the past three years I have attended these meetings and heard many papers and discussions on the work being handled by the safety men of the petroleum industry and on ways and means of controlling accidents. And yet, in all this time I do not recall hearing any discussion relative to the accident hazards incident to the handling and processing of the oil itself with the exception of discussions on static electricity. Therefore I feel that at this time it will not be amiss to point out a large phase of safety work connected with the principal processes of the petroleum industry which seems to be getting a lesser amount of attention by this body than other safety work connected with work only incidental to the industry.

Crude oil and the large majority of finished products made from it are highly volatile and all are flammable. Therefore, by their very nature they contain an inherent hazard and all processes where they are involved must necessarily be of a hazardous nature. It would appear, then, that a careful analysis of the apparatus used in these processes and of the methods employed in the use of such apparatus should command considerable attention from the safety departments if these departments are to render the fullest possible safety service to the petroleum industry.

A modern and complete oil refinery covers a wide range of activity with many and varied processes, a large number of them requiring the heating of the oils to temperatures well above their flash and ignition points. Even the simplest skimming or topping plants cover a number of varied processes with their attendant hazards.

Let me briefly outline some of the major operations in an oil refinery. There is the storage of oil in bulk, usually in steel tanks, some with

no roofs, some with wooden roofs, some with steel roofs, some vapor-tight and others not, some with heating coils and most of them containing products which give off flammable vapors and gases. These tanks must be gauged at intervals to determine the amount of oil they contain. They must be painted on the outside to preserve them; must be repaired at intervals and must at times be emptied and cleaned, necessitating sending men into them.

The oil must be transferred from point to point in the plant necessitating the use of pipe lines and pumps.

In dividing the oil into its constituent parts and finishing them to marketable specifications, fractional distillation must be employed. This is carried on in stills operating only at very low pressure or, in some cases, even under a vacuum. Such stills consist of a fire box, a receptacle for holding the oil while the heat is being applied, which may be either a pipe coil or a large vessel usually cylindrical in shape, various types of fractionating equipment to condense certain of the heavier fractions and cause close separation of the vapors, a condensing and cooling equipment to condense the vapors and cool the products, and a receiving or tail house where the condensed and cooled products pass through for inspection and sampling, and are diverted to the proper tanks.

Intricate Details of the Various Processes

This process necessitates maintaining fires in the fire boxes to vaporize the oil; the operation of many valves to control the separation in the fractionating equipment and to divert the condensed products to the desired point; the taking of samples of condensed products for inspection and test; the charging of the apparatus with oil when starting up; the emptying of the apparatus at the completion of the run; the displacement of all vapors and gases before opening; the cooling of the equipment; cleaning the interior before recharging; inspection to see that the apparatus is in fit condition to operate; the complete, vapor-tight closure of the apparatus; and the displacement of all air before recharging.

The increased demand for gasoline due to the advent of the automobile resulted in the design of various types of cracking apparatus for breaking down heavy hydro-carbons into lighter hydro-carbons suitable for use in gasoline engines. Such cracking apparatus operates under high pressures ranging from 60 pounds upward to many hundred pounds per square inch, and with temperatures up in the neighborhood of 1,000 degrees F. This apparatus consists of a fire box, a receptacle for holding the oil while the heat is being applied, various types of drums for holding the oil under temperature and pressure over a period of time, fractionating equipment under various pressures, condensing and cooling equipment, heat exchangers, receiving equipment for the various products and usually high pressure pumps, in many cases handling hot oils up to 600 degrees F., as well as low pressure hot tar pumps. These processes involve all of the operations outlined under

fractional distillation, and in addition, the operation of high pressure and hot oil pumps and the control of pressures in the various parts of the equipment.

Before certain of the products are marketable they must be treated to remove impurities and to improve their color. This is done usually by one of two methods. Either a batch of oil is placed in an agitator, which is simply a tank with cone bottom, and the treating chemicals are introduced and the batch agitated by circulating with a pump or blowing with air; or the oil is pumped continuously through a series of drums where the chemicals are sprayed in and settled out. The chemicals mainly used are strong sulphuric acid litharge and bicarbonate of soda. The batch agitator method involves the pumping of the oil into and out of the apparatus; introduction of each of the chemicals in turn; agitation after the introduction of each chemical; settling after each agitation; drawing off of the settled out chemicals from the bottom; washing operations between the introduction of each chemical; and a settling and drawing off of the water. The operation of a continuous treating plant consists mainly of continuous pumping of the oil, chemical solutions and wash water and drawing off of the chemicals and wash water from the settling drums. Both methods involve the handling of acids and strong alkali solutions, and transfer of these materials is done either by use of special pumps or by blowing with compressed air from drums commonly called acid or alkali eggs or blow-cases.

Handling the Gas Formed in Refining Petroleum

In the refining of petroleum and its products quantities of gas are formed which must be handled. It is collected from low pressure stills and equipment by pipe lines connected to exhausters which create a constant suction on the line. From high pressure equipment it may be taken away through pipe lines under its own pressure. When used for certain purposes it must be purified and is often passed through scrubbers and other purifying apparatus. Much of it contains light products which can be reduced to a liquid state by absorption in heavier oils or by compression. The surplus gas which can not be utilized at the time of formation must be stored or wasted, and in many cases large gas holders, similar to those to be seen in most cities, are employed.

To send the oil to market it is shipped in various ways. When sent out by tank car it must be loaded into the car from a pipe through an open hatch and the agitation resulting causes vaporization and the release of highly flammable gases. When shipped in barrels, they must be filled through a small opening, by hose or nozzle, and gas is given off and there is liable to be dripping and spilling of the oil. When shipped in cans, the filling is usually done by machines but often the cans are closed by small caps soldered in place.

There are many other processes which it would take too long to describe, even briefly, but the above will serve to demonstrate the varied operations attendant upon the actual process of oil refining. In addition,

steam boilers, electrical power houses, transmission of electricity, by wire, air compressors and air receivers with their attendant operations and hazards enter into the operation of practically every refinery.

It is apparent that practically every operation mentioned has the potentialities of being a hazard. There are three main factors which enter into the safety of these processes.

First, the equipment must be suitable for the job, that is, it must be made of the right material, properly put together and of ample strength. This is a problem of design and an engineering function.

Second, the proper methods must be used in handling the equipment and performing the various operations. This is a problem of operation.

Third, the equipment must be kept in good condition at all times. This is a problem of inspection and maintenance.

What Is Being Done in Design

Let us consider the first fact, namely, that of design, and see what is being done. Only a comparatively few years ago, most of the design was by rule of thumb. The operating man said what he wanted and the foremen of the various trades did the rest. The boilermaker built a still, making it as thick as he thought necessary and riveting it together as his experience dictated. Even at that, we got a pretty good job because we usually had a pretty good boilermaker foreman. It was the same with the pipe-fitting, masonry, and so on. But they did not always get the material best suited for the conditions, nor did they always make proper provision for all of the strains. Today our large companies all have well organized engineering departments and equipment is being designed scientifically. Investigations are being made into the most suitable materials to be used in different locations and under various conditions. Cracking and other pressure equipment particularly is receiving intensive study.

Taking the second fact, that of employing proper methods in the handling of the equipment and performing the various operations, our operating people are giving it considerable attention today. Processes are being studied and analyzed by our executives. In some companies well organized departments are making careful research to find the best method of operation, not only to get the maximum yields of the most valuable products, but also to avoid accidents and fires which may result in long shut-downs for repairs.

Our third fact, that of keeping the equipment in good condition, is being handled in two ways. Maintenance forces composed of mechanics make periodic visual inspection of the equipment, usually during each cleaning period and make such repairs as appear necessary. This is of course, an absolute necessity to keep the equipment operating.

Some of our companies have also an engineering inspection force to make more exhaustive inspections of equipment than can be done during the cleaning period by the maintenance forces. These engineering inspection forces were an outgrowth of the advent of cracking. After cracking

equipment has been in operation for a number of years, serious failures started to occur and the industry began to make an investigation. It was found that cracking equipment deteriorated quite rapidly, especially in some particular places. As it operated under considerable pressure, it could not be permitted to go until leaks occurred or a sharp blow from a hammer would indicate a weak spot.

So gradually these engineering inspection forces were built up to make periodic, systematic inspection of the equipment. The deterioration in cracking equipment is difficult to determine, as it is not visible to the eye, there usually being no marked pitted or corroded areas. Generally the metal has the same smooth appearance as when new. However, the deterioration is not uniform, but often occurs in long waves which can not be seen and for this reason it is difficult to locate the thinnest spots. Parts thinner than others can often be found by sounding with a light hammer, but it takes an experienced and trained man to know the sound. Due to the nature of the deterioration, it has become quite generally the custom to drill holes in various parts of the equipment to determine its actual thickness. These inspection forces also check over all parts of the equipment including pipe, valves, gauges, safety valves, etc., and check up to see that the refinery's maintenance forces are keeping everything in a safe condition.

The Inspection Field Being Widened

The field covered by these engineering inspection forces is being gradually widened and inspections have been made of storage tanks, gas absorbers, gas holders, air receivers, acid and alkali eggs and such things. Men trained to inspect cracking equipment are admirably fitted to inspect any pressure equipment.

Although all the above is being done for safe operation of the actual refining equipment, I believe your accident records will show lost time accidents due to failure of various parts of the equipment or to some operation of the equipment, and I further believe that if you will look into the matter you will find that generally such accidents are of a most serious nature. They may not make up a very large percentage of your frequency rate but I think you will find that if they could be eliminated your severity rate would show a very marked reduction, and, after all, aren't we just as anxious to reduce the severity rate as we are the frequency rate, or more so?

Now that we have considered the various functions of oil refining and the work being done to make it safe, let us consider what the safety department can do to further this work. It may appear that the engineering departments, process operators and maintenance forces are covering the situation, but you can assist materially in advancing this work.

Take the engineering and design. You safety men spend a good part of your time out in the plant. You make inspections and you talk to and get acquainted with the men. They talk freely to you. A member of the engineering department does not hear the men's troubles. You can help by reporting what appears to be trouble with some particular

kind of apparatus or some particular material, and give the engineering department an opportunity to investigate. Are you trying to get and report this information?

Almost the same thing applies to the processing operations. Do the men ever tell of troubles with the methods employed? If they do, do you know enough about the operation to investigate and see if there is any foundation for the complaint? Then is it taken up and followed until a safe method is substituted?

On the maintenance and inspection you can help very greatly. Find the apparatus about the plant which is in need of inspection and then get it inspected. Just at present there is one of our plant safety men who has made a list of every pressure vessel in his plant which is not now being inspected, and he is trying to get his superiors to ask for periodic engineering inspection of this equipment. I understand there are 110 pressure vessels on this list. This is what I mean by helping the inspection force.

Then as you get or can make the opportunity, study every operation and piece of equipment and look for unsafe practices and equipment.

Only a few months ago a vice-president of a prominent oil company asked me if I knew of a safety man who could come into one of his refineries and make an inspection of his refining equipment and processes, point out any part of any equipment which might be dangerous and suggest means of making it safe, point out all parts of the process methods which might be unsafe and make suggestions for making them safe, and point out all points of hazard in the process which could not be eliminated, and tell him how to reduce the hazard to a minimum by laying down the precautions to be taken. Is there any one here who feels qualified to take on that job?

It would appear that there is still a very large field of safety work in the petroleum industry which requires a large amount of study.

Discussion Following Mr. Newcomb's Paper

T. W. WADDINGTON (Standard Oil Co. (N. J.), Elizabeth, N. J.): Supplementing what Mr. Newcomb said, where he spoke of a plant that had a list of 110 pressure vessels and setting the machinery in motion in the matter of systematic tests and inspections, I would like to say he refers to the Bayway Refinery and that this has already taken place. It is unquestionably a step in the right direction. People say: "Oh, yes, we inspect our pressure drums." Sure you do. "When did you inspect this drum last?" "Let's see." They scratch their head and there may be a mark there indicating somebody looked at it perhaps over 18 months ago. But is the inspection periodic and do they know? The vessel may be right at the edge of failure with no safety factor and ready to let go. A water test won't tell you. It may be you will have to drill a hole in the metal to determine the thickness and sound it. This should be done by somebody with experience. Find out actually whether your pressure vessels are ready to let go or not. You would be surprised to

know how many would be thrown into discard when you got through.

THE CHAIRMAN: I would like to ask Mr. Newcomb whether there is such a plan of periodic inspection of pressure vessels. In other words, do you shut down every type of pressure vessel every so often for the object of inspection, the same as we do on boilers? You know, we have boiler washings and regular periodic boiler inspection.

MR. NEWCOMB: Up to date it has not applied to all pressure vessels. It has applied to some of them. All of our high pressure cracking equipment is shut down three time a year for inspection, and we make a thorough inspection of everything. We drill holes wherever we think it is necessary and we don't stint to use the drill. We stick it through any place where we think it is thin and just on a hunch sometimes. We are beginning to do it on other pressure vessels.

Startling Discoveries Sometimes Are Made

Some time ago a man in charge of Bayway's gas plant read an article about a gas holder where the roof had failed due to the fact the rivet heads were all eaten off on the inside and it opened up and the gas escaped and traveled half a mile, hit an open flame, flashed, and carried everything clear back to the holder. So he asked us to inspect his gas holders. We went in there and while we were waiting for a scaffold on the inside the inspector walked up on the roof. He thought he would sound the roof; he gave it a good solid crack with a hammer and the rivets popped out. The man had a good hunch.

We are inspecting gas absorber towers regularly, and we will now inspect all of these 110 pressure vessels in Bayway Refinery periodically. Our periods will vary, depending on the corrosion we find. Hereafter when we make the first inspection on this equipment we will suggest the periods which we think are necessary. They will be at least once a year and on some equipment that appears to be deteriorating rapidly, probably more often.

MR. BURKHARDT: Do you use totally enclosed electric motors?

MR. NEWCOMB: Our motors are usually put in a separate room and our shaft is driven through a stuffing box in the wall. I believe that the company has installed one or two in some outlying stations, but what results they have had from them I do not know.

MR. RISNER: What is the best gas to use to remove the air when you charge your stills?

MR. NEWCOMB: We usually use steam. Anything that hasn't got any oxygen in it will, I imagine, do the trick.

MR. WALLACE: Mr. Chairman, I haven't any question to ask at all. But I plead guilty to not being able to answer the questions that the executive wanted answered. And knowing this, I don't believe there is another man here who would be able to go into a refinery and pick out the theoretical hazards that he has outlined, and tell us whether the equipment was safe and where the hazards are and whether they could be eliminated.

If that is true, why isn't it worth while to develop on Mr. Newcomb's

paper, through committee work next year, something to secure the information that we ought to have? Lots of it is in his paper, but we need more. Certainly the Section could do nothing that would be more helpful in the refinery end of our work than to give us a real insight into the theoretical hazards. I mean those hazards that are not apparent, those hazards which when they do culminate in an accident produce a real catastrophe. Those are the things we want to eliminate if we possibly can, and I wish that from this paper which Mr. Newcomb has given us, which is one of the best papers I have ever heard here, we could develop something that would give us that information. I believe we could do it through committees if the committees would just act.

MR. NEWCOMB: Might I say that I am also one of those who have to plead guilty to not being able to answer the questions that were asked? I told the executive that I didn't know of any man that could do what he wanted done.

Reluctance to Shut Down Stills for Necessary Repairs

MR. TRIBNER: I think there are some of us here connected with smaller plants, and I would like to suggest an annex to that paper which would suggest cooperation between an executive and an inspector. That is my chief trouble, to get the executives to permit shutting down the stills and make repairs which we report are necessary. The production comes along and we have to get it out, get out the material, and they will not put in enough extra equipment to take care of peak loads; and I think there are quite a few of us in the same situation. I think that would be a point worth bringing up.

I know the three accidents I have had in 12 years were all reported and requests made in writing and by telegraph or telephone in most cases; still nothing was done and the first thing the accident occurred.

THE CHAIRMAN: I should say, indeed, that is a very serious situation when an inspector reports such lack of consideration of suggestions on the part of an executive; especially when he backs up that statement by reporting that telegrams and different ways of communication were resorted to, and still no action was received, until an accident happened. That is a serious situation.

ROY S. BOXSM (Standard Oil Co. (N. J.)): I want to back up Mr. Wallace's remarks about the need for definite, systematic codes. I am also guilty of not being able to answer any of the questions; and if the Petroleum Section is to gain the place that it should occupy in the petroleum world, it is going to have to do it through offering something to the petroleum industry that it needs very vitally; to give them something definite, not about or nearly so, but something definite that the different plants, especially the smaller plants, can use.

Of course, the larger plants need it and in most of the large plants there is work of standardization under way now, but if this Petroleum Section could get up something concrete, definite, exact, then we have got a basis of forming and establishing a very definite place in the

petroleum industry, a place that we can occupy and a place we should occupy.

S. W. CANDEE (Tidewater Oil Co., N. Y.): I would like to ask Mr. Newcomb on the reports that are made by the Engineering Department; lots of times that information should be gotten across to the men—not only to the supervisory corps, but to the men. How do you accomplish that?

MR. NEWCOMB: We do a great deal of educational work through our individual inspectors. We make it a point to listen to everything that anybody has to say. We talk to the firemen and we talk to everybody right up the line, and we try to get their confidence and we do get it, and these men talk to us and they come to us when we go into a plant to inspect and we encourage them to bring to us anything of which they are in doubt. It doesn't make any difference how foolish their question is, we treat it just as seriously as though it was something valuable. Probably nine out of every 10 things we get from the men are not worth anything, but we take the time to sit down with that man and show him why it is not and encourage him to come again. We don't make him feel foolish over it, and the tenth one is something which we have found valuable, which we would not otherwise have gotten, and it is worth all the time we have worked on the proposition.

Cooperation with the Mechanical Maintenance People

We work with the mechanical maintenance people and show them what they ought to know about the thing. It has been stated to me that when my men come into the plant, the people operating right down on the stills, the foremen and the still men, all feel that my men come in there as a part of their organization and they just fit right into it. And that is the hardest part of my job—to get these young inspectors to get that idea across and keep it across. They are very likely to get cocky and want to show off their authority, and I have to sit on them all the time to keep them from doing it.

But we have, as far as the cracking equipment is concerned, absolute authority. If one of my men says the repairs have got to be made, the refinery always makes that repair before that still goes into operation, or he has got to shut the still down; and the only people who can over-rule it is the Board of Directors. It has only come up twice and so far we have never been over-ruled.

MR. CANDEE: How would that work if you haven't got a large inspection department?

MR. NEWCOMB: At one time I went around personally and inspected this equipment. You have pretty nearly got to have it under your jurisdiction separate from the refinery. You can't have it under the refinery's authority. It has got to be someone who has got authority and comes under some jurisdiction other than the refinery itself with authority to say that this must be done.

When you have got that authority you have got to be careful how

you handle it. Where you possibly can you had better advise, but sometimes you have got to use your authority. But we never insist if we can get it done any other way, and when we say that a thing has got to be repaired, we try not to tell them how to repair it, but let them suggest it themselves, and unless we can see something wrong with their way of doing it, we let them do it that way. But we always have a way of doing a thing in our own minds before we say anything has got to be done. But we let the other fellow do it his own way if possible. We find it makes a lot better feeling.

JOHN S. SHAW (Hercules Powder Co., Wilmington, Del.): I think Mr. Newcomb touched the key to the secret of real success in safety work when he spoke of listening to every workman, encouraging suggestions. But I want to ask him what he does if after an investigation he finds the suggestion is no good. Does he return to that workman and follow up in an educational way, discuss it with him and tell him why he is wrong and encourage him to keep on suggesting?

Getting the Cooperation of the Employee

MR. NEWCOMB: We do. We sit down with a man and talk to him. Usually the suggestions are verbal. They come to the inspector as he is out on the job and his face is dirty like any still cleaner's. He sits down and he is just one of the men. We carefully explain to him just why we think it is safe, and why he was wrong in the first place, and we encourage him to come again. As I say, we try not to make him feel foolish in any way, shape or manner.

MR. SHAW: I think that is the most important part of safety work.

J. M. STEFFEN (Standard Oil Co., Kansas): I am also strong in the belief that rubbing shoulders with the man actually on the job is the key to the real situation. I have had the experience many times where a man would tell me: "Well, I suggested this to the superintendent or to the foreman long ago but nothing was ever done about it, and I feel almost like never making any other suggestion." That comes from the men themselves, and it is the problem of the safety man to take up that particular suggestion and act as a go-between those in authority and those who make proper suggestions.

Now, I spend a lot of time right with the men, just as has been suggested here. Three-fourths of my time is out in the yard among the various processes. In many cases I have to acknowledge that a certain thing that doesn't look just right to me may be all right, because I am really ignorant of the situation myself and I get a lot of valuable information by just talking with the man on the job; and oftentimes he educates me to things that are valuable to me and at the same time I gain his confidence because he feels free to talk to me.

Then another thing: whenever I make a recommendation to the superintendent (in my particular case I am to make my reports to the superintendent), I make them in writing and keep a copy. He knows that. This suggestion is brought up before the board of directors to be acted upon, especially if it is something that involves the expenditure of con-

siderable money or means the outlay of material and time. We have had a number of instances where my recommendations have been side-tracked or neglected, either through oversight or a refusal to spend the proper time or money, that a little later developed into some kind of an accident; and I had the supreme satisfaction of pulling out my recommendation covering that particular phase and saying "I told you so."

F. A. SCOFIELD (Associated Oil Co., San Francisco, Cal.): There are two studies being made next year in California on refining processes. Mr. Miller, of the Bureau of Mines, will probably check me up on that.

I think that a Bureau of Mines man is going to make a survey and report on safety appliances and processes in the refineries, and then the State Industrial Accident Commissioner is going to do the same and issue orders for California. It occurs to me that in connection with Mr. Wallace's suggestion regarding further study, you might want to keep that in mind. I am not quite certain on it but I am pretty sure that that is going to be carried out. Mr. Prussing, of the Union Oil, can probably tell more about it.

MR. LAU (Standard Oil Co. of Indiana): Am I led to believe that the safety department assumes all the responsibility for all the accidents that occur in the New Jersey plant in regard to process work?

MR. NEWCOMB: In so far as cracking equipment is concerned, we are responsible for any accidents which occur to the equipment—that is, the safety inspection division of the general Engineering Department. It was put up to me personally when I took this job that I was responsible for the equipment, and if any accidents occurred I was to be held for them.

The Safety Department May Take Too Much Responsibility

MR. LAU: I believe that is assuming a lot of responsibility in taking the process away from the real process men. The condition of the equipment lies mainly with the process men. It is their job and they know the work. We come out as inspectors and we probably don't know anything about this equipment, whereas the old timer's know these different processes. I believe the safety department is taking too much responsibility.

MR. NEWCOMB: You will find they don't know very much about the strength of cracking equipment when they operate around 300 or 400 or 500 pounds, and they will tell you it is perfectly safe. You start to figure it and see whether it is or not.

MR. WADDINGTON: I don't know as I have much to add to this discussion, except this—that there is a distinct difference between the responsibility for the physical strength of equipment and responsibility for operation, entirely distinct. Physical condition, from an engineering standpoint as to probable or actual strength, can not be determined by a process man. A process man is responsible for the operation and maintenance of his equipment perhaps, and his obligation is or should be limited there.

I would like to note while on this subject how close you can go to the

safety factor of a drum or tank without something happening. In one of our refineries (and I am not going to mention the particular refinery because something did happen afterwards), back as far as 1913, I was identified with the General Safety Committee just then formed in the Standard Oil of New Jersey. We were visiting one of the plants and had occasion to examine a tank some 60 feet in diameter, 20 or 30 feet high, and there was very visual evidence of deterioration of the material, although they had been very liberal with the paint. An examination and computation of what was left of the metal indicated that there was no safety factor at all. I reported the facts, but in those days safety was not taken as seriously as now, and while we had recognition to go around and make these inspections, our inspection didn't have the weight it has today. The tank held on for four years longer and then let go and deluged the locality, and I think there were one or two injuries as a result.

Had the present recognized inspection been in vogue in those days and if they had been backed up as they are today, that particular accident wouldn't have happened. That is rather an extreme case and we don't pretend to go around and sound all the containers and tanks of that character, but we certainly do undertake to, and actually do, test all pressure vessels and other containers and place the responsibility with one man, keeping it away from the operating force. Many a time an operating man will say: "Oh, well, we will run it once more. We can't shut the still down." That doesn't go. That "once more" might be the fatal time.

This Accident Might Have Been Avoided

MR. NEWCOMB: I know of a case, not in my own company, where there was an inspection force in operation similar to ours, but where the inspector did not have the authority, and he reported to the manager of the plant in which he was inspecting the conditions which he found. He found a still which was in bad condition but he had no authority to close it down. Had the conditions been such in our equipment it would never have made another run. They had no still available to put in its place, but they could have one in two weeks. It ran for exactly one week to a day when it blew the head out of the still and killed eight men.

T. N. SHAW (The Midwest Refining Co., Midwest, Wy.): I believe the duty of safety work can be lined up broadly under one head and that is executive. The fact brought out quite forcefully this morning is one that I have always realized in safety work, and that is that no safety man can be expected to know all branches of the work, and I believe he should really be an executive; that his duty is to initiate inspection. If he happens to be capable of inspecting some particular branch of the work, well and good. If not, get hold of them then in that particular department who are capable of inspecting and follow it up. When an accident occurs, communicate with the department heads, men who are directly in charge of that work. Invariably they know more about it

than you do. If it is a question of strength of materials and things of that sort, pull in your Engineering Department, or whatever department is necessary to cover that particular thing.

The safety man should be a bureau of investigation rather than information. He is the one who should go out seeking the information from the various ones. You get cooperation much better that way. It might be the man on the job that you want to talk to and find out what he did and recommends, or it might be the department head behind the mahogany desk with the glass top. But whatever it is, the safety man is the go-between. He can't be expected to know it all, and if he follows that all along the line from the worker to the executive in the office, he is going to get better results and better cooperation than he does if he goes out and tries to tell somebody else what to do.

Men Have a Particular Pride in Their Own Ideas

If you have an idea of your own you will work your head off to put it over. It doesn't make any difference whether it is the man who has the muck stick cleaning out the still or digging a ditch, if he has got an idea that he thinks can help things, help him put it over. And with the fellow half way up, and with the executive, it is the same way. If you can go into an executive's office and say: "Mr. Jones, I was glad to see today the proposition you spoke about last week works out so satisfactorily," it makes him feel good. Or if you can get anybody else along the line, the same way. Get them all together working for the one aim. And even if you have got an idea yourself to put over, let somebody else think it is his idea and he will put it over for you.

THE CHAIRMAN: On that subject of tie-in between the department head whose department is being inspected, I believe it is generally understood and has been arranged through the industry that on inspection trips the Inspection Committee generally stops in the department and picks up the foreman or man in charge of that department of the company. That seems to me to be a very fair, reasonable and necessary plan.

MR. SHAW (Hercules Powder Co.): And then there is another tie, and that is a standards committee. A standards committee is composed of safety men and engineers, and that committee absolutely ties in the engineering with safety and operations; and no method can be changed, no piece of apparatus can be changed, no new design accepted until that standards committee has acted and passed on this change.

In our company we have such a standards committee working now and we have wiped out a lot of misunderstandings and a lot of work for our safety inspectors, because when a safety inspector is in on the game with the engineer, and the engineer with the operating man, too, then all must be satisfied before the change goes into effect.

J. A. LEAVEN (Standard Accident Insurance Co., Detroit, Mich.): There has been a lot of discussion of inspection certificates. I am interested in accident tabulation and their elimination. I would like to ask if there has been any tabulation of accidents kept and anything of what has

been done toward elimination of a repetition of those same accidents?

THE CHAIRMAN: I think that we may have to defer that for another session. That is a little bit off our regular program. If you will come to a later meeting when we discuss accident tabulation, we will be able to refer to that.

MR. LEAVEN: I thought this might be brought up under the discussion of accidents. I thought Mr. Newcomb might have something in mind along that line.

MR. NEWCOMB: We have nothing in mind along that line, excepting I know when accidents occur they are always of a serious nature. When a still let's go you usually kill a man or two. And on this other equipment you get fatal accidents. A fatal accident doesn't show any higher on your frequency rate, but it shows up on your severity.

I am in a different position than the majority of the men present here in that I simply have charge of the physical inspection of equipment, and I think, too, Mr. Chairman, that some of them are getting the idea around here that I was suggesting that the safety men should do the very work that I am doing. That wasn't my idea at all. My idea was if you people could influence your own companies who haven't such an engineering inspection force as we have, to organize such a force and then you could bring to that engineering force the things which you felt needed inspection and give them the opportunity to do the work which we are doing in our company, that you could eliminate a lot of the stuff and you would know it was safe and you wouldn't have to worry about it. That was what I was trying to get across.

The Plant Safety Men Request Inspections

I think some people got the idea that I was suggesting that the safety men ought to make these inspections which I am making. I don't feel so at all. Mr. Bonsib is the chief safety inspector of the Standard Oil Company and he wouldn't expect, nor would I expect, that he should do these things or have the detailed knowledge. It is a special field which belongs to the engineering department or some equally representative department of the company. But he does bring things to me; our plant safety men bring things to me and call them to the attention of their immediate superiors and they request these inspections.

I might say that those 110 pressure vessels are being inspected today. I have men doing it right now.

L. D. PALMER (Standard Oil Co., of Indiana): I was thinking about Mr. Wallace's suggestion on the thoughts given by our speaker. If I might suggest, Mr. Chairman, if we care to go further with this—I don't know how these matters are handled—but that the chairman appoint a committee to work out the ideas that have been expressed here and bring them back to one of our other meetings, so that we can discuss this matter. I think it is vital. We may all agree on the method that should be used for the inspections according to the desire of the different managements. This one in particular is a very extensive inspection. We could work along that line, if the chairman would care to ask some men

to give us something more definite on that so that we could act on it and arrange for some work during the year on this same subject.

THE CHAIRMAN: This is as regards the development of a safety code in connection with this subject?

MR. PALMER: I would like to refer to the speaker on that. Was that your idea?

MR. WALLACE: It is hard for me to tell what the idea was because it is rather hazy in my own mind. I believe, however, that the code would be a logical method of approach. It would give us a start. What I want to know is things of this kind—when they want to pull off a still, and we want to know what the reasonable temperature is to open that still up, and things of that kind. When you go to the process men you find that they have opened a still and may have a little trouble, they will always tell you that the temperature of the still was down possibly below where it really was. There is going to be an alibi there somewhere. On the other hand, a technical man would know immediately that it was up above a certain temperature, and things of that kind could be put readily in a code. But I don't believe that a code ought to cover all that we ought to get.

I would suggest that we lay the whole subject on the table until one of the other meetings; when the proposition is coming up we could ask for help from some of the other organizations. That will be discussed I am sure at a later meeting. If it is permissible, let's just quit it now.

A Skeleton Code is the Thing Needed

MR. BONSB (Standard Oil Co. of N. J.): What is needed there is a sort of a skeleton code. It is going to be impossible to make a detailed code that would cover all operations because no two refineries operate the same; and if some skeleton form could be drawn up with a few fundamental facts so that each of the different works could have a foundation upon which to build their individual codes, I think that is what is needed the most.

THE CHAIRMAN: We will take that under consideration to be brought up later.

We were to hear this morning from some of our friends in Oklahoma. We had planned for an address on "Training and Supervision of Employees and Foremanship," a paper by Mr. Zimmerman, of the Marland Oil Company, of Ponca City, Oklahoma. Unfortunately, at the last moment it was found necessary to send in a cancellation due to circumstances beyond Mr. Zimmerman's control. We regret exceedingly his absence here.

But, in the meantime, we have approximately the time that was allotted to him, for other subjects, and it occurred to me that this time could be put to very profitable use by opening up the meeting under a general round table discussion, during which time we will try and answer and consider any miscellaneous questions that some of our friends may have in mind. We have about 45 minutes to do that in. I take it that

all of you gentlemen would be favorable towards that, unless you prefer to make a motion to discuss some specific subject. If so, I am ready for that motion for a specific subject for discussion.

MR. PRUSSING (Union Oil Co. of California): There is a question which I should like very much to hear discussed, and that is the form of safety organization which has been found most practicable in the drilling and producing fields. I would like particularly if there is anyone here from the producing fields of the Midcontinent who could tell us something along that line.

On the Pacific Coast our safety work has progressed from year to year but still the drilling and producing fields give us our greatest concern, with only the exception of casual engineering construction. The drilling fields still produce the greatest number of accidents, they still produce the greatest severity rate, and the experience of other parts of the country would be of extreme interest at least to me and perhaps to a number of other men here present.

THE CHAIRMAN: In answer to Mr. Prussing, I think we are very fortunate this morning in having with us a man whom I consider an authority on that particular question, a man who has had a wide experience along those lines. He is here and I would like to present him at least for a few words to the meeting. Perhaps he can make an approach to the subject, at least, and bring out other discussion. I would like to introduce Mr. Ray Miller, who is the safety director of the Midcontinent Oil & Gas Association.

Safety Planning When the Employees are Scattered

RAY E. MILLER (Petroleum Safety Council, Tulsa, Oklahoma): It seems to me that we have developed a number of things this morning that need a lot of thought.

In the first place, most of the discussion this morning has been of interest to large companies. Most of the things said can't be applied to the smaller companies. That is particularly true of large inspection forces or large safety departments. I have been in contact with several hundred companies in the Midcontinent and most of those companies can't afford to do very much organized safety work. They must depend on selling the safety idea through the organization and have the organization carry it on.

Mr. Prussing brought up the question of what could be done in producing fields where the employees are so scattered. I don't know what can be done. We are trying a lot of things in the Midcontinent and I don't know how successful they are. Sometimes I get very discouraged about it. I say this frankly, that darn few men out in the fields take very much stock in safety. That is, despite the efforts that you men are carrying on and the efforts that I am carrying on, very few of them are interested in the proposition. I am thoroughly discouraged about it because I think that view is growing. I believe in the last year or two I have seen a change on the part of

the men in the field. But those men in the field want to know whether or not the executives of their companies expect them to take an interest.

Safety in the oil business—and I am speaking particularly of the Midcontinent; I don't know the other territories so well—safety has not gone across very far yet. It hasn't been received like it must be received. Very few companies in the Midcontinent are carrying on a program that embraces all the men in the fields. Some companies hold a series of meetings through the fields which interest a few of the scattered employees, but those meetings as a rule aren't kept up, the interest isn't maintained, and the results are only moderate.

It seems to me that we must do more work and that work should start with the president of your company, if you please. I often think that if the president of every oil company would spend 30 minutes a month for safety he would do more good than a lot of us are doing in spending our full time at it. If he would have a definite time each month—say, spend 30 minutes each month—or the safety department or the insurance department would report to him the accidents, by causes, by classifications, which have occurred during the past month, he might glance through them and then get the rest of the executives and the department heads together and put it up to them just as strongly as he knows how that accidents must be reduced. Let those department heads call in the supervisory forces under them in their own departmental meetings and put the same problem across to them. Let the foremen take the word back to the job that our company is strictly sold on the idea of safety and accident prevention work and take it to them and force them, if you please, to make safety a part of their everyday work.

Men in the Field Doubt Sincerity of Safety Effort

I don't know whether we are putting the idea across or not, but I simply want to tell you that in my contact with the men in the field they don't believe that the companies are backing the safety program. They just figure that it is somebody's job, and they don't take it to heart to an extent where it gets across.

I would rather hear some discussion on the problem. I would like to hear some general round-table discussion, and you will bear in mind in your discussion that we must suggest things that are possible of achievement, both in the small company as well as the large company. Let's get some ideas together. In place of Mr. Zimmerman's paper we might just as well have discussion on that subject because his subject is one that is very much to the point in accident prevention work.

T. N. SHAW (The Midwest Refining Co.): On the spur of the moment I have appointed myself as a sort of a critic.

Now, you say that the hard thing is for the small company to afford a safety organization. I am speaking now from the producing end of oil. My department covers producing, gas plants, pipe line, electrical department, etc., all in the field. Now, the biggest problem of every producing company is to keep the lifting cost down. Production is going down and

lifting cost going up and the smaller the operating company, as a ~~usual~~ thing, the higher the percentage of overhead, because the executives' salaries aren't spread out over as great a territory; and there are ~~many~~ things that every company has to have in the way of executive organization—can't get away from—and the same organization sometimes will function for a company several times its size.

Now, I made some figures not long ago on what an accident on rod and tubing work cost. I took a period of three months' time. In our producing department more than half of our accidents are on rod and tubing work, and I found in that three months' period that the average cost per accident was \$135. That includes your state compensation, which most of you have, or its equivalent, and cost of repair, hospital bill, etc. Now, if a safety organization could save a couple of accidents a month it would go a long way toward paying for this. If it couldn't save that much you had better get rid of it and get another.

The Safety Department is a Good Investment

But it is a misnomer that a safety department is an expense. It is not. It is an investment. It is sometimes hard to prove that to the management; and it is fine to talk about the humanitarian viewpoint and the saving of life and limb and all that and it sounds pretty, but the thing you want to tell the management is dollars and cents, because after all is said and done at the end of the year, if you are in the red, you sometimes have a hard time paying salaries. And that is the basis for the small outfit to work on. Show your management that you can reduce the accidents enough to pay for the operation of your department (a one-man outfit may be all that is necessary), and he can more than make his salary by keeping down accidents.

If your company has any record at all of what they have cost in the past, if you have an accounting department, you ought to be able to find that out—and we have all got accounting departments and legal departments. I don't believe there is an oil company in existence that hasn't. And they are part of your overhead, and part of their job is telling what these things cost. I doubt if there is a company in existence but what can show that the cost of accidents would pay the salaries of several men. And if one man can take the job as safety inspector or director or investigator, whatever you want to call him, he ought to be able to reduce the accidents enough to more than pay his salary. I believe that the small outfit needs it just as much in proportion as the big one.

MR. MILLER: I think the companies in the Midcontinent are coming more and more to carry on a rather definite campaign in the way of selecting employees first and then their training and supervision afterward. Most of the companies in the Midcontinent now are giving some kind of a medical examination to new employees before hiring them. That isn't working out in the field because the places of employment are so scattered that they can't have one doctor or one group of doctors making examinations. The result is they do it on the contract basis,

have doctors scattered all through the territory and pay them so much a head for passing men to employment. The result is that a lot of examinations are worthless because the doctor is only interested in getting that two or three or five dollar fee:

I was talking on this point at a meeting in one of the large fields in Oklahoma a short time ago. I was urging the foremen when they had a medical examination to look a man over pretty carefully before they accept him through a doctor, and a foreman of a large company got up and said: "I have sent 400 men to our doctor for examination and he has turned one down. I think I have done pretty good." I said I thought he needed a new doctor.

Mr. Gray, of the Peoples Gas Company, has some figures here and I think we would like to hear from him on this very question.

MR. GRAY (The Peoples Natural Gas Co., Pittsburgh, Pa.): We have had a rather interesting experience in accident prevention. The Peoples Gas Company operates about 3,000 miles of pipe line, high pressure trunk line, field and well line and city plant distributing systems. We supply over 100,000 consumers and about 89 cities and towns. We operate 25 compressing stations, with a total horsepower of about 32,000. We have a total of 1,229 producing gas wells. We also otherwise operate five gasoline producing companies. During the period from January 1, 1922, to September 30, 1926, we built six new compressing stations, rebuilt one, improved and enlarged 20, drilled 234 new wells, plugged and abandoned 185 old wells, cleaned out 206 wells, drilled 177 wells deeper, and baled about 350. Also, during that time we built at least five new low pressure plants, laid considerable pipe line, large sized pipe. During the five years we had a total exposure of 14,295,000 hours. We operate a fleet of about 200 automobiles of all kinds.

We started our campaign for safety January 1, 1925. Here are our frequency rates for five years: 1922, 1923, 1924 and nine months of this year. In 1922 our frequency rate was 25.5. In 1923 it was 40.2. In 1924 it was 47.3. In 1925, the first year we started any real safety work, it was 10.1. In 1926, the first nine months, it is 7.1.

Detailed Figures on the Cost of Accidents

On our severity rate, here is another peculiar thing. In 1922 our compensation cost us about \$6,000. In 1923 it was \$13,000. In 1924 it was something over \$26,000, but in 1924 we had one very serious accident, a gasoline explosion in which there were seven fatalities. In spite of the fact that that rate had been increasing double practically each year, the management of the company rather felt that the terrible rate in 1924 was the result of this one bad accident, which was a natural hazard of the business, something you couldn't count at all. In 1925 our total compensation was \$4,900, and for the first nine months of 1926, it is \$2,278.

In our particular case we don't have an organized safety department, as such. We don't have a safety director. We don't have a safety inspector. I have been with the company for something over 20 years, and I have been handling safety work, not as a safety director, but simply as

another one of the general superintendent's jobs. I usually get the jobs that nobody else wants, and I think that that probably is one of the reasons we have been able to do what we have done.

In watching the thing work, it strikes me that so often the company decides they want to do some safety work. They organize the safety department. They go outside the organization and bring in a safety director, safety engineer, who no doubt knows a whole lot more about safety than any man in the organization, but he doesn't in a great many cases know anything about the peculiar problems of that industry. His whole interest, of course, is to make a showing for his department, and in his suggestions for safety he is only concerned with that one phase. He is not concerned with production. He isn't concerned about anything except keeping down the accident rate.

We have local safety committees. In fact, now every regular man in our organization has served a three months' time as an active member of a safety committee in this locality. We started in and appointed three men on a safety committee in each district. We have three principal departments. We have our field department, which has charge of general field work, we have our drilling department, and we have our compression stations. In all cases our committees were made up of three men, one from each of those departments. In other words, if they went out to report on the conditions of drilling a well it wasn't an engineer from the station department or it wasn't a driller, but it was a driller and an engineer and possibly field roustabout.

The Safety Committee's Recommendations Reasonable

The result of that is when you get your recommendations in from your safety committee you have got a fairly reasonable recommendation. In other words, if the station engineer who has entirely different ideas about safety, who is out drilling and makes a suggestion which is absolutely practical from the drilling standpoint, there is a driller on that committee who can say: "That is all right confined to a compressing station, but it isn't worth anything on a well." As a result of that we have been able to do a lot of work the past year in getting real worthwhile suggestions from the men on the job.

Mr. Wallace spoke this morning particularly about the fact of taking the safety work down to the individual. We have an average of between 1,200 and 1,300 men. A lot of those are regular men and a number are casual employees. But we have been able by that method to get what I think I can honestly say is 100 per cent cooperation from every individual.

MR. SHAW: I would like to ask Mr. Gray how many employees they have?

MR. GRAY: On an average about 1,300. We have had as high as 1,575 at times, and there are months when we have been as low as 1,050 or possibly 1,100.

MR. MILLER: There is one company represented here that has been doing quite a bit in the way of field safety meetings of employees. Be-

fore I introduce them, I want to say that I have been collecting actual records from the Midcontinent and trying to analyze them, and I will make a few statements about that.

We have talked here this morning about engineering supervision, maintenance, inspection, etc. We have scarcely touched on the big problem of safety work, educating the employee to work safely. There is our opportunity, I think, to prevent most of our accidents. In these figures I have collected, an analysis seems to show that less than 10 per cent of the accidents in the Midcontinent involved any kind of machinery. Only about one or two per cent are caused by unguarded machinery or failure of equipment. So it seems to me that our big opportunity is educating the boys to do the job in the safest manner.

The Marland Oil Refining Company has been carrying on a system of safety meetings of all employees for a good many years and Mr. Morgan is here, and I think it would be interesting if he would tell us just how they conduct those meetings.

An Organized Safety Meeting Every Month

HAROLD D. MORGAN (Marland Oil Co., Ponca City, Oklahoma): We have an organized safety meeting in every field that meets regularly every month. We have a safety committee of three men. This committee is selected from the workmen in the field. They inspect the field every month and as Mr. Gray said, a man from a lease inspects another lease and a man from a pump station is sent to another pump station. The recommendations they make are valuable because they are practical men. We inspect the field monthly and at this meeting we don't present our recommendations until the committees have presented theirs, and if they bring up the subject we never mention it, but give them credit for recommending it, and make them feel it is their recommendation and back them up in it.

We have had many very valuable recommendations in that way and have reduced our accidents a great deal and cut down our accident frequency.

MR. MILLER: Attendance is compulsory, isn't it?

MR. MORGAN: Yes, we have that as a rule.

MR. MILLER: Everyone who is not on duty must attend or have a good excuse for not attending, and they seem to be getting the program over to the employees in pretty good shape. It is a hard proposition to hold those meetings often enough and in enough places so that you can reach all employees in the producing end, but it seems to be working out very nicely.

Does that help you out any, Mr. Prussing?

MR. PRUSSING: It does, because our own account of accident analysis shows that 10 per cent or less has anything to do with machinery and our first effort when safety work was actively undertaken was directed toward the guarding of mechanical hazards, because while only 10 per cent of the accidents may be due to machinery, still an unguarded ma-

chine is the cause of very serious accidents that produce the large severity rates. Having guarded as well as may be those mechanical hazards, then the problem of educating the man and keeping him up to a standard of safe operation became an extra problem, and to me it is the one problem which you never finish; and the technique and method of constantly keeping that before the men is the thing that most of us have still to learn.

We have tried in one particular field where our operations are scattered, where we have 200 men operating over a very large territory, we have tried to make the safety work, instead of the concern of a safety department, directly the concern of the superintendent. We did that with his full cooperation. He came to us and wanted to know what he could do to reduce the cost of his accidents, because in our form of accounting at my own instigation the cost of accidents is presented to the operating men in such a way that it hits them in the face every month. They have to take it in as part of their operating cost.

We don't assess them the actual cost of accidents month by month for various reasons. One being that a serious accident, a fatality, for instance, will so completely upset their records if it occurs within any one month as to make the statistics of little value. We therefore take the year's accidents, figure out the cost of those accidents on a pay roll basis, just as an insurance company figures rates, and then use that rate on the current pay roll.

The Superintendent Was Hit Forcibly

So if a man has a pay roll for \$100,000 during a month and his rate is \$2.20, he is charged up \$22 for accidents during that month, and he has to take that cost into his accounts; and when he shows the cost of lifting oil, or whatever his operation is, he has to show the cost of accidents per barrel of oil lifted.

That hit this particular superintendent rather forcibly and he asked us what form of organization we would suggest for introducing the safety methods into his particular department. My suggestion was that inasmuch as he had shown that interest himself that he assume the responsibility himself. He has done that and has put one of his own foremen, an operating man, directly on safety work. That particular man has to see all the accident reports. He is, as a matter of fact, being educated as a safety man, although he is an operating man.

I think that is going to work out in that particular field, and in some other fields it may not work out at all. But there it has already worked out to this extent—that when they have meetings, the superintendent harps on the safety subject almost more than he does on any other, because of his own personal interest in it.

MR. MILLER: In the Midcontinent we are trying to assist the various companies in maintaining safety work by safety motion pictures. Possibly some of you don't know what we are doing in this regard.

We make and show two motion pictures a year throughout the Midcontinent field and are reaching about one hundred thousand employees with

them. These shows are made up of three or four or five reels of safety and two or three reels of educational stuff along petroleum lines; and usually a short comedy goes with it to finish the show off. In that way we have about an hour and a half to two hours of entertainment for the employees and their families. It is free to them, and local committees in each case, composed of workmen and foremen on the job, make the arrangements for the show and do the advertising for it, get the crowds out. I think those pictures are going over in pretty good shape.

In addition to that, we have been holding foremen's safety meetings throughout the Midcontinent field, and the attendance and interest seem to be good. We are also putting out posters and carrying on other forms of safety work there. But the interesting part of it is that during the past few months I have been writing out to a lot of foremen in the fields and plants asking them first what they thought of safety in general, what they thought it was doing or could do; asking them, further, what recommendations they had to give on enlarging the program, any suggestions or criticisms they might have to change the program to more nearly meet the demand, and a few other questions along that line. The answers that I have received have been a source of great joy to me because I am getting some of the finest safety letters I ever saw.

When the Field Man Writes a Letter About Safety

You take a field man who is used to hard work, if you can get him to sit down and pick out on the typewriter three or four pages of single spaced information, you know he has done something; and I will say I have gotten some of the finest safety letters I ever read from those men. In the first place, it means those boys think a lot about safety before they could write such a letter, and the fact that they do think is going to help them in their work and help them put safety across to the boys working under them.

I think the program is growing in the producing field and I think the boys are getting ready to receive safety. I believe the time is ripe for a lot more intensive campaigns on the part of the companies. We are just scratching the surface now, and I believe that the time is ready to get down and do some digging.

MR. GRAY: Mr. Miller's statement that they had safety meetings at which attendance was compulsory—our experience has been that the compulsory part of that program defeats its purpose. We have a semi-annual meeting of all the employees twice a year. When I say "all the employees," that means that every compressing station that possibly can be shut down is shut down, every drilling well that is in such shape that it is not a physical impossibility to shut it down is shut down, and practically every man in the district gets in for an afternoon meeting, with dinner in the evening in the early summer.

In that way the men are paid for their time in the afternoon, and the company furnishes the dinner. In the fall we have an evening meeting to which the men come in after working hours. They pay for their own dinner, being in on their own time; and the surprising thing about it is

that men come 25 or 30 miles through mud, they will come in at that evening meeting when they are not getting anything for it and are tickled to death to come. In addition, we have an annual meeting in Pittsburgh, in February of each year, at which we have all of our district engineers, our field foremen, our city plant foremen, and heads of the various departments.

Another interesting thing I want to mention to you. We have had in five years 353 accidents with a total compensation of over \$80,000. Of those 353 accidents there is just one single accident that can be charged up against the natural hazard of the business. The other 352 were perfectly preventable, and should have been prevented, could have been prevented if some individual had just thought about what he was doing when he was doing it.

Back in 1924 Accidents Were Expected in the Business

When we got 140 accidents in 1924, it was said: "That is a lot of accidents, but the natural gas business is a very hazardous business. That goes with it. We always have had them." I think I see a tendency on the part of most of the companies which are doing safety work today to be too well satisfied that a certain percentage of their accidents are natural hazards and there is no use trying to prevent them. Our experience has led me to believe that instead of from 60 to 75 per cent of accidents being preventable, that should be raised. I think in our own case less than one-half of one per cent of our accidents are in any way excusable.

J. M. STEFFEN (The Standard Oil Co. of Kansas): It seems to me that one of the big problems in safety is compulsory attendance at safety meetings; it is a pretty hard proposition if you expect attendance on the man's own time or the time that is his for regular recreation. The whole tendency of the plant or the concern is to pay men for the time they put in for what they are doing. A man works eight hours or more, as the case may be, and the rest is his own time. I am a safety man, and the management is supposed to promote safety; we are getting a stated salary and we ask these men to come out on their own time. You can't very well make it compulsory if you are asking it on their own time. It seems to me that you will have to get the management itself to so present this proposition, that it is so important a part of the operation of the entire plant, that it shouldn't be considered a free proposition.

When you have general meetings outside of working hours in the evening, is your management present at those meetings? Do they really show an active interest? Is your president, vice-president or general manager on the job or are they off somewhere to a party or picture show; are they expecting you to carry on that safety work? As long as you have that kind of a condition existing, you are going to have an uphill proposition, and it seems to me your education has got to start from the top just as well as from the bottom. The management must realize that if their safety work is worth while, that they

must spend some money for it, and they can't expect the average worker to work for safety on his own time gratis.

Now, wherever possible, that monthly meeting of any kind should be held on company time. When you do that, then you can come to the man and say: "Here, from two to four this afternoon we are going to have a safety meeting and we want you there." He is not losing any time. He is getting paid his regular salary for that meeting. You have got a chance to compel him to come to that meeting.

Then, also, the management itself should feel interested enough that at least a goodly representation of them are present at this meeting. Those are some of the things that I have had to contend with. Men say: "I am in the Midcontinent field and I have been to some of these motion pictures that Mr. Miller has shown in our town. We had a very good attendance. It was free and it was well advertised and a good place provided but the general feeling is—well, they are expecting us to attend this for the good of the plant. Yet they are putting it at a time when we must take our time, that regularly we use for recreation, to attend to the business of the company." And they go to this picture show and don't find the management present.

MR. GRAY: I think the first job is to sell your management. And even at meetings we have in the afternoon, we don't say: "Here, fellows, we are going to have a meeting. We want you there." We say: "We are calling a conference in a district at a certain time and dinner afterwards and would like to have every man in this district at that meeting." We get practically all of them. If somebody doesn't come we don't say: "You are getting paid for it, why don't you come?" After all is said and done, there is only one way we are going to get this safety work across at all, and that is by cooperation from top to bottom by each individual. We have these three meetings a year. That doesn't mean that that is our educational campaign. Our fellows are getting safety education three times a year. It isn't being crammed down their throats.

In that connection, I have a man here who is chief engineer of a pump station, and I would like to have him say just a word about safety education at the plant.

MR. GRASSMAN: We practice safety at our plant and when we put anybody out on the job we tell them to work with safety.

MR. MILLER: Gentlemen, I think it is time to stop the general discussion. I will turn the meeting back to the chairman.

THE CHAIRMAN: I was very much taken up with the remarks of Mr. Steffen, on the question of the attitude of the management toward the safety program, and I want to say that I will take occasion to consider the matter and make a response to his remarks at some other meeting, because I have a little to say in defense of the management on that question I don't want to let get by.

ADJOURNMENT

WEDNESDAY MORNING SESSION

October 27, 1926

The Wednesday Morning Session, October 27th, 1926, of the Petroleum Section convened at 9:45 o'clock at the Tuller Hotel, Detroit, Michigan, Chairman E. J. Senne, Vacuum Oil Company, New York City, presiding.

THE CHAIRMAN: Gentlemen, this is the second day of the sessions of the Petroleum Section, and before going to our regular program, it occurred to me yesterday that we were not quite alive to the proper relationship in this room, notwithstanding the wonderful setting provided here for us. In other words, we were like a lot of Indians in a tent, or we might compare ourselves to Omar Khayyam, the "Tent Maker," in this beautiful setting. Rather than endure that distant relationship, I would have you feel like first cousins. Won't everyone of you shake hands with the man next to you, make acquaintance, swap stories and at the same time get some good information? Get acquainted, boys. You will find it will be to mutual interest and we will get along much better. So I will just call a recess for handshaking and general approval of each other.

(The session recessed for a few minutes in order to enable the members present to get better acquainted.)

THE CHAIRMAN: Gentlemen, we will now proceed with our regular program, and the first speaker this morning is a gentleman whom we have not had the pleasure of meeting at any of our previous congresses, as I recollect, but a man whom we have heard about because his fame has preceded him. We have read much about his activities and heard of the wonderful work he was doing on the Pacific Coast; so I am sure that he has a story this morning that will be of special interest to all of us. Mr. F. A. Schofield, manager, Industrial Relations, Associated Oil Company, San Francisco, Cal.

SAFETY INSTRUCTION AS A PART OF THE SALES PERSONNEL PROGRAM

**F. A. Schofield, Manager, Industrial Relations, Associated Oil Co.,
San Francisco.**

When the personnel department has charge of safety work as well as employment and training, it is possible to provide instruction regarding accidents as a part of the regular educational program. The advantage of such coordination lies chiefly in the possibility of combining accident prevention with educational meetings and in presenting labor turnover and accident statistics as a unit. It is important to let the operating head see that low labor turnover and low accident rates generally go together.

Before undertaking a program of this kind it is necessary to investigate accidents reported and determine the most serious causes and means of prevention. From an analysis of accidents of the sales department of this company the following classification was obtained:

A. Injuries resulting from the use of the automobile:

1. Sprains and bruises.
2. Cranking automobile.
3. Inflating tires.
4. Auto collisions.
5. Burns from radiators.
6. Particles in eye.
7. Auto doors.
8. Miscellaneous.

B. Injuries from other causes:

1. Handling barrels and drums.
2. Falling against objects.
3. Slipping and falling.
4. Infection.
5. Miscellaneous.

It was easily determined that sprains and bruises, cranking automobiles, and handling barrels and drums accounted for about 40 per cent of all the lost time accidents reported.

Cranking Automobiles

Cranking automobiles was the cause of seven accidents with a loss of 48 days. Both the sales and personnel departments were convinced that instruction in the proper method of cranking was required. Accordingly the training bulletins for service station men carried pictures and instructions on this subject. Truck drivers were given personal instruction by mechanics. In addition a special poster was prepared showing a member of the automotive department in the act of cranking a truck as it should be done, and a talk on this subject was given by the same member at the regular educational meetings throughout the entire sales district.

During all of 1925 only two accidents were reported from this cause, neither of which resulted in lost time. It was considered, therefore, that this problem was practically solved and efforts turned to other types.

But in 1926 six accidents of this nature have already been reported, four of which have resulted in a total of 141 lost days. The average working force has increased almost 50 per cent in the last two years, and more accidents may naturally be expected, but it seems evident that lack of continuous instruction on this subject for new men has been partly at fault.

Bruises and strains, except in the case of automobile collisions, are nearly always the result of carelessness, and individual instruction, together with the usual safety posters and letters, will help to reduce them. In the case of strains resulting from handling barrels and drums.

the problem is largely a case of improper methods of holding or lifting, and nothing can take the place of instruction for the new man.

Our refinery has long since recognized this and has developed a training system through pictures that has proven very effective. The correct and incorrect methods of performing every operation in handling drums in the barrel house, while loading cars and moving from one part of the building to the other, have been photographed and pictures placed on a special bulletin board. Not only has this plan reduced the accidents to a minimum, but it has greatly increased the efficiency of the worker and lessened the time taken for a new man to become acquainted with the best methods of doing his work.

Similar instructions were incorporated into posters for plant men in the sales department, and while the results obtained were satisfactory, plans are now under way for more complete instructions in accordance with the refinery practice referred to.

Organized for Safety Work

While the accident record in the sales department compares favorably with that of the other large marketing companies in California, we are not yet satisfied. Increased numbers of sales plants means that proper supervision is becoming more and more difficult. A safety engineer has therefore been appointed in the personnel department, whose work combines first aid instruction with general safety work. For example, he is training two men in each of 77 plants in the care and use of the first aid kits.

Two special first aid kits have been prepared for our use. One is small (known as an "Oil Kit"), intended for use at service stations and rotary lifts. The other is a larger one intended for bulk plants and shops.

Over 100 bulletin boards have been placed throughout the sales district, and National Safety Council posters, together with special notices and letters, are being regularly distributed. In addition, safety meetings are held in all districts in connection with other educational activities. Motion pictures, lantern slides, charts and demonstrations are used to put over the idea of accident prevention, while banners and other emblems are freely used as incentives.

One district operating in a mountainous territory, although having a small force, has set up a record of no lost time accidents from October, 1923, to September, 1926, and in recognition of this the company presented it with a silver loving cup. This has created much favorable comment in the community and has served to stimulate continued care in accident prevention.

The necessity for sales instruction is so well established in most companies that little difficulty is experienced in obtaining cooperation for training plans. But the subject of accident prevention has been ordinarily considered an engineering matter and somewhat outside the regular training program. Our contention is that the two can be coordi-

nated very effectively and, once established, the safety man becomes a valuable part of the general training program.

THE CHAIRMAN: I am sure we are deeply grateful to Mr. Scofield for his very interesting address. If there are any questions you care to ask Mr. Scofield, I am sure he will be glad to respond intelligently.

MR. BONSB: (Standard Oil Co. of N. J.): In the statistics Mr. Scofield gave he had sprains and bruises. Aren't sprains and bruises a result and not a cause?

MR. SCOFIELD: Sprains and bruises, in our accident report, are frequently due to a certain thing, such as lifting a barrel. It might be lifting a board. We classify that in the sprains and bruises. We found that most of these sprains and bruises were due to handling drums and barrels. I tried to bring that out. From our standpoint I don't see how we could classify all down the line. They are all sprains and bruises. Then we tackle all the things that went with it. The Union Oil has done a great deal in eliminating sprains and bruises due to improper lifting and handling of barrels, and we have tried to do the same thing.

THE CHAIRMAN: In answer to Mr. Bonsib's question and also elaborating on Mr. Scofield's answer, I might say that in our company we have the same problem. We have numerous sprains and bruises. They are caused by such a multiplicity of causes and conditions that we found it necessary, instead of itemizing 15 or 20 causes, to classify them under "incidental to occupation."

MR. BONSB: We classify those as lifting, pulling, pushing or reaching. I think that is the direct cause. It is more illuminating. It is much clearer.

In the Standard Oil Company of New Jersey our biggest problem is in the sales department, and I envy you for the results in your sales department. Personally, the Standard Oil Company has not been as successful in the sales department as it has in other departments. However, we hope to steal some of Singleton's thunder and try to do as well as he has.

THE CHAIRMAN: The next paper will be delivered by a gentleman who needs no introduction before this Congress, a man who has had charge of the activities of the Petroleum Section of the Atlantic Division for the past year, a man with wide experience, representing one of our largest industries.

I take great pleasure in introducing Mr. Waddington of the Standard Oil Co. of New Jersey.

SAFETY METHODS AND ACCOMPLISHMENTS IN SOME ATLANTIC SEABOARD REFINERIES

Thos. W. Waddington, Standard Oil Company (N. J.), Elizabeth, N. J.,
Bayway Refinery

In the preparation of this paper the purpose kept in mind was to present briefly, yet as completely as available data would permit, a review of the safety organization, procedure, featured activities and

specific safety results existing and obtained at a number of our Atlantic Seaboard Refineries.

In reviewing the replies received to letters soliciting information from some of the companies, one is impressed with the fact that safety has grown to be an underlying and fundamental consideration in practically every branch and functional operation of the oil industry. It is true that some of the companies are further advanced along certain lines of safety development than others, but from these reports, individually and collectively, we have the most convincing evidence of the general and sustained interest of men and management in thinking, organizing and designing for, and acting safety.

Atlantic Refining Company

Starting with the Atlantic Refining Company, we find that their safety department comes directly under the Industrial Relations Division and is headed by a safety engineer with eight safety inspectors under his direction. The safety work includes general or specific inspection with consequent recommendation for improved safety conditions, guards, appliances, etc. There is a general safety committee comprised of representatives from five divisions of the plant, namely, operating, mechanical, packing, sales and miscellaneous. Each of these divisions has safety committees composed of foremen in their particular departments. These divisional or departmental committees are assigned to inspection work by the safety engineer, and their findings and recommendations are reported to and acted upon at weekly meetings of the general safety committee, the safety engineer presiding.

An inspection system has been established whereby all tanks, sewers and conduits must be inspected and passed as "gas free" by the safety department before workmen are allowed to enter. Previous to this time several fatal accidents occurred due to asphyxiation. Since its installation no fatalities have occurred from this cause. A foremen's class in first aid to the injured has been established.

Bulletin boards, with frequent change of subject matter, are utilized for the information and education of the workmen.

A dispensary is maintained for examination or first aid treatment of injuries. Included in the personnel are two full-time doctors and a nurse.

No comparative figures were obtainable indicating specific reductions in "lost time accidents," but we are assured that the safety idea has taken hold and that accidents are on the decrease.

Tide Water Oil Company

The Tide Water Oil Company to date has featured safety work more particularly along the lines of fire prevention. Regular periodic field and plant inspections are conducted by the local plant management to eliminate unsafe conditions where found.

Safety educational work is carried out through plant publications, posters, safety talks, etc. This is being supplemented with the recent

institution of foremen training and safety work at their Bayonne plant. A more detailed and coordinated safety program is now in contemplation and will probably be put into effect during the coming year. This will include, among other features, the reporting of accident statistics to one central statistical bureau. Tide Water is particularly proud, however, of its record in the field of fire prevention, which, since the institution of its fire prevention program four years ago, shows that their average annual fire losses have been reduced close to 70 per cent.

The Texas Company

It is unfortunate that we are unable to give an outline of the Texas Company's safety organization. However, the Texas Company's activities in the field of safety are so well known to the Petroleum Section in particular and safety circles in general, there is little new information that this paper might contribute. Every safety man in the oil industry looks forward to the receipt of his copy of their publication, the *Look Box*, and turns with interest and anticipation to behold and read the latest adventures of that now famous safety exponent "Gassy Gus."

As to the safety accomplishments of this company, we have but to note the published figures of their accident reductions in the August *Look Box* to appreciate the magnificent work being done by this organization. These figures show that at the northern and southern terminals of this company in 1919 there were 228 lost time accidents, equaling 14 accidents per 100 employees. This has been cut down through the succeeding years until the first half of 1926 shows but seven lost time accidents, or one and one-half per 100.

Vacuum Oil Company

Each of the several plants of the Vacuum Oil Company has its safety engineer, who is responsible to, and under the direct supervision of, the company's safety supervisor. Quarterly meetings are held at the different plants under the chairmanship of the safety supervisor, at which every safety phase or feature, problem and suggestion are compared and discussed.

As the new employee is generally recognized as a potential accident hazard, the Vacuum's safety organization concentrates on his education by safety talks and group meetings. The work is further carried out by properly distributed bulletin displays, distribution of National Safety Council calendars, and novel features in the line of accident score boards, such as "Safety Ball Games," "Safety Channel Swims," etc. In this latter respect Vacuum differs from some of the other companies in the fact that the records of their several plants are shown and entered into competition for the lowest accident score, thus creating a friendly inter-plant rivalry to see which may make the best showing for a current month. They also set aside certain months of the year for intensive safety drives.

All of the above features, together with an intimate contact between

the safety workers and the men, together with articles and illustrations appearing regularly in the *Vacuum Oil News*, have produced the most enviable results in the line of accident reduction. The records show that the Vacuum Oil Company had 70 per cent less lost time accidents in 1925 than in 1920. Their experience being 213 in 1920 against a total of 63 in 1925. Their frequency rate for 1920 was .57. This has been reduced yearly until in 1925 it was but .15, a most gratifying example of what properly executed safety work can do.

Standard Oil Company of New York

As to the Standard Oil Company of New York, we will not attempt to discuss their organization or its accomplishments, as Mr. F. W. Burt, safety supervisor of that company, will later present a paper that will do much greater justice to the safety work of that company than the limitations of this review will permit.

Standard Oil Company (N. J.)

The safety organization of this company consists of the following: There is a chief safety inspector, or engineer, with headquarters at the company's general offices, who spends his entire time in visiting and inspecting all refineries and company plants of whatever character. There is also a general safety committee composed of a safety engineer, or director, from each of the several refineries; the chief safety inspector being also a member of this committee, the chairman of which is selected and appointed by the company's manager.

Most of the refineries have their own safety committees appointed by their local management, the personnel varying at the different plants. Some of the smaller plants include all foremen as active members, while at the larger plants, where the number of foremen involved would render this impracticable, the active members are frequently appointed so as to have an equal representation of the trades or other occupations with the supervisory force.

Most of the plants are divided into zones, and systematic monthly inspections are made by members of the committee as directed by the plant safety engineer and in the general instructions printed and furnished for their guidance. The results of these inspections are reported at the monthly meetings of the local safety committee, the safety engineer presiding. Action is taken by the committee on reports submitted and specific recommendation for the elimination of hazards, erection of guards, the removal of obstructions, installation of additional fire fighting equipment, or safety recommendations of whatever nature are set forth in full in the minutes, mimeographed copies of which are submitted not only to the general superintendent of the plant, but to all committee members, foremen and the heads of departments interested. The recommendations are numbered and followed up for prompt execution.

The company has also established a safety inspection division of the general engineering department, whose particular duties are to inspect

and pass upon the serviceability of all refinery equipment designed for operating under high pressure and temperature conditions.

The general safety committee meets quarterly at one of the company plants. At these meetings, which usually take from two to three days, all major safety problems are discussed, safe procedures formulated and standard codes and specifications worked out either in detail or outlined for further elaboration by the safety inspection division. The conclusions or recommendations of the general committee are written up in detailed minutes and turned over to the general engineering department for review and comment, then in turn submitted to the company's managers, who pass upon and specifically approve or disapprove recommendations rendered. Upon approval of any recommendation, code or standard, all plants interested are notified by the central management with instructions to carry out or observe each particular recommendation, safety code or procedure approved.

Discussion Has Covered Hundreds of Safety Subjects

The general safety committee, from the time of its reorganization, six years ago, to date, has discussed some 900 safety subjects, resulting in 360 specific recommendations, 80 per cent of which have been approved and put into effect, among some of the more important of which are:

- Use of safety belts.
- Storage battery isolation and ventilation when charging.
- Checking blue prints for safety.
- Adjustable platform for tank car filling racks.
- Containers for fresh air hose and mask.
- Filtering and changing of oil transformers.
- Gas engine testing.
- Fuse boxes, cautions to be taken on old and new installations.

Numerous inspection forms and specifications have also been prepared, approved and put into effect covering: inspection of tools, gas masks, tank before cleaning, etc.; also standardized specifications for welding gloves, hammer handles, and clothing suitable for different occasions, including high laced shoes, "hard toe" safety shoes, gaiters, quick detachable leggins, etc.

Major Safety Codes have been approved, as follows: Part I—Guards for transmission machinery and mechanical driven equipment; Part II—Scaffolds and working platforms; Part III—Safe handling of sheet steel; Part IV—Regulations for welding, burning and hot work in refineries.

Major Codes are being compiled and approval is pending, as follows: Part V—Regulations for operating fuel oil and gas burners; Part VI—Safe operation of refinery field machinery; Part VII—Use of proper goggles for various trades and operations about refineries.

The safety education of a new employee in the New Jersey company starts at the employment office. Using the practice at the Bayway Refinery as an example of the general procedure, the applicant is first interviewed by the assistant employment manager, who gives him a

thorough examination as to personal as well as vocational qualifications. These are noted down, and if satisfactory he is sent to the medical department where he undergoes a thorough physical examination. If he passes this test, he then goes to the record room where facts pertaining to his personal and domestic life and previous employments are recorded. He then returns to the assistant employment manager's office and, after a general talk on working safely, his attention is called to pivoted blackboards, on the first of which appears in large type two cardinal safety rules, which he is instructed to memorize, which read as follows:

Various Exhibits on the Safety Blackboards

1. "Here is your first A B C—Always be Careful."
2. "Notice to Men Seeking Employment—Unless you are willing to be careful, to avoid injury to yourself and fellow workmen, don't ask for employment. We do not want careless men in our employ."

Signed by the Plant Superintendent.

Then on succeeding leaves of the blackboard appear illustrations and exhibits of:

1. Proper and improper clothing and shoes—Noting that shabby, loose, torn, carelessly mended trousers, jumpers and sweaters are strictly prohibited, and that thin soles, soft tip, rubber soled and rubber heeled shoes are strictly prohibited.
2. Illustrations showing the contrast between proper and improper clothing—including unsafe footwear. Samples of overalls, jumpers and safety shoes that can be purchased at the local storehouse, are also shown.
3. Rule against smoking and carrying sulphur matches—Illustration showing damage caused by smoking. Exhibits showing the difference between sulphur and safety matches.
4. Injuries—Splinters and injuries of any kind must be reported first to foreman, after which employees must report immediately to medical department. (An employee is given first aid in the event of accidents and is properly advised as to consultation of personal doctor in the event of sickness.)

Photographs then follow showing cases of blood poisoning as the results of carelessness, the employees having failed to report promptly to the medical department for treatment. Photographs showing results of neglected burns.

5. Goggles—Goggles must be worn when assigned to any work which may cause injury to the eye.

Photographs showing severe burn through neglect to wear goggles. Sample of goggle supplied employee.

Exhibit of goggle broken when worn, but saving man's eye.

6. Tools and Material—Caution in handling. Exhibit showing pictures of broken fingers, toes, arms and legs.

7. Unsafe Tools—Exhibit of mushroomed chisels, hammers, drills.

machinists' hammer taped and mended together, home-made open-end wrench and monkey with sprung jaw.

8. Illustration showing up-turned nails in broken board and picture of resultant accident.

9. National Safety Council poster illustrating right and wrong way of lighting fuel oil burners.

At the conclusion of these instructions, the employee is handed a first aid card for safety committeemen. One side of this card is addressed to the particular foreman as a safety committeeman, then follows the name of the employee, date of employment and request to instruct him in the safe practices of the department, and have him sign the card, then return to the safety department. Immediately below is an acknowledgment of having received the safety instructions from the foreman, a blank space for the signature and check number of the new employee, and date. On the reverse side of the card is an appeal to the foreman as a safety committeeman with "Plant Slogan" and Universal Safety seal, also printed notation at the bottom addressed to the chairman of the committee, reading, "I am returning this card properly signed for your information and record," with space for date and name of foreman. The foreman, when satisfied the man understands the safety instructions given to him, has him sign his name, or in the case of the illiterate, make his mark on the card, the card is countersigned by the foreman and returned to the employment office for record.

When the use of this card was first considered, much skepticism was expressed as to its practicability. The satisfactory experience of over six months use, however, has eliminated all objections and has led the company to consider its adoption at the other plants.

Some of the Safety Procedures that are Featured

Some of the Safety procedures featured at all of Standard Oil Company (N. J.) plants are:

Continuous safety education of the employee by personal contact on the job.

Supervisory responsibility.

Group meetings of foremen.

Medical attendance and ambulance service.

Monthly safety letters and comments on safety records to department heads.

Accident score board, varying features.

National Safety poster display throughout plant.

Distribution of National Safety Council calendar.

Plant papers featuring safety articles, illustrations and cartoons.

Safety badges worn by Safety Committeemen, and, at some plants, by all foremen as Honorary Committeemen.

Continuous campaign to sell safety shoes.

Periodic safety drives.

Fire drills.

Safety inspection of tools, riggers equipment, pressure vessels other than boilers, gas masks, scaffolds and ladders, fire fighting equipment, also conspicuous display of posters and other safety kinks of plant interest. As an example, at the entrance to Bayway plant, attention is attracted to a brightly painted life size outline of a traffic policeman, with one hand upraised and the other pointing to an empty barrel on which is painted "STOP! Before going into works drop your careless habits and parlor matches, etc., here."

At the Bayonne and Bayway Refineries monthly reports are compiled and mimeographed copies issued to all departments showing lost time accidents in each of the several departments and subdepartments, particularly noting by green stamp those departments 100 per cent safe. The Bayonne reports show causes, i. e., machinery or equipment, human element and supervision. Bayway adds the records of each foreman, also a departmental summary of lost time accidents for each month of the preceeding year, each accident being denoted by a black cross. A similar record is shown on the same sheet for the corresponding months of the current year, in red. Monthly minor accident totals for major departments are also indicated. These reports not only stimulate departmental rivalry, but give at a glance departmental and plant comparisons and are a constant safety reminder to the entire supervisory force.

Making Effective Use of Safety Flags

Bayway also, imitating the example of Mr. T. N. Shaw of the Midwest Refining Company, Casper, Wyoming, adopted the use of safety flags on November 1, 1925, with most satisfactory results. A 5x8 flag was designed with the "Universal Safety" seal in white on a green field. Six flags were assigned, one each to the four major mechanical departments and two to the process department. The flags are raised over their respective departments the first of each month, at which time a seventh, or plant flag is raised from the staff at the main office building. The first accident occurring in any department pulls down the plant flag, as well as the department flag, for the balance of that month.

By the use of safety flags, departmental pride is appealed to, resulting in keen rivalry to keep the flags waving.

Safety flags were later adopted and are now used at the Charleston refinery.

In preparing and submitting reports of lost time accidents at the different Standard Oil Company (N. J.) refineries, in addition to setting down the usual statement of facts, all circumstances connected therewith are carefully analyzed by the local safety organization or committees, as to cause and responsibility, and a specific statement made as to what can or should be done to prevent a recurrence of a similar accident.

The lost time accident record of the manufacturing department, Standard Oil Company (N. J.), for the calendar years 1921-1925 shows the following:

Year	Number of Cases	Frequency Rate per 100 Active Employees Per Month	Frequency Rate per 1,000,000 Hours of Exposure
1921	768	.57	28.38
1925	410	.27	13.16
9 mos. of 1926	230	.21	9.86

It will be noted that the reduction amounts to 63 per cent when the frequency rate is computed on the basis of 100 active employees per month and to 65 per cent when computed under the National Safety Council system.

The two refineries that show notable decrease in accident frequency for the nine months of 1926 are the Eagle works, with a frequency rate per 100 employees per month of .09 and Bayway refinery with .16.

Throughout all of the safety activities recited, most of the safety engineers and inspectors of the different companies, or their individual plants, are aided by and kept in touch with the National Safety Council through the Regional and Petroleum Section officers or committees; by correspondence, meetings, bulletin service and safety calendars; as well as by our ably edited monthly news letter, a new and most important feature that we feel has come to stay.

Limited time and data prevents reviewing the work of other companies in the Atlantic group and represented in the Petroleum Section, which are also making substantial progress in the cause of safety.

I would like to say, gentlemen, I have a limited number of those forms, cards and procedure at Bayway and Bayonne in the matter of reporting accidents, and I will be glad to give these to any who desire them.

THE CHAIRMAN: I will say that this valuable contribution by the Standard Oil Co. of New Jersey will certainly bear closer scrutiny, and I want to thank Mr. Waddington for bringing with him further copies so that we can make a study of their procedure.

Is there any further discussion on Mr. Waddington's paper?

FRED W. LAU (Standard Oil Co. of Indiana): May I ask what form of discipline the Standard Oil of New Jersey uses in case of accidents, violation of safety rules, etc.?

MR. WADDINGTON: There is some very distinct punishment handed out for direct violation of safety. If it is done wilfully and you can prove that it is done wilfully, a man gets the gate. However, he can be disciplined and has been disciplined for slips in observances by time off. The local safety committee, which is composed of what we call company representatives and employee representatives on the Industrial Relations plan, passes on the cases as to cause. Maybe I didn't make that clear in the paper. In New Jersey we have a state compensation law; but in addition to the state compensation law, if the man is at fault,

then the company's benefits will be withheld. They are withheld very often. I will ask Mr. Humphrey if that isn't true.

MR. HUMPHREY: (Standard Oil Co. of N. J.): In the case of a man violating the safety rule, the company benefits—which are full-time payment of wages—are limited only to the state compensation, which is about one-half.

MR. LAU: I may state in that connection that with the Standard Oil Company of Indiana we have between 4,500 and 5,000 men. We have our foremen as safety inspectors. Our managers say we don't need any more men. We have 250 foremen and they are safety men. An unsafe foreman has no place in this refinery. Then he means business, and in the last year we have practiced discipline and we found out that discipline has solved that problem to almost nil. If the foreman slips, he slips also the other way. He is either demoted or discharged. If the men violate safety rules they are discharged.

The Severity Rate Is Much Lower This Year

I might say our accident records—I will not blow my own horn or anything of that sort for our company—but on our accident rate so far this year we had 57 lost time accidents among 4,000 men. Although we are a little higher than last year, our severity rate is 90 per cent lower this year, due to the fact that our manager has told the boys that he will not stand for anything at all. They know it, from the department heads down to the lowest man. Discipline is the main factor in putting it across. We have tried the other ways and it doesn't go across so well. We have gotten it down to a point where I am looking for more information to get it down lower. I don't know how we are going to do it.

THE CHAIRMAN: Will you tell us the different degrees of discipline that you have, the nature of that discipline?

MR. LAU: In what particular line?

THE CHAIRMAN: As a whole. For instance, you have a man there who has disregarded a law or a rule and he is up for sentence.

MR. LAU: He is either demoted or discharged. In the first offense we demote him, and that means a reduction in pay. That is the biggest advertisement you can have. If there are 20 men in the gang and a man is demoted, the rest of the men know it and it hurts his pocketbook.

THE CHAIRMAN: Is that same man able to regain his former standing?

MR. LAU: At the discretion of the foreman. If the foreman sees fit to put that man back in his old job he decides to do it.

THE CHAIRMAN: The foreman is the sole judge?

MR. LAU: Yes.

MR. HUMPHREY: I would like to ask the gentleman how serious an accident has to be in order to discipline the foreman?

MR. LAU: That depends entirely on the manager. He decides the discipline for the foreman, whether it is a discharge or a demotion. In most cases it is a demotion. He is set back in the gang. If he is a regular foreman he is set back to a riveter or caulker.

MR. WADDINGTON: Do I understand that the foreman is disciplined if he has an accident, regardless of cause? If the cause is due entirely to a man's carelessness and the man deliberately does it, as most of them do, is that foreman disciplined?

MR. LAU: It all depends on the causes.

MR. WADDINGTON: I am led to believe from your remarks that the foreman is disciplined rather than the men for not observing the lessons that have been taught them, that the foreman is disciplined rather than the man, unless in your actual examination of the facts somebody judges that he is not at fault. I don't know how you are going to succeed along those lines.

THE CHAIRMAN: I believe what the gentleman from Indiana intended to say is that the foreman is subject to discipline along the same lines as the worker is. He didn't mean to say if a workman makes a mistake that the foreman is disciplined. Am I correct?

MR. WADDINGTON: His methods differ in no way whatsoever from the Bayside or Bayonne. If a foreman is at fault he gets the discipline the same as the man. The safety committee determines whether it is the man's fault or the supervisor's fault, and the action is taken as a result of their findings.

A Comparison of Foremen's Safety Efficiency

L. D. PALMER (Standard Oil Co. of Indiana): To supplement Mr. Lau's account of this, he told me a story of a manager reviewing the accidents of the year and he found in one department a number of foremen had six lost time injuries doing the same kind of work that other foremen in that plant were doing, and I think two of these foremen were demoted because they showed a very poor accident score. They were doing the same kind of work. So this is comparable with the other foremen. Possibly it was on account of careless employees. We feel that the foreman is the key in this situation and that he is responsible for this education of men just the same as the rest of us.

We have several thousand men, and we figure that we must use the foreman in this work and that he is responsible for careless men just the same as he is for insufficient work in other lines. So these two foremen, I believe, were demoted and other men put in their place, and these men are making fine records. These men know that if they show a poor score at the end of the year it means something to them, and that explains the point asked by Mr. Waddington. You don't pick out a case where an employee pulls a bad stunt and hang it onto the foreman. That sort of discipline, I believe, is producing very fine results.

MR. SHAW: I would like to ask a question in regard to the pressure you bring on your foremen with regard to safety. Is reward for safety work either to foremen or to gangs or individuals advisable or is it not? Will it get results or will it not? I mean reward in the way of an extra day's pay a month, or a day off with pay, or at the end of the year two weeks of vacation with a day to it for month, because he has gone through a year without an accident; or some other form of re-

ward? I would like to know if anyone has any experience or knows anything about that?

THE CHAIRMAN: Mr. Shaw, if you will allow, we will rather delay this for a round table discussion a little later. We are a little pressed for time today.

I was very much pleased and gratified in looking over our announcements of the visitors we had yesterday that we had the honor of having with us a deputy commissioner from the Department of Labor from the state of New Jersey. If that gentleman has honored us again today I would like to have him present himself.

Cordial Cooperation Enjoyed from the Oil Men

JOHN ROACH (Deputy Commissioner of Labor in Charge of Health Sanitation, Hygiene and Safety, New Jersey): I have been suffering from a bad case of sinus and if anybody here has ever suffered from sinus trouble, you can understand what kind of a night I had last night with it.

I am very much pleased to be at this meeting. It seems to me that our good friend from New Jersey has evidently started something in the discussion line with a paper on Standard Oil practices on safety matters that he read this morning. I know that we receive very cordial and most substantial cooperation and support from the oil group in New Jersey in enforcing the mandatory provisions of New Jersey's labor laws. If we received the same support, coupled with the same intelligent engineering application of safety principles in all other lines of endeavor throughout our state, I feel safe in saying that we might easily reduce the size of the enforcement bureau in our state and save the taxpayers \$200,000 or \$300,000.

I am enough of a democrat and a believer in democracy in the broad gauged way—I am not speaking about the kind that we find in some of our municipalities—but I am enough of a democrat and a believer in representative self-government to hope that the time is not far distant in our country when industry as a whole will grapple with this problem of accident prevention so as to make unnecessary the appropriation of funds by state governments to enforce laws based on the police power of the state.

We have had enough experience in mandatory enforcement of labor legislation in our state to know that the most effective safety measures are not those that are enforced by shaking the policeman's club at the plant manager. I know, however, that we have not yet arrived at that splendid state of self-administration of government when we can expect all people in all lines of endeavor to operate their plants with the greatest measure of safety unless their activities are in a measure supervised by state effort.

You know in our state we have mandatory, definite engineering rules of procedure for almost every processing method that is carried. For instance, our boilers must be constructed according to definite standards—not propounded by the state legislature which probably even in its

wisdom would not know much about boiler construction. But boiler construction rules are framed by the A. S. M. E. and we adopt the code. If we ask the industries to erect a guard about a piece of operating equipment, the method of construction is outlined in a book of rules and the rules have been prepared by sound engineering organized effort and represent the best thought in that line. So that these definite things that the state asks industry to do are based on good sound operating practice.

Now, briefly, in our state if you want to know how carefully the oil industry is run as compared with other industries—while we haven't severity and frequency rates in all lines of effort as complete as you have in the petroleum industry, still we know that in our state roughly we have probably 450,000 manual workers who come under the provisions of the Workmen's Compensation Law. We know that last year we had about 50,000 individual reportable accidents tabulated by the Statistical Bureau, or one for every nine people, roughly. These 23,000 people milled through the Compensation Division and received compensation benefits that for administrative purposes, such as overhead and the wage payments themselves, totalled about \$9,000,000—quite a heavy burden on the state.

But I wouldn't lift my voice to lighten the burden were it not that in addition to the financial burden we have the terrific loss of life and limb to consider. There were 350 lives lost and 23,000 broken men and women that milled through the bureaus asking for compensation who are, in my judgment, immeasurably more important than the mere expenditure of dollars and cents.

The Scrap Heap Gets Few Men In New Jersey

So that I do say very feelingly that we have received wonderful, systematic, intelligent and generous cooperation from the oil group. You know the reason that I stand before you and make this announcement is because it means that the scrap heap in our state is not receiving any appreciable addition from the petroleum industry. I shouldn't wonder but what the same condition prevails in other states. I know when we send down to Bayonne and say we are going to have a meeting at our industrial museum, that is all that is necessary. We will find a fleet of heavy buses starting away from various plants and our industrial museum on that occasion will be filled to overflowing.

It is an inspiration and indeed a great pleasure to me and other men engaged in this life saving work to know that at least one branch of New Jersey's industry can be properly placed in the safety column, and for that reason I like to make this announcement. I only regret that it is not possible to go through all the basic industries of our state and say that management men in the state have cooperated in such a way as to bring them up to the splendid point of conservation achievement noted in the oil industry.

I thank you gentlemen for giving me this opportunity of just getting up here before you and forgetting the sinus for a few minutes and saying these few words.

THE CHAIRMAN: Mr. Roach, on behalf of the Petroleum Section, I wish to acknowledge the very fine spirit in which you approached us to-day. We are very happy indeed to have you with us and we accept your advice and commendation with a great deal of pleasure. May I ask you on your return to Trenton to convey to Dr. McBride, Commissioner of Labor, our best wishes and greetings from this Congress; also the assurance that we appreciate his and your kind interest? We are ready at all times to cooperate with state officials and other government agencies on matters pertaining to safety, and I trust that you will take back with you a feeling that your visit has not been in vain. Certainly we want you to feel that we were delighted to have you with us.

The next subject on the program is one which I am sure will be of considerable interest. It was prepared after extensive work, after considerable research, by the United States Department of Commerce, Bureau of Mines, Experimental Station of Pittsburgh. The paper was prepared by Messrs. Yant and Fowler, and I am very sorry to announce that due to conditions not within his control, Mr. Yant will not be able to present the paper in person, but we surely have a man here who is competent and able to do that for him, and I take great pleasure at this time in presenting Mr. Forbes, Supervising Engineer of the Bureau of Mines at Pittsburgh.

HYDROGEN SULPHIDE POISONING IN THE TEXAS, BIG LAKE, TEXAS, AND McCAMEY, TEXAS, OIL FIELDS

**J. J. Forbes, U. S. Department of Commerce, Bureau of Mines, Pittsburgh
Experiment Station**

In a previous investigation of the toxic gases given off in the transportation and refining of Mexican and high sulphur crude oil it was concluded that hydrogen sulphide was the most toxic gas encountered. A report of this study has been published as Bureau of Mines Bulletin No. 231, which describes the occurrence of hydrogen sulphide, symptoms and effects from poisoning, methods of treatment, and protective equipment. This study was devoted almost entirely to the handling and refining of the crude oil after leaving the wells, no attention being given to the production. However, in the course of that investigation it was alleged that a certain amount of trouble had been experienced around wells in Mexico.

Rather recently, during the development of oil fields in Texas, a "poison gas" was encountered that constituted a decided health and safety hazard. The magnitude of the trouble deemed it to be of sufficient importance for the Bureau of Mines to accede to the request of the operators for an investigation. Reports of Investigations, Serial No. 2776, describes this investigation and is intended to supplement the information given in Bulletin No. 231. Due to the length of this report only excerpts and briefs can be given here. Copies may be obtained by writing to the information Service, Bureau of Mines, Washington, D. C.

This investigation as given in the title was conducted in the Pan-

handle, Big Lake and McCamey oil fields, all these being situated in Texas. The work undertaken in each field included:

1. Examination of the gas coming from representative wells at various locations in the field; also analyses of the gas-air mixtures to which the workmen were or might be exposed.
2. Observations of symptoms of poisoning and severity of these symptoms.
3. Observation of the conditions of exposure that produced the symptoms.
4. Study of ways and means of protection and prevention.

The whole survey was made in order to determine general conditions relative to the hydrogen sulphide hazard in the three fields, rather than a detailed study of individual properties. However, representative data were gathered and from these findings, recommendations have been made that should help reduce the hazard in these and similar fields.

The prevailing conditions in the Panhandle, Big Lake, and McCamey fields were similar to those reported in Bulletin No. 231. The characteristic odor of hydrogen sulphide could be detected almost anywhere in the field; also there was pronounced darkening of white lead paint on houses, of brass valves and fittings, and of silver money. The symptoms caused by this gas—both acute (as unconsciousness and subacute as eye and respiratory tract irritation)—were identical with those produced by hydrogen sulphide. With the exception of slight gasoline-vapor intoxication and the possible existence of gas-air atmospheres containing an insufficient amount of oxygen to support life, no indications of other toxic gases were noted. The examinations of the gases and gas-air mixtures were therefore confined to analyses for hydrogen sulphide content. A brief of the conditions found follows:

The Panhandle Field

The Panhandle field (stated by some authorities to be 20 miles wide and 100 miles long) was too large to be covered completely during the period of this investigation. The study was confined to an area approximately 20 miles in diameter, located about 50 miles northeast of Amarillo, Texas, with the town of Borger as its central point.

There are two distinct types of wells in the Panhandle field, one known as the "granite wash" and the other as the "lime." Both produce gas in large quantities but there is a distinct difference in the gas composition.

The average results of analysis of hydrogen sulphide in samples collected from 20 different wells within a radius of 10 miles from Borger, Texas, show that:

1. In the "granite wash" wells neither the gas coming from the "big gas" stratum above the oil nor the gas coming from the oil contains more than 0.01 per cent hydrogen sulphide. (Also no distinct odor of hydrogen sulphide was detected.) This amount appears to be negligible from the safety standpoint.
2. In the "lime" wells both the gas coming from the "big gas" producing stratum above the oil and the gas coming with the oil has a

hydrogen sulphide content between 0.20 to 0.60 per cent by volume. There appears to be a regular variation between different parts of the field. The gas from a well approximately 10 miles southeast of Borger, on what probably is the edge of the "lime," contained 0.20 per cent hydrogen sulphide; this well was not making oil and is beyond the present radius of active drilling in the field. Wells within an estimated radius of three to seven miles southwest, west, northwest, north and northeast of Borger contained 0.45 to 0.55 per cent; and wells east of Borger in the Dixon Creek region contained 0.55 to 0.65 per cent. Two samples from wells north of the Canadian River, the one approximately five miles and the other approximately 10 miles northwest of Borger showed 0.46 and 0.26 per cent respectively. Both of these wells were in the "lime."

From these data it appears that hydrogen sulphide occurs in the gas from all lime wells within the area examined.

Observations made regarding symptoms of poisoning showed that no symptoms of hydrogen sulphide poisoning occurred among the men working around the gas coming from "granite wash" wells though they were exposed to gas-air mixtures under gas concentrations and working conditions similar to those of the lime wells. It will be remembered that the gas from these wells contained less than 0.01 per cent hydrogen sulphide.

Injurious Effects of Hydrocarbon Gases

However, exceedingly high concentrations of this gas will dilute the air below the point that will sustain life. The addition of 25 to 30 per cent of gas to ordinary air will reduce the oxygen content to 15 or 16 per cent. The low limit of a safe atmosphere for the average man is 15 to 16 per cent of oxygen. The physiological action of atmospheres markedly deficient in oxygen is very rapid. There are no significant warning symptoms before unconsciousness occurs.

The injurious effects of hydrocarbon gases are well known. The symptoms of dizziness, numbness in the legs, drowsiness, or possible exhilaration, preceding unconsciousness are usually recognized.

Accidents due to atmospheres low in oxygen and high in hydrocarbon vapors are liable to occur in the derrick cellars or other confined spaces at "granite wash" wells unless the men take proper precautions. Recovery is usually rapid if the victim is immediately rescued and taken to fresh air. Artificial respiration should be given if breathing has stopped or become impaired.

Although no hydrogen sulphide poisoning was found to occur with the granite wash wells in the field, two distinct types of symptoms occur in the men working around the "lime" wells. One of these is irritation of the eyes and respiratory tract following a relatively long exposure; the other is unconsciousness attending a very short exposure. Eye and respiratory tract irritation is very prevalent among the men working in the gas from "lime" wells. It mainly occurs among drillers, tool dressers and men making bradenhead connections. These men are

exposed in varying degrees from the time of drilling into the gas until the last casing is set and the bradenhead connection made, and even after that there may be sufficient gas leaking around the bottom of the casing or coming with the oil to constitute an exposure.

The eye irritations range in severity from mild conjunctivitis to swelling and bulging of the conjunctiva, photophobia, and temporary blindness. In many cases they are extremely painful and occasion a large amount of lost time. Often drilling is suspended due to the entire drilling crew being affected and unable to work. The same condition prevails among the bradenhead crews, the closing in of wells having frequently been delayed several days.

It is a rather common occurrence to find men around the wells with their hats drawn down over their eyes or wearing dark glasses to protect them from strong light, and many appear daily at the emergency hospitals for treatment. One prominent doctor in the field told the writers that he estimated that he had treated more than 1,000 cases of conjunctivitis during the first six months of 1926. However, the effects are temporary and readily yield to treatment.

A large number of cases of respiratory irritation also occur, although not as frequently as the conjunctivitis. The respiratory irritations of the nose, throat, and lungs often lead to rhinitis, laryngitis, and bronchitis. In some cases there is coughing and a feeling of fullness in the chest.

The recorded cases of unconsciousness have occurred to men making the bradenhead connections in the cellar, or doing similar work when the gas is escaping in that place. The time of exposure preceding unconsciousness is very short, often but a fraction of a minute, and there is no significant warning symptom. The victim is often aware that he is in strong gas and has a sudden choking sensation but usually becomes unconscious before he can get away.

Although there have been many of these cases, no fatalities have occurred. This is due to quick action on the part of fellow employees who have rescued the victims and removed them to open air. Recovery in air is rapid, and the men usually suffer no marked ill effects, being able to go back to work if necessary. In a few cases there is nausea and headache, and in others body injury has occurred due to falling on pipe clamps or fittings.

The Big Lake Field

The Big Lake oil field is situated approximately 350 miles south of the Panhandle field in Reagan County, Texas. It is much smaller in area than the Panhandle field, is older, and in a more settled state of development.

Two types of gas are also found in the Big Lake field but these are in different strata of the same location rather than in different locations in the field, as in the case of the Panhandle. The upper gas is sweet and occurs in large quantities, some wells have flowed as much as 87 million cubic feet per day. This gas is only produced for fuel, the lower

gas being too poisonous and corrosive for use around men and in engines, boilers and heating appliances.

The "poison gas" is present with the oil but fortunately not in large quantities. If the same volume were present as in upper gas or in the Panhandle field, the effect would be disastrous. Analyses of eight samples of the poison gas collected from eight different wells, oil separators, or flow tanks into which the wells were producing, show amounts of hydrogen sulphide ranging from 8.1 to 10.5 per cent. The concentration appears to vary with the location of the wells. Those wells in the extreme east part of the field produce the larger amount, and those in the southwest the lesser.

The sweet gas contains less than 0.01 per cent hydrogen sulphide and no health hazards exist other than those from hydrocarbons as described under the "granite wash" gas of the Panhandle field.

Symptoms of the types described in detail in discussing the Panhandle field also occurred in the Big Lake field. However, the field is older, the men have had more experience with the gas, and the drilling campaign is much less extensive. Also the volume of sour gas is relatively small, so that few symptoms were observed at the time of making this investigation. Many rumors, which were confirmed by conversation with the physicians, indicated that in the earlier days of the field the conditions were similar to those now prevailing in the Panhandle. The men are now cognizant of the dangers and have learned to avoid the gas.

Four deaths are alleged to have occurred in the past from acute poisoning. Before the dangers of the gas were well known and before the depth of the poison gas zone was accurately determined, a well was unexpectedly "drilled in" one night, and the gas killed both the driller and tool dresser—the only men present at the time. They were found dead on the derrick floor by a foreman, but because of the large accumulation of irrespirable gas he could not recover the bodies at that time. Accordingly, he started for help and had proceeded but a short distance when the gas became ignited and set the well and derrick on fire.

In two other cases men died from exposure to hydrogen sulphide gas while gauging flow tanks.

In conversation with gaugers and switchers it was learned that many rabbits and birds are found dead around the wells and tanks. The men stated that these dead animals are usually found after a calm, oppressive night when the barometer is low and there is little or no air movement. One man stated that he had collected a pile of more than 100 dead animals. The writers wished to observe these, but due to a heavy rain which flooded that portion of the field on the preceding day, they could not be found.

The McCamey Oil Field

The McCamey oil field is situated about 25 miles west of the Big Lake field in Upton County, Texas. It is a new field and appears to be in about the same stage of development as the Texas Panhandle, although a great deal smaller in area.

Although some gas producing strata are encountered above the oil the poison gas in this field occurs with the oil in a lime formation. The gas is present in relatively small quantities but the concentrations of hydrogen sulphide are high, averaging about five per cent.

Several men reported that they had become nauseated while working on top of flow tanks and one gang of men connecting up a field tank were affected by the gas. No eye symptoms were noted at the time of the investigation, but a doctor in the field gave information that all of the usual types of symptoms of hydrogen sulphide poisoning had occurred.

Recently a gauger died from exposure to the gas on top of a flow tank. A well "came in" at about 7 o'clock in the morning. There was no control head on the eight and one-quarter inch casing, and the well flowed "wild" for about eight hours. The initial production was estimated to be at the rate of 10,000 barrels per day. It is reported that because water was coming with the oil the well was flowed into open storage for some time after it was brought under control.

The gauger lived in a tent approximately 100 yards from the well. About 3 o'clock in the morning of the second day he went on top of a flow tank to gauge its contents while another man opened the gate valve. As soon as he opened the gauge hole cover, a puff of gas escaped from the opening and he fell on the roof of the tank.

The other man heard the noise of the fall, and the unconscious gauger was immediately taken off the tank, but there is some question as to whether or not he was taken entirely out of the gas area. Effort was made to revive him and a doctor was summoned, but the man died after being unconscious for about one hour and a half.

General Discussion

As has been stated, the concentration of hydrogen sulphide in the "sour" gas in the Texas Panhandle field ranges from approximately 0.20 to 0.60 per cent by volume. A table in Bureau of Mines Bulletin No. 231, shows that an exceedingly toxic atmosphere can occur in a mixture of this gas with air. If the gas contained only 0.20 per cent hydrogen sulphide, it would require a mixture of equal parts of gas and air to give a concentration of 0.1 per cent hydrogen sulphide. In this case unconsciousness would result about as quickly from lack of oxygen as from the hydrogen sulphide present. On the other hand, with the higher concentrations found in the Texas Panhandle (0.60 per cent) a toxic atmosphere could be created containing 17 to 18 per cent oxygen, a respirable amount.

A mixture of one part of the Big Lake gas (which contains about 10 per cent of hydrogen sulphide) in 100 parts of air would be highly toxic. The McCamey gas is also exceedingly toxic, the minimum mixture with air causing immediate unconsciousness being in the ratio of one part gas to about 50 parts air.

Analyses of a large number of samples of gas-air mixtures collected

on the derrick floor, under the floor, in the cellar, and in various other places show that the workmen are often exposed for long periods to concentrations of 0.01 and 0.02 per cent hydrogen sulphide in air, sometimes for short periods to 0.03 and 0.05 per cent, and occasionally for very short periods to 0.10 per cent, or higher. In several of the working places where samples of the gas were taken, cases of eye irritation were observed and in one instance irritation of the respiratory tract resulting in a fullness in the lungs and coughing.

Analysis of gas collected from a cellar where two men had become unconscious a few hours before showed 0.10 per cent hydrogen sulphide.

The concentrations and symptoms found in these oil fields parallel those found in previous work, and the detailed descriptions of symptoms in this report are almost identical with those found to occur in the handling and refining of Mexican and high sulphur crude oil.

Treatment

Conjunctivitis.—Consultation with physicians in these oil fields who have been treating these cases advise that the following treatment for conjunctivitis has given excellent results—not a single case failing to respond to treatment, where the patient has done his part by following instructions.

1. Relieve pain by drops of butyn, or butyn and epinephryn, or in severe cases halocain.
2. Follow with campho borate. One doctor varies this practice by using boric acid ointment.
3. Drops of colloidal silver iodide (neo-silvol), or argyrol (5 to 10 per cent).
4. Throughout the treatment use hot compresses alternating with a cold compress if pain is too great.

Rhinitis, Laryngitis, and Bronchitis.—Irritations of the nose, throat and lungs are treated symptomatically. One doctor has had good success in the use of "anespray" for the throat.

All of these treatments should be under the supervision of a competent physician, and although the symptoms may appear trifling, they should receive medical attention at once due to the complications which often arise. Although the application of hot and cold compresses in themselves will relieve pain in cases of conjunctivitis, and irrigation with boric acid will be helpful in slight attacks, the difficulty of obtaining sterile compresses and eye cups together with the difficulty of self-diagnosis as to the severity of the attack, makes "home remedies" and "home treatment" inadvisable. If a man had a natural tendency toward eye or respiratory weakness, his exposure to hydrogen sulphide gas might result in a complicated condition that would prolong the recovery period. This makes it especially imperative that all cases should be treated by a competent physician.

It is reported that in the Panhandle district some practitioners of little experience are dispensing solutions containing cocaine to be used as an eye wash in cases of gas conjunctivitis. This is a very dangerous treat-

ment because the pain is relieved temporarily, and men will go into the hydrogen sulphide gas repeatedly when they should be receiving proper care. The continued application of such eye washes would undoubtedly result in corneal ulcers and in the permanent injury to the patient's eyes.

In many cases of acute hydrogen sulphide poisoning there is an immediate cessation of respiration. Thus any treatment to be effective must be given immediately and so simple that it can be given by fellow workmen. There is no time for summoning aid before beginning to resuscitate the victim. In view of this the following treatment is outlined.

1. Get the patient into fresh air.
2. Give artificial respiration, if breathing has ceased, become markedly labored, or impaired.
3. Summon a doctor.
4. Give inhalations of oxygen, if available, through an inhaling apparatus similar to that described in Bureau of Mines Bulletin No. 231.

If breathing has ceased or ceases during treatment, artificial respiration should be continued until breathing resumes, or at least for a period of three hours.

Protective Equipment

Employers should furnish the following protective equipment and insist that men working in atmospheres containing hydrogen sulphide gas wear this equipment. The men should be instructed in the proper use of each type.

- (1) For work in cellars, inside of tanks or other confined spaces, where high concentrations of hydrogen sulphide gas may occur, men should wear a hose mask equipped with a blower. Workmen should not enter these places without a safety belt and life line.
- (2) For work on the derrick floor where concentrations of hydrogen sulphide are likely to occur, that will irritate the eyes, men should wear a gas-tight type of goggle. Goggles with water dams to overcome fogging of the lenses, and non-shattering glass are recommended.
- (3) For gauging tanks and for other outside exposure including the derrick floor, where low concentrations of hydrogen sulphide gas exist that would irritate the respiratory tract, suitable canister type masks should be worn.

Education in the limitations of the canister mask is essential. A canister mask is a filter, not a generator of oxygen, and is intended only for low concentrations of hydrogen sulphide. They should never be worn in cellars and other confined places where concentrations of hydrogen sulphide are as high as in these fields. The writers talked with one man in the Panhandle field who had been overcome by the gas in a cellar while wearing a canister mask. According to this man's statement, he had been in the cellar only a short time when the vapors broke through the

filter. He was aware of this by the "taste" (odor), but before he could reach fresh air he fell unconscious (and injured his back in falling).

Canisters should be used in accordance with the instructions of the manufacturers as they are in a position to know the contents of the container and the safe working time that is permissible before discarding it. The life of a canister is relatively short.

One company is meeting these difficulties and maintaining proper supervision of its breathing equipment by having a first-aid man in the field whose duty it is to take care of all breathing equipment and to be present at wells when the bradenhead is put on.

Objections to wearing hose masks on the ground that they can not be used in the cellar when putting on the bradenhead are either due to lack of proper information or to biased opinion, as the writers observed this equipment in use at a number of wells. Men who have worn hose masks claim that their movements are not greatly hindered by the hose and they appreciate the protection given by this breathing equipment.

Methods of Protecting the Men from Gas

Care should be taken that the blowers are sufficiently far enough away from gas so that the men will be sure to have an uncontaminated supply of air. As a matter of extra precaution, a man should be designated to watch each hose and safety line and to keep them from becoming tangled.

While apparatus for protecting men from hydrogen sulphide are essential for certain specific duties, it appeared that the majority of the cases of poisoning could be averted by using mechanical devices to keep the gas away from the places frequented by men and by devising methods of procedure which would not expose men during certain operations. A number of these are suggested in the copy of the report which has been given you. No doubt many more would be suggested to the alert safety engineer who has more time to study the conditions and developments.

Precaution is another item of extreme importance in all safety work.

Many of the cases of irritation were the result of carelessness, negligence, or lack of knowledge of the danger on the part of either the employee or the employer. Men would often heedlessly stand on the leeward side of the hole or in the stream line flow of the gas. Workmen should be instructed to avoid the gas whenever possible by working on the windward side of the outlet from which the gas is escaping. Under no condition should a man stand directly over a thief or gauge hole on a tank. Three out of five reported deaths due to hydrogen sulphide gas in these fields, have occurred to gagers on top of tanks.

I have endeavored in this brief of Mr. Yant's and Mr. Fowler's original report to give you the outstanding features attending the occurrence of hydrogen sulphide poisoning in these three fields. Also I have made reference to means of protection and prevention which are not only applicable to this field but to analogous problems in the petroleum industry. In all new safety problems it always requires a certain time to gain a comprehensive view of the situation and to work out ways and means

of coping with it. However, we can often gain time and profit from a background of what were analogous problems.

In regard to the discussion of this paper we are very fortunate in having with us Mr. Ray Miller, chairman, Mid-Continent Division, National Safety Council, and safety director of the Petroleum Safety Council of the Mid-Continent Oil & Gas Association, who has been with Mr. Fowler in the Texas Panhandle and is in a position to discuss the subject from first hand information.

THE CHAIRMAN: Mr. Forbes, before we call for a discussion of this paper I want to express the thanks of this Section. I consider this paper one of the outstanding features and one of the best contributions to this Section. The whole paper breathes naught but the idea of conserving human life and preventing misery and death, and it behooves all of us here, especially those interested in the producing territory, to arrange for the widest distribution of that paper. I am sure it will be received with much interest by everybody concerned, and I recommend it for consideration and all should be sure and get sufficient copies to see that they are widely distributed.

Policy of the Bureau of Mines is Criticised

MR. WALLACE: Mr. Chairman, it is useless to say anything more regarding the paper that Mr. Forbes has presented to us. We always try to have a paper in any of our divisional meetings from some of the Bureau of Mines group; we always know that they are going to be worth while.

The ridiculous part of it to me is that the stingy policy on the part of the Bureau of Mines has made it impossible for men like Fowler and Miller and the other boys that we all know, to attend these Congresses. It seems to me like putting your light under a bushel. The light is there all right, but they are covering it by a stingy scheme; and I would like to make the motion, Mr. Chairman, that a committee on resolutions be appointed, the purpose of this committee being to draw up resolutions expressing the sentiment which I have in mind, and that a copy of these resolutions be given to every member of the Petroleum Section with the request that they be forwarded to their Congressmen. I expect to take it up with Dan Garrett as soon as I get back to Houston just as enthusiastically as I can. Let's see if we can't help this Bureau, which is one of the few departments—I am a patriot, too, gentlemen—but it is one of the few departments in our Government that make me proud that I am an American.

I have all the confidence in the world in the Bureau of Mines. There is not a particle of commercialism in it. Nothing in the world but a real, honest desire to help in every instance where they can; and we have just started the contact in the last two years between the Bureau of Mines and the petroleum industry, and it is very regrettable if they spoil it at this time by a stingy policy.

(Mr. Wallace's motion was duly seconded.)

THE CHAIRMAN: It has been regularly moved and seconded that this Petroleum Section, by a committee to be appointed, draw up resolutions for presentation to the various Congressmen expressing the regret of our Section over their meagre policy, hoping for a little wider distribution of funds for convention travel. We would particularly stress the necessity of additional funds for convention travel.

All in favor of that please say "aye."

(The motion was carried unanimously.)

MR. SHAW: I would like to ask Mr. Forbes if hydrogen sulphide gas is heavier than air.

MR. FORBES: Slightly heavier, yes. Carbonmonoxide is 0.97; CO₂ is about 1.5. Hydrogen sulphide is slightly heavier than air.

MR. MILLER: I would like to add to Mr. Forbes' paper that that condition is terrible down there. There are several hundred companies operating there in various sizes and degrees and practically none of them are taking care of the situation in any comprehensive way. Most of the larger companies that are operating there have dumped in a lot of safety equipment, but as far as I could find, few of the men on the job knew how to use it. I find gas masks that are still locked up in their trunks and have never been used; we found the inhalaters had never been hooked up, the oxygen tanks were still wrapped up, and we found a few that had been partially hooked up and the valves were leaking so they could not have been used, and the condition is bad.

The General Field Conditions Are Very Bad

The general field conditions are about the worst I ever saw in any field. The cellar runways are invariably broken down, filled up with trash, the bracing and shoring is caved in, there is no room for a man to get out and conditions are rotten. I think those of you who are interested down in that field ought to take some steps to take care of those things.

We held a series of meetings down there, just finished up last week, getting the foremen together, to try and impress on them the dangers not only from the hydrogen sulphide, but the gas and fire dangers, and tried to show them ways of cutting down the necessary time of exposure to that gas, and also show them ways of protecting themselves during the necessary exposure. I think our meetings were good, but we only reached a very small number of people, simply because most of the companies operating there failed to accept our invitation to take part in the meetings. Those who did, I think, found the meetings worth while. Mr. Fowler and I took care of the meetings and I think we did some good among a few foremen. It is a serious question.

MR. CHAIRMAN: If there are no further questions, I might close this subject by stating that there has been a definite, concrete, plain warning sounded here this morning in the paper that has just been delivered. The warning has come in a technical way and from a practical standpoint. There is no doubt that the conditions exist. There certainly is no ques-

tion but what the facts are as stated, and it behooves us all to concentrate on that particular phase of safety in our industry and do some real work on the line of prevention of accidents in the producing fields. I hope you will all consider that thoroughly and make it a strong point to put that over and leave less important things go by the board.

Before closing the meeting I wish to make an apology to our Nominating Committee who were first on the program and unfortunately are now last. But I think they will realize the conditions under which we were working this morning and be satisfied to have their recommendations presented at this time.

The Nominating Committee sends this letter to me addressed to the Council:

REPORT OF THE NOMINATING COMMITTEE

Your Nominating Committee respectfully submit the following names for Sectional officers during the coming year:

For General Chairman the committee recommends the name of Mr. V. R. Currie, of the Texas Company, Houston, Texas.

For General Vice-Chairman for the coming year, Dr. R. P. Anderson, of the American Petroleum Institute, New York City.

For Chairman of the Pacific Coast Division, Mr. Charles M. Butler, General Petroleum Company of Los Angeles, Calif.

As Chairman of the Midcontinent Division, Mr. Ray E. Miller, of the Midcontinent Oil and Gas Association, Tulsa, Oklahoma.

As Chairman of the Atlantic Division, Mr. Thomas W. Waddington, Standard Oil of New Jersey, Elizabeth, N. J.

The committee further suggests that the selection of a Sectional Secretary be left to the option of the Sectional chairman.

Gentlemen, you have heard the nominations. What is your pleasure?

MR. SHAW: I move that nominations be closed.

(The motion was duly seconded and carried.)

THE CHAIRMAN: Consequently, the secretary will cast the ballot for the unanimous election of the gentlemen named. May I at this time request Mr. Currie to present himself as our new chairman?

(At this point Mr. V. R. Currie, the newly elected Sectional Chairman, assumed the chair.)

MR. WALLACE: Might I say that Mr. Currie threatened to kill me if he was even suggested as chairman of the Section for the coming year? So you can all attend my funeral at 4 o'clock this afternoon.

THE CHAIRMAN: Mr. Chairman and Members of the Petroleum Section: I am not going to take up a lot of time or even endeavor to give you a talk at this time.

I don't think that there is a member of this Section but who would feel very keenly the honor of being elected as Chairman of the Petroleum Section. I grant you that I am accepting this chairmanship over my own personal protest. At the same time, I want to say that I accept it and

I am going to put my shoulder to the wheel and endeavor to try to make a success of the job for the next 12 months. I can not but realize that we have made wonderful strides in the past few years in this Section, and I foresee for the future the greatest possibilities in the work of the Section.

I am accepting this chairmanship not in any way as a recognition for any individual work, but I am doing so as, if you please, a compliment to the hundreds of our boys in the ranks who have in the past 12 years served on our safety committees; to the foremen in our plants, who are awakening to the responsibility in connection with safety which rests upon their shoulders; to the assistant superintendents of our plants, who as a rule are the chairmen of our plant committees and on whose shoulders we are placing the responsibility for the accident prevention work in their respective plants; to the superintendents and general superintendents of those plants who I believe in most cases are thoroughly sold on the necessity of accident prevention work; to the assistant managers and managers of the departments who are ready and willing at all times to put their stamp of approval on practically every sane safety suggestion that is presented to them, either by the chairman of the central committee of safety or by the plant superintendent; and last but not least, to the president of our company, who as manager of the manufacturing department 12 years ago this week made the first announcement and made the appointment of our first safety committee. I do not think it is necessary to state here that he is thoroughly sold on the necessity for safety work and is not only giving us every bit of encouragement possible, but is really insisting on more effort being expended along that line.

I want to thank you for this great honor which you have bestowed upon me and I am going to accept this election with one provision, and I believe that that one provision or condition can be readily met—and that is that I have the full cooperation of every one of the officers of this Section and of the entire membership. I believe that I can count upon that.

MR. SENNE: I believe I voice the sentiment of our Section in answering your last suggestion. First I wish to congratulate you personally on your election. I believe the Section has done wisely in the selection. I want to promise you my fullest support during the year and with that support I am sure will go the hearty cooperation of each and every member of our Section. I wish you success and good luck, Mr. Currie. (*Applause.*)

ADJOURNMENT

THURSDAY MORNING SESSION

October 28, 1926

V. R. CURRIE, Chairman

Supervisor, Employment and Service, The Texas Co., Houston, Texas

The Thursday Morning Session of the Petroleum Section, October 28th, 1926, convened at 9:50 o'clock at the Tuller Hotel, Detroit, Michigan, the newly elected Chairman, Mr. V. R. Currie, of The Texas Co., Houston, Texas, presiding.

THE CHAIRMAN: Gentlemen, I am going to suggest that following the papers that are read this morning we confine as near as possible the discussion to the subject matter of the papers, inasmuch as there may be a few matters that the members would want to bring up before we adjourn. I think that there is some unfinished business, and if we can get through in time it will give us a little time for the discussion of miscellaneous matters.

The first speaker on the program is a young man who is comparatively new in safety work. He has only been associated with it, as I understand, the last 12 or 18 months—Mr. R. H. Farrell, now safety director of the Marketing Division of the Buffalo District of the Standard Oil Company, and he is working directly under the supervision of Mr. Burt at headquarters.

I take pleasure in presenting to you Mr. R. H. Farrell.

**LOWERING THE ACCIDENT CURVE AND MAINTAINING
INTEREST IN SAFETY WORK**

**R. H. Farrell, Safety Director, Marketing Division, Buffalo District,
Standard Oil Company of New York, Buffalo, N. Y.**

The widely extended scope of the petroleum marketer's business activities and the demands for service made upon him today cause him to take a special interest in lowering the accident curve and maintaining interest in safety. A marketer's safety problem is not solely one of operating motor equipment on traffic congested highways. It includes literally dozens of unrelated problems, among which the hazards connected with gauging tanks, slippery ladders and loading platforms, handling underground tanks and curb pumps, loading and placing of heavy barrels and drums of oil and the numerous details connected with tank and pump installation and repair work, the digging of holes, chipping concrete, and the supervision of men at many different stations stand out prominently.

Years ago before the advent of the motor tank wagon and motor truck, deliveries were made by horse-drawn equipment, which was a slow way of delivering. Almost our greatest hazard was the runaway horse or runaway team but today an entirely different traffic situation confronts the marketer and he has to solve it as best he may.

Horse-drawn equipment has been replaced with up-to-date, fast-moving equipment fully two to five times larger than the old equipment. With this change we had the problem of converting the old tank wagon driver into a chauffeur for motor equipment. This man was one who had been used to a team controlled by the whip and reins. He was a man who, when placed on this new equipment, jumped from a walk to a run and was placed on the streets and highways with fast passenger cars and trucks. Of course, accidents began to happen and with these accidents the thought of preventing them came to mind.

Our company always endeavored to procure careful drivers and to train them to exercise the highest degree of care in operating, with a fair degree of success.

However, early in 1925, we decided to institute an intensive campaign for the better education of drivers and helpers in safety work, and to see what results, if any, would be shown in cutting down the number of accidents and what reaction would come from the men. In one department a plan of holding meetings was started. At the first meeting the man in charge of handling the accident work gave a talk on courtesy on the highway, rules and regulations pertaining to motor vehicles and in general a talk on accident prevention. We continued these meetings, holding them once a month on the same day, if possible. At first there was little reaction. The explanation seemed to be that we had to contend with the type of man who felt that accidents were a part of the day's work. It was soon apparent that it would be necessary to go into the matter of education with hammer and tongs in order to prevent these accidents, so we kept pounding away with our educational activities. These meetings were continued and we arranged to have outside speakers talk to our men.

Getting the Active Help of Prominent Men

In the Buffalo district we invited the district deputy of the New York State Motor Vehicle Bureau to talk to our men. He gave a very good and profitable talk, explaining new laws and regulations, particularly explaining the ruling of New York state, wherein a driver could lose his license for careless driving and if the license were revoked, the driver would not be permitted to drive for a period of one year. This one point caused our men to pay strict attention, and we noticed that they took more interest after this meeting.

In our Rochester territory we secured the services of the city chief of traffic, who talked on violations.

In another we had the services of the director of safety from the Chamber of Commerce, etc.

The men began to take an interest in these special talks, for they soon realized that these meetings were going to be of assistance to them in the day's work and a benefit to the company. The feature which seemed to have most effect on them was the reading of the reports of accidents which had happened since the last meeting and the explaining of ways and means on how these accidents might possibly have been minimized.

We next started the plan of posting a chart in a conspicuous place to show the record of accidents happening on the road for a six-months' period. This chart carried the names of all drivers in the vertical col-

An intensive campaign lowered the accident curve.

umn. In the horizontal column after each driver's name, we blocked off each week with the date through a six-months' period. In the horizontal column after the driver's name, we entered a zero for a slight accident and an X for a serious accident. This aroused great interest and seemed

to have the effect of cutting down the number of accidents. Drivers, being human, did not care to see a mark after their names. Quite a bit of talk went on among the men who had no accidents and this talk had a good influence upon the man who was inclined to be careless.

During the latter part of the year 1925, we realized that in order to reduce accidents materially and to lower our curve, it was necessary to introduce the spirit of competition. Several plans were advanced, such as medals for drivers not having accidents, cash bonuses, etc. However, we finally adopted the plan of dividing our drivers and helpers into teams. We had 104 men at our largest delivery station and we divided them into two teams, going over the list of names carefully so as to balance up as nearly as possible the drivers who apparently seldom had accidents with those who were less fortunate. We then held a meeting and informed the men of our plan. After we had selected the teams, it was decided that a record should be kept of every accident and the team having an accident should be charged with one point.

The Men Were Kept Informed of the Contest Leaders

The contest extended over a period of eight months and at each monthly meeting we told the men which team was leading. We did not tell them the number of accidents which separated them. The contest included slippery winter driving and summer driving. Much enthusiasm was shown at these meetings, some men going so far as to call down a driver who had an accident and who caused a mark to go against their team. I recall one day overhearing a certain driver telling another that he was "tickled pink" because John Jones was not on his team. It seems that John Jones was unfortunate enough to have had two accidents in one month and he came in for a great deal of razzing.

During the contest a close check was kept with the warehouse superintendent so as to remove the names of men who had resigned and to add the names of new men employed. This kept our teams well balanced. At the end of eight months we held a meeting at which the men were told that the contest was over and that at the next regular meeting we would announce the winning team and that it was decided the winning team would receive as a reward an evening out to take in a show and a supper afterwards which would be held at the expense of the company. There was a great deal of speculation during the ninth month as to which team would be the winner.

Our announcement of the winning team was met with great applause. We found that team No. 2 had won the contest, with a record of 28 accidents charged against it for the eight-months' period. Team No. 1 had 40 accidents. The expense of this party was approximately two dollars per man and we feel that we have been repaid many times. The party was attended by the winning team, the superintendent of the warehouse, his assistant, the assistant manager of our company, the special agent of the division and the safety men. There was no business talk that evening except that the winning team was complimented on its achievement and urged to do even better in the months to come. Our record for the

period of this contest compared to the eight months for the same period of the year previous is as follows:

January 1, 1924, to September 1, 1924, out of our Buffalo district we had a total of 93 accidents. In the same period for 1925 during the contest we totaled 68 accidents. Incidentally, for the eight months of the year 1926 we have a total of 37 accidents. The interest aroused by this contest continued and we kept on holding our regular meetings.

Last spring we received an invitation from the Buffalo Chamber of Commerce for our drivers to attend a safety course for truck and taxicab drivers to be held once every week on Thursday evening at 8:00 p. m. The invitation was posted on our bulletin board and the response of our men was so great that approximately 70 per cent of the drivers at our Buffalo station signed up and attended these meetings. At one of these the speaker of the evening was Joseph Godfrey, Traffic Chief of the Buffalo Police Department. During his talk on the subject of cooperation with the police, Chief Godfrey made the statement: "In all my experience as a police officer, neither I nor any of my men has had to warn or stop a Socony driver for violating the traffic laws." He added that this statement was substantiated by his men.

Similar series of meetings were held under the auspices of the Rochester Chamber of Commerce, and while these meetings were being held a notice was run in the Rochester paper that the Standard Oil Company of New York had the honor of having the greatest number of men attending this lecture course.

Evidence that the Men Had the Safety Spirit

All this simply shows that our men must have caught the safety spirit and that every day in every way the men are doing their utmost to avoid accidents and thus lower our curve.

The latter part of 1925 we also started a bulletin system, as we felt that the general industrial literature on safety did not apply to our business. We decided to send a bulletin to each tank wagon station in our field once every week which was to carry a short paragraph pertaining to safety. Pointers given to our drivers were such as carefulness in driving, attention to driving, duty of the men to the company and obedience to traffic laws, etc. These bulletins are sent out every Saturday morning from our safety department so that they reach the stations on Monday morning. Each station posts the bulletin on the bulletin board where every man will see it. The system has reached a point now where the stations look forward to the bulletin coming in on Monday mornings, and we believe this little piece of work helps us considerable in keeping down the number of accidents. At some of our stations when these bulletins are received, the man in charge of the station gets his men together and they discuss the thought presented. A special bulletin was prepared and sent out to all stations calling attention to the particular hazards of winter driving and urging that winter accidents be minimized as far as possible. The reaction to this bulletin was

very far reaching, not only in our own organization, but even finding expression in the editorial column of the Olean Evening Times.

Our experience in safety work leads us to the firm conclusion that the secret of arousing and sustaining interest in safety work is to keep the safety idea everlastingly before the man in one form or another and often by combination methods to give the men a definite safety goal to shoot at. The particular brand of safety we endeavor to sell our men is the common sense variety and not the visionary.

The first of January, 1926, we called our men together to announce to the drivers, helpers, warehousemen and repairmen that the big idea for 1926 would be safety. We have been fortunate in selling this idea and our men are carrying it out in first-rate style. Consequently at the beginning of 1926 we adopted the slogan, "Let's Make Socony Spell Safety."

We have been greatly helped in our efforts to reduce accidents by the whole-hearted cooperation of our manager, special agents, superintendents and the educational literature and comparative statistics sent to us by our New York City executive safety department.

Wanted to Organize the Safety Work Completely

These are only a few illustrations of the methods we have been using and which we find have been helping us in keeping interest in safety.

All of the foregoing is one phase of safety work which confronts the marketer. Along with this the marketing department has the feature of the handling of the men in the warehouse, at the tank wagon filling station, on the trucks in the repair shop areas and at service stations.

We realized the importance of safety work and its extent and we wanted to organize it completely. Accordingly on April 1, 1925, we formed in our Buffalo territory what we term our "General Safety Committee" to handle matters pertaining to safety in our warehouse and repair shop. This committee was appointed by the management. The committee in turn selected a subcommittee to function with it. Immediately a meeting was held. The safety man, general committee and subcommittee attended. The duties and functions of the committee were explained by the safety man. It was decided then to hold another meeting after this one, one week forward, and to talk on the items picked up by the safety subcommittee and to hold an inspection of our general plant to get an idea of conditions throughout the entire plant. These meetings and visits were held once every two weeks after this.

Reported suggestions were promptly looked into by the general committee and if found to be as reported, the chairman of the general committee notified the management, who immediately made changes recommended. Several reported unsafe practices were investigated and when found unsatisfactory were immediately rectified, which action gave the men the satisfaction that cases brought to the general committee's attention were not forgotten, but were given consideration and rectified if warranted.

We held a general meeting with all our men and told them of our interest in their safety. We told them of the accidents which had hap-

pened and how they might have been prevented in many instances. First-aid kits were placed at many points throughout the shops and warehouses, and we generally kept the idea of safety before our men in all possible ways. We also procured first-aid booklets and distributed them throughout our territory. We held meetings with our foremen and put the responsibility clearly up to them. After a foreman was made to feel that we held him personally responsible for an accident, a noticeable decrease in lost time accidents was noted. Our safety department secured posters from the National Safety Council, which we are continually using. Two of the more recent ones which have caused considerable comment are "Sixty Years And Still Going Strong" and "A Good Safety Record Means Happiness For All."

These service posters were placed on large bulletin boards near the principal entrance to our station in clear view of employees. It is surprising to note the interest and the study the men make of these posters.

Men Wanted to Keep Their Banner Flying

About the time we adopted the 1926 slogan, "Let's Make Socony Spell Safety," a banner was placed in one repair shop with the words "Boosting Safety, 1926." This banner cost 38 cents and we used four because there are four floors at this repair shop. The idea we gave the men was that this banner was to hang suspended from the ceiling of their floor so long as there was no lost time accident, and that should an accident occur the banner would be taken down and kept down for 30 days. This banner was placed on each floor, not with the idea of having competition among the men, however, as this could not be done because the work on each floor is entirely different, but to keep the thought of safety ever before them. The men got the idea so well and became so enthused over keeping their banner flying that a competition soon arose anyway, as the men on one floor determined to keep the banner flying longer than the one on the next floor, etc. So, with no effort on our part, a keen rivalry was started, and we are proud to say that we had no lost time accidents up to September 1, 1926.

Proceeding from the warehouse and repair shop to the service stations, owned and operated by the marketer, let us consider for a brief moment the marketer's newest safety problem. We find that we have to contend with a comparatively younger group of employees who have not had the training of years in discipline, who generally come to us with the "take a chance" spirit. The danger of being burned or scalded when filling radiators of customers' cars, the inflation of old or worn tires and smoking around a station present the chief hazards. Horseplay in one form or another seems to be easy for the men to indulge in during moments while temporarily disengaged. When a new man is employed as a service station salesman he is told of these special hazards and cautioned to use the utmost care to avoid accidents. We also hold our man in charge personally responsible for the behavior of men at our stations. We make use of our bulletin system by sending special ones to service stations which are pertinent to some particular phase of service station safety.

Summing up, we feel that our efforts in educating our men in safety have been worth while and highly beneficial both in the results shown in lowering our accident curve and in inculcating the safety spirit in our employees. The outstanding accomplishments in our efforts to reduce compensation accidents have been that we have not had a single lost time accident in our Buffalo auto repair shop for nine months. Many potential lost time accidents have been averted by the desire of the men to avoid spoiling their particular department's record and also by the constant supervision of the superintendent and foreman.

Our compensation figures show that we have reduced our lost time hours fully 25 per cent in 1926 in our Buffalo field over 1925. The success of our efforts to reduce vehicle accidents is best portrayed by the accompanying graph. We are proud to point out that our frequency rate is consistently lower in 1926 and that we have both "literally" and figuratively made Socony spell safety.

Systematic Inspection of Physical Equipment

THE CHAIRMAN: We are indeed indebted to Mr. Farrell for his very comprehensive and very interesting paper. If there are any questions or any discussion you wish to have with reference to that paper, the floor is now open to you.

MR. SENNE (Vacuum Oil Co., New York): I would like to ask Mr. Farrell whether they have any systematic plan of inspection of the automobiles and how often that inspection of the physical equipment occurs?

MR. FARRELL: We have our motor vehicle inspector out of our Buffalo auto repair shop, and he has 328 vehicles under him. He is on the road continually and we follow up by keeping a record of our stations, our tank wagon stations, out of our Buffalo, Rochester, Jamestown and Olean stations. We keep our records so that he is continually making the rounds, and he checks the equipment for brakes, steering columns, and, of course, defects in operation.

At our Buffalo station we have our home repair shop. That is where all of our overhauling repair work and painting is done. In Rochester we have two men who inspect the equipment at that station. In Olean we have two men and in Jamestown we have two. Our territory takes in the western end of New York state; for example, from the Canadian border to the Pennsylvania line, and east about 50 miles east of Rochester, or coming up to the Syracuse boundary.

MR. SHAW (Hercules Powder Co., Wilmington, Del.): I would like to ask Mr. Farrell if between inspections the trucker has trouble, will he tie up the truck? Has he instructions to phone into the nearest station? That is, if his truck should go bad between inspections, will he tie up his truck?

MR. FARRELL: The driver knows that he is to get in touch with the man in charge of the station. He is to tie up until he can get a mechanic. Understand, we have four B. and M. groups, which, as I said, are Buffalo, Rochester, Jamestown and Olean, and at each of these we have a car connected with our repair shops. If a man is 20 miles out of Buffalo and

should have trouble and he thinks his steering column is wobbling or his brakes won't hold, he knows he is not allowed to run that truck. He calls that station, and our repairman goes out in his Ford jitney and he fixes the truck up or it is towed in.

MR. SHAW: In your contest, after the four months did you find any lagging of spirit, any reaction? What incentive did you give them after the contest was over?

MR. FARRELL: From September 1st to the first of the year, we had no contest of any sort. We took the month of September to keep them guessing as to which team was the winning team. In October we came along and had our party. The fellows who didn't attend the party figured they missed a good time, because everybody there did have a good time, and the talk around the plant was quite general on this party.

Then we came along with the chart, and that is arousing interest. We had it for the six months, and then we started in again the first of July for the second half and the men don't know. We have put the idea into them so well that they don't know when we are going to run another contest. We are leading them to believe now that we are going to run a contest without telling them. We can afford to give another party. We can take 50 men out at \$2 a man.

Physical Defects of Men Influence Accidents

MR. SCOFIELD (Associated Oil Co. of California): In our experience there must be a very close cooperation between the medical department and the driving department. Else we find a very serious source of accident. A very excellent driver may have an accident reported for which he may not be to blame, and on careful examination we find it is his eyesight and not his own carelessness. I am going to believe that we ought to have not only a beginning examination of eyes, but a periodic examination of eyesight of all drivers. I am sure that it is a problem we should give more attention to. Have you done that?

MR. FARRELL: We have not done that in so far as having any systematic check-up, but if an accident comes in and it looks as though the driver misjudged distance (we will say) we immediately talk to that driver and ask him what happened. "Well, it looked to me as though I could get through there," or "It looked to me as though I had time enough to stop." We immediately send that fellow over to our repair shop and a mechanic driver is put on to him and he is given another test similar to the one we give our new drivers. If that man thinks that fellow's vision is off a little bit, he tells the supervisor, and we then have that as a check-up.

MR. WALLACE: That recalls an article that I read in one of our Texas papers, making the statement that there was about an average of one man in seven that lacked the perspective in his vision that was necessary to judge the distance between two cars, one going his way ahead of him and one coming farther away towards him. And we all have that experience often in judging a car ahead of us. Another fellow will duck around and put us back on our own side of the road. The chances are

he is not a road hog, but simply one of those fellows that haven't that ability to judge perspective. I think that is one of the most vital things we can do with our truck drivers—to give them very clear perception, not only on their ability to judge distance, but their ability to have perspective.

RAY MILLER: There is one hazard around service stations that I don't think has been mentioned here, and that is open drain pits. I have run across quite a few accidents of that kind; kids running around the stations at night will fall into those places and are sometimes seriously hurt. I know of a few companies that have a practice of building a rail guard around them with a gate to allow access for a car, where others have a sliding door cover on little rollers or something of that kind, which they can slide on the way.

I wonder if that isn't something that ought to be taken care of?

THE CHAIRMAN: Can someone answer that question?

MEMBER: May I say that in New Jersey it is against the law to use a drain pit, on account of the danger from fumes and the fire danger from the pits, and we are using elevated ramps that they run up on and we now have a regular piston affair and shoot them up there on hydraulic machines. You will find no pits in Jersey.

I think it is better to get rid of the pits, not only from danger to the kids but other people.

MR. MILLER: I think most stations are equipping themselves with an elevated platform, but so many of the older stations do have lots of the old type underground drain pits.

THE CHAIRMAN: The next speaker I have known more or less intimately for approximately 40 years. There is a great deal that I could say about him, but very little that would show up well on paper. Mr. Wallace yesterday morning in his more or less rough and ready illustrations—so common to Texans—stated that he hoped to lay a safety egg during this convention that might incubate into a great many little safety chickens that would be of benefit to all of us. I trust that if any of you took his remarks to heart and since that time have been attempting to follow out his suggestion and have made failures of your attempt, that you will kindly lay the failures on the outside.

TRAINING THE FOREMAN IN SAFETY

V. R. Currie, Supervisor, Employment and Service, The Texas Company, Houston, Texas

Twenty or 30 years ago in industry, the best foremen were numbered among those who were able to chew huge quantities of tobacco, use profanity with emphatic intonation, and whip any man in their gang. Those were the days of brute strength and awkwardness—the foreman furnished the striking example of brute strength, and the workers admirably filled the bill of pure awkwardness. But, in looking back over the industrial road during that brief span of years, what a change has been

wrought; how differently we are obliged to attack the problems of production today which, in the final analysis and in spite of all our intricate mechanical devices, are more and more dependent upon the human factor?

We have come more and more to realize the acute economic value of the workman and to appreciate the fact that there is a vast difference between just a man on the job and a worker on the job. The former represents the class of some 30 years ago; rough, untrained, more or less willing perhaps, but possessing no definite objective, spurred on with no particular incentive; and only able to produce through the peculiar trend of the era rather than through any efficiency of individual effort. The latter are those we find today in the harness of production, in those concerns which keep growing and going in spite of the keenest possible competition; who are possessed with the objective of human happiness; who are carried forward through ambition aroused by the proportionate measure of wages and production; and who have been trained and taught in the most efficient manner of doing their tasks. There has truly been a tremendous change in the handling of our affairs and in the manner of producing those things upon which rests what we choose to call prosperity.

No Change in the Human Factor Since Ancient Times

But, in spite of all the changes which have taken place, there has been little or no change in the human factor. This today stands practically as it stood in the days when the pyramids were under construction; man still has two eyes, two arms, ten fingers, and ten toes; his fingers still create the desires of the mind; he is still susceptible to the same temptations and pitfalls, enthuses over the same factors, sulks over the same dislikes, and as a matter of fact, he is still evolving under the handful of universal laws which govern both his health and his happiness. It is quite likely, since we have come to appreciate the economic value of the worker, that we have overlooked the fact that he has changed but very little, if at all.

Conceding the fact that the good old Golden Rule has always been one of the universal laws of safety, and having recognized the economic value of the worker, we have found ourselves confronted with the tremendous problem as to how all this human wastage could be stopped. And, even then, it seems, we did not totally awake to the fact that there had been practically no change in the human factor. Under the same old universal laws, the worker found himself floundering about in the sea of changed conditions without having been taught practical and effective methods of adjusting himself to meet them.

I contend that the first few pages in the history of organized industrial safety are as plain as the nose on your face, that in almost every effort we have put the cart ahead of the horse. We started out by telling the worker he had to be safe. Then we asked him to be safe. Later, we told him what might happen to him if he wasn't safe; and just now we are beginning to get down to brass tacks and have begun to show him how and help him to be safe.

Now we are just beginning to get out of our swaddling clothes of accident prevention work and are getting up on our feet and taking a few forward steps. A few years hence, when the foggy industrial atmosphere of cripples and fatalities begins to clear, we are probably going to say that such is the harvest from the early seeding. Some of it may be, but then the biggest part of that improvement is going to be because we have at last gotten on the right track after planting the right seed.

For the last 15 years in industry, we have been doing a great deal of talking about safety; but the truth of the matter is, that's about all it has amounted to—just talking. If all the energy that has been expended in talking safety could be commercially harnessed, we could sell Niagara Falls to the Fiji Islands and still have a surplus of power after generating electricity for the United States during the next 100 years. Mind you, I'm not against talking. That's fine and necessary, but before we do very much of it we should have something definite to talk about and firmly and clearly fixed in the minds of those to whom we are talking. Glancing back over the last 10 years of industrial safety, I'm of the opinion that we might just as well have been talking to these millions of workers in the language of the Hottentots. True, we have drawn them a few pictures and posted 'em on the wall, we have made them some promises and a lot of threats about safety, but we've failed to cut the long hair and remove the false whiskers and really and truly introduce the rank and file of our industrial plants to genuine safety in a practical way.

Industrial Safety Effort Needs Continuous Enthusiasm

One big trouble with industrial safety, as a whole, is the fact that there is not sufficient consistent enthusiasm behind it. You start from Maine and go on through to California and you'll probably find the so-called safety program being carried on in every plant. But it's of a passive nature, it lacks the pep and ginger to really get it across and keep it across. Never in my life have I seen anything win out that didn't have enthusiasm behind it, and that holds good for everything from a football game to filling orders for locomotives on time. Maybe, in the matter of industrial safety we've been waiting and expecting that the lone worker would stand there on the job all by himself and all of a sudden get enthusiastic about safety, just as a holy roller might get the power, or a poet his inspiration. If we've been thinking that, then we've been kidding ourselves for a long time, and now the industry which fails to respond to the industrial gong of reason and begins to get its workers as enthusiastic over safety as they are over pay day is going to be permanently forced out of the race for better business.

I don't know who does get the workers enthusiastic over pay day. Maybe they do that all by themselves. But in plants where the production is reasonably high and the quality a bit higher, I know that trick is done by the foreman. And when it comes to the item of safety enthusiasm, he is the only one who can put it across to the boys in his gang.

For a number of years I have given the matter close and careful study and it is my honest opinion that in industrial America there is no better fitted and equipped organization to furnish the propelling power of enthusiasm, clear the underbrush of misunderstanding, and open up the field of intelligence and reason to our millions of workers than the foreman.

When all is said and done, isn't it his job to care for his men? Of course, if you began to analyze the job of any foreman you would run into any number of complexities, but inasmuch as the basis of every effort must begin with the individual, the fact is obvious that production results, or any other kind of results, are only gotten through proper and constantly improved guidance and supervision. And, don't lose sight of the fact that cripples are poor producers, or that results from any portion of the work force confined to the hospital have no commercial value.

Explaining the Plans to the Rank and File

We made a careful analysis of the matter and came to the conclusion that we had best explain thoroughly to the rank and file that about which we had been talking so loud for so many years, and we further came to the conclusion that if safety was to go over the top and stay over, it would have to be accelerated with a lot more enthusiasm than had been shown in the past. To the question as to how we could carry this out, there was but one answer—the Foreman.

And so, with the whole-hearted and enthusiastic endorsement of the management we launched at our Port Arthur Works in April of this year a safety training course for foremen which was absolutely fitted to our particular line of work and our particular type of workers. In this course we have not been under the delusion that it was a panacea for all of our accident evils, but we have rather regarded it from a practical angle and simply endeavored to transmit to the rank and file, through the foreman, an intelligent and enthusiastic picture of the thing that we had been talking about for so long a time.

a success. Of course, a great deal depends upon your interpretation of the word "success", but like any other course of educational training the answer lies in the future acts and attitudes of those affected. A child might be placed in school and continue there until it had attained a college degree. One might ask if its education turned out to be a success. And the answer would be in the future application to which the individual would put those things learned through an educational medium.

We know that we have aroused enthusiasm, at least on the part of the foremen, and my observations of life have taught me that enthusiasm is as contagious as the measles. Then, too, people who shy at it often contract it. The course was purely optional. At its inauguration, invitations were sent out to 150 foremen. On the same day they were sent out, 148 acceptances were received. If that's not enthusiasm, then I

have failed in my interpretation of the word. And it is borne out by the fact that at each meeting throughout the entire course, those 148 men were present, except in some few instances where it was almost a total impossibility for them to be there. On the original invitation each foreman invited to attend was asked to indicate his reason for acceptance. Almost without exception the reply was in order that they could learn more about safety to pass on to their men who really needed it. There certainly is no question about their needing it and we have every reason in the world to believe that it is being passed on, and that it will continue to be passed on.

Every foreman who attended the course has the proper entry made in his personal efficiency folder. We are going to follow the thing up so far as he is concerned, and we expect that he is going to keep hot on the trail of safety so far as his men are concerned. At future times when foremen may be proposed for promotion or increase in wages, we are going to check back on the accidents in their departments and find out whether or not there has been an improvement. If there has been, then there must be two factors which are right; the course must have been right and the foreman himself must be right. That combination applied to any job can do but one thing, and that is to build men who are right.

A Foreman's Course Contained in Lectures

On account of the brevity of time and the magnitude of the object, this foremen's course was put over by the lecture method rather than through any kind of open forum. The men who delivered the lectures were carefully selected and each one was not only vitally interested in the subject of safety but was specifically qualified to handle the particular subject to which he was assigned. The subjects covered in the course were:

The Foreman as a Safety Committeeman.

Accident Reports and the Value of Accuracy.

Compensation versus Carefulness.

Accident Causes and their Removal.

What is the Safety Program and Who is Responsible for it?

The Reflection of a Safe Plant.

These lectures were bound in book form and distributed to each foreman attending the course.

It can not be expected that the reaction to any particular subject will be felt the day following the lecture. But it can be expected that there will be a normal improvement in the accident situation through the fact that we have taken a long step forward in the matter of properly educating our workers through the logical channel, which is the foreman; that the foremen will intelligently understand the managerial point of view as regards the safety movement and the reasons therefor, both the human and the economic angles; and that we may find greater contentment in our forces through the fact that there will be more men

doing the right thing in the right way and doing it day after day without break.

In our industrial organizations, there are still a lot of important problems which confront us, and there are a number of these serious and complex problems which, in the final analysis, will have to be solved by the workers themselves. In the interest of healthy production, there is nothing finer than the friendly intermingling of capital and labor, but they can never mix well in an unsafe plant. I am firmly convinced that if every iota of trouble between capital and labor was settled satisfactorily right now that it would all go wrong and break out anew in the morning unless the issue of safety received the same careful consideration that might be given to production. I don't believe that the horrors of ignorant carelessness ever have been fully portrayed. I don't believe that there is a pencil black enough to draw a picture which will do it complete justice. I don't believe that there is a tongue eloquent enough to tell the sad details of its horrible story. Of all the ravages which we find in industry, the misery, the loss and failure which are brought about through careless practices are by far the widest and the deepest.

Our analysis of the situation pointed to the fact that this condition existed largely because the man on the job didn't exactly know what it was we had been talking about all these years, nor was he properly enthused in putting over what he did know. So we launched the foreman's safety training course in order to give him a fair chance as an individual, which in time will be bound to make the company just a bit better. Mighty oceans are made up from drops of water and great industrial organizations are made up of individual workers. There are none so humble that they do not merit careful consideration, and we believe that their appreciation of consideration through our foreman's safety training course will be reflected in a permanent lowering of our accident record and a better understanding from the general superintendent on down to the worker who watches an isolated gate.

If you should ask me if we feel that it paid, I should answer you by asking if you feel it has paid you to attend this Congress.

Lecturers Were Chosen From Outside Plants

THE CHAIRMAN: I might add to the paper that we have also had installed another regular foremanship course—that is, the training of foremen, which comprises 12 lectures, one of which deals with the subject of safety. So that both in the safety training course and in the regular foremanship course we are reaching the foremen on the subject.

If there are any questions that the members would like to ask, I will be glad to answer them.

MR. SHAW (Hercules Powder Co.): Do you buy a fixed and selected course, or do you go out and pick your speakers in your own neighborhood?

THE CHAIRMAN: We wrote the course and picked out our own speakers.

The speakers in the Safety Training Course were company men located at other plants, but men who knew the subject and knew what they were talking about. Those lectures in turn were typewritten and later delivered to the men.

T. N. SHAW (The Midwest Refining Co., Midwest, Del.): Mr. Currie, you say you picked men from other plants. Should we infer from that that you think it ill advised to have men located in plant A (we will say) talk to the men in plant A? Is it better for them to talk to men in plant B, and the official from plant B talk with men in plant A? Do you think the absentee representative can put something over better with the men than a local man? Is that the reason for it?

THE CHAIRMAN: Not altogether. At the same time, I think on a course dealing with the subject of safety, it gives the local plant a better opportunity of really advertising among their foremen the next speaker and the subject than it would if they announced that one of their own men was going to talk. That is just a little interest that is created there through that method.

I might say that in the regular foremanship course, however, the various lectures were delivered by the local men, the men at that very same plant, the first of which was delivered by the general superintendent himself and the next, the following lectures, by what we might call the experts in that plant dealing with subjects that they knew something about. A general storekeeper might come in and give the foremen something about storehouse records and the proper method of handling stocks, and the chief clerk might be brought in on the lecture pertaining to filling out of reports correctly, etc.

Details of the Two Safety Training Courses

MR. SENNE: About what is the average length of time that you allow for delivering a single lecture, and do you allow or do you have a discussion by the men on the floor regarding that lecture after it is given?

THE CHAIRMAN: I am going to speak of both of these courses, both the safety training course and the foremanship course, because I feel they dovetail into each other.

The Safety Training Course extended over a period of six months. In other words, one lecture was delivered on the last Thursday of each month. The time selected was shortly after the whistle blew in the afternoon, and the men assembled in the cafeteria; as a general rule the lecture lasted from 30 to 40 minutes and an opportunity was given for the discussion of the subject should any of the men wish to do so. Following the lecture and the discussion in the Safety Training Course we gave the foremen their evening meal. In other words, it was not a banquet but just cafeteria style, and they had their meal on those evenings out at the plant.

The Foremanship Course, however, was compulsory. That also was on the men's time held every Thursday evening for a period of 12 weeks. That has not been completed in its entirety as yet, and our present plan at the conclusion of that course is to give a banquet to all of the foremen

and at that time present to them certificates for those that passed the necessary grades.

On the Foremanship Course following each lecture, each foreman is handed a questionnaire pertaining to that lecture which he has two weeks in which to fill out, and return to the office. Those answers are graded and those passing the satisfactory grades are awarded certificates or diplomas, as we might call them, which will be presented at this banquet.

MEMBER: I have found the Foremanship lectures the best thing that has come to our aid in the last few years. But I discovered something that might be of interest. I was absent one time and I asked one of the foremen to conduct a meeting, get an outside speaker and get his men together, and it was wonderful the effect that had on the man. We had to start at the top and you got the thing down to the foreman, and it is up to the foremen to get it to the men. In the larger industries you can extend that to have different foremen have meetings at different times and they certainly are putting it over.

Various Foremen Are Selected to Deliver Talks

THE CHAIRMAN: We find that assigning to the foremen occasional tasks of that kind creates a great deal of interest. We do that to a large extent in connection with our safety rallies, which are held periodically over the year. During those rallies, which usually last a week, we select various foremen throughout the plant to deliver talks to groups every day, and the reaction from those talks has been very, very good.

I recall that one of our engineers during one of these safety campaigns was giving a talk on fire equipment. In other words, at the main gate at noontime, in talking to possibly 1,000 men, he had samples of the various pieces of our fire-fighting equipment, such as the 40 gallon foamite engines and the other extinguishers. He taught them through his talk how to use those extinguishers, if the opportunity should arise, and it was only a few weeks after that a fire broke out in our carpenter shop and one of the workers who had heard that lecture promptly looked for a fire extinguisher and knew how to use it, and put that fire out without it causing any damage. Later on he stated that had it not been for hearing the engineer talking upon the use of fire extinguishers he would not have known what to do, and the chances are that we might have lost the building.

MR. LAU (Standard Oil Co. of Indiana): At the conclusion of this six months' course, you start a new school each year, or does it end there; or do you wait until you get new foremen into it?

THE CHAIRMAN: It is hard to say. We have just completed the course and the chances are that in about six months we may do something of the same kind, but probably along different lines. We will keep after them. We may change our program somewhat, but we have started out to educate the foreman on safety and we are going to keep it up.

The next subject on the program is also from a member who needs no

introduction to you gentlemen. He comes from a rather long distance, and, has, I am quite sure, a great deal of information that we can carry back with us. I take pleasure in introducing Mr. George F. Prussing, secretary of the Safety Board of the Union Oil Company, of Los Angeles, California.

EXPERIENCE IN SOME RECENT OIL FIRES

George F. Prussing, Secretary, Safety Board, Union Oil Company of California, Los Angeles, Cal.

I brought with me from Los Angeles two reels of motion picture films that were taken last spring at the two great fires about which you all read in the daily press. Before showing those pictures, and those are really the meat of the argument as far as my part in the program is concerned—it might be well to give you a little narrative account of what took place at that time. Even though you read in the press of those fires last April, the peculiar coincidence of two tremendous fires 250 miles apart, almost at the same instant, needs some explanation, as do perhaps the reasons behind the fact that in two places there were stored such quantities of highly flammable oils.

The California fields have been notorious in the fact that their production has come in surges. Back in 1910 the Union Oil Company, for instance, took over a well that had been abandoned by a former drilling concern when they had a fishing job, and after sidetracking what was in the well, suddenly brought in the greatest well that California has ever known, the Lakeview gusher, which ran uncontrolled for months, forming tremendous lakes of oil as fast as it was humanly possible to dam up the reservoirs and little valleys around the well site.

That is in measure typical of what has happened ever since, except that not all of them have come in uncontrolled. But there have been in the past 10 or 15 years many fields brought in in which the production has far exceeded the capacity of the market to absorb it, and in some instances has taxed the facilities of the oil companies to produce and erect tankage in sufficient volume to take up the production in excess of consumption.

That was particularly true in 1921, 1922 and 1923, when Signal Hill, Santa Fe Springs and Huntington Beach were at the height of their production. It has been common in California, especially in those fields producing the lower grades of oil, to store that excess production in what we term ground storage, reservoirs, sometimes lined and sometimes unlined, but in almost every case great earthen saucers dug into the ground and covered with timber roofs, which in turn were made waterproof with ordinary composite roofing. I suppose in the last 25 years there have been 50 or 70 such reservoirs built, ranging in size from 100,000 barrels capacity to 4,000,000 barrels capacity, and in area up to six or seven acres.

It has been necessary to build those reservoirs because of the volume

and rate of production, and the greatest number of them were built about 1922 and 1923. The Union Oil Company had built a number of them, and at the San Luis Obispo reservoirs, just back of the Pacific Coast, there were in April of this year six such reservoirs. They ranged in size from 750,000 barrels capacity to 1,300,000 barrels, and in dimension from circular saucers 500 feet in diameter to reservoirs more or less race track in shape, 400 feet across and 1,000 feet long. At that time four of these six reservoirs still contained some of the highly volatile refining crudes produced during the flush production of 1923. About two of them contained asphaltic crudes of low gravity with very little gas.

Refining crude reservoirs had been made as entirely gas tight as wooden roof structure may be made, and these were connected with a gas absorption or gas recovery plant operated in connection with the tank farm machinery. In addition to the earthen or underground storage, there was located at this tank farm a group of nineteen, 55,000 barrel steel tanks of old construction, still equipped with their wooden roofs, not yet replaced with steel, but these roofs in turn had been made gas tight and were connected with the vapor recovering plant. The steel storage was also equipped with a modern foam-extinguishing system operated by gas engine drive. The entire facilities were located on a farm of some 400 or 500 acres several miles from the nearest town and situated on a fairly level valley floor, surrounded by low-lying hills. It was about seven or eight miles along the connecting water ports from the Pacific Ocean.

California Has a Relatively Low Lightning Rate

California has a relatively low lightning rate. I have looked up the Government records for the past 50 years and I notice that the southern part of California has a lightning frequency rate of approximately one and one-fourth lightning storms per year. The west coast of Florida at its southern extremity has a lightening frequency rate of about 300 lightning storms per year.

These reservoirs have been built, many of them, for 20 or 25 years, and the experience of the companies of California has been that they had been thus far immune to either direct hit or inductive ignition in lightning storms. That freedom from lightning hazard had become traditional. Nobody worried about lightning so far as underground storage went, until July, 1925, when a reservoir near Bakersfield, California, was struck by lightning and burned out.

Immediately the oil companies discovered that their supposedly safe reservoirs were not immune from lightning. They got into touch with those agencies that had done so much toward making transmission lines safe from lightning—the General Electric Company, and others of the large electrical laboratories—and began working out the technique of lightning protection. Dr. Peak, of the General Electric Company's plant at Pittsfield, Mass., is probably the leading exponent of lightning protection for large structures, and his services were immediately called

on; as were the services of Professor Schaffer, now with the Johns Manville Company.

A good deal of experimental work was done by these men. Dr. Peak recently had printed in the A. P. I. proceedings of the Los Angeles meeting last year an article which is perhaps the last word on lightning protection. And as early as the spring of 1926 one of the California companies had already contracted for that form of protection which Professor Schaffer and Dr. Peak had recommended.

Among the companies dealing with the electric companies for this form of protection was the Union Oil Company, and at the time that those fires occurred on the Pacific Coast, in April, Dr. Schaffer was already getting under way to visit the Pacific Coast and make specific recommendations covering our hazards. So that the companies weren't exactly asleep on the job, although they had not yet actually protected any of these structures.

The California storms are of peculiar form. They take shape way out on the Pacific Ocean in great cyclonic storms 500 or 600 miles across, which sweep in toward the Pacific Coast and south and southeastward. They start with a wind in one direction and then during the course of a day the wind almost boxes the compass and toward the end of the first day of wind, rain falls. That is almost typical of the California storms.

One of the Great Pacific Storms Swept In

✓ About April 5th ~~such~~ a storm began out on the Pacific Ocean and the weather reports show that it moved in its regular course toward the coast, and on the morning of April 7th the first rain squall hit the coast at the port of San Luis Obispo. About 7:30 that morning, the men working at the tank farm checked in at the time clock and stood there under the eaves of the building waiting for the downpour, which had just begun, to cease. It was in the nature of a small cloudburst, raining at the rate of about three inches per hour over a period of several minutes. With it there was some distant lightning, and as they stood there waiting for the rain to cease, there was suddenly a tremendous flash of lightning with a simultaneous clap of thunder, and followed immediately by a concussion and uproar that knocked the men almost from their feet. It was immediately apparent to these men who were looking out across the tank farm that three of the six large reservoirs had ignited and that the roofs had been blown completely off.

The concussion of that simultaneous explosion of those three reservoirs was so great that it knocked out the plate glass windows of the stores in San Luis Obispo, nearly four miles away. We have a very definite time record of its occurrence from the weather station at San Luis Obispo because the seismograph needle was knocked completely off the sheet and made a definite smear at about 7:35 in the morning. Just at that instant, also, a recording thermometer in the same town showed an immediate drop of 12 degrees, probably as the result of that rain squall.

Hell broke loose just about that time and the men, a dozen or so of them, each a member of the local tank farm fire department, immediately went to their station. Foam was put on to the 19 steel storage tanks as a matter of precaution against chance ignition should another lightning bolt strike the farm. The two families living in the tank farm, families of watchmen and foremen, respectively, were gotten out; notice was sent to the Los Angeles office and to the local railroad, the Southern Pacific; and a call was put in for men to build emergency fire walls where they would do the most good.

There had never been any thought in the layout of that plant that more than one reservoir might ever be on fire at the same time, and it was immediately apparent that if the boil-over from those three reservoirs was to be stopped from sweeping the entire area, an immediate emergency dike must be constructed.

Within a relatively few minutes there were several hundred men on the job working in a terrific downpour of rain and in a gale that increased from 20 miles an hour to 50 miles an hour during the succeeding 12 hours.

Graphic Description of the Firing of the Reservoirs

Less than 15 minutes after the first bolt of lightning struck and those three reservoirs went up, another tremendous flash occurred and a fourth reservoir ignited. There is no question in our minds from the evidence which we have obtained from many eye witnesses that not one of the four reservoirs was directly struck by lightning. It seems that lightning struck somewhere in the area of the reservoirs, perhaps very close to them, perhaps on some metal object. There were a great many pipe lines all over the ground, small boiler plants and electric pumping stations scattered throughout the area. But there is no evidence whatsoever to indicate that any one of the four reservoirs was directly struck. And that seems to be borne out by the fact of their simultaneous ignition, that the cause, whatever it was, release of an inductive charge on the roofs, was incurred at the time of this lightning flash but was not actually the flash itself.

The reservoirs burned relatively quiet for the succeeding several hours. About 14 hours after ignition the first slop-over occurred. It was noticed, however, during the later hours of the afternoon and evening that each heavy gust of rain caused an effect on the surface of the reservoirs. They frothed up, gas clouds appeared, the column of smoke which originated directly from the burning surface and extended perhaps a mile into the air, was suddenly turned into a torch and the oil level in the reservoirs seethed up toward their banks.

A little after 9:00 o'clock, however, the start of the typical boil-overs was noticed, and oil from one of the several reservoirs ran down its bank, crossed its fire wall and got into the creek below. These creeks are, of course, nothing but run-off ravines, dry most of the year, but at this particular moment because of the tremendous rate of rainfall, they

were full to their banks, and this burning oil was very quickly carried down through the canyon toward the Pacific Ocean.

The frequency and violence of these slop-overs increased during the succeeding three hours. Observers and workers were feverishly building dikes between the reservoir area and the pump house, at which site was located also the foam pump house and the tanks. But at 12:00 o'clock the violence of the gas clouds seemed to presage a boil-over of maximum intensity and every man was called out of the area. The last man had scarcely left the reservation when all four of those reservoirs seemed to boil over simultaneously and with tremendous violence.

It was estimated that the height of oil wave coming over the banks of the reservoir was at least seven feet, and that the velocity of that wave traveling across the flat ground was in the neighborhood of 40 miles per hour. Those waves spread in every direction and to a distance of close to a mile on the down-hill side. They swept over the permanent and temporary or emergency fire walls; they crossed the barriers of sheet steel that had been erected around the pump and boiler house, swept through the foam pumphouse and put it out of business; put all the facilities of the pumping plant out of business; burned the warehouses to the ground in almost an instant, and swept through the first row of steel tanks. Five of these ignited within a few minutes and with rather violent explosions.

The Outstanding Event of the Conflagration

At the same time, over toward the other side of the farm the oil swept into the fire wall around the nearest of the two reservoirs containing asphaltic crude, and within a moment the fifth reservoir was added to the fire.

And then occurred what is probably the outstanding event of that entire conflagration, for with the tremendous heat from the several hundred acres of burning ground now covered with this mass of oil, tornadoes, of such violence as to be directly comparable to the ordinary tornadoes of the middlewest, swept from the burning area and out toward the eastward or leeward side of the tank farm.

The first of these to be noticed swept across the roof of the sixth reservoir and tore tremendous patches of roofing material out of it and some of that roofing material was a week or so later brought in by ranchers 40 miles away and identified as part of that roof. Oil from the reservoirs, still burning, was picked up by these tornadoes and carried into the sixth reservoir, and that in turn was added to the fire. More tornadoes formed.

In all, the weather observer counted between 300 and 400 of them. Some of them picked up houses lying toward the east of the reservoir area, others took trees, fences, garages and other standing structures. One house was picked up just after a young woman and her sweetheart had left the door, picked up behind them, carried over their heads and dropped several hundred feet away, killing at the time two men—her father and grandfather, who had refused to leave the house.

Other homes were unroofed and in general the effect was typical of tornado conditions.

That continued for a period of three hours, during which the fire burned with such violence that the reverberation of it was felt miles away and caused plaster to be shaken from the roofs of dwellings, caused plate glass and other windows to be vibrated as far away as the port of San Luis, and in general made the night hideous for everybody within miles. Gas clouds coming from the fire burned to a height of nearly a mile and were visible for a distance of 100 miles around.

From that point on the fire died down slowly, added to only by the remainder of the steel tankage as boil-overs from one tank swept into the basins around its neighbors and set those tanks on fire. Finally, about five tanks remained, these being on a slightly higher elevation and isolated by emergency fire walls. These five tanks came through the disaster with some of the asphalt dripping from their roofs where they were exposed to the heat, but unburned and undamaged.

The Same Storm Swept Down the Coast to Another Farm

Such a fire would go down in history as probably the greatest tank farm fire ever known in the United States; but on the second morning, on the morning of April 8th, this same storm going in its leisurely course down the Pacific Coast, reached the district south and east of Los Angeles, Orange County, one of the large producing sections of California; and there in turn set fire in almost identical fashion to the Stewart Tank Farm of our company.

This tank farm, except as to size and amount of oil stored, was nearly identical with that at San Luis Obispo. The reservoirs were newer but in general the conditions were the same, except that there was a small more-or-less obsolete topping plant connected with the storage which had been used for topping the refining crudes carried in the earthen reservoirs, so that the lighter fractions might be put in the steel storage and the heavier residuum run back to underground storage.

There, too, two reservoirs were set on fire simultaneously, and in their initial boil-over engulfed a third reservoir. The other three at that point were at a considerable distance and were saved by the difference in topography or elevation, that really took them out of the exposure bank.

The steel tankage at the Stewart Tank Farm was exposed although not as seriously as was that at San Luis Obispo. In one instance oil from the boil-over came within 80 feet of one of the steel tanks and caused such gassing in the tank that the relief valves were unable to take care of it and the roof bulged slightly and the sides along the top angle were drawn in. But the tank did not flash. It had been covered with a heavy blanket of foam and that may or may not have been the reason for saving it.

However, the small refinery was completely destroyed except for the steel tankage which was modern, and these several tanks came through

the fire entirely divested of paint, blackened and bulged, but not ignited. They burned at their vents at various times as various waves of oil passed them, but these vent fires were extinguished after the ground fires had died down, by the usual stunt of throwing a wet blanket over them. A good example of what steel storage can be exposed to without failure.

Such, then, is the narrative account of the two fires in California. About 3,000,000 barrels of various grades of oil were consumed, with a total loss of perhaps \$15,000,000, part of which has been spread around the country through some 66 insurance companies that carried part of the risk. The structures themselves, of course, were uninsured, as was the damage to the surrounding country, which the Union Oil Company, though perhaps not legally liable, has assumed dollar for dollar.

California Oil Properties Now Have Modern Protection

The work of protecting underground storage and other wooden roof oil containers naturally received a tremendous impetus through these fires, and it is common now in going about California to see the reservoirs not only of the Union Oil Company, but of other concerns, completely shrouded with the Faraday cage, the net-work of telephone wires running back and forth over the surface and grounded to prevent the accumulation of static or induced charges on their wooden surfaces; and in between the reservoirs on the reservoir farms you will see the typical radio towers extending 100 to 200 feet into the air at such points as to completely cover by their blanket of protection the reservoirs in their neighborhood. Those towers, if you will read Professor Peak's paper, you will see are assumed to have a protective influence over a circle equivalent to four times their height, and they are so situated to overlap and cover the reservoir areas.

What their protection ratio is, no one knows. The laboratory experiments apparently indicate a usefulness of about 90 per cent. But that is so much in excess of what has been done before and the relative cost of that protection is so low that they are being utilized almost uniformly throughout the Pacific Coast.

By way of explanation of how our moving pictures were made—within 12 hours after the fires had started, the magnitude was so obvious that the news reel companies—Pathe and others—sent photographers to the two sites and took these pictures. I afterwards bought up for the company the negatives and had prints made which were titled for use in teaching our own men something of the magnitude of oil fires in an attempt to inculcate some ideas of carefulness on the part of the men working around the reservoir site.

THE CHAIRMAN: Yesterday morning a Resolutions Committee was appointed to draft some resolutions in connection with the attitude of Congress in so far as provisions for expenses for conventions are concerned in connection with the representatives of the Bureau of Mines.

I am going to ask Mr. Senne, who is the chairman of that committee, to give us a word as to what has been done.

MR. SENNE: The matter is really still quite uncertain as to the mode of approach, but it was the consensus of opinion of the committee that perhaps we had better draw up a form of resolution to be submitted first to the membership and then have the membership submit a copy of these resolutions to their Congressmen in the various districts. The idea is that it is apparent that sufficient funds are not available to the representatives of the Bureau of Mines to enable them to disseminate the information, the valuable information, that they have in hand; and the idea was for us to try and create some influence which would lead Congress perhaps to increase the appropriations to allow more funds to be available so that the Bureau of Mines at certain times would be able to send their representatives to the various congresses and conventions which appear during the year throughout the country.

The nature of the information that is sent out by the Bureau of Mines is of such great importance and has been considered of such great value that we feel that it isn't broadcast enough, and in order to obtain the greatest publicity, best results would be had by having representatives direct from the Bureau of Mines present the papers in question. That is the idea and purpose, and as our chairman has told you, the committee will endeavor to draw up satisfactory resolutions which will be sent to each member so that if they see fit they may pass it along to the proper Congressmen or Government officials within their territory. And you will receive a copy of those resolutions in due time.

Two Fatalities from the Great Conflagration

MR. WALLACE: Mr. Chairman, I move that the committee be given the unanimous consent of this Section to spread that resolution on the minutes of our Section as unanimously passed by this body.

The motion was seconded and carried unanimously.

THE CHAIRMAN: The Petroleum Section owes Mr. Prussing a vote of thanks for the splendid address and for the pictures which he has shown to us this morning, and on behalf of the members I want to express our sincere appreciation to Mr. Prussing for your address.

The matter is now open for discussion in case there are any questions which you want to ask Mr. Prussing.

MR. RUSH (Texas Company): As I recall the narrative Mr. Prussing gave us, he mentioned the loss of two lives. I would like to ask if there was any further loss of life?

MR. PRUSSING: Those two fatalities were the only fatalities which were chargeable to those two fires. There were no lost time accidents or serious injuries of any sort among our own men. These two men were the only ones who happened to be in any of the houses that were destroyed. We attempted to get them out, but they were on their own property and didn't want to leave. However, one of our men was laid up for a number of weeks afterward because of a stroke of apoplexy.

which he suffered while watching the fire. We charged that against the fire because we carried it as a compensable case.

So you can say the fire had practically no casualties so far as the oil workers were concerned.

THE CHAIRMAN: During the previous two days' sessions several questions have come up which the chairman advised the members they would be given an opportunity to discuss at a later time. I want to say just a word before that as to the appointment of committees.

It is the duty of the new chairman to appoint the various committees and that will be done as near in the future as possible. I am going to ask that the regional chairmen appoint their own committees as soon as possible and advise me the results. The same holds true of the Executive Committee, which will be appointed by the chairman as soon as possible.

Appointment of Section Secretary Is Made

The Nominating Committee in their wisdom left the selection of a secretary to the new chairman. That is a rather embarrassing proposition, but at the same time, it was felt that one should be selected that would work closely with the chairman and, if necessary, relieve him of some of the duties. It is more or less expected that a secretary would be appointed in the locality where the chairman is. However, I am going to change that a bit. I am going to appoint a secretary in the northeast, with whom I will have very close contact and contact by wire, who has a very keen interest in this Section, and who, I feel, will keep in close touch with the members in the northeast; and I will endeavor to do so in the southwest and on the Pacific Coast.

I am going to appoint A. A. Nickerson, Manager Employment and Service, New York, as your secretary for the next year. Mr. Nickerson is also with the Texas Company.

Mr. Senne mentioned the fact that the transactions of the Petroleum Section would be printed separately and as soon as possible from the transactions of the National Safety Council; of course, included later in the National Safety Council transactions. But in order that we may have copies as soon as possible and from which many of you will want to make your reports to the management, we have made arrangements for the printing of our transactions in a separate pamphlet. It will be necessary, however, for you to let us know if possible now just how many copies you will need. We have thought that, perhaps, it would be an excellent plan to get enough copies to distribute to foremen and others whom we might believe interested. So if possible I would be glad to have you notify me before leaving just how many copies you will need.

There is another matter. Following the close of the meeting this morning I should like to have you assemble on the Bagley Street side of the Tuller Hotel in order that I can get just a few feet of moving picture films of this Section. I have my camera with me and I believe that

would be of interest at some later time when some of you also may wish to exhibit such a reel.

Mr. Senne promised Mr. Shaw and others that a few moments would be given over to the discussion of prizes and bonuses for accident prevention work. I am going now to lay the subject open for discussion.

MR. WALLACE: I hope I am not out of order, but before Mr. Shaw takes up that discussion, the question I am quite sure to come up at this meeting was some form of affiliation or cooperation between our Section and the American Petroleum Institute, and the thought that I had in mind the other day was that the paper presented the first day of our meeting by Mr. Newcomb offered a really wonderful foundation for the start of that cooperation. Mr. Newcomb analyzed the various departments and suggested the hazards that might occur in each of those departments, the hazards, possibly, that might cause the real catastrophes that we all hope to avert. And I would like to make a motion at this time, Mr. Currie, that a committee consisting of our past chairman as chairman of the committee, continue to work for affiliation between this Section and the American Petroleum Institute, so that they can have something definite to present to the Institute at their meeting in Tulsa, Oklahoma, on the 8th of December.

(The motion was seconded and carried unanimously.)

Discussion of Suggested Changes in Congress Sessions

THE CHAIRMAN: Mr. Shaw wants to bring up his question now and we will be glad to hear from him.

If there are any suggestions which the members wish to present at this time in connection with the next Congress, that is, as to the program or method of holding the meetings, etc., we shall be very glad indeed to hear from them.

I think for the past two or three years we have divided our meetings into three morning sessions. If that is felt satisfactory, we will be glad to arrange for that next year.

MR. MURPHY: I would like to suggest in line with a subject that was brought up the other day in connection with the refinery process hazards that we might have more technical papers in the future on technical hazards. Our process men, of course, understand the dangers in connection with processing work and they look after those pretty well. I think a safety man, however, is not right on his job unless he understands all those thoroughly, and such papers presented here might be of benefit not only to the newer safety men in the industry, but to some of us who have been at several Congresses.

THE CHAIRMAN: Thank you very much, Mr. Murphy. That is a good suggestion and will be taken care of.

MR. CANDEE: It has been said that "fools rush in where angels fear to tread," and I am afraid I am in that boat now; I am in no position to make a suggestion. But I am in charge of the Personnel Relations of the Tidewater Oil Company, and safety will come under our department. That is why I am so interested in these meetings. It just struck

me during the sessions we have been attending, would it be possible to conduct our meetings in both morning and afternoon sessions? Have two days or three days. Many men come on for the whole week. If we had them straight sessions, a great many men that I have discussed it with are more interested in the Petroleum Section meetings than they would be in the general sessions.

Don't take that too seriously because this is my first year in attendance.

MR. SENNE: In answer to Mr. Candee, I would say that that matter has been considered for a number of years past, and it is the feeling among the men that if we brought them together and kept them in our meeting room for two sessions a day the thing would perhaps drag on too much. While we realize that we have sufficient problems to discuss, I don't think that we should give these problems to our men in overdoses. Furthermore, we belong to the National Safety Council and if you will glance through the general program you will find that at other sessions interesting programs are given, quite as important as our own. For instance, the program on medical matters.

Delegates Benefit by Attending Other Section Sessions

There are a good many of the plant physicians who attend here, while our sessions very seldom offer anything in regard to development of matters along that line. They can go to the other meetings and mingle with other plant doctors there, and there are innumerable chances for the men to broaden out by attending other meetings. Not alone that, but it would give them a chance to compare the enthusiasm and the nature of the work that other Sections are doing with their own. It has a broadening effect on the men to let them mingle with others outside of their own industry.

That was the thought. But if the idea prevails that we can further our own interests by keeping together, I have no objection; perhaps that can be very well regulated. But, personally, I believe that we should allow a certain time to visit other Sections and that would be my recommendation.

MR. SCHOFIELD: Mr. Chairman, I would like to get the group that I am interested in together and I wonder if the rest of them wouldn't feel the same. I see that some of us are from the refineries and some from the producing fields and some from the sales, while most of us are from the whole general field: and if you are going to get a technical paper, too technical for the entire group, it isn't going to fit the needs of all of us. If it is going to be a technical paper, I think it should be a round table for the refinery men or the sales group where they can get down to as many details as they want. I am not altogether in favor of too many technical papers at a general session.

THE CHAIRMAN: If there are no further matters, the Chair will recognize at this time Mr. D. J. Wallace, past chairman.

MR. WALLACE: I should like very much to give the floor to Dr. Anderson of the American Petroleum Institute.

R. P. ANDERSON (American Petroleum Institute, New York): Mr. Chairman, I am in the same situation as the man from New Jersey the other day who had sinus trouble. On the contrary, I can't make a speech the way he can; so, consequently, I feel I haven't much to say to this group session.

I wasn't able to get here on Tuesday. I was able to be here a short time on Wednesday and today. I have enjoyed the sessions very much. I don't know whether Mr. Wallace had in mind any particular topic to talk on. If he has, I should be only too glad to attempt to do it.

MR. WALLACE: Dr. Anderson, the thing that I am vitally interested in, and I am sure that we all are, is some contact that we can have with your organization that will be wonderfully helpful to both of us. I know there are none of the larger companies and very few of the smaller companies that are not vitally interested in safety. And it is so much easier to get the heads of our companies together at an A. P. I. meeting than it is at the Petroleum Section, or any of our local sections. So that if we could get some form of contact with them we could get ideas across to the presidents of the various companies that we can't get across at these Sections by personal contact. And my hope was that the American Petroleum Institute will lend us their facilities in developing food for safe practices for process work, standards for equipment—not too definite; neither should the process work be too definite. But general principles that might possibly sometime avert disasters. The thing is so intangible in my mind that it is very hard to express. But if you could draw on your imagination just enough to get my thought, then you could develop it so that it would be intelligible for all of us.

Hazards That the Safety Engineer May Not Perceive

But you know around the refineries and fields and around the pipe lines, also, there are hazards that no safety man has been able to find, hazards that the safety man hasn't the technical knowledge to recognize. Those are things that we would like to get into, and things that we have got to get into if we will make our work what our companies expect it to be. We would like to know the characteristics of the various oils and the stills at various stages of operation. We would like to know when the process men take down a still, take off a still, whether they are pumping it at a safe temperature or not; whether the conditions that govern the routine methods in refinery work are as safe as they could possibly be made. And that requires a technical knowledge which you people have that we don't have. So I don't see why that wouldn't be a very logical basis for some kind of an affiliation.

DR. ANDERSON: I can't speak officially for the American Petroleum Institute. So far as I know, the directors of the Institute have not yet considered the question of cooperation with the Petroleum Section of the National Safety Council.

Speaking for myself, personally, and for the staff in New York, I may say, however, that we feel that there should be close cooperation between

the Petroleum Section and the National Safety Council and the American Petroleum Institute. We realize that the safety work of the industry should largely be carried out through your organization and through your connection with the industry. If we can help in any way we ought to do it.

I presume most of you know that we are contemplating a group session on safety at the meeting at Tulsa in cooperation with the Petroleum Section of the National Safety Council, and we hope in that way to start this good work along.

I feel sure, too, that if Mr. Wallace would present the thing he has in mind through the directors of the Institute with regard to detailed cooperation that his suggestion will be given very thorough consideration.

THE CHAIRMAN: If there are no further questions to be drawn I will entertain a motion to adjourn.

MR. WALLACE: I would like to incorporate a vote of thanks to our past chairman and those who have so ably assisted him in the worthwhile work that has been carried on in the Sectional meetings, not only for the program we have been listening to for the last four days, but the real advancement that has been made in the work out in the fields where it counts. And there has been in the last three years a real advancement in safety work—in the production fields and in the pipe lines and in the refineries; and I think that our past officers should be very, very proud of the work that has been done under their jurisdiction. I would like to ask for a rising vote of thanks to our past chairman and his associates at this time.

(The convention rose and applauded in accordance with Mr. Wallace's suggestion.)

MR. WALLACE: We would like to hear Mr. Currie say something about the flowers.

MR. SENNE: Mr. Chairman, I am afraid that perhaps our worthy chairman is not aware of the purpose and intent of these flowers. I rise to the occasion.

At this time, Mr. Chairman, if you will permit, it gives me great pleasure on behalf of the boys of this Section, to present to you this very small gift and token of our esteem and evidence of our high regard, wishing you a very successful year. (*Applause.*)

THE CHAIRMAN: To tell the truth, I didn't know exactly what was intended, because the good looking young lady that brought the flowers in a while ago said they were for Mr. Senne. So I was just awaiting the opportunity of presenting them to Mr. Senne on this occasion.

ADJOURNMENT

Plant Publications Section

New Officers of the Section

CHAIRMAN: FORREST W. BOSWELL
Buick Motor Company, Flint, Mich.
VICE-CHAIRMAN, RAILROADS: CHARLES E. KANE
Illinois Central Magazine. Illinois Central Railroad Co., Chicago.
VICE-CHAIRMAN, GENERAL: SPENCER G. HORD
Eastman Kodak Co., Rochester, N. Y.
VICE-CHAIRMAN, PETROLEUM: C. A. WARD
Pure Oil Co., Columbus, Ohio
VICE-CHAIRMAN, CHEMICAL: BRONSON B. TUFTS
Hercules Powder Co., Wilmington, Del.
SECRETARY: N. L. DEVENDORF
Consumers Power Co., Jackson, Mich.

Committees

MEMBERSHIP: N. L. DEVENDORF, Chairman
Consumers Power Company, Jackson, Mich.
PROGRAM: G. A. DOELLER, Chairman
Dayton Power & Light Co., Dayton, Ohio.
PUBLICITY: E. T. WILKINS, Chairman
General Electric Company, Schenectady, N. Y.
SERVICE: ERNEST AUGUSTUS, Chairman
Mead Pulp & Paper Co., Chillicothe, Ohio.
JUDGES: S. W. ASHE, Chairman
General Electric Co., Pittsfield, Mass.
SPENCER G. HORD
Eastman Kodak Company, Rochester, N. Y.
RALPH H. WHEELLOCK
Narragansett Electric Lighting Co., Providence, R. I.

October 26, 1926

G. A. DOELLER, Chairman,
The Dayton Power and Light Company, Dayton, Ohio

THE opening session of the Plant Publications Section of the National Safety Council, held in the Ball Room of the Statler Hotel, Detroit, Mich., convened at 9:50 o'clock, Mr. G. A. Doeller of The Dayton Power & Light Company, Dayton, Ohio, presiding.

CHAIRMAN DOELLER: We are very pleased to see such a good turn out. I think this is the biggest group we have had at any of our meetings in the past five years. Perhaps the attendance has been stimulated by the contest.

Each representative here will be interested in knowing that we have 145 entrants in the contest. The judges have had some job, as they will tell you at the meeting tomorrow noon, and I am hoping that every one of you will be with us at the luncheon meeting. Mr. Ashe, the chairman of the judges committee, has a lot of interesting things to tell us about this contest.

This past year we had two very interesting regional meetings. The first was in April. At the invitation of Mr. Ashe of the General Electric Company, the Section met at Pittsfield, Mass. We had a very interesting program, a profitable meeting, and we were entertained by the General Electric Company with a demonstration of their man-made lightning.

Then in June, at the invitation of Mr. R. H. Ferguson of the Bureau of Safety, Chicago, we met for a one day session in Chicago. That was another very interesting meeting.

There is a little problem that confronts our Section, that is, tying it in with the other 20 sections of the Council, each of which has its own peculiar accident problems. Our Section doesn't have any particular hazards, but we, through our magazines, spread the gospel of safety, and the problem, then, is to tie in with other organizations in the Council.

We are planning this year to take that thing into consideration by electing four vice-chairmen instead of one, as we have in the past. These four vice-chairmen will represent some of the larger groups, such as, perhaps, the steam railroads, public utilities and some of the other groups in the Council. It is an experiment. We are going to try it out for a year.

Nominating Committee Is Appointed

At this time I will appoint the Nominating Committee and they will make their report at our meeting tomorrow afternoon. Miss M. T. Stevens of the Baltimore & Ohio Railway, chairman, Mr. N. L. Devendorf of the Consumers Power Company of Jackson, Mich., and Mr. H. F. Lovering of the New England Power Co., Worcester, Mass.

The program calls for reports of committees. Most of our activities have been taken care of by our regional meetings. Will Mr. Augustus report for the Service Committee?

ERNEST AUGUSTUS (Mead Pulp & Paper Co.): I have received communications from a number of editors and I have reported to them the activities of the Plant Publications Section and tried to help them out, giving them the information they wanted; and I think there have been several new members added to our Section as a result of that.

There is just one other thing I forgot about at Chicago and I have been requested to bring it up here; that is the idea of reviving or start-

ing up a new publication, along the line of the "Blue Pencil" by Bert Barnes.

I got in touch with several printers and I haven't gotten very much satisfaction. The thing they want to know before they will agree to go ahead and put out a publication of that kind is what circulation we can assure them. I have one man who is willing to put up the money. I told him the Section didn't have any money to finance the thing. He is willing to put up the money and start the publication provided we can guarantee a certain mailing list. That is something your Service Committee for next year might think over.

CHAIRMAN DOELLER: Mr. Price, chairman of the Membership Committee, have you anything to report?

Membership and Publicity Committees Report

W. D. PRICE (Warner Gear Co., Muncie, Ind.): The Membership Committee of this Section has had rather a difficult job. I believe it is more difficult to get attendance at these conventions and the regional meetings than to get membership in the industrial sections. There has been quite a good deal of effort put forth by the committee. I believe some of the results are evident here today by so many new editors coming into the sectional meeting.

There is a big job ahead. I think every one of us should consider himself a member of the Membership Committee to spread the gospel of how plant publications may promote safety work in our industries.

CHAIRMAN DOELLER: Miss M. T. Stevens, of the Publicity Committee, have you anything to report?

MISS MARGARET T. STEVENS (Baltimore & Ohio Railroad, Baltimore, Md.): We have had a page in each issue of the **NATIONAL SAFETY NEWS** since the last meeting, I believe; and Mr. Fish, the editor, has been kind enough to publish everything.

We receive in our own office a great many exchange magazines. Whenever a new magazine has come in, I have always taken the matter up with the editor of that magazine and invited him to the Plant Publications Section and told him something of the work of the Section. I also call his attention to the page in the **NATIONAL SAFETY NEWS**.

Just before this meeting, we collected a group of photographs of the different officers and individuals concerned in the Plant Publications Section and sent them, together with a description and history of the Plant Publications Section, to the Detroit papers. I haven't been able to check up on the papers to see whether they have used it.

CHAIRMAN DOELLER: The current issue of the **NATIONAL SAFETY NEWS** has a write-up by Miss Stevens telling somewhat in detail of the work of the judges.

We try to keep our membership list up to date. Of course, it is very difficult with a list of almost 900 names of editors of plant magazines, so if you will give us your name and address, we will be glad to put it on the list.

Just one other small matter and then we will hear the papers—that

is, cooperation with the other safety agencies. I don't mean by that the other sections, but other groups fostering safety. For instance, I have learned we have 65 local safety councils throughout the United States. Do you editors cooperate with the council in your own city? There is the Education Division of the Council. This is a wonderful source of material for your papers, particularly those that run a home section and a kid's page. They have all sorts of good material that you can adapt to your paper, particularly in the line of posters that the children prepare. Some of them are good enough for covers.

We would like for you folks to sponsor regional meetings. Let's have a half dozen this year. About the only way we can have them is for someone to invite the Section to come to his town. The officers of the Section will help in formulating your programs.

Our first paper is by Dr. W. A. Sawyer of the Eastman Kodak Company, Rochester, New York.

SELLING HEALTH TO EMPLOYEES THROUGH THE PLANT PUBLICATION

Dr. W. A. Sawyer, Eastman Kodak Company, Rochester, N. Y.

We believe that health for employees means a knowledge of how to live with the fewest days "laid up" for repairs, to work and play abundantly, and to attain a ripe and enjoyable old age. Our effort has been to sell such health.

Perhaps we have had a better insight into the existing state of health of our workers than many organizations, because of our intimate touch with them through the sick benefit plan. We feel that we can put our finger on the principal causes of sickness, and on that as a basis much of our propaganda for health is built.

We know that some employees are sick many days each year because a concept of health has never been presented in a way to arrest the attention or intrigue the desire. Daily personal routine and present and future health status seem to many quite irrelevant, giving a rather fatalistic idea of health as a thing one is born to possess or as a something bestowed upon one from some intangible source, and not at all a condition to achieve or to be maintained.

In an attempt to offset this so-called blessed state of ignorance, our magazine has carried a monthly message to the employees giving them information in as delectable a form as we could on subjects pertaining to health.

Rest, food, clothing, ventilation, elimination, recreation; the proper balance and relation of these, their quality and quantity, are entirely too often matters of chance and feeling, or circumstance and environment.

Health education with emphasis put on the positive side is stimulating and life-giving. Such knowledge encourages. Health education is not helpful which stresses aches and pains. This answers the criticism that too much knowledge of self leads to self-centeredness and imaginary ills.

We have been trying to put across a definite program since 1920, and we believe the corner-stone of the work is to gain and maintain confidence. This is accomplished in many ways, through sincerity, sympathy, and real "delivery of the goods," whether the contact be great or small.

The procedure, or how we do this, can best be discussed by going over the titles of the articles which have appeared in our *Kodak Magazine*. They may be grouped under following general heads:

Service given through the medical department

Physical examinations

Ventilation

Respiratory diseases and their prevention

Infectious diseases and their prevention

Teeth and tonsils

Eyes

First aid

Nutrition

Quacks and nostrums

Miscellaneous

In our procedure we have tried to keep in mind the importance of keeping all articles on health as short as possible, using simple language, avoiding technical or scientific words. Space does not permit of entering into a subject deeply, and furthermore most people do not have the foundation to understand a detailed discussion of such subjects. We have tried to present the subject in a human-interest way so as to make it readable. This is difficult.

We never believe in advising a thing without giving a reason. Just telling a person to do a certain thing without a reason, means nothing.

We keep in mind the family circle back of the man or woman, and often prepare material for the benefit of the family. This is perhaps one of the most valuable opportunities to exert real influence. The printed page carries great weight in the home.

We realize that we do not know the one best way to do it, but our experience as we go along guides us.

Now as to the titles of our articles. They perhaps indicate our way of approach, and comprise an outline as follows:

Health Articles in Kodak Magazine—1920 to 1926

Medical Department, Visiting Nurses, Health Classes

Our Medical Staff

Medical Department (three installments)

Visiting Nurse, Industry's Humanitarian

Friendly Visitors (Visiting Nurses)

Health Classes for Girls at Premo

Health in the Home (Health Lectures in Schools)

Physical Examinations

Value of Physical Examination

Taking a Health Inventory

Our Health Examinations—A Letter of Appreciation

Ventilation

Home Furnace
Hot Water Heat in the Home
House Air
Open Windows—Why?

Respiratory Diseases

Preventing Colds
Colds
It's Just a Cold
I never Have a Cold
Influenza
Keeping Fit in Cold Weather
Pneumonia—Will It Get You?
Pneumonia

Infectious Diseases

How to Avoid Diphtheria
Avoid Typhoid on Your Vacation
Tuberculosis (Taking a Health Inventory)

Teeth and Tonsils

Importance of Good Teeth
Your Children's Teeth
Dental Hygienists
"Save the Surface and You Save All"
Pyorrhea
Tonsil Operations at Dental Dispensary (two installments)

Eyes

Your Eyes (article and insert)

Accidents, First Aid, Resuscitation

In Case of Accident (telephone numbers of medical staff)
Accident Cases Treated by Medical Department
The Chance Taker (neglect of small injuries)
First Aid
Fresh Blood (folder)
Uses of Iodine
How to Revive a Suffocated Person
How to Revive a Drowned Person

Nutrition

Eat Right to Keep Right
Milk Habit Growing
Nutrition Adviser
"Munching Habit"
Daddy, Give Me a Penny
New Tonic Versus the Old (spring tonics)
Health Coupon
How to Win
Diary of a Flapper's Stomach

We expect such returns as any educational program through the printed page achieves:

- (1) Growing general interest and confidence in the subjects.
- (2) Individual instances of benefit.

- (3) A clearer knowledge on our part of method as a result of success and failure.
- (4) The realization of a fundamental advertising principle, that where emphasis is repeatedly placed, an impression will be made.

Such work as selling health to employees is a long-time campaign, and will only bear results in any large way after many years. Knowing that we have made an impression in a few cases gives us sufficient faith to go on hoping to reach the larger group eventually.

We have been so prone to measure things by figures and what we so often like to call "hard cold facts" that we forget the intangible and necessary element in such venture—faith—or a vision of the possibilities, which encourages us to push on for the good that is unquestionably done, though immeasurable.

All health truths must be iterated and reiterated until they become a part of the subconscious mechanism and to be practiced without effort. This can only be done when in some way the individual has been impressed with a health expectancy.

CHAIRMAN DOELLER: Dr. Sawyer, I wish to thank you in behalf of the Section. I now have pleasure in introducing Mr. D. C. Hunter of the National Cash Register Company, Dayton, Ohio, who will discuss Dr. Sawyer's paper.

DISCUSSION BY MR. D. C. HUNTER OF DR. SAWYER'S PAPER

I shall make a few remarks about selling health, not confining myself to selling health through the plant publication, but just selling health and safety in industry, because, after all, you men as editors and we who are here as safety men and health men are reaching for the same goal—we all want to make this business of selling health and safety a success, and whether you do it through the plant publication or the doctor's office or through posters, lectures or talks, whatever it may be, we all want to reach the same place.

Some weeks ago I was attending a meeting in Dayton and the speaker talked about the cumulative curve of knowledge, and that sounded pretty highbrow to me; but the longer I listened, the better it sounded, and I tried to apply it to selling health and safety to the folks in industry.

It started something like this. We all start out here at the same level. We take the new man who comes into our factory and he starts right here. His first contact is in the employment office, and there he gets a little knowledge. This curve of knowledge starts up. Then if you have physical examinations, he goes over to the doctor and is examined, and this curve goes up a little higher. Later he goes out in the department and his foreman talks to him. He tells him what you are trying to do along the lines of health and safety. He tells him about the guards on the machines and that sort of thing. Finally this curve comes up, way up here some place. Then the foreman forgets about the fellow and nobody else pays any attention to him and the curve starts

down. It gets way down here some place and the first thing you know that man is injured. We say it is his own fault; we told him all about that when he came in here. We blame him for it when, after all, I wonder if it isn't our own fault because we didn't carry our selling plan all the way through.

We are inclined to lose our enthusiasm. When we start out we are all worked up and raring to go, but we sort of quiet down after a little while and lose our enthusiasm.

I believe if you ask any sales manager: "What makes a good salesman?" he will say, "One of the first things is enthusiasm." A man has to be sold on the product he is going to sell and he has to have that unbounded enthusiasm to carry him all the way through. I believe that is one of the assets of a safety man or doctor in industry. He has to have that pep and enthusiasm to keep on going regardless of how black things may look at times, and he must be able to impart that enthusiasm to the man on the bench.

Safety Departments Are Selling Organizations

Speaking of selling health, do you know I like to think of our safety departments and medical departments as selling organizations and advertising departments, because, after all, they are very much the same. It is hard for us to see the results of what we do. It is hard for the advertising man to see the results of his advertising. I believe if you asked a merchant to tell you the direct results of his advertising, he would be unable to do it. If you asked him to cut it out, he would tell you to jump into the lake; he couldn't afford to quit advertising. It is the same way with the executives; if you asked them to eliminate the medical and safety departments, they would tell you they couldn't afford to do it.

I heard a story about a farmer who ran a general store. A newspaper man persuaded him to put an advertisement in a weekly paper. Six weeks passed and another newspaper man came along and again asked him to put an advertisement in his paper. He said, "Nothing doing. The last time I did it, I sold everything in the store. You will never get me to do it again." In our industries we keep selling and advertising but our results don't come quite so fast.

We will say that our medical department and safety department are sales organizations. The next thing we have to have is salesmen, and in industry I believe the foreman in the factory is the best salesman you can get. He is the key man, but you have got to sell him first before you will get results. How are you going to do that? There are many ways. You have got to get him to come to you with his problems. There is nothing that does me any more good in the office than to see our foreman come into the office and start an argument about some condition in his department. When he does that, he knows the medical department can aid him, or he wouldn't come. You have got to get him to consult with the medical department.

Our medical director said to me, "You have only two foremen in the

go a lot better than some gruesome story about a man who had his hand cut off. There are times when you want that sort of thing.

To go back to the start, don't lose your enthusiasm. Keep on trying. Don't become discouraged. It is hard to see results. But you must remember Rome wasn't built in a day.

CHAIRMAN DOELLE: Mr. Hunter, I wish to thank you in behalf of the Section for your discussion of this paper.

We will now take a few minutes for your questions and your part of the program.

JAMES E. WEBER (Swift & Co., Chicago): I am wondering if any of you run against the same problem that I do, whether it is purely local in my outfit or whether it is general, and that is getting the proper kind of cooperation from your medical department; I mean on preparation of written material?

The Doctor Thought the Material of Little Value

I had a rather unusual situation a while back. I picked up some material, I don't know where, that I felt was of value so far as plant health was concerned, health to the employees, and I sent it up to the medical department with a recommendation that the head of the medical department lend me his signature on the thing, or use it in the preparation of some article of his own. He sent it back with a refusal based on the fact that it wasn't sufficiently technical, it didn't have enough figures in it. That is a point of view that might possibly be rather general. I have been trying to get my medical men there to talk in the plant language when they use the plant publication. If there were any method by which we could put the screws on gentlemen of this same description, I think it would help a great deal.

I don't believe a great deal in the efficacy of outside health articles. I believe your greatest help comes when the articles are signed by someone whom the men in the plant know. You should have your local men do it. How to sell this cooperation to the men in my plant to a greater degree is my problem.

FRANK L. GREENYA (Fisk Rubber Co., Cudahy, Wis.): I think that there is a general tendency on the part of the medical profession to keep their knowledge pretty much to themselves. There may be isolated cases, but my experience is that they desire to lend a certain mystery to the medical profession, and in very few cases have we been able to get the proper kind of cooperation.

However, we are running a column on health in our paper, rather a short column covering various things that may be in season, such as rheumatism in the fall and artificial respiration in connection with swimming in the summer, and a few more things like that. Here is the thought that has occurred to us and we intend to carry it out and I think will connect up about as well as an article written by the local plant physician.

We have purchased for all of our employees for the last three years

the calendars issued by the National Safety Council. Every one of those calendars goes into the home. On the calendar for 1927 the back of each month covers a treatise on various diseases. We intend in our column to cover in brief just what is covered on the back of that particular calendar and then refer them to the calendar which is hung up somewhere in their homes, which is making a tie-up possible. We feel that would be as good as a personal message from our plant physician because this message from the physicians of the National Safety Council is of sufficient importance in the minds of these men to properly guide them. I offer that as a suggestion and possibly a solution of this gentleman's problem.

H. D. LIVERS (Southwestern Bell Telephone Co., St. Louis, Mo.): I am not inclined to accept any statement like that for this reason, as a rule I don't believe the doctors are writers. They don't know anything about writing and generally they are so busy that if they could write, they wouldn't have the time to do it. If they had lots of time to do it, I doubt whether we would want that kind of a physician to take care of our people. We like the fellow who is up and doing, has plenty to do in his own line of work, and let him forget about writing for us. We tried to get them to write for us and we found it was impossible. They just can't write. That is not the only thing that is true of a doctor generally; he can't even keep his own books. The fellow would starve to death if he didn't have a secretary.

Working in Cooperation With the Doctor

As far as our health articles are concerned in our magazines, not so especially in our plant paper for employees only (we also have a paper that is distributed to employees all over the Southwestern System), we are trying to present a concise treatise on health, prepared by a layman and approved by our physical director. We have selected a young lady who by research finds out for herself the things that our people ought to know, and she writes them in the language that they can understand, not the technical article that you would expect from a doctor.

I hope I have helped the doctor just a little bit. I don't believe in blaming it all on the doctor. We really believe it is up to the people in charge to get it over the best way possible.

W. A. TIRUS (Western Electric Company, Chicago, Ill.): We have a rather large staff of doctors, about 15 of them, and we have, of course, a variety of points of view from which to draw.

In an effort to give our doctors the supervisor's point of view in connection with accident and sickness problems, we have made use of the entire staff to teach our lay instructors in first aid courses; selecting these instructors entirely from the supervisory group. Those doctors have carried their classes through a full series of instructions, under Red Cross supervision and they have had a chance to meet the men at close range, find out wherein they failed to get the hospital or the doctor's angle of the problem, learned what it was the doctor must

say to the laymen in order to carry the story to them and how it must be said.

We also have a system of supervisory staff meetings which we carry on through the winter season each year. We propose this winter to have doctors address those staff meetings on the particular winter hazards of respiratory diseases.

With respect to the plant publication angle, we select the doctor, send one of our staff publication men to see him and interview him. He comes back and writes the story in lay language, submits it to the doctor for his approval to print it over his name. That method has proved effective in our experience. In fact, a series of articles have been printed in both our general company organ and in our local plant organ, and it has proven to be of sufficient interest so we are preparing to reprint them in booklet form.

CHAIRMAN DOELLER: I would like to have some of the editors of the smaller companies give us their experiences. We have heard the experiences of the larger groups that have staff physicians. The problem then is, what are you going to do in the case of the small company which does not have a full time doctor?

The Average Material From a Doctor High Class

S. W. ASHE (General Electric Co., Pittsfield, Mass.): I have been interested in the judging to see the way the health material has been handled in the different magazines, and I don't know that I am in entire sympathy with the suggestions that the doctor can't write, because, as you know, Dr. Oliver Wendell Holmes was one of our greatest physicians. You take Dr. Sawyer's material in the *Kodak Magazine*; it is the finest material you can get hold of, and if you listened to Dr. Sawyer's paper, you know it is not a hit and miss proposition; he has been studying. I would say that the average material that came from a doctor is better material than came from the average editor. I think it depends entirely on the personality and the training of the individual himself, and if a doctor has a certain amount of creative ability, and they are usually pretty deep students of human nature, the editor can perhaps help him a little bit. I think he gets an insight of human nature that probably the editor doesn't get.

Regarding the small plant, we are doing a little thing that might help the small plant. Last fall I was put on the committee to investigate tuberculosis in Massachusetts and we are getting up a special inserted page of material on how to drive tuberculosis out of industry. It also discusses general health material. If any of you want material of that sort (it is very carefully edited), we would be very glad to send you a copy of that page. It doesn't necessarily confine itself to tuberculosis. It takes in different things. We are distributing the page throughout New England as a way of getting the editors back of it.

MISS RUTH CADE: We have about 1,500 employees with just one physician. Our physician writes an article for us every month. It is hard work. I work harder with the doctor in getting the article from him than I do getting out the whole magazine.

The doctor writes in an interesting manner. He uses common English that everyone understands. He gets his message across. He writes on general health problems, not confining the articles to the men in the plant. He generally consults me early in the month to see what I am featuring during that month and then he tries to tie his article up with the rest of the magazine. Many people tell me that even though they don't read the whole magazine, they tear out the doctor's article and keep it.

HERBERT W. ALLEN (M. Wile & Co., Inc., Buffalo, N. Y.): Mr. Ashe stole all my thunder. Of all the magazines that come to my desk, I admire the *Kodak Magazine* most, particularly the articles that Dr. Sawyer has written. They have a lot of punch and they get right under the skin of the employees in the plant.

In Buffalo we have a hard time getting doctors who will write things of that sort. I always thought it was a very healthy city and the doctors hadn't much to do.

I would like to know if Dr. Sawyer would consent to letting others have his articles to publish in their magazines under his signature. I don't believe it makes a lot of difference what the signature is, so long as the article hits home.

Experience in Cooperating With a City

MR. LIVERS: When I made the remark that doctors were not writers, I wasn't picking on Dr. Sawyer because we get his paper every month and we like it very much. I was talking generally of doctors as writers, and I still maintain that doctors are not writers.

EUGENE T. WILKINS (General Electric Co., Schenectady, N. Y.) Through our magazine, *The Schenectady Works News*, we have been cooperating with the city in trying to eradicate diphtheria, and I think that is a big proposition for all plant publications—to help in civic work, because if the city doctors are trying to put over something in your city or town, the plant publication is undoubtedly of assistance in that work. The medical profession in Schenectady is highly pleased with the work that is being done through our paper in helping them to promote this propaganda.

I must say that sometimes I have a little difficulty in cooperating with my doctor in the plant because he is such a busy man. He has 20,000 people to look after, and naturally he can't write very readily; he hasn't the time for it. So usually when an article is to be prepared, I write it myself through his suggestions and then submit it to him for approval, and in this way I think it works out all right. It is best for plant publication editors to do that kind of work. Don't depend on your doctor. Interview him first, write the article, take it back to him for correction and I think in nine cases out of 10, he will approve it.

I want to ask Dr. Sawyer about enclosures. Usually when enclosures are put in the plant publication and are delivered in the plant, we

find that sometimes they are strewn on the avenue and through the street because it is an unexpected thing that falls out of the paper when they receive it and oftentimes it is not picked up. Therefore I have done away with enclosures because I feel they are sometimes overlooked.

I don't know what the experience has been in other plants. In our plant the publication is delivered at the pay window and they are in a hurry to get out. They pick up the magazine, or it is handed to them. The enclosure drops out and they haven't the time to pick it up. I don't think you get the same results as when it is bound in and taken home.

MR. AUGUSTUS: It seems to me the editor himself has to sell safety. The editor can do a whole lot to sell safety. Of course, it depends to a large extent upon whether you have a full time doctor or whether you have a periodic medical examination, but you can link up the experience in your own plant with health, if you have a medical department.

Articles for the Magazine Written by Many Doctors

We have tried out the idea of taking the records of the medical department of the time lost for various causes. All of us are intelligent enough to know what the fundamental principles of good health are. We don't need to go to a doctor and have him tell us to drink six glasses of water a day and get enough rest. The only thing is to call it to the attention of the men in the plant.

We also try to get the local doctors, not only our company doctors but various reliable physicians around town, to write articles for us or else give us an interview and in that way we are not trying to put over a company proposition in the man's opinion. If you have a company doctor who writes articles on health month after month, the employee believes the doctor is paid to do that and consequently doesn't pay much attention to it. Then there are men who have family physicians and they believe what they say. If you have an article by his physician one month and the next month there is an article by another physician, he has confidence in those physicians while he may not have confidence in your company physician. I believe these articles written by outside physicians are read much more than the articles written by our own physicians or someone on the staff.

I want to ask Dr. Sawyer one question. In cases of smaller plants where they do not have full time physicians or possibly no physician at all, what is your opinion of the service put out by the Life Extension Institute and also by the American Medical Association? They put out health articles free of charge to the medical profession.

DR. SAWYER: Somebody said the articles should be signed, or at least they should be known as some one individual's articles; in other words, there should be a personality back of it. I think that is an excellent idea. Take the articles appearing in the daily press. They largely get across because of the men who write them, their personality and style of presenting the subject.

Someone said they used material that came to them from other sources because their doctor was too busy, didn't write or couldn't. That is a good idea. I would suggest that you use your ideas. If the doctor doesn't like them, maybe he will get busy and write some. There are many sources from which to secure health articles. The American Medical Association is publishing a health magazine. If you haven't read it, get acquainted with it. They are sending them out to anybody who wishes shortened summaries or summaries of articles that appear in the magazine and it is very good material, written by the best men in the country, and you can't go wrong.

Our own New York State Department of Health sends out material that has been broadcast through the Schenectady station. The insurance companies also have good material. The Life Extension Institute material is very good and it is presented very well for popular consumption.

You said doctors are not writers; that is probably true, by and large, and yet it is surprising what good articles you can get from doctors if you can get them interested in this phase of medicine. The average doctor is patching up health. We were taught in medical school to heal the sick; we weren't instructed to teach prevention—that is something new. Those in industries have gotten that slant; perhaps the safety people have given it to us, trying to prevent the thing from happening. Doctors who once get it are tremendously enthusiastic about it, and perhaps if you keep at it, you can get your doctor to go after it. If he can't write, you can do it for him.

The Problem of Enclosures with the Magazine

Spence Hord writes a good many of the articles in our publications. I wish I could, but it takes a lot of time if you want to do it well. We are having several people do it. Our articles on nutrition and diet are thrashed out with our nutrition adviser. She and I work it out ahead of time and she does the actual work. Sometimes Spence Hord does more work on it. Lots of times I give him some few facts and he whips them into shape.

Concerning the enclosures, I don't know what to say. I will ask Spence Hord to answer that question. And the question of whether copies of our articles could be used I will refer to him also.

SPENCER HORD (Eastman Kodak Co., Rochester, N. Y.): Answering the question about the enclosures, when a man gets the magazine, the first thing he does is fold it and put it in his pocket. We have kept close track of every magazine thrown away and also these enclosures. It is seldom that we find a magazine thrown away or an enclosure lost out of the magazine. In fact, for six years I have had a standing offer of a dollar a copy for any magazine thrown away and I haven't spent a dollar yet.

MR. LIVERS: I would like to know whether there are statistics among the different industries represented here that prove that a healthy man has fewer accidents than an unhealthy one?

CHAIRMAN DOELLER: That is a good question. Dr. F. L. Rector, Editor, *The Nation's Health*, Chicago, Illinois, can answer that question. He will look into it and send you a report.

We now come to the fourth part of our program, "The Value of Pictures and Cartoons in Safety Work." We shall have the pleasure of hearing from Mr. A. D. Gans of the Safety Department of the Baltimore & Ohio Railroad Company, Baltimore, Maryland.

THE VALUE OF PICTURES AND CARTOONS IN SAFETY WORK

Arthur D. Gans, Safety Agent, Baltimore and Ohio Railroad Company, Baltimore, Md.

Safety is my job. I am sold on it, both as a job and as an element necessary to national and civic life. I consider that the safety man, who endeavors to save life and limb, holds a job second only to him whose duty it is to save souls—your minister or your priest. For this reason I feel it to be an honor to address a gathering of men and women such as are represented here, for I know of no class of people who have the power to do more in the cause of saving life and limb than you editors of plant publications.

Think of it! The power of the press is recognized; "the pen, truly, is mightier than the sword"—but all the newspapers in the world, all of the books in the great libraries of this country are no more widely read among your own group of employees than is your plant publication. Even the men who are foreigners will take home the plant paper for their children, now in our free schools, to read. And how simple a way is this for you to spread safety education!

The only question that arises then, is: how can we best present this information? The answer is simple—by pictorial illustrations. The old saying, "what your eyes see your heart believes" is a true one. I tell you of something unusual that I have seen; perhaps you will believe me; maybe you won't. But if I happen to have taken my camera along and snapped a picture at the time of the happening, then you open your eyes in wonder and say, "Well, I'll be darned!"

The same holds good with the printed word; the picture clinches the story and makes it the more conceivable, the more believable, and therefore, the reader remembers it long, long afterward. No matter how well written a story may be, or how well the details may be brought out, it will be made more interesting by the addition of a picture or a cartoon.

Thousands of years ago, it is said, human beings first communicated with each other by means of signs and gestures; then came the drawings—the hieroglyphics. About 3,000 years ago several nations conceived and used, in part, the alphabet; by mixing "ear pictures" with "eye pictures." There is a certain analogy between speech and writing, and it is easy to believe that the first written imitations of sound were associated with objects.

From the letters of the alphabet, words, phrases, sentences were formed. With growth of consciousness and intelligence, primitive man found a need for a better way to converse and transmit thought. During all these thousands of years, signs and gestures were a part of the communication of thought. As man became more experienced in speaking, he, to an extent, gave up the use of gestures. Only when in a hurry, or excited, would he use his hands in motion. Pictures in action were printed with written words and descriptions. Even today many people depend a great deal on their hands to express their thoughts. There is an old saying that if you tied some people's hands, they couldn't talk.

In the case of a child we can assume that gestures at first accompany all vocal utterances, and that they convey more definite information as to the child's wants and feelings than his half-murmured, unintelligible words.

It seems to be an innate necessity, not only among primitive people, but among our groups today, gathered for a common activity, with hands or feet, that the vocal chords be used. Sailors rowing, laborers pulling on a rope, track men moving ties sing or chant. The college yell accompanies a football game and spurs the players to renewed activity.

Action Puts Pep Into the Illustration

Action, gestures, were at first undoubtedly an aid in spoken language. And in transcribing our thoughts to writing, if we leave out pictures or cartoons and depend entirely on written and printed words, I feel that we are making a mistake and not taking advantage of the teachings of 3,000 years.

Action is eloquence, and the eyes of the untrained more learned than their ears.

An untrained man will remember what he sees longer than what he hears or reads.

As an example to prove this, let your imagination work a bit and pretend that you are factory workers or railroad shopmen attending a safety meeting. I am telling you about four men, one of whom lost an arm, another a leg, the third his head and so on. What I tell you, perhaps, goes in one ear and out of the other. But watch me illustrate it like this:

Now, my friends, we will imagine that this sheet of paper represents a man, or a number of men, all of whom are healthy, vigorous, strong and in full possession of their mental faculties—clean-cut railroad men.

The tears I make in the paper will represent the years of work and experience these men pass through in pursuit of their daily duties.

I believe that we all realize that railroad work is no more dangerous than other work. Careful railroad men are in less danger than men working at many other trades.

The slogan, **SAFETY FIRST**, is not a selfish one. It does not mean, "Look out for your own safety first, and let others take chances;" it means, "First of all, think of safety, your safety and the safety of all those who are working around you, and those who are directly or indirectly affected by your work."

The average American seems to delight in taking chances—with his money in stocks and bonds, a quiet game of poker, or "galloping dominoes." And he takes chances daily, running in front of street cars, automobiles, jumping on and off moving cars and in hundreds of other ways. He gets used to taking these chances and coming out unscathed. But one day, something happens. He miscalculates the distance, or his foot slips and he is done taking chances.

Every Man Has One or More Dependents

Almost every man has someone depending on him financially and for his love and affection. Every time he takes a chance he not only risks his own life and limb, but he jeopardizes the happiness of his family and friends, who will suffer by his death or by his partial or total disability.

Try always to remember the A, B, C's of Safety—**ALWAYS BE CAREFUL**. For the sake of your family and friends, for the company by whom you are employed, and for your own sake.

Then, when your day's work is done, your family and friends will have the pleasure of your love and company, and you will not be handicapped by the loss of an arm or a limb.

And when you are through your trials and tribulations in this old world, and pass to the great beyond, I am sure that you would prefer to go as these boys have gone.

Everyone of these men knew his A, B, C's thoroughly, lived to a ripe old age and made his last trip, carrying full equipment.

Now, if they had not practiced safety first, this man would have taken a chance, slipped under a car, and lost his legs. This man would have lost his right arm. This man would have lost his head. This man would have refused to wear goggles and lost his eyes.

(At the end I have four skeletons, hand in hand. Design torn from a sheet of plain white paper.)

Now, I'll warrant that even some of you "highbrows" will remember that. It's because your eyes saw it.

Pictures and cartoons are a quick way to drive home a message or thought. On Sunday morning the newspaper is delivered at my doorstep. Do I read the news section first, the sport section, or the advertising section? I do not. I pick out the eight pages of funny cartoons and they get first attention. Visiting friends early on Sunday, I have seen the children looking for the cartoon section, but father gets it first and the children have to wait.

I do not believe, of course, that we can do away with writing and use only pictures and cartoons and blue prints to convey thought.

On the other hand, I don't believe we do the proper thing when we turn out a finely written book, magazine, pamphlet, etc., without illustrations, particularly if it is meant for workers to read.

And we need to be careful in using pictures and cartoons to see that they convey the meaning we wish them to illustrate. This brings to my mind the story of an Englishman, in a Parisian restaurant, who had his mouth set for mushrooms. He could not read, write or speak French, so on the edge of his bill of fare he sketched, as best he could, a mushroom. And the waiter brought him an umbrella.

In safety work we have to appeal to the workers not to take chances, violate safety rules, or indulge in unsafe practices. We make our appeals by safety talks and by safety bulletins, through the pages of our company magazine, pamphlets, booklets, circular letters, etc. Over 90 per cent. of our appeal must be a printed one. The amount of personal contact with the worker that we would like to have is impossible. We must teach him safe methods, warn him of dangers, caution him against taking chances by the means of the printed word and descriptive pictures and cartoons. All during the year I come into close contact with men in all branches of the railroad world. I find that they will keep and read an illustrated article, but in most cases they hardly glance at a printed leaflet which is not illustrated.

The Picture or Cartoon Must Attract

In order to make the pictures or cartoons attract the man, they must be of something that he will recognize at a glance, of a man doing something that he does, or sees others do. They must be full of action—interesting. If the picture has an auto in it, make it a "flivver." The average worker won't appreciate the lines of a Rolls Royce.

The average worker likes a good laugh. Amusing things appeal to him more readily than those of a serious nature. He is interested in photographs. He will read and enjoy cartoons more quickly, possibly, than any other kind of a picture you can give him. He will take a clever cartoon around and show it to his friends, and comment on it.

It has been said by some safety men that human safety is a serious matter and should not be made light of. But the right kind of a cartoon does not make light of safety; it emphasizes the need of it. Sometimes it does make fun of the careless worker, but I believe there are some men who need to be shamed into working safely, all other known methods having been tried and failed. The right kind of cartoon simply translates the safety story into the language of the worker.

I have heard some safety men give safety talks, and I have read articles written by safety experts that I have found two serious faults with. First, the men talked too long, and the articles in question were too long. Secondly, the men used words in their talks and print that the man on the firing line did not understand. They have forced me to resort to the dictionary and I feel that in some cases the man who prepared the talk did the same thing. It is my humble opinion that

as long as we give this sort of talk and write this kind of article, just so long will we fail to realize our desire—to plant the safety message on fertile ground.

This reminds me of the story of the instructor who had charge of the final exercise where thirty young men were to be ordained and sent out as ministers. In his final talk he told them: "You are about to go out and take charge of a church. You will be at the head of that church and in many things you can do as you please. If you so choose on Sunday you can give a sermon that will last two or more hours. No one will be able to say you nay. However, I want to caution you from my own experience. After the first half hour's talk, you will not save any souls."

When we talk to little children we don't pick out the longest words in the dictionary to use in telling the story to them. Neither do we talk down to them with baby talk. But we tell the story in the simple language that they understand. Otherwise the message falls "flat," because it goes over their heads. And "Applesauce!" "Bunk!" you'll find them commenting to each other when the lecture is over.

Set before the average worker a page of generalities, such as

"Safety is the most important element in the life of a human being. In order to guard against the manifold dangers to mankind, if we would live to the allotted age of threescore and ten, etc.," and you'll find that the workman, like the children, will yell "Bunk."

Write About Safety in Human Interest Stories

The workman wants concrete examples. And if you want safety stories to "go over" you must hand them to him in a manner that is so attractive he'll reach out and get them. Educate him, YES. But don't depend on the process of education to avert all disasters today. Education takes time and results will show themselves tomorrow. But how about today? "Tonight's the night" as the boys in the army used to say.

My plea to you is to write safety stories, human interest stories. Lots of them, short and snappy, so that he who runs may read. And illustrate them, if you would insure their "soaking in."

After I had started to write this paper, Miss Margaret Talbott Stevens, associate editor of the Baltimore and Ohio Magazine, better known as "Aunt Mary," sent me samples of many of your plant publication magazines to read. On perusing their pages I was agreeably surprised and pleased to see that many of them had grasped the same idea; they had clever cuts and cartoons and short, snappy stories on safety that drove home the safety message. So, to an extent, I feel that you are already doing just what I am asking you to do, to run safety human interest stories, short and to the point, without a lot of generalities, illustrated, to drive them home. But there is room for more safety in 99 out of every 100 plant magazines.

From 1913 to 1924, 966,428 persons lost their lives in all kinds of accidents; the injured list runs into many millions. There is certainly no

greater work, no higher service, than in attempting to reduce this terrible toll of death and injury. The combined circulation of the magazines and papers represented here must amount to hundreds of thousands. You have in your hands the means of rendering a real human service. Regardless of what you have done in the past, I beg you to give more thought and space in your publications to safety—in the homes, on the streets, in our shops; on the railroads, public safety, industrial safety, every phase of the accident situation.

Teach safety to your men, your women and to your children. The children of today are the workers of tomorrow. Translate safety to them by pictures, cartoons and stories. And impress upon their minds this greatest of all human commands, "safety first."

CHAIRMAN DOELLER: I want to thank you, Mr. Gans, for the very interesting talk you have given us. The next speaker will be Mr. R. T. Solensten, formerly of the National Safety Council, now with the Elliott Service Company of New York City. He has two viewpoints.

DISCUSSION OF MR. GANS' PAPER

R. T. Solensten, Elliott Service Company, New York City

Being designated to open the discussion on this subject, it was my privilege to read an advance copy of Mr. Gans' very excellent paper, and as I was going through it this thought came to me: that possibly I could make better use of my time if I did not try to elaborate any of the points which he brought up in his paper, but rather try to offer a few suggestion to the safety man who is called upon to contribute a safety page or section to his plant magazine.

Undoubtedly if there are safety men in the audience who have heretofore been sold on the use of illustrations, they certainly must be now, after listening to Mr. Gans and witnessing his interesting, instructive and convincing demonstrations.

The most convenient and practical type of illustration which a safety man can use in connection with the plant publication work will be the photograph. Every safety man should have a camera or should have photographic facilities available to him. The best pictures which he will be able to obtain are those which can be taken in his own plant. Photographs are interesting because life is interesting. Photographs reflect life. We are most interested in those aspects of life with which we are most familiar and which are closest to us and which most directly affect our own personal welfare. Whether we realize it or not, it is probably true that every one of us is more interested in seeing his own picture in the paper than seeing the picture of the Queen of Roumania.

The photographs which the safety director will be able to obtain will fall into three general classes; first, the news pictures; second, the instructive or purely educational pictures; and third, the picture with an emotional appeal.

There are numerous possibilities in every industrial plant for interesting news pictures which can be given safety application. For instance, in connection with this present congress. Undoubtedly many plants are sending as delegates, foremen and employees who have made good records in accident prevention. The safety director should not miss the opportunity to take a picture of the delegates boarding their train or starting off in their fivers to attend the congress. This, of course, should be accompanied with a write-up telling workers why these men have been selected and written in such a way that it will stimulate interest so that other employees will strive for similar recognition.

Another possibility for news pictures is the installation of any new safety device. This is not only a matter of general news interest but it will also give the safety director an opportunity to help sell to employees the idea of using this new device. If a picture is taken showing the foreman or superintendent operating it, the picture will carry the suggestion that these men are thoroughly sold on its use and that the workmen should be likewise sold.

Another suggestion for news pictures is the portrayal of danger points in the shop which have been guarded at the suggestion of the safety committee. Such pictures will be most effective when shown with contrasting photographs showing the condition before and after the safety committee's inspection, and later improvement. It is suggested that when such pictures are taken, men be included in the composition of the picture so as to bring life into it. Inanimate objects are less interesting when shown alone, and for that reason it is always better to portray them in connection with something that has life.

Articles Written About the Long-Service Employee

Another possibility is to hunt up employees with long service records who have had no accidents. Some of you plant publication editors will recognize that I am not saying anything particular to you here because I know a great many of you have done this, but there are also many publications which are starting up from time to time and whose editors have not had the experience you have had, and new safety contributors are not as keenly alive to the problems as you are.

These articles on the long service employees should be illustrated with pictures of men at their jobs rather than simple photographs which may have been taken in a photograph gallery and borrowed for the purpose of making a cut. You don't want a photograph album; you want a publication of pictures which have life and action and impression in them, pictures that will be recognized as natural in the shop in which you are employed.

If you ever have such a wonderful piece of news as one workman saving the life of another, for instance by administering the prone pressure method of resuscitation at the crucial time, by all means play that up in a story and illustrate it with pictures not only of the victim but also the man who saved the life; and furthermore, if the man

who saved the workmen's life is given a medal for it, by all means arrange to have a little ceremony in presenting this medal and take a picture of the general manager or president of the company presenting this token of honor to the man who saved his fellow workmen's life.

Those pictures are not only interesting, but they also inspire others to make greater records and greater achievements in behalf of safety.

Another possibility is pictures of men who have been winning prizes in your scheme of getting suggestions from employees.

Another possibility is the more or less ordinary but effective picture of men who have saved their eyesight by wearing goggles in conformity with safety rules. The picture of a man's goggles with one or two lens broken, showing that his eyesight had been saved by the use of this safety device, is always effective and it is nearly always heeded. Similarly when a man has been operating a machine with gloves where he should not have been wearing gloves, if his glove is caught and torn, you can sometimes get a very effective safety lesson across by showing the picture of the torn glove and telling what might have happened to the hand if he had not been able to release it, or telling what happened to the hand that was not released.

Pictures in Connection With First Aid Work

Very often it may be effective to show the man who was injured, if the injury was not too severe, standing in front of the machine and holding the glove and thereby making it more emphatic and impressive.

Another possibility for a news item or a news picture is in connection with your first aid work. One of the most effective means of showing the value of first aid is to show that the doctor who administers first aid does actually use first aid himself, that he practices what he preaches. So if you hear of a medical director cutting his finger while changing the tire on his car, by all means go out and pose him in a picture getting first aid and then write your story showing that our doctor believes in practicing what he preaches. That is always effective in intensifying the idea of getting first aid for minor injuries.

Then again there are numerous possibilities of getting interesting news pictures of the results of accidents which occur from time to time in the plant. These, of course, should be used very judiciously, and always when using them, the article accompanying the picture should point out how the accident could have been prevented, and if possible, run pictures illustrating the method by which this accident might have been avoided.

Another possibility which I have not seen used very often is in connection with your bulletin board. Nearly every plant which has a shop magazine also has a bulletin board. Very often it is difficult to get men to take proper interest in the bulletin boards. Therefore, it might be interesting and helpful to show a photograph of the most interesting posting of your bulletin board during the month and have one or two men looking at this board, and write up a little article the purpose of which would be to arouse a little curiosity as to what

was being posted on these boards to stimulate interest and get the men to go and see what is on the boards. In such cases it is necessary to have material on the boards which when reduced in the size of your cut, will still be legible.

In the matter of instructive pictures, the most common and perhaps the most serviceable type of pictures are those which show the right and wrong way of doing things. I don't mean that the employee will first learn how to do things by reading your plant publication. I don't mean that at all, because in any well organized plant your foreman will show your men how to do their work, but by illustrating these things and running them in the publication, you back up the foreman's instructions and you not only have an interesting picture which will make your magazine more attractive and useful, but you also help the general plan of production by backing up the foreman's instructions.

Other possibilities for interesting pictures in the instructive line are pictures of workmen's feet, showing the kinds of shoes they wear and how good shoes will prevent accidents and how bad shoes will contribute towards causing accidents.

Along the general line of clothing, we might show a picture of a young housewife hanging out her husband's overalls after the washing and calling attention to that as a feature of safety because if a man continues to wear greasy overalls in the plant, he is making his garments a fire hazard.

Pictures May Suggest Lessons Indirectly

Then there are possibilities of both direct and indirect suggestions. Take such a common thing as the projecting nail in a board. There is a possibility of not only winning support for your safety work from unsuspected sources, but also developing an interesting picture by getting hold of some less well known employee in some humble capacity and pose him in the act of picking up a board with a nail in it and disposing of it so it will not be a hazard to anyone else.

These are little things, of course, but they are the things that count in preventing accidents. Then there is the possibility of combining also with that the thought of the accident avoider as against the accident preventer. The accident avoider will see that nail and he will step over it and won't get hurt, but the accident preventer will see it, pick it up and put it away so it can't harm anyone, and thereby prevents accidents to others.

Pictures of neat, orderly conditions in the shop are helpful in stimulating interest and suggesting that such conditions make not only for efficiency but also for safety. Pictures of labor safety devices can be played up showing that they not only save time and muscular effort, but that they also save men from possible injuries, and there are plenty of possibilities of showing contrasting pictures, the old method with the new method, and showing how much more efficient and safe the new method is.

I want to mention one or two examples of what I speak of as the picture with emotional appeal. Pictures of children are always interesting and always appreciated by the workmen and their families to whom the plant publication is brought. Many times interesting and appealing illustrations can be prepared from group pictures of employees' children, babies, and writing a sort of sentimental, emotional appeal with it, pointing out that the future of these children depends on the success attending our safety efforts in this plant.

Another possibility for pictures with an emotional appeal is something that may appeal to the pride of the workman, that will stimulate his taking pride in his plant. For instance, I can well imagine a series of pictures that a plant publication editor might run which would be entitled, "Things We Are Proud Of." Among the things that can be featured under such a general series would be the accident record which the plant is making, and many fine illustrations could be prepared by making graphic representations through charts or diagrams or specially prepared models or something of that kind for photographing, and then showing the president of the company or the general manager and some of the safety committee congratulating each other on this splendid record.

Things to Keep in Mind in Taking Photographs

In taking photographs there are just a few things to keep in mind. Pictures to be interesting and effective must have life in them or they must have action or they must have dramatic qualities and they should have the feature of novelty. Furthermore, they should be as far as possible, pleasing and should not be depressing. Pictures of men doing things should be taken in close-up views and an effort should be made to get clear pictures which are properly focused and properly exposed and have them printed on glossy paper so they can be reproduced to the best advantage in the magazine.

I have been talking most of the time on photographs, but I think you all realize how important it is always to encourage whatever local talent you have to submit drawings and photographs for reproduction in the magazines. These may be crude, but nevertheless they are effective because they are recognized by employees as being done by Tom or George; it is not professional, but it is our own.

I think that the safety man can very well afford to spend a very great deal of his time planning and taking pictures. If an analysis were made, I think it would be true that the safety movement, the wonderful success of the safety movement owes just as much to the illustration, the photograph, the drawing, the cartoon as it does to all the eloquence and oratory that has been given here at these congresses for the last 15 years; and therefore, my suggestion is that you get a camera, learn how to use it, spend time in planning pictures and taking pictures, keep your editors supplied with good, live, interesting photographs, with good well-written articles on safety, and I am sure that the plant publi-

cation, as is indicated on your blue print poster here, will help to reduce the accident rates.

CHAIRMAN DOELLER: Mr. Solensten, I wish to thank you for your paper. I will appoint the resolutions committee as follows: W. D. Price, Warner Gear Co., Muncie, Ind.; V. H. Kupferer, Studebaker Corporation, South Bend, Ind.; and A. A. Belmonte, Union Carbide Co., New York City.

MR. ASHE: Gentlemen, the editor who is the winner in the contest this year, Mr. Bergh, of the Northwestern Bell Telephone Company, has just had a very serious operation and is in the hospital, so he will not be in our sessions.

It has been suggested that it might be a nice thing to send him a little telegram of condolence and congratulation and some flowers, so if any of you want to give a little contribution to Mr. Price, he has agreed to take care of it, if that meets with your approval.

ADJOURNMENT

WEDNESDAY AFTERNOON SESSION

October 27, 1926

The meeting convened at 2:40 o'clock, Mr. G. A. Doeller, presiding.

CHAIRMAN DOELLER: It is very encouraging to see the growth of this Section.

Before calling for the report of the Nominating Committee, I might preface it briefly by saying (as I explained yesterday), that we are changing one of the sections of the By-Laws to provide for four vice-chairmen instead of one. The thought back of it is this: with the growth of the Section and the growth of the whole safety movement, it was thought wise to have a more intimate contact with the other sections of the Council. As an experiment, we are selecting candidates to represent some of the larger industrial groups. With that brief introduction I will ask Mr. Lovering to give the report of the Nominating Committee.

REPORT OF THE NOMINATING COMMITTEE

MR. LOVERING: Your committee submits the following candidates for officers for the ensuing year. For chairman, Forrest W. Boswell, editor *Buick News*, Buick Motor Car Company, Flint, Michigan.

Vice-chairman for Railroads: Charles E. Kane, Illinois Central Railroad, Chicago, Illinois.

Vice-chairman for General Industrial Group: Spencer Hord, Eastman Kodak Company, Rochester, New York.

Vice-chairman for Petroleum: C. A. Ward, Pure Oil Company, Columbus, Ohio.

Vice-chairman for Chemicals: Bronson Tufts, Hercules Powder Company, Wilmington, Delaware.

Secretary: N. L. Devendorf, Consumers Power Company, Jackson, Michigan.

With the chairman representing the Automotive Section, and the secretary representing the Public Utilities Group, there are six general classifications on the slate.

CHAIRMAN DOELLER: You have heard the report of the committee. What is your pleasure?

(Upon motion duly made and seconded, it was voted that the report of the committee be accepted.)

CHAIRMAN DOELLER: It is in order, if you see fit, to make nominations from the floor. I hear none, therefore a motion will be in order to instruct the secretary to cast the unanimous ballot for the officers as nominated.

(After motion duly carried the secretary cast the unanimous ballot for the officers as nominated.)

CHAIRMAN DOELLER: Mr. Secretary, can you tell us approximately what the registration is?

SECRETARY STRICKROTT: We have about 125, I would say.

CHAIRMAN DOELLER: Those who were in attendance yesterday heard the report of the Service Committee on the possibility of starting a magazine. There wasn't any reaction to that report, and unless you want to make any suggestions at this time, we will give the committee further time on that. They will perhaps circularize the entire membership of the group with a questionnaire. The whole thing hinges on the possibility of building up enough circulation to make it worth while. We will give you a final report in the mail.

ERNEST AUGUSTUS (Mead Pulp & Paper Co., Chillicothe, Ohio): I would like to say that this printer I talked to agreed to make us a proposition with the understanding that we editors would cooperate with him in editing the magazine. If we select a committee that would take care of submitting the material to him, he will take care of the printing and any advertising. We will have to take care of the editing end of it. We will have to contribute various articles to the publication, and edit those that are contributed by others.

CHAIRMAN DOELLER: I think it would be fine to have a little plant publication of our own. It would act as a clearing house for this group of editors and those who are affiliated with the Section but who can not attend the meetings.

Section News in the Headquarters Magazine

A. H. RICHARDSON (General Electric Company, Erie, Pennsylvania): I think that instead of starting up a new publication (we have so many to read and view each month now) that we would all obtain more benefit if we cooperated and helped put over the Plant Publications page in the **NATIONAL SAFETY NEWS** and possibly get it increased to two or three pages. We might obtain the same results from that as we would from starting another publication that we will have to help edit and work out ourselves. I would like to make that recommendation that the committee take this matter under consideration.

CHAIRMAN DOELLER: The committee will do that. We have heard some very good suggestions. If there are no further suggestions on this, we will leave the subject.

Regarding the question of what we, as editors, can do to further the safety program, I would like to leave this thought with you: that each one of us act as a center in our own industrial groups, if you please, and try to sell memberships in the National Safety Council and in our own Section throughout this coming year. Let's try to double the attendance at our meeting next year; let's have 300 present. We have over 900 on the mailing list. We have, however, to take into consideration the great distances that some of the men have to travel. That is the one objection to the annual congresses, so we are planning regional meetings.

We had two successful meetings last year, and we are hoping that the new officers will see fit to have at least two and perhaps four this

year in the various sections of the country, permitting the editors who otherwise could not attend to meet and talk over these problems.

This brings us then to the business of the afternoon. We are to hear, first, from Mr. Milton B. Herr, editor of the *Pennsylvania Telephone News*, Philadelphia, Pennsylvania.

THE COLOR IN BLACK AND WHITE

Milton B. Herr, Editor, "The Telephone News," Philadelphia, Pa.
