- 4) 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100
- 5) 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100

2. In all cases, the spectroscopic curve was obtained in such a fashion as to give a straight line plot of the treatment given the pigment or the index of refraction of the pigment. This gives a smaller pigment particle or a better dispersion. The appearance of electron micrographs and specific surface measurements by nitrogen adsorption are shown to correlate with this index.

EXPERIMENTAL

1. Spectrophotometric curves

The general technique of obtaining spectrophotometric curves is described in KM-51-43 and will not be repeated here. It will be noted that all measurements were made on the "C. E. Recorder Spectrophotometer" using the light path cells placed farther away than normal from the integrating sphere to minimize the error introduced by scattering some scattered light as transmitted light.

Index = $\frac{\text{Optimal Control} - \text{Initial}}{\text{Optimal Control} - \text{Initial}}$ $\frac{2}{3}$ $\frac{2}{3}$

1. Where the standard for the color of the
of the extended column is 100% of the color
at the effect of spectra, which is 100% of the color
of the column and is present in the column of the
of the column. The column color is 100% of the
of the column measurements, based on the color of
of the column to about 30 ml of a 6% solution of
of the column, visual inspection of the column
of the column is about right. The color of the
of the column is used in the column color of the
of the "Electro" solution.

Fig. 2 illustrates dispersions of RT-525-D in an oil-soluble RT-525-D is the manganese salt of, Fed 20 + BOM. When making a non-aqueous dispersion such as this, the technique is to blend the pigment with a medium that will keep the pigment dispersed but which will not dissolve it. In this case, amyl acetate was ideally suited. The curve indicating a small particle size is that of the standard, whereas the large particle size curve is that of a laboratory preparation giving a pigment of larger average particle size is the standard. The particle size index of the standard pigment is 15.1 as against 60.3 for the laboratory preparation. Average particle diameter calculated by specific surface measurement on these two pigments is 0.12 microns for the standard and 0.27 microns for the laboratory sample. This calculation assumes a specific gravity of 1.6 and is made using the equation in the footnote. Electron micrographs of these two samples are also shown in the same figure. No detailed study was made of the relationship between

Particle Diameter (microns) = 6
Sp. Surt. (sq. meters/gram) & Sp. Gr.:

particle surface measurements, electron micrograph measurements, and particle size index but it can be seen that the present correlation agrees.

4. Application of Light Scattering to the Particle Size Index

Fig. 3 shows the application of this technique to the determination of the particle size index of a sample of V.I. & P. No. 1. The distance of the detector is 1.5 cm. The particle size index obtained by this light scattering method is 12.8.

The vehicle solids in this case all are in the range of 0.1 to 1.0 microns. The V.I. & P. No. 1 has a particle size index of 12.8. This is due to the fact that the vehicle solids are in the range of 0.1 to 1.0 microns. If the vehicle solids were all in the range of 0.1 to 1.0 microns, the particle size index would be 12.8. The vehicle solids in this case are all in the range of 0.1 to 1.0 microns. The particle size index obtained by this light scattering method is 12.8.

5. Application of Light Scattering to the Particle Size Index

This illustrates a dispersing technique which is used for the determination of the particle size index of a sample of V.I. & P. No. 1. A sample of V.I. & P. No. 1 is dispersed in a solvent. The resulting paste is worked with a spatula. As the paste gets too thick to be worked, it is diluted with a drop of solvent at a time and the shearing action of the spatula is continued. After 5 minutes, a portion of the paste is removed and diluted with solvent. Further dilution is made until the paste is of a concentration for light transmission measurements.

Fig. 4 shows light transmission curves and electron micrographs of SD-265-D, SD-63044 as compared to a laboratory sample of P.V. particle size. As can be seen, there are two minima of about equal magnitude. This allows a choice of minima in calculating the particle size index. In this case, if the shorter wave-length minimum had been used, a little difference would be shown between the two pigments, but the longer wave-length minimum is chosen and the particle size index is calculated from the equation:

$$\text{Particle Size Index} = \frac{\text{Minimum optical density (455 m\mu)}}{\text{Maximum optical density (wavelength around 600 m\mu)}}$$

This makes the particle size index 12.8 for the standard and 16.1 for the experimental pigment.

ANALYSIS T-3601 is made up of the following:

Butyl Acetate	37.0%
Toluol	35.0%
Ethyl Acetate	12.5%
Butyl Alcohol	12.0%
Ethyl Alcohol (23A)	3.5%

[illegible][illegible]

UP - Order of Article - W

For a brown pig and there is no variation in the visible part of the spectrum. The transmission curve of the film is constant from the blue end to the red end. In spite of the irregularities of the wall, there will be no loss of precision in the use of the film in the visible spectrum. Precision will suffer somewhat in the near infrared, in regions where the wall thickness is of the order of the wavelength, but even so, sufficient precision is possible to obtain useful index.

Fig. 5 illustrates two M-P lacquers dispersed in polyethylene. Both light transmission curves and electron micrographs are shown. The curve labeled "large" has an index of 5.5 and the curve labeled "small" has an index of 3.1. The index in this case is defined by the equation,

Particle Size Index	1	Optical Density at 400 mμ	0.03	0.04	0.05	0.06	0.07	0.08	0.09	0.10	0.11	0.12	0.13	0.14	0.15	0.16	0.17	0.18	0.19	0.20	0.21	0.22	0.23	0.24	0.25	0.26	0.27	0.28	0.29	0.30	0.31	0.32	0.33	0.34	0.35	0.36	0.37	0.38	0.39	0.40	0.41	0.42	0.43	0.44	0.45	0.46	0.47	0.48	0.49	0.50	0.51	0.52	0.53	0.54	0.55	0.56	0.57	0.58	0.59	0.60	0.61	0.62	0.63	0.64	0.65	0.66	0.67	0.68	0.69	0.70	0.71	0.72	0.73	0.74	0.75	0.76	0.77	0.78	0.79	0.80	0.81	0.82	0.83	0.84	0.85	0.86	0.87	0.88	0.89	0.90	0.91	0.92	0.93	0.94	0.95	0.96	0.97	0.98	0.99	1.00
		Optical Density at 400 mμ	0.03	0.04	0.05	0.06	0.07	0.08	0.09	0.10	0.11	0.12	0.13	0.14	0.15	0.16	0.17	0.18	0.19	0.20	0.21	0.22	0.23	0.24	0.25	0.26	0.27	0.28	0.29	0.30	0.31	0.32	0.33	0.34	0.35	0.36	0.37	0.38	0.39	0.40	0.41	0.42	0.43	0.44	0.45	0.46	0.47	0.48	0.49	0.50	0.51	0.52	0.53	0.54	0.55	0.56	0.57	0.58	0.59	0.60	0.61	0.62	0.63	0.64	0.65	0.66	0.67	0.68	0.69	0.70	0.71	0.72	0.73	0.74	0.75	0.76	0.77	0.78	0.79	0.80	0.81	0.82	0.83	0.84	0.85	0.86	0.87	0.88	0.89	0.90	0.91	0.92	0.93	0.94	0.95	0.96	0.97	0.98	0.99	1.00

There is no assurance that the degree of dispersion in the x-rays both the electron micrograph dispersion and the light scattering dispersions but the appearance of the micrographs does correlate the particle size index.

2. Application to Molybdate Orange (57-421-21)

Molybdate orange pigment has a larger particle size and larger specific gravity than those pigments previously discussed. This means

1- 1000 microns scattering can be used as a factor reflecting the light
transmission. Scattering adequacy is superior to the conventional
method which has been satisfactorily defined. From so, it is possible
to find light transmission curves of materials using a diagram which
direct and other are same principles apply.

1- The light transmission curve of a material is defined by the equation
1- $I = I_0 e^{-\mu x}$ where I is the intensity of light after passing through a
thickness x of a material with a coefficient of absorption μ . The standard
SD 92500 has a coefficient of absorption $\mu = 0.13$. The specially treated sample
SD 92500 has a coefficient of absorption $\mu = 0.13$. In this case is defined by the equation,

$$\text{Particle Size Index} = \frac{\text{Optical Density}}{\text{Thickness of Sample}}$$

1- From the surface measurement, the diameter of a spherical
particle of 0.13 microns is SD 92500 and 0.13 microns. The diameter was
calculated using the formula in the figure and a specific gravity of 1.6.

1- Again, there is perfect correlation but the difference in
the diameter of the electron micrographs is not the same as the
difference in the particle size index. The main reason for this is
the difference in the measuring method. The electron microscope
measures the diameter of the particle in the plane of the particle
which is projected and hence some light is lost. The particle
measured by a micron adsorption method is the average
diameter. The micrograph of the experimental sample shows a larger
diameter which may well account for the difference in particle size
shown by the specific surface measurements.

CONCLUSION

As time permits some work is planned to make light transmission
measurements over very small light paths allowing a more direct
comparison of the results obtained by the electron microscope and light
transmission.
