SUBJECT: Vinyl Chloride

In response to your recent request, I have quickly surveyed the available information on the acute toxicity of the vinyl chloride. In particular, you requested guidance regarding the appropriate Emergency Response Guideline (ERG) for vinyl chloride monomer. The ERG is the maximum airborne concentration below which it is believed that nearly all individuals could be exposed for up to one hour without experiencing or developing irreversible or other serious health effects or symptoms that could impair their abilities to take protective action.

Pertinent information regarding the acute inhalation toxicity of vinyl chloride has been summarized below.

There are numerous studies describing the acute effects of vinyl chloride exposure in animals; these studies indicate that mortality is not elicited in animals with 1-hour exposures until concentrations in excess of 100,000 ppm are achieved. Prolonged and repeated exposure to lesser concentrations (1000-10,000 ppm) are well tolerated.

Vinyl chloride monomer was once utilized as an anesthetic; concentrations of 10 to 20 percent (100,000 to 200,000 ppm) were used. Difficulties encountered because of flammability, induction of cardiac arrhythmias, and high volumes required to produce surgical anesthesia discouraged its use.

Several reference texts indicate that signs of central nervous system effects occur at concentrations in excess of 1000 ppm, however the actual concentration and duration of exposure are not indicated. More definitive studies on the acute effects of vinyl chloride in humans indicate that acute exposures to concentrations in excess of 8,000 ppm produce varying degrees of early intoxication in some subjects, experienced as dizziness,

UCC 107956

R. E. Plevan  
November 21, 1990

lightheadedness, and nausea. In studies conducted by Dow, some subjects exposure to 6,600 ppm for 30 minutes experienced dizziness, drowsiness, loss of equilibrium, and persistent nausea. Exposure to lower concentrations (780 - 4,100 ppm) for 1 hour resulted in no definite response, except slight nausea, headache, and sleepiness in two individuals exposed to 1,400 ppm.

#### Recommendations

In view of the potential for early intoxication noted in some individuals at concentrations of 8,000 and 6,600 ppm, an ERG of 5,000 ppm is recommended. This represents the maximum concentration that would afford protection against central nervous system effects for the majority of exposed personnel.

Very truly yours,

  
Carol J. Maslansky, Ph.D., D.A.B.T.

|                    | 6600           | 30 min    | dizziness, tingling of lips, sleepiness, thickness of tongue, loss of equilibrium, persistent nausea, unpleasant odor |      |
| humans             | 6000           | 30 min    | dizziness, drowsiness                                                                                                 | 2    |
| humans (estimated) | 100,000        | 30-60 min | dangerous to life                                                                                                     | 8    |
|                    | 5,000          | sev. hr.  | max. allowable conc. without severe acute effects                                                                     |      |

OTHER: Carcinogenicity studies were positive; teratogenicity were negative. Has shown mutagenic response in bacteria and yeast but was negative in a dominant lethal study in mice. Has been associated with chromosomal abnormalities in human lymphocytes; frequency was normal following reduction of exposure (R-5,6). Using methodology proposed by the National Research Council's Committee on Toxicology and based on a version of the multistage model for calculating carcinogenicity risk (R-4), 1700 ppm would be appropriate for protection against a potential carcinogenic hazard resulting from a one-hour emergency exposure to vinyl chloride.

HUMAN EXPERIENCE:

ODOR THRESHOLD: varies greatly ( 300-4000 ppm)  
(R-14): unpleasant at 6600 ppm, slight at 4100 ppm.

IRRITANCY: (R-1): 100,000 for 1 min = slight irritation in mice, rats. No irritation noted in humans. No warning properties because of relative lack of odor and irritancy.

UCC 107959

Emergency Exposure Planning Guideline\*

1-hour EEPG: 1000 ppm

Rationale

An EEPG of 1000 ppm is believed to be appropriate for protection against both transient central nervous system effects and irreversible health effects.
