In treating the personal element which is invariably the cause or at least connected with most accidents the questions of failure and statistical results as to the numbers of accidents and their relations to the various hours of the day and the time of labor have been gone over time and again. But now I believe it is the tendency to turn from these things and recognize a still more important phase than that of fatigue, the whole mental condition of the men. The ability to keep attention constant, to resist distraction by chance happenings in the workshop, and especially the always needed ability to foresee the movements of various machines, cranes, vehicles, and the other fellow, which are acknowledged as extremely different from man to man. True we have men who practically never have an accident, because they feel beforehand, even, what the other fellow, or the confused operator and the unskilled mechanic will do, while others relatively often experience accidents of all kinds because they do not foresee how matters will develop. They can hardly be blamed, as they were not careless, and yet accidents did result from their personal quali-

ties; they simply lacked foresight. All this naturally turns one to a psychological analysis which indeed is a deep subject where the farther one goes the more apt he is to get lost in its realms.

Aside from the man's psychological make-up we may consider some of the secondary factors such as the man may be too daring, and may like to run risks; he may be old or he may be young; or he may still need discipline; he may be too familiar or he may not be sufficiently acquainted with local conditions; he may be ignorant as to the laws of forces, etc. Any one of these coupled with the fact that he may have something on his mind or troubles of his own.

The human element is therefore a very complex force to try to harness so as to help the safety problem, for it is dealing with human nature and the inner man. Fortunately each of us has within himself a guide, a pilot, a mental doctor, an intelligence that understands the winds of life and how they blow.

The inward pilot is our own thought and conscience. We all know that every man who does what he ought not to do knows perfectly well that conscience is trying to pull him away. Thus if you ignore conscience and thought, you resent the suggestions of the better side of your character, the human side rebuking the animal side. Fortunately for the human race conscience is never silent.

Apart from the fact that consciousness is the first sign of mental life and activity, it is of the first importance because it is the basis of all sense of individuality and responsibility.

Now that we are sure each worker has thought and consciousness, what has he on his mind? Why does he not think of safety? Why does not every instance of accident justly awaken his fears and quicken his vigilance?

#### THE MECHANICAL AGE

According to the old and well-known classification, mankind has gradually progressed from the hunting and fishing stage to the pastoral stage, then to the agricultural stage, then to the handicraft stage, and finally to the machine stage of production, the mechanical age of the present time. Here we have that phenomenon which we call the nervousness of our time, the lack of composure, the hurrying, the restlessness pervading all walks of life. Through the peculiarity of business relations in all branches not only of economic, but of social life, this restless spirit prevails.

In this age, moreover, labor has frequently become a disagreeable, repulsive act, in the depths of the earth and amid the noise, dust, and heat of many factories of today. Labor has become more and more monotonous and unrhythmical—mere piece work of unvarying nature in the modern great industries built up by division of labor and consolidation. The laborer is now separated from his work. He creates no longer; he fashions no longer; he brings nothing to completion; nothing appears as his work, nothing in which his labor is embodied. He is no more than a secondary wheel in a gigantic mechanism. The direct personal contact of the employer and the employee through which ethical conditions existed has been lost through the aggregated system of production.

## THE MODERN INDUSTRIAL WAGE EARNER

The modern industrial wage earner becomes a characteristic representative of that artificial race of men now growing up in cities. Away from his natural environment, that is away from home, the thousand-fold spiritual ties and tender sentiments are lost. His home is the world, he is a child of the world, who now stands only in a business relation with his employer; services are rated on both sides at a money value. The uncertainty as to the means of his livelihood, the fact that he does not know from day to day whether he is going to earn his bread, for an industrial depression may result in the wholesale discharge of laborers, and thus widespread famine, the fear of losing his job is perhaps foremost in his mind.

In most factories the laborer who is not doing well simply loses his position, and by such an unfortunate experience he is not mentally enriched, but is impoverished, as he has lost much of his self-confidence, and of his joy in labor. This limitless waste of human material, this pitiable crushing of joy in the day's work and the crippling of the economic output only help to aggravate his morbid mind.

Again the wandering from calling to calling is more frequent in America than anywhere else. To be sure, this was the advantage that a failure in one vocation does not bring with it such a catastrophe as it does in Europe, but it contributes much to the greater danger, that any one may jump recklessly and without preparation into any vocational stream.

It is this continual change which brings to the laborer a consciousness of his position. The stretch of bare work without periods of proper relaxation and recreation will grind about a breakdown in his better judgment. His nights without proper rest are fatal to his highest efficiency on the following days. In other words, the man whose mind is ill at ease or who isn't properly fed, and who is up against the necessities of the dwelling houses in cities may make out about as well as he can. So we see that while labor is the sanction of life, as the director of energy it has ceased to round out the worker into a complete man, and hence to make him peaceful and contented.

The point that I wish to make is that accidents that are due to the personal element are not due so much to carelessness or foolhardiness as to ignorance of hazards and the proper way to do the work, the hesitancy in asking questions and what is in the worker's mind.

Young men, especially when they predominate in any department, are a potent factor in the accident report, especially in the accidents that the Company cannot prevent. They smash more equipment and are more severe on machinery, and while they have less accidents to themselves, due to their agility, their eagerness, chance taking, and speed, particularly in departments handling hot metal, they make all signs at the cross-roads read "Danger Zone" instead of "Safety Zone."

Diagonally opposite we have the men with long years of service behind them, the old men, the men who less easily adjust themselves to radical changes in the art of production or mechanical equipment. They have

not the elasticity of youth and are less able to think themselves into an artificial situation.

Age being the natural outcome of life, we must reward long, faithful service by placing these men in zones of almost complete safety, a number of which can be found in any industry, where the work is of such character that it will bring satisfaction to the man and stabilize the workings of safety.

#### FAMILIARITY ENGENDERS BLINDNESS TO ENVIRONMENT

Familiarity, strictly a human element, is peculiar the way it affects different men. Often you see material or objects that have been dropped or promiscuously placed on a board with a protruding nail awaiting an innocent victim, in the gangways or other much frequented places in the shop. While it is of course an act of selfishness, another human trait, on the part of any one that sees these objects in passing them, not to remove them or bend over the protruding nail, so as to protect the other fellow, some peculiar trait in his inner make-up bids him not to do it. After that has taken place these objects in question become familiar. Then this familiarity means that a man will exert more energy in trying to pass around these objects many times during the day, than he would in removing them at the first instance. He then has a typical case of that form of blindness called familiarity, which I might say is very contagious. While the objects are really there, he does not see them; he naturally or automatically goes by them and forms an accustomed habit.

He is a good deal like the thousands of New Yorkers that pass the Woolworth Building six days in every week. Perhaps they watched that mighty pile lift itself from its foundations and raise its gilded dome to the clouds. Yet I venture to say that nine-tenths of them have really never seen it. A stranger comes to the city, like the visitor comes to our shop, and the structure leaps into his vision like a lion from a thicket. He carries home a clearer impression of it than most of the folks who work within its walls. So familiarity may breed blindness—as well as contempt.

The innocence of compressed air, as it is generally known to the unskilled artisan, deserves more than a passing remark. Only lately in passing through the foundry I saw two men, one a white foreigner and the other a negro, tussling together with an air hose, that was emitting its colorless compressed content, as the object of possession. They stopped momentarily while I passed. As I proceeded farther on my way a passing glance showed that the friendly struggle was proceeding again as at first. I retraced my steps, and being a member of the safety committee, took it upon myself to inform the men in question that they were playing with something very dangerous. The expression on their faces plainly showed that they knew better and that there was no danger. The foreigner then said with an air of sureness, "This is no electricity, it can't hurt you." A little explanation on my part revealed to him that while they were only playing, as it were, there was the possibility of an agonizing death, broken ear drum or other serious injury. The colored man was an interested listener and no doubt will heed the warning in

the future, but the foreigner perhaps really did not understand, and still retains that possibility of accident, which, when it does happen will be charged to the personal element, and behind the personal element is ignorance.

While on the subject of power as it is stored in wires and pipes we must also consider the force of gravity as another potent factor. While neither of these are personal elements, their forces are so enormous, so capable of destructive violence, and their application to industry so complex, that one can not conceive of an engineer as failing to recognize that the personal element must enter as an important consideration.

The force of gravity, that great unknown reality, which is the element that causes so many accidents, such as the falling of objects either human or otherwise, should have some consideration. Also the position assumed by the worker, carelessly, thoughtlessly, or otherwise when dealing with that element calls for a mental reaction that is in most cases strictly a personal matter.

Men frequently place themselves between two objects attracted together by this mysterious force, such as occurs when lowering barrels, machinery, etc., down skids, or passing under stationary and moving lifted loads. By so doing they place themselves right in the path of danger, depending upon the ropes, chains, and hooks that hold the body in equilibrium, not knowing that these holding devices have some dependence on the human element in themselves, for they were produced by man.

In this connection anything that will teach or enlighten the worker such as a little instruction relative to the proper position to assume would be of value to offset the personal element attached to this hazard, for without it he would have to learn from the school of experience which oftentimes is a very expensive lesson.

After considering the worker with all his faults it is worth while considering his nearest associate, the foremen; the one that carries on the orders from the higher ups, and the one that we must look to for results both in production and safety.

#### PROBLEM OF THE FOREMEN

The foremen alone present a problem in themselves, for while they can take one of the two sides in safety, either for or against it, and they are above the average worker in intelligence, they present a peculiar case.

There are three classes of foremen; First, the indifferent class, or those that belong to the "what's the use brigade" and take the stand "Let things come as they may". Second, the doers class; those that do the little things, for they are disciples of the clan that believes success comes to those that do the little things—it's the little things in life that count. Third, the masters class, those that believe in themselves, believe in their co-workers; they enjoy what they have and work for what they get, and are those that say "good morning" to their companions at the start of the day.

As a plant is known by the foremen it keeps, it therefore is a big advantage first to get all foremen into this third class and get them to

believe in safety, then we have added 50 per cent to the power of the dynamo.

The human element in safety demands the assistance of the foremen if we are to attain any results at all. It must be put squarely up to the foreman in every and all industries in hopes that some may be awakened to caution and vigilance. I don't mean to say that he is a "cure all", but inasmuch as he is in direct personal contact with the laborer, he can encourage him to freedom and confidence, if he (the foreman) will avoid any such appearance of superiority as may overbear and depress those under him.

Safety must not only reach the surface. It must be made to penetrate deep so as to reach the depths where this accident malady takes root; it must reach the man himself, and by that I mean the laborer of the lowest rank, as well as the skilled mechanic. It should begin at the top with the manager, superintendent, and safety engineer, and without the co-operation of those on the lower rungs of the organization ladder little can be accomplished. Every cheek should be flushed with confidence and every eye should sparkle with eagerness to endeavor to make the draught of life long and sweet.

Life is sweet to every individual, and whether he be white or black, or whether he is mentally or morally equal to his superiors in the shop, the air of indifference which is so conspicuous in some that handle help should be laid aside, because, on the accident report sheet there is no distinction, for each accident that is in the total of the day is represented by a figure, and in this figure may be included the foreman himself.

While serving on a safety committee, we were making an examination of the Carpenter Shop. Our practice called for the foreman to accompany the safety committee on inspection trips in his department. This one occasion brought forth one of the peculiarities of which foremen are sometimes possessed. This foreman was well on toward life's expectancy, and being from the old school, was naturally or otherwise inclined to view the safety committee with a little skepticism.

Several of the guards on the high-speed woodworking machines were off to one side, and not in place, while the operators were working these machines. The foreman was naturally asked the question of why the guards were off and why he permitted the workmen to operate the machines without guards. These questions animated his feelings and excited his nerves, while his answer stimulated his muscular movements, for his hand and voice started to work in synchronism. Among several things that he said, this one stood out very prominently, for he used a great sweeping gesture with his hand saying: "Why, we don't need any guards on these machines. We haven't had an accident up here for years." Just then the scrutinizing eyes of the committee saw that there were several fingers missing from the hand that was waving so gloriously in fond recollection of the past.

You know the mind has some peculiar characteristics and one of them is that it remembers the pleasant things best and tries to forget the unpleasant things, just as the gambler remembers his winnings and not his losses. So it was with this carpenter foreman. He remembered that

they did not have any accidents for several years, and had forgotten about his mishaps which were the unpleasant thoughts. When the truth became known it was found that each finger that was missing was the result of a separate accident.

This living example of the "guardless days" will no doubt be a good advertisement for better protection, after he is educated to regulate his thoughts by those of reason, and that safety is a real necessity and not a menace and that the safety committee does not belong to the "what's the use brigade".

The next class of foremen, those that do the little things—the littlest thing they do is to help save their brothers from accidents, and to protect the interest of their employer. This is the class of fellows that have to have accidents occur continually in order that they may be stimulated up to a high pitch in safety, for they are otherwise unable to help themselves in this great humanitarian effort.

The last class of foremen, the type that can listen to the voice of wisdom and learn from the experience of others. They are like the captain of a great battleship, though he may be the greatest fighting sailor in the world, will take the advice of the pilot, give over the command of the ship to him, and control of the helm, when he is in that pilot's troubled waters. They are the ones that can be trusted and depended upon. They know the location of switches for lights and machinery, and are not at a loss as to what to do in case of an emergency. They are not quitters and never plead mental bankruptcy. This class, when properly instructed, always prove to be for safety from center to circumference, for they are conservative enough to be absolutely safe and liberal enough to satisfy fair-minded people.

When safety committees can work with men of this last class they can with almost infallible certainty point out, not only what work can be undertaken with fair hope of success, but also what slight modifications or additions and diminutions will more than double the safety power.

#### VALUE OF BULLETINS

The value of bulletins can only be appreciated by watching the attraction they have for the average employee. The reason for this is because the worker sees in the pictures the other fellow, just as the accident happened, and naturally accidents always excite curiosity and crowds. These bulletins should be placed in choice locations, such as near the drinking fountain or lavatory, the places frequented most by the worker during the working hours of the day. The worker can easily fall into a rut, in so far as safety is concerned, but when he sees the bulletin his mind is momentarily diverted and aroused by the substance brought out by a properly illustrated bulletin. The reading of the bulletins is restful as well as educational, especially if they are convincing and put up in a sensational manner like some of the popular newspapers of the day, that appeal to the more uneducated classes, and if they are short, snappy, new, forceful, and right to the point, much like the present day advertisements along the highways. They cannot fail to bring results, for their message is working every moment of the twenty-four

hour day. This will be of great assistance to all concerned in safety, for the laborer will soon discover that they are treasure houses of infinite capacity, always open to them, and the wise shall think about them to their advantage.

#### THE SAFETY MOVEMENT

This humanitarian movement called safety is something that will be with us for all time. It is a branch of engineering that has been neglected in the past by our colleges. It had its origin in the school of experience. We must regard everything that we do as dangerous. Failure is dangerous, and everybody knows it. So if we are to succeed we must sow the seeds of safety for the future harvest.

The young students attending our colleges and universities that will be the men of the future, those that will take up the problems that we leave on our departure, should have as part of their course, a certain amount of safety instruction. To turn them out into the great industrial world of today, cut off from the great thoughts that have been brought to light in the last decade, is like sleeping at our post during a siege, yes, I might say it is like sleeping at our post during an attack.

The engineers of today, those especially that have charge of men doing designing of industrial equipment, are perhaps more proficient than their predecessors were in the art of safety. This is noticeable in all the latest equipment, for much of the up-to-date machinery has had some safety thought while being developed on the drafting board. This finished product with all sorts of positive features, the result of careful thought and study, is today presented for productive labor to the worker, who, even though he may not be possessed of intelligence, good judgment, common sense, good eyesight, good hearing, good memory, or quick perception, or one who is able to concentrate his attentions completely on any matter in hand, makes less accidents in relation to output than the days before the advent of safety. So as time goes on the personal element that man is endowed with shall be harnessed so completely while he is doing his work that it will be very closely regulated.

I hope to see the day when all equipment layouts, in fact all ideas that are developed on paper in the drafting department, for construction purposes, will have to pass the Safety Department, composed of trained competent technical men, where it will receive the stamp of approval or a cut out by the censor.

The early beginnings indicate clearly that the goal can be reached only through exact and scientific principles, and that the mere naive methods as here-to-fore used cannot be sufficient for real, persistent furtherance of industrial safety.

Such of the personal elements that appertain to the psychological functions of attention, memory, ideas, imagination, feeling, volition, suggestibility, ability to learn, ability to discriminate, judgment, space sense, time sense, and so on, should have some introspection so that the lack of self-discipline, which is the cause of most mental inertia, can be corrected. These are the problems for the psychologist.

The fitness of employees for any vocation that may test the particular

complex unified combination of attention, imagination, and intelligence, will, and memory, which is essential for a special kind of labor, is a problem for the vocational counselor as well as the psychologist.

These are problems in psychology which would require perhaps volumes, if the human element was resolved into its component parts to test every single elementary function in its isolated form. And I only mention these in hope that some writers, in the meetings that are to follow year by year, will treat them so as to enable us to see our problem and obligation with a little clearer light and help us in our safety problem, and make the solution of the problem a matter for our personal attention and aim.

This question of personal safety is very broad. It is something that we can only see part of, the outward cast of man, his inner make-up we must learn. The result in so far as accidents are concerned, we can analyze and only draw conclusions, because the ordinary individual knows very little of his own mental functions, on the whole. He knows them as little as he knows the muscles which he uses when he talks or walks.

The company that I am connected with is facing this problem of accidents that they cannot control, accidents that are up to the man himself, with the idea of final solution as their aim; sparing no expense in this problem of the hour, in the endeavor to deliver its employees home in the evening to their wives and families in as good condition, if not better, than when they were received at the gate in the morning.

A welfare department composed of a vocational counselor to attend to the needs of employment, a safety engineer to protect and safeguard the interest of both employer and employee, and a welfare man to look after his environment and needs, is now an established fact. This set of men are specialists in their vocations, and this branch of the organization while comparatively new is now regarded as a valuable asset and is mentioned here because of its direct relation to the subject of this paper.

Finally, safety is to industry what hygiene is to medicine. It is, broadly, the science and art of preserving life and health, as currently restricted, not by curing disease, but by the prevention of accidents, through the removal of their generating causes. As we cannot remove them until they are known or truly inferred, the science advances with that of medicine, and had no general basis until the last decade, during which unprecedented progress was made in all branches of medicine, than which none is more important than that of preventive medicine.

If the many thousands of injury and many hundreds of death cases can be reduced by this great humanitarian effort to a half, then the conditions in the great basic industries of America will be relieved of much responsibility. But the whole world of industry will have to learn the great lesson, that of the three great factors, material, machine, and man, the man is not the least, but the most important.

ADJOURNMENT.

## THURSDAY MORNING SESSION

**CHAIRMAN OARTEL:** The first speaker this morning is Mr. Nicolaas Prakken, of the Pawling and Harnischfeger Company.

**SAFETY FEATURES OF OVERHEAD TRAVELING CRANES  
FROM THE STANDPOINT OF CONSTRUCTION AND DESIGN**

**NICOLAAS PRAKKEN. PAWLING AND HARNISCHFEGER COMPANY.  
MILWAUKEE, WIS.**

It is a pleasure, indeed to tell you something about traveling cranes, because you know that in any plant the overhead traveling crane is called upon very heavily to take part in production. It is certain that the overhead traveling crane is one of the most abused pieces of equipment that any plant, mill, or machine shop has installed in it. The question arises, when you are talking to a purchaser, one that is enlightened or one that might not be enlightened, "What overload will this crane carry?" If you asked him how much of an overload he could carry, he would say, "I am not in a position to carry any overloads". Oftentimes people do carry overloads, and when they do, they naturally show extreme fatigue, which means an overloading of the system, and they have to recuperate through rest.

A gentleman who had been assistant general manager of a telegraph office stated that all that was needed in a crane was simply some pieces of iron on the sides and bolts on the end for the truck ends to hold the wheel.

The traveling crane divides itself naturally into the electric overhead traveling crane and then a combination of the bridge with a monorail hoist. So that this transfer crane, with its monorail hoist running on the lower flange of an I-beam, possibly with a special track, can run off the spur beams to any part of the plant. In connection with the transfer crane comes a floor operated hoist. The floor operated hoist is operated in the same manner as the transfer crane, with its cage controlled monorail hoist; the only difference being that instead of the man being in the cage, he is walking on the floor with dependent ropes in his hands. Then in connection with the transfer train, cage controlled or floor controlled, you have your accessories such as switches and turn tables. These accessories, incorporated in a system with curves, makes it possible to give service to the different parts of the plant.

The standard overhead traveling crane is made in three units: the trolley, the bridge, and the cage. The bridge, being the part that spans from side wall to side wall, is composed of girders the bridge machinery, foot walks, electrical equipment, and the truck ends. The truck ends must carry the entire load, especially when the trolley is moved over to one side with its full capacity. On each wheel then, you will have one-quarter of the weight of the bridge plus one-half the weight of the

trolley and one-half the weight of the load, plus the additional movements that the bridge machinery goes through, added to the wheel on the truck and adjacent to the bridge machinery. That wheel, then, must carry the greatest part of the load, and it is important from the standpoint of design and construction to see that you have a bearing there that will absolutely withstand, with a minimum amount of maintenance, the loads that are imposed upon it.

#### THE TRUCK ENDS

The truck ends in a well designed crane are usually of a box section with cast steel truck housings securely riveted in between the channels forming the side members of the truck end. In the ends of the channels are riveted cast steel truck ends with M. C. B. bearings. The pin is keyed to the wheel and revolves in round post journals on both sides. Comparing that kind of truck journal with the other type that is put on the cranes, that costs less. You simply have the two truck channels with holes bored through the end and a pin put through these holes with keeper plates to hold the pin in place, and the wheel revolves on the pin. Now you can see there that the wheel that is revolving on a pin has not the same bearing per square inch of projected area that the type of truck end has where you have the standard M. C. B. bearing with a pin keyed to the wheel, the pin revolving on a bronze bearing on both sides. Ordinarily the pressures figured in the design are about 800 pounds per square inch of projected bearing area.

In selecting truck ends for design, the size for the wheel load parts, you must consider first the service that it is to render. We will take, for instance, a foundry where you have the top crane that is at the top of the building, used for cleaning-out purposes. It goes to one end of the foundry, picks up its burden, carries it over the heads of the other cranes and goes down to the other end of the building and dumps the castings. Possibly that foundry is 300 feet long. Here you have a minimum amount of hoist duty and a maximum amount of bridge duty. The truck ends, the wheels and the bridge machinery are called upon there to perform the greatest part of the duty which that crane is called upon to perform.

We will consider, in comparison to that, the crane which is working on the runway underneath, for working on the floor. Here you have the hoist doing the greatest work. It is lifting off flasks, turning them over, drawing patterns, and the bridge travels a minimum. There you must give first consideration to the work that the hoist must do. On floor work, if a crane makes twenty lifts per hour, it is doing exceptionally well, unless a man is taking material from one part to another, as in piling up finished work.

#### THE TROLLEY AN IMPORTANT PART

Then in the consideration of an overhead crane for magnet duty, the trolley again plays the most important part in its operation. It has been found that a magnet crane, in unloading scrap, (and it seems almost

impossible that you could get that many lifts out of a crane) will make as many as 90 lifts an hour. Contrast 90 lifts an hour in a shop, and you can see that you have again got to give study to the type of trolley, its size, for a crane to perform that work. So in selecting a magnet crane, the safest manner, if you wish a 5-ton crane for magnet service, is to take a 10-ton trolley and put it on a 5-ton crane and call it a 5-ton crane because the work that the trolley can do is limited entirely by the heating of the motor. Fifty to sixty-five per cent of the hook movements are empty hook movements. The minute you place a magnet on the hook of a crane, you place about one-third of the full load capacity of the crane on the hook of the trolley. That requires more current consumption and consequently your motors heat to their rating earlier in its operation than it would for standard crane service. If you take the standard 5-ton crane trolley of any manufacturer and use it for magnet service, using 90 hoists an hour, you will find that that trolley will shake itself to pieces, irrespective of the metals put into it, in a period of three to four years whereas if you take the 10-ton standard crane trolley of any make and impose upon it a 5-ton load for magnet service, you will find that that trolley will stand up indefinitely, or for the natural life of a crane.

The truck ends are of the box section M. C. B. journal type. Where two cranes are on the same runway, they should be provided with bumpers. Bumpers are mounted at the top end of the cast steel truck ends. That is one of the safety features. Now supposing two cranes, weighing about 40 tons apiece, come together, you can see that you must have a very substantial type of truck end in order to withstand that jar. The bumpers are simply a precautionary measure so that the wheels will not come together and destroy the flanges. Covering the rail should be a very substantial rail fender. The rail fender covers the rail, projects around it, so that in case there is any obstruction on the rail, or a man's hand is on the runway rail, that might be working on an adjoining shafting or running up the column, his hand will not be crushed off. In addition rail chocks should be present on the truck end. The real chock is a part of the steel truck end casting projecting around the rail but clearing the rail so that no resistance will be offered in the traveling of the crane. In case a rail breaks (which happens quite often), the rail chocks will hold the truck end on the runway rail. If greater resistance is offered on that side, the result would be a twisting of the crane, enabling it to leave the runway; but the rail chocks would hold the rail to the runway and prevent disaster.

With respect to the end trucks on an outside crane, the wind pressure on that outside crane is tremendous and some lock must necessarily be provided to prevent the crane from running off the end of the runway in case of a storm. There are two methods of locking an outside crane: one is that the foot brake is on normally and in order to release the traveling you apply pressure to the foot brake and it releases the foot brake which is attached to the foot brake start. Normally at night the operator runs his traveling crane to the end of the runway. On the end

trucks are provided arms, and by the use of a lever the operator throws this lock right over the end of the runway which holds that securely and makes it impossible for the wind or a storm to blow that crane away from its locked position. So you have that lock, and normally the foot brake which is on in the normal position.

#### THE GIRDERS

You have various conditions to be met in the industries such as chemical plants, where gases are present, and plants where the acid fumes from the product which is being manufactured attack the metal. It is obvious that the design of the girder should be such that the maintenance men can get at every square inch of its surface with paint, in order to resist the fumes of the acid. The web girder there and the lattice box girder are the best types. The box girder is a poor type of girder because the inside is enclosed and it is difficult to get at it, in order to paint it. The box girder, which carries the bridge machinery, or the plate girder, carries the maximum amount of load. It is merely a matter of stresses to get the proper proportions of that girder, to determine its lateral strength. In cranes that operate over furnaces, especially some that are found in the northern part of this country among the copper people, in placing the mass copper into the furnaces, the crane must stand over the top of that furnace sometimes for periods of half an hour, and longer. The top of the furnace gives off a heat of 2400 degrees Fahrenheit. With ropes on the crane, the strength of them is naturally determined by the hardness of the rolling produced in the individual wires of the strands. Heat will anneal and soften those cables and render them practically useless. It has been found necessary in some instances of that type to use chains because chains are improved by annealing, although they do not give the usual warning that cable gives. The box girders are likewise again necessary because the box girder, for the same strength as an I-beam and channel construction, has more radiating surface. I am speaking with respect to short span cranes. The I-beam and channel section there can be analyzed as an infinitesimal number of fine steel wires welded together. It has less radiating surface for the same strength, than a box girder has, and consequently where heat is the criterion, you should have as much radiating surface in the girders of your crane as you possibly can obtain. The bridge machinery, the bridge motor in the box girder type is mounted on a bracket and this bracket is usually level with the floor.

#### THE FOOT WALK

The foot walk should extend solid to girder, with a six-inch angle iron bordering the foot walk, so that there is no possible chance that any tools, wrenches, or parts of equipment, during repairs, can be kicked off onto the floor. Bordering this foot walk also should be an angle iron member hand rail, and oftentimes it is specified by several of the people that this hand rail shall be fenced or covered with wire. That is a very good provision. The foot walk now is completely baffled, you might say, so that

there is no possibility of any parts being kicked off onto the floor, and as the foot walk extends solid to girder, whether it is made out of plate or wood, depending upon the service required, any particle that might be resting on that foot walk is safe from being kicked off the load.

Oftentimes the construction of the trolley demands that you have a foot walk on the opposite side. That is very desirable because you always must perform work on that trolley on one side or the other and in order to save expense to the purchaser, a short foot walk is usually put on the opposite side, where the trolley is of such design that to get at it you must provide a walk there. In the past some of the purchasers have required that we build a foot walk over the end of the bridge. If you have plenty of head room, that is possible, but usually the head room is barely enough to put a foot walk over, and it is common practice by a number of people at the present time especially when building costs are excessive to reduce the height of the building a foot or two and then pay the crane manufacturer a couple of thousand dollars more to design a special crane to get into the limited head room. When a crane manufacturer gets to that point, his production is decreased because he must give time, if he accepts this order, in order to get out the crane that will go into that head room. It means that he must get more for it because the majority of the buyers are buying standard types of cranes. So that is an obsolete pattern you might say, that you have no use for.

#### THE TROLLEY

The trolley parts are the trolleysides, girts, gears, gear cases, drums, and electrical equipment—the electrical part is the limit switch. The trolleysides on a good high-grade trolley should be the box section. The girts should be of structural steel. The equalizing sheave is usually placed within the girt. The motors, if they are for a standard type of service, are mounted on the trolleysides. If they are of the mill type, two girts are usually placed in between the trolleysides and the mill motors are mounted in between the trolleysides. The gear cases are totally enclosed, and the individual reductions are placed within these gear cases and they run in oil. The specially desirable feature of the entirely enclosed trolley gear case is that one reduction is found in each individual case, which means that both of the bearings are contained within the same casting, and consequently your gear centers will always be maintained. Where it is necessary to have three bearings in the same casting, where the drum comes over to the rear trolleyside, the second reduction will be on the same side. The top casting holding those bearings should be in one casting, so that the two centers would be maintained, and the third bearing for the drum on the rear trolleyside should have a recessed housing. That will hold all of your bearings in alignment.

#### THE TROLLEY BRAKE

There are many different types of trolley brakes on the market. There is the trolley brake of the multiple disc type and then there is the trolley

brake that is of the brake type which is used in a frictional contact with the surface of the pulley. They all seem to hold up.

#### THE LIMIT SWITCH

The function of the limit switch is to stop the upward travel of the hoist. The most universally accepted type of limit switch is one of double weight type. Springs are undesirable on any of that nature. The weight that is raised by the block is heavier than the weight that is attached to the switch on the box. The block is fitted with a pan, and attached to the weight is a loop of rod-iron; the two cables coming from the equalizing sheave pass down through this loop of iron attached to the weight. This lower weight is attached to a shift wheel of the sheave by a cable. As the hook block travels upward, it is guided so that the pan will strike that weight, irrespective of the swinging of the lower load block. As it carries up the weight, the weight on the sheave will open the contact, this being merely a relay circuit, and it will open the contact with the cage. That contact is simply this: connected with one side is a wire of low amperage connected with your switch box. Then the other plunger runs over through your coil on your contact or circuit brake, if you wish to call it that, to the other side of the line. The instant the switch is thrown in, the contactor closes the circuit; the limit switch is closed on the hoisting position. Now as the block raises the hoists, it lifts the weight; the other weight on the sheave pulls open the contact which is nothing more than a keeper plate across it; it interrupts the circuit of the magnet coil and your contactor opens, and on your dynamic brake, the instant it opens a contact is made on the bottom of the shift. It makes the motor perform as a generator until the brake on the motor shaft has time to act. That has been found to be one of the best methods of control.

#### THE CRANE CAGE

There are cages of various types. Some are enclosed; some are too small for a man to move around in. We have made all kinds of them; so have all the other manufacturers. A cage should be roomy. It should have ample space so that the operator can move around in it; so that he can view all parts of the building, so that he can look down over the front of the cage and can look to one side or to the other. If the manufacturers would buy a crane like the manufacturer of cranes would like to make it, I know every crane manufacturer in existence would put every possible safety feature on a crane.

The finest type of crane cage that any one could ask for is one that is roomy, which has a lever stand in the front, so that in hoisting you lower your lever forward. Hoisting backward, the movement of the lever then indicates the direction in which the hook is going to go. Some men have even gone so far as to state that in breaking in a new operator they would like to have the bridge motor controller on this side (indicating), so that he would push his lever back that way, and in going this

way he would push the lever over that way (indicating). But we have to put them all in the front of the cage.

The back of the cage should contain the controllers and the switch-board equipment. That should be enclosed; and when the main line switch is thrown in, there should be a lock on those panel doors, so that there is absolutely no chance of the operator or anybody else opening those doors for any kind of work until the main line switch has been pulled out, which then would not lock the doors. That undoubtedly would be the best type of crane, because operators very often have been jostled and have fallen back against switches and the lock. Any projections on the doors would necessarily mean that a man walking along the inside of the cage could possibly catch his garments on them and it might arrest him in his work one way or the other.

A new place has been found for the resistances. The resistances have been mounted on the side of the cage and on the foot walk. One of the nicest places is on a sub-floor under the floor of the cage, on which the operator walks. Trap doors lead from this floor immediately to the sub-floor beneath, that can be opened, and all the resistances are immediately available for his inspection. In case the resistances are mounted on the bridge walks, repair men and the like can get up there, they can probably use it as a rest for tools, screw drivers, and the like which sometimes fall between the resistances, short circuit them, and the result is that you have a blowout and your crane service is held up. By placing them underneath the floor you have a space there entirely for the resistances, that can likewise be screened in, and it is always there for inspection; it is not used as any tool rest, and it is simply a space reserved for the grid resistances. The general purchasing public appreciates that and in many instances we have found that they have insisted that their buildings be made higher, in order that the resistances can be housed and mounted on a sub-floor.

#### LOCATION OF LADDER FOR BRIDGE WALK

The ladder going to the bridge walk should be in such a position that the floor of the cage is always beneath the operator. You have often-times seen a number of traveling cranes in which the operator has to climb up and swing on the outside of the cage, and then climb up this ladder to his foot walk. Our company is just as guilty as the rest on that, because that used to be common practice years ago. It is not so any more. In case the operator is subject to fits, etc., that employer does not know the habits of his employee, and the man would not only be likely to injure himself but he would also endanger the lives of the workmen working underneath the crane. Therefore, by having the ladder from the cage to the foot walk, so that the floor of the cage is always beneath the operator, you eliminate that hazard that the operator or some one else might fall off to the floor.

#### TRANSFER CRANES

The transfer crane, so far as the bridge part is concerned, is the same type, in construction, truck ends, and girders as the bridge of the stand-

ard traveling crane. Attached to the box member that spans from truck end to truck end is an I-beam, the I-beam being mounted on its lower flanges, either T-rails or what is known as the cross-section of the American Bridge Company; that is an angle iron which has one of its legs rolled to take the angle of the standard I-beam, but the tread on which the wheel runs is horizontal; it is used to a considerable extent in mills, chemical plants, etc., where acid fumes are present. The structure is painted with an asphalt paint, but the surface of the whole track cannot be painted because the trolley wheels of the monorail hoist are running over this track continuously. The result is that the tracks are being pitted by the acid fumes.

In the registering of the transfer crane, with its spur, it is necessary that some exact method of registering and locking be placed on that crane, as well as baffling. Sometimes a crane is locked on both sides simultaneously; sometimes a crane locks alternately, first on this side and then on that side (indicating). That is done by a locking device. It is necessary to register that crane exactly because if it is not registered exactly, you are going to have trouble with your truck ends and a gradual bumping and wearing away of the parts.

#### VARIOUS METHODS OF REGISTERING TRANSFER CRANES

There are different methods employed in the registering of transfer cranes with the spur runways and different methods of locking. One is that of coming up with a target two points like this (indicating). The instant that the targets come together, the operator stops; traveling very slowly, of course, and by assistance of the bell cranks in a lever connected to the cage throws in a pawl. The motor to the cage is in a monorail hoist. As he throws in that pawl, the baffles are raised on the I-beam, which holds the case control monorail hoist on the transfer crane as it is passing back and forth in the base, and keeps it from running off the ends, either side, in case the operator should momentarily be overcome or forget that he is near the end of the crane. Those baffles are either of the interlocking type, which come into the end of the beam, or of plate metal, which falls down in this manner on both sides and engages in the truck ends. As soon as a register is made, in case there is a transfer crane in the next bay, that he wants to run onto, spur baffles should be put on the spurs that work in connection with the baffles on the transfer crane. The other type of baffle, as I explained, is one that drops down, this way (indicating) and that is actuated by the throwing of a lever, which throws out two rods. The function of the one rod is to ride along a plate that is made in that manner (indicating), as it rides along this plate and comes to the top, registration is made the instant that that rod comes to that position. Back here about two feet from the end of that plate is the baffle; the baffle arm that raises the baffle and gives clearances, so that the monorail hoist can pass underneath. On another plate over at this side, which is notched in this manner (indicating) is then a square bar that falls into position there and holds the transfer crane into place.

In the spur connection, where it is necessary to baffle the spur, this rod that comes up in this manner raises underneath the long angle that has its pivot point back there (indicating), with another arm here raising up this baffle, and as the arm from the transfer crane raises up in this manner, it likewise raises the baffle upon the spur. If there is a transfer crane in the adjacent bay, it is likewise baffled.

The operator is in position to travel over any system of runway that you might have; he is registered; it is locked; it is impossible for any one to take that bridge away until he comes back.

In traveling over the runway, we encounter switches. Switches are again baffled, the same as I have mentioned with respect to these plates; that is, with the plate sections that drop down over the I-beam. The spurs as well as the tongues must be baffled because you can see that a tongue can be thrown into a central position in between the two spurs and if the tongue is not baffled, the operator could run right off the end of the I-beam. The other type of baffle, which is more secure than the type that drops down, is made out of plate, because this type that drops down this way (indicating) is made to conform to the standards of the hoist. In case you put a smaller hoist on it, it might run right in between the baffles. So the baffle would have to be changed in the event that you were to make a change at any time, by putting another hoist on the runway.

Then there is the interlocking type of switch in which a section is cut out of the side of the I-beam and a heavy cast steel arm comes right in there in this manner (indicating). The locking part is a section of metal, possibly about that long (indicating), about that high, two inches thick, connected to a very strong arm. As the switch travels from one side to the other, we will say it is lined up on this spur going off to a curve, this lock is off in that position, and as the I-beam tongue of the switch travels over here, this lock moves over to that point and locks in position, and opens this one. In order now that the monorail hoist will not fall from the runway, it is essential that some provision be made in the matter of safety catches, to prevent it from leaving the runway. One type employed is a steel collar which is cut in half and bolted around a turned portion of the trolley part, which is steel, and the frame part of the hoist which is steel, with about one-eighth of an inch clearance in between. In the event of a cage pin breaking, these two curved surfaces, or the collar, would hold that right into place and prevent the hoist from falling. This type of lock has the advantage over the other type in that you can travel to any point for repairs, but before you can make the repairs it is necessary to fasten the monorail in position by a chain, to take up the distance that the hoist body has fallen on account of the king pin breaking.

The other type consists of two steel castings that fit over the lower range of the monorail I-beam, but still with sufficient clearance so that it offers no friction to impede the travel of the monorail. In the event of a king pin breaking, the safety catches would fall on the runway; the hoist itself would stop right there, until you had gotten chains and taken up the slack, so that you could run to a point to repair the machine. The

safety catch is just as good as the other type, and it costs about one-third of the price, and that oftentimes makes a big difference to the man who has his hands on the pocket book.

That covers pretty generally the field as far as safety features are concerned. The cage on the cage controlled monorail hoist is the same as that on the traveling crane, only that a man riding on a monorail hoist should have a cage adapted so that he can be seated at his work. On account of handling long loads, the glass should extend way down to the floor, baffled with rods of iron or angle iron in front, so that the loads swinging back and forth will not break the glass. In the floor of the cage should be a good section of heavy plate glass, so he can look downward; in case he has an 85 or 90-foot lift, he can then see the movements of his hook. If he is handling a bucket or a magnet, and control his hook and the movements of his crane as he wishes.

#### ELECTRICAL MAINTENANCE

We now come to the repair item, which is electrical maintenance. That is very hazardous, especially where you have to employ operators who do not understand the general conditions about the plant. Oftentimes when work is being done on the crane, the repairman goes for some tools or some materials and somebody get up into the crane and starts it off, and if a man is working, he is injured. There are two ways in which that can be overcome. One way is by placing in the cage a cabinet containing the main line switch, which is absolutely locked, and the repairman, who is working on the crane should keep the key to that lock in his pocket. As soon as he is instructed to make any repairs on that crane, he goes up, unlocks that lock, opens the door to that cabinet, pulls out the switch, closes the door and locks it, and he keeps that key in his pocket until every last repair is made on that crane. That works out all right when only one man is working on the crane, but supposing there are two or three men working on that crane, that means possibly one fellow who is holding the key might finish his work before the other fellows do, and the result is that he would be waiting on the job until the other fellows were finished. So that the best system which has been found and used is that in one side of the line you place the series of plugs, the type that is made right in your own repair shop, and have a series of two, three, four, five plugs on this side of the line. The minute one of your repairmen is instructed to repair anything on that crane, he takes one of the plugs out and puts it into his pocket, and he keeps that plug in his pocket until that job is completed. If two men are on, each man has one of those plugs in his pocket. Now that absolutely insures that the crane cannot be operated until all of those plugs are placed back in their receptacles, and it insures that no danger will be occasioned by any one in the plant getting into the cage and starting off the crane, because no current can flow through until all of those plugs are in.

All equipment should be blown off at least once a week. In many plants it is found that they give the oiling to a certain individual. That might be necessary in a large plant, but in a small plant where there are

a comparatively small number of cranes, the crane operator should have entire charge of that crane; he should be charged with the responsibility of seeing that the crane is in good running condition, and he should know at any time of the day what the condition of his crane is. Good common sense on the part of the operator; that he is watchful; that he gets his night's rest; that he is alert and awake while he is in that cage: these are all very essential. A man who is awake in a cage and knows what he is doing, can make more money—(and it has been proven so time and time again) than a foreman on the floor, because in order to get out material, you must move those materials by machines.

CHAIRMAN OARTEL: I am sure this talk will furnish a very valuable contribution to our minutes, and that it will be very useful to refer to when any of you want to buy a crane.

Now have any of you any questions to ask Mr. Prakken?

#### DISCUSSION

MR. FRANK LABARRER (Carbon Steel Co.): Mr. Prakken has gone over this limit switch proposition very nicely and comprehensively. While I understand fully how it is operated for the upward motion, I do not understand how the contacts are made for the downward motion, when the switch is in operation.

MR. PRAKKEN: The down motion is not connected in any way with the limit switch. The contacts are made to the control, and then for lowering they are made through the controller. The limit switch only works in the upward direction.

MR. LABARRER: In connection with the progress along the lines of lever control, Mr. Prakken has mentioned there is a precautionary measure of covering some of the parts of the resistance as it was likely that the operator would be thrown against the contact points. Now I would like to know what progress is being made as to a centering device for this labor operation, so that if the operator falls, the lever comes to the center automatically?

MR. PRAKKEN: Mr. Labarrer, the centering device is usually a notch, and on the lever type I do not know of any device that is out, excepting some that require a man absolutely to bring it to one point and lock it there. It would require some heavy types of springs. There are springs that will throw the controllers off in places; that is in the cage, but we have not furnished any of them, I will admit. But on the floor control hoists, where the man is walking along a floor and is apt to stumble, with pendant ropes, the controllers are of the spring type. The instant you let go of a rope, the controller will throw itself off, irrespective of hoisting or traveling in either direction.

MR. LABARRER: Then you will admit it is a question for treatment?

MR. PRAKKEN: Yes sir.

MR. HOMER J. WEEKS (American Steel & Wire Co.): I should like to ask the speaker how many brakes he recommends on the hoist of a crane of 25-tons capacity and upward?

Maybe I can state that a little clearer in this way: The dynamic brake is simply a retarding brake; it doesn't hold the rod. Do you consider that one solenoid brake is sufficient in connection with the dynamic brake, or would you recommend putting on one brake on your armature shaft and one on your intermediate shaft?

MR. PRAKKEN: There are usually two brakes placed on a crane of high capacity: one on the intermediate shaft and one on the motor. In connection with that, the magnetic switch panel is almost always put in a cage.

MR. J. A. NORTHWOOD (Cambria Steel Co.): Due to some criticism sent in to general headquarters in Chicago regarding standard signals for crane, the headquarters asked Mr. Oartel, Chairman of the Metals Section, to appoint a committee to look into this matter. This committee was appointed, with Mr. H. K. Burgwin of the Crucible Steel Company as Chairman. The committee met and went over various standard crane signals and from that they have drafted a new schedule, which we wish to make a report on today. Mr. Burgwin was unable to be present and asked me if I would make this report.

A meeting was held in the office of the Chairman of the Metals Section, Carnegie Building, Pittsburgh, on Tuesday, August 31, 1920, at which the following schedule was adopted unanimously:

I am not going to take the time to read these various standards, and we only wish to send this to the headquarters office, where of course it will have to be approved by an official committee, but we would like to make this report at this time.

CHAIRMAN OARTEL: All right, Mr. Northwood, this will be referred to headquarters in the regular way, and they will refer it to the Safe Practices Committee, who will give their comment or criticism on it, and it will be handled by the new officers.

Our next topic is "Safe Practices in Blast Furnace Operation", and our speaker is Mr. L. A. Touzalin.

### SAFE PRACTICES IN BLAST FURNACE OPERATIONS

L. A. TOUZALIN. ASSISTANT SUPERINTENDENT BLAST FURNACES, SOUTH WORKS, ILLINOIS STEEL COMPANY, SOUTH CHICAGO

A description of safe practices in blast-furnace operations from an operating man's standpoint includes the consideration of safety devices and the best methods of promoting safety thinking. As a rule, the operator is not familiar with statistical details and you will, therefore, pardon me if my treatment of the subject neglects to a certain extent this side of the question.

When the "safety first" slogan was first seriously taken up by the industries of our country it was perfectly natural that the installation of safety devices should receive first attention. For several years such installations could not be carried on fast enough to meet the needs of the hour. In fact, the average operator's first definition of a safety inspector

would probably be "a pestiferous individual whose business it was to hound the operating departments with the everlasting question: 'When is the installation of such and such a safety device going to be completed?'" Comparatively little attention was paid to the study of the best methods for promoting "safety thinking." Prizes, buttons, bonuses, etc., were awarded to those who proposed the best safety devices to overcome well known serious mechanical hazards. Gradually as such safety devices came into more common use it became noticeable that while the diminution of accidents was very gratifying, it was, nevertheless, not in proportion to the installation of such equipment. It was then first realized that the concentration of effort in developing devices had possibly overshadowed and neglected to a certain extent the practice of teaching workmen to *think* safety. Developments during the last few years have made it more and more apparent that the greatest weapon for cutting down accidents is the instilling of safety thinking in the minds of the workmen. I believe that the majority of blast furnace superintendents would prefer to operate a plant having a well-trained *safety thinking* organization than a plant containing most of the up-to-the-minute safety devices known, with an organization indifferent to safety *thoughtfulness*.

Mr. McKenney, in his paper on Safety Committees, has discussed the methods employed by our various departments at South Chicago, to stimulate the thinking of safety in the minds of the workmen. As he has pointed out, the success which these methods may achieve depends, to a large extent, on the interest and co-operation of the men at the top, assistants and foremen. Blast-furnace executives can display this interest by frequently attending the meetings of their committees and by strongly enforcing the proper and continuous use of safety methods, rules, and equipment. If safety equipment is neglected and allowed to stand idle or out of repair, the workmen are not slow to infer that the term "safety first" is a catch phrase only, and not a high ideal, and token of appreciation of the value of human lives.

#### BLAST-FURNACE HAZARDS

The consideration of safe practices around blast-furnaces naturally hinges on blast-furnace hazards; for the greater the hazard the more intense should be the application of safety methods. If time permitted, it would be interesting to start at the docks, proceed through the stock house to the furnace tops, from the tops to the cast house, and from there to the pig machine, ladle house, etc., and trace the gradual development of safe practices and equipment to overcome hazards encountered at these points. In the limited time at our disposal, however, we must be content to dwell upon the most serious of these hazards only.

All blast-furnace men will undoubtedly agree that the most serious hazard in connection with the operation of iron blast-furnaces is the handling of blast-furnace gas. While it is true that the improvements made in blast-furnace construction and operating during the last ten years have largely reduced the necessity for workmen to come into contact with furnace gases, these very improvements, to a certain extent, have

made the gas more treacherous and dangerous to the operating crew should they come into contact with it. In the days of hand filling the top fillers were apt to consider a gas headache as a normal condition under which their work was to be done. The men were wont to boast as to their ability to "eat the gas." These men were brought down from the tops and scattered along the cast-house gangs by the replacement of hand filling by the automatic skip hoist. Shortly after this new development, the use of washers for cleaning the gas was inaugurated, and when these same "gas eaters" encountered their old friend in a cold, wet, and clean condition they received a severe shock. They suddenly discovered that their former boast of "knowing when they had enough gas" was no longer applicable. They had simply to take a whiff or two and Presto!—they were out of business. They failed to realize that the gas, which had formerly been fairly visible, hot and light enough to rise and diffuse rapidly, after being washed, had become practically invisible and odorless, and of such lower temperature and greater density that its presence was not apparent until it had made itself evident by its sudden effects. There was a period when several serious gas accidents were required to convince these old timers that a change had occurred in the properties of blast-furnace gas. It did not take long, however, to demonstrate to all concerned, that the only safe way to treat washed blast-furnace gas is to stay away from it.

#### WHEN A BANKED FURNACE RESUMES OPERATION

One of the greatest gas hazards is the seepage of gas through furnace walls, foundations, and surroundings whenever a banked furnace resumes operation. At such times gaseous areas will accumulate in most unexpected locations, and too much emphasis cannot be laid on the importance of the most rigid watchfulness at this time. At South Works our experiences during the past two years of alternate banking and "blowing up" have resulted in the following method of procedure under such conditions. Just before blowing up, two or three of our practice men are sent out to gather the men into groups and to explain that the furnace in question is about to resume operation. Each man is instructed to watch his fellow workmen. The Blower assigns a partner to each man whose presence somewhat near the furnace is necessary, and these men are instructed to watch each other for any symptoms of the effects of gas. Patrols, in pairs, are placed at safe distances from the furnace and at locations which will enable them to see and prevent any one approaching the furnace from any direction.

Many accidents have resulted and many lives have been lost by men working in a furnace or in its gas equipment when such furnace was out of blast and disconnected from other furnaces by water seal only. In unaccountable ways the water has been lost at the seal or violent slips on other furnaces have blown enough gas through the seal to cause serious trouble. The only positive means of preventing such accidents is the ironclad law prohibiting any individual or group of men, under ordinary operating conditions, from working at any location in a furnace, dust

catcher, washer, dryer, water seal, or any part of the furnace equipment where he is protected solely by a water seal. When such work is to be done the furnace in question should be protected by a plate or goggle valve. This positive means of protection becomes very simple if water seals with adjacent flanges for plate valves are installed just beyond the dust catcher and just before the clean gas main. At South Works each of our eleven furnaces is now so equipped and it is possible to shut off any individual furnace by first filling a water seal and then turning a goggle valve or inserting a plate on the dead side of this seal. Under extraordinary conditions, occasions may arise when it is necessary to send a man into a place protected by a water seal only, but in such cases the man doing the work should either wear a gas helmet, or where impossible to enter so equipped, should have a life line securely tied about himself, and extended to a safe location outside of the manhole.

The ordinary manhole provided in dust catchers, washers, gas mains, etc., is of such size that a man under normal conditions can just about squeeze through. It is an exceedingly difficult task to get a man through the hole if he is in a partial or completely unconscious condition. In all future construction man-holes should be made large enough to admit freely a man fully equipped with a gas helmet apparatus.

Provision is made on all of our furnaces for inserting a goggle or plate valve in the main when a furnace is to be relined, banked or down for repairs, as mentioned above. In some cases, however, the necessity might arise for repairs to be made at some point in our gas main where such provision cannot be made. In such a case, when men are working behind a water seal only, it is our practice to have the water seal carefully inspected regularly, the inlet and overflow outlet, water valves locked with safety locks, and the bottom discharge valve securely blocked or locked. We believe that these precautions carefully followed will adequately protect men while working in such locations. Where provision is made, it is our practice to insert the goggle valve or plate when men are going in a main, and to have the water seal also full as an extra precaution.

#### INSPECTION AND CARE OF BREATHING APPARATUS EQUIPMENT

From a safety as well as an operating standpoint every blast furnace plant should have an up-to-date, self-contained, breathing apparatus equipment, but it must be borne in mind that the most efficient gas helmets made are only safe when they receive constant attention in keeping up the equipment and when worn by men who have been thoroughly trained until they feel absolutely familiar with the apparatus. The responsibility for maintaining our gas helmets in first-class condition was at first put up to certain men in each branch of the department, but this plan did not prove a success and for the last two years we have had one man whose sole duty it was to keep our 21 gas helmets in first-class usable condition at all times, and to take charge of training our helmet squads. Our breathing apparatus is housed in wooden cabinets with glass panel doors. These cabinets are of sufficient size to allow each set of apparatus to be hung at the height of a man's shoulders. They were designed with

two purposes in view. First, to make the apparatus accessible and ready for instant use or inspection. Second, to protect the apparatus from dust. The apparatus is hung completely assembled with the exception of potash cartridges, which are kept on a shelf immediately above the helmet. When a man desires to use a helmet for relief or emergency work, he inserts a new potash cartridge and, after putting on the apparatus, tests it thoroughly for leaks. If he desires to put on the helmet for practice work only, he uses a potash cartridge which has been previously used for this purpose, and is sealed with rubber stoppers. Our helmet man systematically inspects each helmet once a week. If the helmet is in first-class working condition he attaches a seal, and should this seal be found broken at any time it is an indication that the helmet has been in use since his last inspection. A written report is filled out after each inspection and a copy submitted to the Assistant Superintendent in charge of that particular department.

Before the World War it was difficult to instill confidence of the workmen in gas helmets but the trench helmets used for gases other than carbon monoxide received so much publicity in our newspapers during the war that men have lost, to a great extent, their fear of them. Each of our departments has a helmet squad consisting of men who have been examined by the Company physician and thoroughly trained in the use of the equipment of our helmet man. This squad is made up of day and night men and at least three are always on the job on either day or night turn at each group of furnaces. A siren whistle is blown in case of any gas emergency and all helmet men immediately proceed to the nearest helmet station and prepare to enter the gaseous area. Drills are frequently held, and several times during the past year certain men in the relief squad have been told to hurry to the office, get on a helmet and rescue a man from the bustle pipe of a furnace. When the relief man arrives at the bustle pipe he finds the foreman lying down beside a bag of sand. The foreman then directs him to lower the bag carefully to the ground. The best record made so far is a total of  $5\frac{1}{2}$  minutes from the time the man started to the office for his helmet, until the bag of sand touched the ground below the bustle pipe. The furnace in question was located about 500 feet from the office.

One of the most recent developments in appliances to assist in overcoming the hazards of blast-furnace gas is the appearance of a new carbon monoxide detector, which I note will be discussed by a later speaker. It may be stated that should this instrument be found practical and positive it will fill a long-felt want in blast-furnace practice.

#### HOT METAL AND CINDER BURNS

Considering the next serious hazard after gas, we come to hot metal and cinder burns. Here again emphasis must be laid on the importance of safety thinking. And a safety-thinking workman thinks for the other fellow as well as for himself. The best evidence of safety thoughtfulness in an organization is the care and advice which older furnace men bestow on new employees in regard to safety precautions. In these days of

great labor turnover this lack of watchfulness of the older men over the less experienced may be the cause of many accidents.

Several devices have been brought into use during the last few years to counteract the hazard of burns around blast-furnaces. Among the most important of these may be mentioned the Bates Cinder Notch Stopper, the Berg Automatic Mud Gun and the Mullin Tapping Machine. At South Works we are at present installing the Bates cinder notch stopper on our furnaces as they are relined, and our experience with this device so far promises good results. Like all new equipment, it will require months of use to obtain the confidence and appreciation of the men. Insistence is often required to establish the routine use of a safety device, which, once established, is henceforth an absolute necessity. We have not as yet had experience with the mud gun and tapping machine, mentioned above, but have heard some recommendations and some criticism of both. Two devices which have recently been put into use in our plant and which tend to cut down burns from splashing and sparking at the iron notch are a chain screen which is lowered in front of the hole at the end of the cast and through which the mud gun muzzle is inserted to stop the hole, and a splasher plate which is raised above the trough, and swung away from the hole at the end of the cast, by one man, operating a hand wheel, at a safe distance from the furnace.

The keeper, first helper, and cinder snapper of each furnace are required to wear safety leggings whenever the iron or cinder is running, i. e., at flushes or casts. These leggings were unsatisfactory as originally purchased on the market, but with some few changes to make them lighter and more flexible are now well thought of, and freely used, by our furnace men. Wire masks are sometimes used by the keepers when they close up the hole. These do not impede the vision and are preferred by our men over goggles. Two other devices which tend to cut down burns in our cast houses may be touched upon. One is the arrangement of sheaves and cables which are used to pull all shutters from a safe distance, thus making it possible for the man doing this to keep out of range of sparks or shots of iron. The other is the heavy cast-iron bridges which are conveniently located at several points along the iron and cinder runners. These bridges make it possible to cross the runner without danger of stepping or falling into the stream of molten metal or cinder.

#### MECHANICAL HAZARDS

Taking up next the mechanical hazards, the skip hoist undoubtedly stands first as the source of accidents. It is true that the use of safety locks, rigidly enforced, has done much to overcome the great element of danger due to the possibility of men being run over, crushed, or caught by moving parts, but in spite of this safeguard, near accidents have demonstrated the necessity for some method of quick control to check the movement of the skips, should a man be found to be in danger. In order to take care of this condition we have installed safety switches, readily accessible to any one standing at the side of the skip pit; so that by simply throwing a switch the power is cut off, and brakes automatically applied to the hoisting machinery.

As our furnaces are relined all skip inclines are covered, on the bottom and sides, with steel plates to prevent injury to those below from falling material.

Owing to the compact construction of stock houses, serious collisions have occurred between scale cars where one car happened to be stationary under breakdown repairs, and the other operating. Men working under the stationary car have been injured from the resulting shock. In order to prevent such occurrences, our stock houses are provided with suitable skids which are placed on the rails at a safe distance from each end of a car under repairs to protect same.

The usual form of snorting valve used to by-pass the cold blast into the atmosphere, when it is desired to take the wind off the furnace; and the blow-off valves, which are operated to release the pressure from stoves taken off the furnace and put on gas, have given blast-furnace plants the reputation of being the greatest noise producers in steel mills. It is safe to predict that within the next few years blast-furnace plants will be operating as silently as any other department of the mills. Patent blow-off valves are now on the market which permit the discharge of air from three-pass stoves to be directed into the stacks. The muffling of two and four pass stoves is easily accomplished by connecting the blow-off valve directly to the draft flue. The snort valve may be muffled in the same way; i. e., by connecting the outlet to the draft flue. Both of these plans are at present in use at South Chicago and we believe that the elimination of these violent noises is conducive to greater safety to the operating force; not to mention the prevention of partial or complete deafness to the man whose duty it is to operate these valves.

The above items are the most important of a vast number of improvements and safe practices, or devices, which have been brought forward during the last decade. Statistics show the wonderful results of the continuous efforts being made to safeguard human lives in this field of industry, and there is no reason why this progress should not continue until blast furnace accidents closely approach the irreducible minimum. It is certainly true that the reward, in the satisfaction that lives have been conserved and suffering greatly alleviated, is sufficient to justify the efforts required to maintain eternal vigilance in the daily routine of the manufacture of iron, the master metal.

CHAIRMAN OARTEL: Are there any questions you wish to ask Mr. Touzalin; or is there any discussion?

I just wish to state that the CO Detector will not be demonstrated today; it will be demonstrated tomorrow, as we are putting on our practical demonstration of the investigation of an accident today, just immediately following this.

With your kind indulgence while we shift a little scenery, we will put on the demonstration. Before putting it on, I would just like to make an announcement in regard to it. You remember at the Metals Section meeting at Cleveland last year Mr. H. J. Weeks, of the American Steel & Wire Company, staged a Court of Inquiry, which met with so much favor on the part of those in attendance, that your officers decided

to put on something along the same line this year, and so we had prepared by Mr. J. R. Mulligan, of the Bethlehem Steel Company, this practical demonstration of the investigation of an accident. You will see on the stage, when the curtain is drawn, a machine shop office, with all the equipment. The characters I wish you to note, which we are trying to emphasize, are two foremen, William Light, who is a Twentieth Century foreman, and his treatment of a new employee. The other is Samuel Stone, an old-time foreman, and his treatment of the new employee is very different.

## FIXING THE RESPONSIBILITY FOR AN ACCIDENT

### A SKETCH

PREPARED BY J. R. MULLIGAN, SUPERVISOR, ACCIDENT PREVENTION AND EDUCATION, BETHLEHEM STEEL COMPANY, BETHLEHEM, PA.

#### CAST OF CHARACTERS

1. William Light, A 20th Century Foreman, George T. Fonda
2. Sam Stone, Foreman, "An Old Timer," W. E. Watters
3. George Brown, A Guide Boy from the Employment Office, D. P. Kennedy
4. Frank Cole, A Bench Worker in the Machine Shop, V. A. Lewandowski
5. James Smith, A Bench Worker in the Machine Shop (Also a member of the Shop Safety Committee), J. A. Northwood.
6. Leo Wise, A Shop Clerk, J. H. Jeffery
7. Thomas White, Operator of Lathe No. 2 in the Machine Shop, F. A. Nilles
8. Harry James, a New Employee, W. E. Megraw
9. Roy Lang, a New Employee, J. R. Mulligan
10. Charles Metz, A Plant Safety Inspector, H. E. Steinmetz
11. John Telford, Superintendent of the Machine Shop, J. A. Oartel.

#### PART I

#### SCENE FURNISHINGS

A combination office-workroom in the machine shop.

A work bench with vise and hand tools, emery wheel in operation, foreman's desk, table with blue prints, First-aid kit, safety signs, telephone, chairs, etc. (Arranged as per sketch.)

#### ACT I

Frank Cole and James Smith at work at bench.

William Light, foreman, writing at desk.

Enter at Door "A"—George Brown, a guide boy from the Employment Office, accompanied by Harry James, a new employee. Foreman Light

arises from his desk and steps forward to meet them, Brown introduces James to Foreman Light who shakes hands with the new employee and gives him a hearty welcome to the shop. Light questions new employee as to his former machine shop experience, then introduces him to Cole and Smith at work bench (both greet the new employee warmly and tell him they will be glad to help him in any way possible). Light gives James a Safety talk on the general hazards of a machine shop, presents him with a pair of goggles, takes him over to the emery wheel, puts on the goggles and shows him how to hold a tool or job when grinding, tells him of the necessity of wearing goggles when grinding and in all other cases where flying particles are liable to strike the eye. Light tells James of the necessity of keeping tools in good shape as "mush head" tools are both inefficient and dangerous to the user. Light gives the new employee instructions about punching time card, starting and quitting time, lunch hour, tool room, toilet facilities, etc. Tells new employee to come to him for any information he needs, that he will be glad to help him in any way possible. Foreman Light now selects a blueprint from table and accompanied by James exits at door "B" into machine shop proper where he assigns James to work on lathe No. 1. After introducing him to Thomas White, operator of Lathe No. 2. (As the new employee passes Cole and Smith at the work bench, they wave to him and both say "Good luck.") Smith and Cole converse at work bench after which Smith puts on goggles and grinds tool at emery wheel. Foreman Light enters at door "B," he is accosted by Cole as he passes the work bench, who questions him about the work. Light replies in a very cheerful spirit and then passes on to his desk. Smith finishes grinding at the emery wheel and resumes work at the bench.

Enter new employee, James, at door B, stops at work bench and shows "Mush head" tool to Smith and Cole, tells them he is going to take Foreman Light's advice and keep his tools in safe condition. Passes on to emery wheel, puts on his goggles, grinds tool, finishes and exits at door B.

CURTAIN

PART II ACT II

(Scene and furnishing same as in Act I.)

Cole and Smith at work at bench.

(Foreman Stone sits writing at desk.)

Stone arises from desk and goes over to work bench, finds fault with the work of Smith who shows Stone that his work is done according to the blueprint. (Smith and Cole show that they resent the attitude of Stone and also that they are afraid of him.) Stone gives a tirade against what he terms "Sunday School Management" and concludes with the statement that he will not brook interference from any one and that he will run his department as he "Damn pleases." Stone resumes seat at desk and writes.

Enter Brown guide boy at door "A" accompanied by Roy Lang, a new employee. They both advance to center of room. Stone scowls at them

from desk and resumes writing, keeping them waiting three minutes. Stone finally arises and starts toward exit B, is accosted by Brown who introduces Lang to him. Stone does not acknowledge the introduction but snatches the employment card from Lang's hand and scowls at him as much as to say "What the —— are you doing here." Stone looks at card and with evident incivility, questions Lang as to his previous machine shop experience, questions the veracity of Lang's replies. Finally Stone snatches a blueprint from table, hands blueprint to Lang, roughly pushes Lang toward door B and following Lang to door points to Lathe No. 1, in machine shop and tells Lang "Get to work."

As Stone returns from door B he is questioned by Cole as to a detail of his work. Stone gives a very uncivil reply and passing on resumes seat at his desk and writes.

(Cole and Smith converse and shake hands.)

Enter shop clerk, Leo Wise at door A. Papers in hand, advances to Stone's desk, seeking information as to finished material. Stone gives uncivil reply, swears, arises as if to throw Wise out of the office. Exit Wise hurriedly. Stone gives another tirade on present "Red tape" methods as compared with "Old time" methods and then resumes writing.

Enter Roy Lang at door B with tool in hand for grinding, advances three steps in room and looks toward Cole and Smith, hesitates as though he would like to have information but is reluctant to ask for same from men he does not know. Advances to center of room, hesitates and looks toward foreman who is writing at desk, looks about and sees emery wheel, takes one step toward it, again hesitates and looks toward workmen and then toward foreman. Finally Lang advances to emery wheel. (As he does so foreman Stone turns around, notes Lang's going to the emery wheel, and then resumes writing.)

#### THE ACCIDENT RESULTING IN THE LOSS OF LANG'S RIGHT EYE

Lang looks about emery wheel as if looking for something. Not finding it, hesitates, looks across room toward Stone, again hesitates, and then with evident reluctance starts to grind tool on emery wheel. Grinds tool for about one minute, then drops tool to floor, covers face with hands and shrieks "My eye, my eye," staggers and falls to floor. Smith and Cole rush to his assistance, raise him from the floor and seat him on a chair. Smith gets First-aid kit and prepares to give First-aid, examines Lang's injury, then rushes to shop telephone and summons the Plant ambulance, returns to assist Cole in applying bandage to Lang's eye. In the meantime Stone arises leisurely from his chair, advances toward the group and says, "What's the matter with him?" Cole replies, "He didn't wear goggles and he got binged in the eye by a chip from the emery wheel." Stone replies "He told me he was an experienced mechanic, and if he was, he should know how to use an emery wheel without getting chips in his eyes. Anyhow, I told him to wear goggles, if they are of any use. I worked twenty years without them and I have two eyes yet."

In the meantime Smith and Cole have dressed and bandaged Lang's injured eye. Lang groans with pain, and keeps repeating "How can I

work at my trade if I lose my eye, what will become of my family." Smith, the shop Safety Committeeman quiets him and questions him as to how the accident happened. Lang, between spasms of pain replies as follows: "No one told me where I could get goggles and I didn't want to bother you fellows to find out. I thought I should wear goggles but when a boss is as grouchy as he is and me just hired I didn't want to have him get sore on me. I wasn't going to ask him if I was supposed to wear them nor where I could get them."

Safety Inspector Metz arrives with ambulance at this point (entering at door A). Metz questions Lang as to the cause of the accident. Lang replies repeating statement given to Committeeman Smith. Smith and ambulance driver help Lang to the ambulance through door A. Cole resumes work at bench. Metz, remaining, questions Foreman Stone as to whether he warned Lang of the general accident hazards of the machine shop, whether he supplied Lang with a pair of goggles and told him to use them especially when grinding on the emery wheel. Stone evades answering Metz's direct questions but replies as follows, "If Lang was an experienced machinist he should know the hazards of a machine shop, but I told him to wear goggles." (Smith, returning through door A, hears the latter part of Stone's reply and shakes his head.) Stone resumes seat at desk. Metz moves over to the work bench and questions Smith and Cole, making notes of their replies. Metz then passes into machine shop through door B to get the evidence of Thomas White, Operator of Lathe No. 2.

#### CURTAIN

### PART III—ACT III

#### FIXING THE RESPONSIBILITY OF THE ACCIDENT

##### HEARING THE EVIDENCE

|                                            |                           |
|--------------------------------------------|---------------------------|
| The Shop Safety Committee                  | The Witnesses             |
| John Telford, Shop Sup't, Chairman.....    | George Brown, Guide Boy   |
| James Smith, Bench Workman, Sec'y.....     | Frank Cole, Bench Workman |
| Thomas White, Operator of Lathe No. 2..... | James Smith               |
| William Light, Foreman.....                | Thomas White              |
| Sam Stone, Foreman.....                    | Sam Stone                 |
| Charles Metz, Plant Safety Inspector       |                           |

CHAIRMAN TELFORD: Our Safety Committee meets this morning to hear the evidence and fix the responsibility for the unfortunate accident which happened in this department yesterday morning. This accident happened to Roy Lang, a new employee, while using an emery wheel and as a result I am informed, Lang will lose his right eye.

We will first hear the reading of the written reports of investigators as to cause, or circumstances bearing on this accident. I will now call on Foreman Stone to read his report. Stone reads as follows:

Machine Shop Dept., Sept. 29, 1920.

This man, Roy Lang, was struck in the eye by a flying chip, while a new employee who was fully instructed by me as to his duties in the shop, including the wearing of goggles.

(Signed) Sam Stone, Foreman.

CHAIRMAN TELFORD: We will now hear Safety Committeemen Smith's report. Smith reads as follow:

Machine Shop Dept., Sept. 29, 1920.

Accident Case 13:

Roy Lang, a new employee, started work in this department September 29 at 7:30 A. M., injured September 29, 7:50 A. M. Roy Lang struck in the eye by a flying chip from a tool which he was grinding on the emery wheel in the machine shop. Lang was a new employee and was injured 20 minutes after starting work. He was not wearing goggles at the time of the accident as required by the Safety rules of this company in using an emery wheel. While giving First-aid to Lang immediately after the accident he made the following statement to me in the presence of Frank Cole, of this department, "No one told me where I could get goggles and I didn't want to bother you fellows to find out. I thought I should wear goggles but when a boss is a grouch and me just hired I didn't want him to get sore on me. I wasn't going to ask him if I was supposed to wear goggles nor where I could get them. I didn't see any goggles about the wheel and thought I'd take a chance." From my own personal knowledge and also the evidence of other employees in the shop who had any knowledge of the circumstances bearing on this accident, I believe Lang's statement of the circumstances leading up to this accident to be true and correct.

(Signed) James Smith,

Machine Shop Safety Committee.

CHAIRMAN TELFORD: We will hear Safety Inspector Metz's report.

INSPECTOR METZ: That part of my written report bearing on the immediate cause of the accident which will result in the loss of Lang's right eye, agrees exactly with Lang's statement as just read by Mr. Smith. This statement was also made to me by Lang shortly after the accident. I called on Lang at the hospital this morning and he again repeated the cause of the accident agreeing in full detail with his original statement as made to Mr. Smith and also to myself.

(Reads)—I further find upon a complete investigation of all the circumstances connected with this accident the following facts for your consideration:

1. That Lang was not properly received as a new employee should be by Foreman Stone of this department.
2. That Lang was not introduced to near-by employees by Foreman Stone as is the rule and custom in this plant.
3. That Lang was not made acquainted with the general shop rules and regulations by Foreman Stone as is required in this plant before assigning new employees to work.
4. That Lang was not instructed by Foreman Stone as to the general

accident hazards of the machine shop and particularly that Foreman Stone did not present Lang with a pair of goggles, as is the rule and custom in this shop in case of all new employees; that Foreman Stone did not give particular instructions as to the required use of goggles on specified classes of work in the machine shop and especially that Foreman Stone did not instruct Lang that goggles must be worn on all emery wheel work as a direct result of which Lang will lose his right eye.

5. That Lang was not properly assigned to his work on Lathe No. 1. by Foreman Stone. Necessary both to Lang's efficiency and his safety.
6. That Foreman Stone's attitude toward the new employee, Lang, was of such a nature as to give Lang a FRAME OF MIND—in which condition he was especially susceptible to accident.

All of which I submit as result of my investigation as to the cause of this accident and to substantiate my conclusions, as above stated, I have summoned the following employees as witnesses in this case:

George Brown, Guide Boy  
Frank Cole, Bench Workman  
James Smith, Bench Workman  
Thomas White, Operator Lathe No. 2.  
(Signed) Charles Metz,  
Plant Safety Inspector.

CHAIRMAN TELFORD: Before hearing the witnesses summoned by Safety Inspector Metz, I wish to give Foreman Stone an opportunity to make any statement or ask any question he may see fit, now that he has heard the reading of the accident investigation reports. Foreman Stone, you have the floor.

FOREMAN STONE: Nothing to say.

CHAIRMAN TELFORD: We will hear the witnesses in order as named by Inspector Metz and I will call George Brown as the first witness.

Chairman Telford questions and Brown answers:

QUESTION: George, what are your duties?

ANSWER: To guide the new men from the Employment Office to the department where they are to work and to introduce the new men to the boss.

QUESTION: Did you guide Roy Lang to this department yesterday?

ANSWER: I did.

QUESTION: Did you introduce Lang to Foreman Stone?

ANSWER: I did, but Foreman Stone took no notice of it.

QUESTION: Didn't Foreman Stone shake hands with Lang?

ANSWER: Not much!

QUESTION: He didn't welcome Lang to the shop?

ANSWER: About as much as he would a case of Small Pox!

QUESTION: What did Foreman Stone do when you presented Lang to him?

ANSWER: He jerked the Employment Card out of Lang's hand and asked him some questions about where he worked before, he then took

Lang to the door over there and told him to "Get to work." I went back to the Employment Office.

QUESTION: Did you hear all of the conversation between Foreman Stone and Lang?

ANSWER: I did.

QUESTION: What time elapsed between the time Foreman Stone took the card from Lang's hand and his telling him to "Get to Work?"

ANSWER: From two to three minutes.

QUESTION: Did Foreman Stone introduce Lang to any of the men here in the shop?

ANSWER: No, sir.

QUESTION: Did foreman Stone explain anything to Lang about the rules of the shop or about the work he was to do?

ANSWER: No, sir.

QUESTION: Did Foreman Stone give Lang a pair of goggles as required by the shop rules, or say anything to him about the necessity of goggles on dangerous classes of work?

ANSWER: \* He did not give Lang a pair of goggles, neither did he say anything to him about wearing goggles.

CHAIRMAN TELFORD: That will do, George. Frank Cole is the next witness.

QUESTION: Frank, what do you know of this accident?

ANSWER: I do not know anything other than the evidence given by George Brown. I agree with all that he has said except that I could not hear the conversation between Foreman Stone and Roy Lang. I did hear Foreman Stone tell Lang to "Get to work."

QUESTION: Were you present here in the shop and in a position to see all that transpired between Foreman Stone and Lang?

ANSWER: I was present and saw all that happened.

QUESTION: How long did Stone and Lang converse before Lang was told to get to work?

ANSWER: I judge between two and three minutes.

CHAIRMAN TELFORD: That will do, James. Thomas White is the next witness.

QUESTION: James, what knowledge do you have of the circumstances connected with this accident, other than related in your written report.

ANSWER: My knowledge of the circumstances other than given in my written report agrees exactly with the evidence just given by Frank Cole. I work beside him and saw everything that happened in this case as he saw it.

CHAIRMAN TELFORD: That will do, James. Thomas White is the next witness.

QUESTION: Thomas, what is your occupation?

ANSWER: I am on Lathe No. 2.

QUESTION: How far is your lathe from Lathe No. 1?

ANSWER: About fifteen feet.

QUESTION: Tell what you know of the injured man, Lang, starting to work on Lathe No. 1 yesterday morning.

ANSWER: I happened to be looking toward the door at the time and as I did the boss and the injured man appeared in the doorway. I saw the boss point to Lathe No. 1 and saw the injured man start toward it.

QUESTION: Did Foreman Stone accompany Lang to the lathe?

ANSWER: No, sir.

QUESTION: Did Foreman Stone appear at Lathe No. 1 at any time previous to Lang's being injured?

ANSWER: No, sir.

QUESTION: How long was Lang at Lathe No. 1 before going out to grind the tool?

ANSWER: About 15 to 20 minutes.

QUESTION: How did Lang act while at Lathe No. 1, did you notice anything particular?

ANSWER: Yes, he was in a daze, as though something was bothering him, and couldn't get his mind set on his work.

QUESTION: Why didn't you go over to help him?

ANSWER: I would have but the boss won't allow it.

CHAIRMAN TELFORD: That will do, Thomas. Inspector Metz, do you have anything further to offer in this case?

INSPECTOR METZ: Nothing, sir.

CHAIRMAN TELFORD: Foreman Stone you have heard the evidence of the witnesses summoned by Inspector Metz. You now have the opportunity to question or cross examine the witnesses or make any statement you may see fit.

FOREMAN STONE: I have nothing to say.

CHAIRMAN TELFORD: Inspector Metz, what is the accident record of the Machine shop department for the year to date?

INSPECTOR METZ: It depends upon the foreman in charge. Under Foreman Light the accident record of the machine shop is one of the very best in the plant, with but one slight accident this year to date. Under Foreman Stone the accident record of the Machine shop department is one of the worst in the plant with a total of 12 lost-time accidents for this year to date, several of which were quite serious involving lost members.

CHAIRMAN TELFORD: This will conclude the evidence in this case. Do any of the members of the Safety Committee have any questions to ask? (Pause.)

CHAIRMAN TELFORD: Gentlemen, you have heard the reading of the written reports and the verbal evidence of all the witnesses who had any knowledge whatever of any of the circumstances leading up to this unfortunate and preventable accident, through which Roy Lang lost his right eye.

It is now our duty as the Safety Committee of this department to weigh the evidence in the case and place the responsibility for this accident exactly where it belongs without fear or favor, and in this connection I wish to assure you that as Superintendent of this department I fully recognize and fully accept the great responsibility that rests upon me to do everything possible on my part to prevent accidents to my men, to

make the shop not only a safe place but also, as far as possible, a pleasant place where men may work. To seek to achieve that spirit of good fellowship and co-operation between management and men so necessary to the mutual advantage of both parties in this twentieth century struggle.

CHAIRMAN TELFORD: (Briefly develops the following):

- A. The Foreman's responsibility in Accident Prevention
- B. The Twentieth Century Foreman vs. the Old Timer
- C. Our obligations to the new employee. The least we owe a man seeking employment is common courtesy man to man. (Develops the evidence in the case step by step by contrast.)
  - 1. The Foreman's reception of the new employee who is a stranger to his surroundings vs. Stone's reception of the new man.
  - 2. Instruction as to shop rules and facilities vs. Stone's lack of instructions.
  - 3. Safety instruction, general.
    - Safety instruction, particular vs. Stone's lack of instructions. Goggles and their use. (The new man six times more liable to injury than the old employee.) (In a large Steel Plant covering a four year period, 75 per cent of all eyes lost were on operations on which goggles should have been worn.)
  - 4. Introduction of new man to near-by workers, vs. Stone's failure to introduce new man.
  - 5. General instruction on machine to which worker is assigned, vs. Stone's lack of instruction.
  - 6. Stone's personal attitude toward Lang.

Gentlemen, the evidence in the case is direct and conclusive. Inspector Metz's charges have been clearly proven in every detail. As members of this Safety Committee, I am sure we are all of one mind as to where the responsibility for this accident should be placed and it remains for me as Superintendent of this department to pass judgment. Samuel Stone, you are directly responsible for the accident resulting in the loss of Roy Lang's right eye. Neither this department nor this company can longer afford to continue the service of a man of your type. You are discharged from the service of the company to take effect at once.

FINIS

ADJOURNMENT.

#### FRIDAY MORNING SESSION

CHAIRMAN OARTEL: We will first have the report of the Nominating Committee.

#### REPORT OF NOMINATING COMMITTEE

MR. W. C. TITUS: The Nominating Committee begs to present the following nominees:

For Chairman, Mr. W. E. Watters, National Malleable Castings Co.

For Vice-Chairman, M. J. A. Northwood, Cambria Steel Company.

For Secretary, Mr. J. R. Mulligan, Bethlehem Steel Co.

(These men were elected.)

CHAIRMAN OARTEL: I am very sorry that Mr. Watters is indisposed and not able to be here. The Vice-Chairman, Mr. Northwood, is present, but has requested me to continue with the program.

At our convention in Cleveland there was some discussion about giving prizes or bonuses as an inducement to safety and the thought appealed so much to the officers, in making up their program, that they thought it would be a good idea to put it on and thresh it out; so we invited Mr. J. C. Smith of the Inland Steel Company, and Mr. Philip Strémmel of the National Enameling and Stamping Company, who both voiced their opinions last year, to prepare papers on the subject, and we asked Dr. Chaney of the Department of Labor at Washington to sum it up. So we will first listen to Mr. Smith.

## PRIZE AND BONUS SYSTEMS IN SAFETY WORK

J. CLAUDE SMITH, INLAND STEEL COMPANY, INDIANA HARBOR, IND.

Statistics gathered through many years have indicated that approximately not more than twenty-five per cent of all accidents are preventable through the use of guards and safety devices. After the dangerous conditions in an industrial works have been safeguarded it is usually found that not more than from one to two per cent of the accidents that occur may be charged to lack of safeguards. Realizing these facts it becomes readily apparent that about ninety-eight to ninety-nine per cent of all the accidents that occur are concerned with the human element in the organization.

A further analysis of the statistics will probably reveal in most industries that approximately fifty per cent of the accidents may be charged to the hazards of the industry and fifty per cent to the negligence of the workers, although as a matter of fact these are more or less arbitrary figures. However, it must be admitted that all accidents that occur are preventable through care and caution on the part of those injured, their fellow workers, and the operating officials. It therefore appears that the problem of the prevention of accidents is to sell safety to the organization.

The solution of the selling problem is accomplished through education carried on in every possible way to stimulate the interest and secure the co-operation of all employees.

One of the most effective educational mediums through which to advertise safety and to reach the workers is through a prize system. The advantages of such a system are:

1. It can reach all employees in the organization.
2. It can be used to advertise safety in a most effective manner.
3. It will stimulate interest on the part of the workers in accident prevention activities.

- a. By causing employees to read their rule books and to pass an examination as to knowledge of the safety rules.
  - b. It will reward employees for sending in suggestions to prevent accidents thus causing them to look for dangerous conditions and correct them.
  - c. Group action and interest can be secured by awarding prizes to departments or divisions by prize systems.
4. The prizes if properly selected build up a company spirit through the wearing of same by many employees.
  5. The winners of prizes receive acknowledgment and reward for their special interest and co-operation and this inspires others to make a real effort to assist in preventing accidents.
  6. A cumulative psychological effect is secured which has a real value in the success of all branches of the industrial safety movement.

Bearing these reasons for the awarding of prizes in mind it is most important that the prizes be most carefully selected. It is my opinion that any prize given should be practical and useful, having a permanent value. Its value as an advertising medium should also be most carefully considered. Presuming that a safety emblem has been adopted by the company this emblem should appear on all prizes that are awarded. It also seems to me that the emblem should represent and signify safety.

#### SAFETY SERVICE MEDAL

One of the most popular and practical prizes ever given out is the safety watch fob. At the Inland Steel Company's works we call it safety service medal. This medal is given to all employees who are in the service of the company at least six months who pass an examination on the safety rules and who avoid causing accidents to themselves or others which cause a loss of time during a period of six months. The safety lapel button or pencil clip is an attractive award used in getting new employees to read the safety rules and pass an examination within ten days after being employed. Working these prize stunts in co-operation with the foreman who is encouraged to insist that each man in his gang either has a safety lapel button or a safety service medal goes a long way toward training and educating employees to prevent accidents. A card is given to each new employee describing these prizes at the time he is employed at the Employment Office.

Several thousand safety service medals have been given out at the Harbor Works of the Inland Steel Company and men wearing these medals stand out as the best men in the employment of the company. It is amusing and yet significant to observe how highly these medals are valued by the workers including those who can speak only a little English. They will come in the office and ask for chain watches and point out what they want. When they get it they tell their friends about it and they come flocking to the safety office in their spare time and so spreads throughout the works.

Prizes for all employees in departments for accident prevention records attained or in competition with other departments stimulates interest.

and enables a very effective accident prevention campaign to be successfully put across. The prizes may consist of tooth brushes, pocket dictionaries, collapsible drinking cups, cloth caps, pocket combs, match cases, pocket mirrors, fly swatters, ash trays, knife sharpeners, tie clasps, cuff buttons, tie pins, etc.

#### PRIZE WATCHES TO FOREMEN

The foremen in the departments can be stimulated to renewed efforts through the awarding of prize watches to foremen obtaining the best results, eliminating each foreman as he wins a watch but retaining his interest by encouraging him to assist the other foremen and penalizing each foreman who has a serious accident by placing him at the foot of the list. This plan gives superintendents and foremen a chance to win safety watches and helps to secure greater co-operation on their part.

It is necessary to have variety in carrying on accident prevention campaigns of this kind as the same stunts tried too many times fail to maintain interest and therefore it is up to the safety director to figure out new prizes and new plans to keep up interest at all times.

A stunt which has been worked out successfully at the Indiana Harbor Works of the Inland Steel Company in departments where special effort seems to be needed to reduce accidents is the "Safety Gold Watch Raffle Contest."

#### SAFETY GOLD WATCH RAFFLE CONTEST

This contest is based upon the department getting through a month without having any accidents causing a loss of time. Each man in the department is seen by the "Plant Preacher" from the Safety Office and is talked to by him about safety and what it means to the workers and is given a chance of getting a gold watch provided the department gets through the month without having any lost-time accidents. His co-operation is thus secured and his interest aroused by the chance he has to get the watch and by the record which his department achieves if no one is injured. He thus takes a very active interest in preventing accidents. The coupon or card which he receives is numbered and is carefully prepared to retain his interest in preventing accidents.

If the department gets through the month without having an accident causing a loss of time a public raffle is held and the gold watch is given to the man having the lucky number. Advantage is taken of this occasion to deliver a short safety lecture to the assembled workers by the superintendent, foreman, or the safety director. In large departments this contest can be so arranged that the various natural divisions are considered separately and if one division has a lost-time accident they are eliminated from the contest. By such an arrangement continued interest is sustained throughout the month.

#### TAKE PHOTOGRAPHS OF THE MEN

Another method of reaching the men and preventing accidents that has been successful is the stunt of rewarding departments that get

through the month without having any lost-time accidents by taking a photograph of the men in the department and giving one of these photographs mounted on an 11 x 14 card to each employee. On the back of each picture is attached a letter of congratulation and encouragement from the safety director.

All of the workers greatly appreciate these photographs of their fellow workers in which their own faces appear and set a high value on them. These photographs are also published in the monthly Safety publication giving publicity and due credit to the department and encouraging others to cut out accidents and receive photographs. The photographs are usually given out at noon when the men are eating lunch or a special time is appointed to get the men together and safety talks are given by the foremen or safety director.

#### PRIZES FOR SUGGESTIONS

Suggestions from the workers throughout the entire plant can be greatly stimulated by offering prizes for suggestions to prevent accidents. These prizes should preferably be awarded monthly and the names of the winners should be announced in the safety publication together with a halftone showing illustration of the several prizes to be awarded and the rules governing the awarding of same.

#### COST OF THE SYSTEM

The cost of prize or bonus systems can be limited to almost any specified amount but if practical results are to be obtained it should be fairly liberal. In a works employing several thousand men the cost will be approximately from one hundred to two hundred dollars a month for a fairly liberal system.

The number of prizes to be awarded will depend on the size of the organization. A fairly good rule is one prize for each five hundred employees.

All suggestions should preferably be turned in direct to the Safety Department either through Suggestion Boxes placed near the Safety bulletin boards in the various departments, through the works mail, through the safety inspectors at the safety office, or through members of the safety committees. It will be found that the best results will be obtained by these methods of turning in suggestions. In very few instances will nearly as good results be obtained by compelling suggestions to be turned in either through foremen or superintendents.

Prizes may be awarded either by the Central Safety Committee, Chairmen of Safety Committees at regular monthly meetings, or by the Safety Department. All awards should be approved by the Departmental Superintendent or by the General Superintendent.

The prizes may be given out publicly at monthly meetings of safety committees, at mass meetings, at departmental noon meetings or at any other opportune time, or may be given out privately. Publicity as to the names of the winners should be given in the monthly safety publication.

Records kept as to the value of prize systems in securing suggestions

from the workers show that before prizes were given out there was approximately 100 suggestions per year without a prize system. After the prize system had been installed there were 609 suggestions turned in during the year.

The purpose of giving prizes is to stimulate interest, secure co-operation, advertise the safety-first movement. It is in my opinion a lubricant that enables a safety machine to operate smoothly and effectively and it certainly makes a hit with the workers.

It has long been recognized that men will die to win medals of valor on the field of battle—and we are now endeavoring to demonstrate that they will make efforts to save lives to receive medals and tokens of honor. Men are only grown children and from my experience in the awarding of nearly 10,000 prizes for one company I can say the prizes were sincerely and deeply appreciated by the men who received them and that the wearing of these prizes represents something real and significant to their fellow workers and to their superiors.

Prize systems will work out best in large organizations and are mostly needed there although from my experience in comparatively small organizations employing from three hundred to a thousand men I believe the prizes are just as much appreciated and will do just as much good although I do not believe they are quite so necessary, as in smaller organizations there is a closer contact and in the larger organizations the prize system brings about this closer contact.

It has been contended by critics that prize systems are all wrong both in theory and practice as the only effect is to reward the employee for something he should do as a duty. This in a sense may be true but as yet we are far from the ideal and anything that works out for the practical benefit of both the employee, the employer, and society as a whole has a high value as a practical asset in the great safety movement.

Admittedly it is difficult to state just what percentage of accidents may be prevented through prize systems. It is my idea that prize systems are merely to be used in putting safety across. There is no practical method of ascertaining just exactly what percentage of accidents may be prevented by any one thing. Just how necessary prizes are depends on circumstances and conditions which those in charge of the work must meet. Accident prevention campaigns may be operated successfully without prize systems but it is my opinion after several years of experience that no matter what the conditions are accidents can be reduced through the operation of carefully worked out prize systems and that greater co-operation can be secured from the workers even after every other method or system is in use.

#### CASH PRIZES

Now we will take up the matter of cash prizes. In looking up this subject I ran across a little story which I believe illustrates the efficiency of cash bonuses. One of the great trans-Atlantic liners was out in the Atlantic Ocean, and, by making special efforts the Captain stated that it would be possible to reach New York that evening, thus effecting the

saving of a twenty-four hour delay in the operation of the boat, and it would save the feeding of 1,200 people for one day and also keep them out of quarantine. The Captain of the ship sent down word to the firemen: "If you get into port tonight, each fireman will receive one pound bonus." Well, the ship got in; which I believe proves the efficiency of the bonus system. That is just one instance of it.

#### EXPERIENCES OF OTHER COMPANIES

Mr. J. G. Hatman of the Semet-Solvay Company, Birmingham, Alabama, said: They have a system where they give one-half of the savings that are made in accidents. Ten per cent is given to any man who has no time-losing accident during the month. The reports of results are astounding. Two plants, six months previous to the prize system, had 134, 200, 300, and 400 hours in time-losing accidents. At Plant No. 1, after the bonus system was installed, there was 95,000 hours' work with no accidents, and at Plant No. 2, 100,000 hours' work; 34 hours time-losing accidents. The bonus system cut it down to a minimum.

Mr. John M. Woltz, Youngstown Sheet & Tube Company, reported, at one of our Safety Congresses here, giving out a gold watch to each foreman having no accidents. There were 150 foremen eligible and nearly all got watches. This resulted in an accident reduction of 70 per cent.

W. C. Wilson, D. L. & W. Railway Company: They have a system of giving out gold watch charms. This watch charm is given out to one man in each division. They have a contest in which the men in that division vote for the man who is going to get the charm, which stimulates interest. One of their men who got the charm did not have a chain, and he immediately went in and bought a gold chain so he could display that gold charm—which shows the interest they have in it.

They also have a flag which they give to the best division. This is awarded in public and arouses a great deal of interest.

Mr. Chandler, of the Dodge Manufacturing Co. at Mishawaka, Indiana: They have a bonus system in safety work. They give two days' extra pay for every man in the department, if the department has a perfect accident score. If there is no perfect department, next to the perfect department prevails. The results were: in the first eight months they did not really sell the idea to the men. After they got the idea sold (and I might say that the whole secret of this thing is the selling of the idea: no matter what your system is, it has to be sold), they had one-half of their departments with perfect accident prevention records. The accident prevention cost per \$100 payroll in 1910 was 50c; in 1911 it was 22c; in 1912 it was 11c; in 1913 it was 7.9c; and in 1914 it was 7c; that is, through this bonus system in some of the work, their cost in the period of five years per \$100 payroll was reduced to one-seventh of what their cost was before they put in the bonus system.

Mr. Evanston, of the U. S. Coal & Coke Co. of W. Va.: They have a bonus to foremen. This bonus is based upon the idea of \$5.00 extra each month if the foreman has no accidents in his gang. After six months of getting through without any accidents in his gang, of the period of

six months, they give him \$10.00 extra each month as long as he continues that record, in addition to the \$5.00, making \$15.00 a month in addition to his regular pay. The results were: No bonus system—1 fatal accident for each 100,000 tons of coal mined; bonus system in effect and sold to the men—one fatal accident for each 500,000 tons of coal mined—one to five. I think that surely proves that it is worth while.

In looking up this subject, I found that some of the railroad companies (which might be applied to our present problems in the work) were giving out a bonus to motormen and to engineers who got through without having any accidents. The Dallas Railway Company in Dallas, Texas, claim they have derived benefits from the system.

There are a number of other companies that have also gone into this matter. The Armstrong-Cork company, at Lancaster, Pa., report very good results.

It has been our theory and opinion that all of these prizes have helped to reduce accidents. I do not want to convey the impression that I believe that any bonus system, whether it is cash or prizes, will entirely solve the matter of accident prevention. As I stated, I believe they are merely a lubricant, merely a medium through which the safety idea can be put across, but we cannot neglect the guarding of machinery; we cannot neglect the organization of safety committees; we cannot neglect our inspection work or our educational work, or any part of the work, but it all has to be carried on just as efficiently as possible. However, the prize system and the bonus system will certainly help to make it much easier to accomplish results than if you do not have them.

CHAIRMAN OARTEL: Mr. Philip Stremmel will now present the other side of the question.

### SHOULD PRIZES BE GIVEN FOR SAFETY WORK?

PHILIP STREMMEL, SUPERINTENDENT, HOT MILLS, NATIONAL ENAMELING AND STAMPING COMPANY, GRANITE CITY, ILL.

No rewards or premiums should be given for safety work, as it has a tendency to make our men more interested in prizes than in promoting safety. In other words, it cheapens the great cause of Safety in the minds of men whom we are desirous of reaching, by holding up to them the thought of prizes rather than the thought of Safety.

In the beginning the Creator made man physically perfect and endowed him with everything necessary to his well being,—a perfect manhood. When the time came to offer sacrifices to their Creator, Abel offered more acceptable sacrifices than did his brother Cain, and though both did well and gave the best they had, Abel's sacrifices were the better of the two: as in everything, some are capable of doing better work and giving better service than others. It was then that selfishness crept in (just like the man who is thinking more of the prizes he is going to receive than of the safety and protection of his brother) and Cain contrived to slay his brother. Hoping to cover up the evidence, he hid him in the sand, but the Creator called and asked him, "Cain where is your

brother?" At which Cain became all puffed up and sought to evade the question by saying, "Am I my brother's keeper?" The structure of humanity is so built that that which seems useless must repose on the strong, and as a great leader of men has said, "No man liveth unto himself alone". It is evident that we cannot evade the responsibility of looking after our brother.

As the safety movement, like all others, necessitates the process of education, the result will depend largely upon the spirit which actuates and the motive of accomplishment; not self-aggrandizement or the securing of a cheap fob, knife, cuff-buttons, or the fact of being favored by being placed on a safety committee, or by being permitted to mingle or dine with a bunch of the good fellows, but the fact that we have the right to be our brother's keeper.

Should prizes be given for Safety Work? No! Serving on a committee for one's church, lodge, club, or any other organization, does not need the incentive of a prize to get the interest of the members, but the spirit of what the organization stands for is enough incentive for one to do his duty. So with Safety First:—one must sell the idea to the workmen, and this can be brought about by education which will give lasting results, and cannot be accomplished by the giving of prizes.

The idea of safety in our plants has come so quickly that many fail to catch the spirit of self-sacrifice. As any big undertaking must get started on the right line, so must safety be founded on principles of service to one's fellow man (as the Big Brother Movement) and the workmen must be educated in carefulness and loyalty to rules that are made for the best interests of all. Loyalty cannot be bought or stimulated to do better service by giving prizes or premiums, but must be brought about by the satisfaction of knowing that one has done his duty to company and fellow workmen by having a part in making the mill or factory a better place in which to work.

Safety work is one of helpfulness, and what bigger job can a man find to do in the eight hours or more he is at his work than to look out for the best methods to do better work or safeguard dangerous places in the mill or factory. Then why give special inducements for one to perform his duty to his brother workmen? If we have a real desire to be of service to our fellow men, one does not have to join a lodge to be a brother to this or that man, but can participate in constructive work each day in dealing with a big man's problem.

One of the best things that a safety committee can do for the morale of a plant is to have meetings of the different departments, helping each to co-operate in lessening accidents. Men working for a big movement like this cannot do their best work if they are on a committee only a few months for a prize.

At this point, I am reminded of a piece of service rendered by one of our men in saving the lives of two workmen who were working on a yard engine standing at the foot of a long incline in our plant. This act, the saving of the lives of these two men is one that no prize or premium could buy. The spirit of self-sacrifice will come out in men if

given a chance to express the feeling of trying to do a kindness for one's brother workmen.

The motive for doing safety work is one of the greatest opportunities of getting all our men to think and study the conditions in which they are working and to co-operate with other departments in making a safe place to work. If there are men who will not serve on committees because no prizes are given, then it is up to the safety engineer to sell the idea of doing the greatest good to the greatest number, for in the safety movement, because of its strength and popularity, there is a place for every one. In a lodge or club all cannot expect to be leaders, but in the safety movement with a well-organized safety committee, we can interest all of our men in the work. One interested in the work only because prizes are given will serve while the prizes are offered, but after the same are given to the lucky individual they lose interest in the work.

The principle on which to work in the cause of Safety, is to set a standard that is reasonable for men to follow, then all who are interested have the satisfaction of knowing that they are doing a co-operative and loyal piece of work, which is the greatest and best reward that a man can receive.

More harm than good arises from the giving of premiums or rewards, for one usually finds that jealousy in different departments arises when a single or a few prizes are offered, when one or two men of nearly equal ability carry off the prize to one department of the factory and leave the other departments with very inadequate recognition of their efforts.

The next year when you get the committees together, after such a procedure of giving prizes and rewards, many will refuse to serve or try for a prize. A meeting of all the committees, held monthly, with suggestions from all departments, all working for the good of the safety movement and interested from the humanitarian standpoint, will be of better service to fellow workmen and company, will accomplish more real good for all concerned than all the prizes or rewards that can be given.

We all remember the old Christmas treat,—how the Sunday Schools were crowded a few Sundays before Christmas, but that is all changed now. All up-to-date Sunday Schools teach the principle of giving to those less fortunate at Christmas rather than coming to Sunday School to receive gifts. The safety movement can learn from this experience that the easy way does not pay in any game well worth striving for, but the result getter is the man or the committee that works day in and day out for the protection of his fellow man.

Safety is so new a game that it is more the question of education than one of lack of interest. It is the question of getting our safety committees educated to what is expected of them. They do not lack interest, nor are they unwilling to do their part. But if they cannot be educated in safety and the value of protecting themselves and their fellow workman, how then can prizes of any type get permanent results? Our newer methods of education are going after the greatest good to the greatest number, without awarding prizes.

A few weeks ago in St. Louis, the Playgrounds had over 10,000 children taking part in a field day. I noticed with interest that in scoring for the different events that it was a mass proposition rather than an individual one, for after all, the teams were not stronger than the weakest child taking part. All the children were striving to get the weakest member of the team to do better work.

So with safety; no mill or factory is stronger than the weakest employee. The individual in our plant who needs safety education most is not the one who will be able to make a record to win a first, second, or third prize, but it is the man in a department who needs some one coaching him, to help him think safety, rather than the alert employee who is thinking safety not so much for himself or the other man, but a pot hunter, trying for some prize.

Safety will not prosper by the giving of prizes, nor will it become of great importance to men, but if presented to them from the standpoint of loyal service, rendered in the interest of their fellow men, showing them that they have a large part in the game of Safety in the saving of life and limb, you will be able to receive larger and better results, which the giving of no amount of prizes can accomplish.

Shall prizes be given for Safety? Again I say, NO!

CHAIRMAN OARTEL: You have heard both sides of the question. We will now hear from Dr. Chaney of the United States Bureau of Labor Statistics.

## DISCUSSION OF THE TWO PAPERS ON BONUS SYSTEMS

DR. LUCIAN CHANEY, U. S. BUREAU OF LABOR STATISTICS.  
WASHINGTON, D. C.

I am not going to undertake to express an opinion upon the merits of the discussion. You are perfectly able to form your opinion without assistance from me. But what I am going to do is to ask the question and answer it for the largest group of plants which have so far been studied, from the statistical standpoint. How does it work? What does it do? What can you expect of it, if you do undertake to work with the bonus system? I am concerned particularly with the bonus system in the sense of the money payment for certain definite results.

There are about four types of motive which appear in the discussion which we have had so far. First, the humane and human motive. Rather curiously, it seems to me, in a commercial and materialistic world, the Safety Movement started almost everywhere; the men who began it started on the basis of the safety of life and limb (it was a question of humanity with them), and a large share of those pioneers of the Safety Movement have looked with a good deal of suspicion upon the proposition to introduce anything of a commercial nature into it.

Then we have the motive of personal distinction. Most of us swell up a bit when we are conscious that our fellows look at us a bit distinguished from the rest of the ordinary men in the fold.

Then there is the motive of competition. We all like a contest and we all like to win.

Then finally, there is the motive of economic advantage. "Shall I somehow get something tangible in the way of economic return?" "Shall I be better off?" "Shall I be able to buy something more than I would be able to if I did not enter upon this particular effort?"

Obviously there is not any use in comparing plants of an entirely different character. If we are to see how a given procedure operates, we must at least choose concerns which deal with the same sort of thing.

Inasmuch as my own work has been very largely with the iron and steel business, I naturally turn in that direction, and I isolated from the reports which are on file with our Bureau those pertaining to blast furnaces, steel works, and the heavy type of rolling mills, such as slabbing heavy structural metal, and I undertook to find out the course of accident history in those plants, so far as it can be shown by statistical compilation.

Here is the record from the year 1912 to the year 1917, of the frequency of accident. The plants with the bonus plan registered the greatest decline, and particularly the more rapid decline in the first two years, at which time the bonus system was inaugurated. They also maintained, after they had reduced their accidents to that point, a lower rate. You will see here somewhere an indication of the effect of the war. The war period pushed up accident rates everywhere.

Well, that looked very favorable for the bonus system, so far as the reduction in frequency of accident was concerned. However, when I examined it a little more closely, it did not look quite so favorable because it was perfectly evident that this fall in accidents was largely due to the elimination of minor injury.

So I had to work out, as I am accustomed to doing, the conditions so far as the severity of accidents is concerned.

The non-bonus plants have maintained a pretty constant reduction in the severity of accident. They started at a certain point; they dropped down—they terminated at the far end in 1917, at a considerably lower point than they started. What about the bonus plants? They dropped down in the first year and then they began to go up, and they ended in 1917 at a point higher than their record in 1912, so far as the severity of their accidents was concerned.

It seems to me that three conclusions are justified: First, this grouping is sufficiently large, extends over a sufficiently long period of time, and is sufficiently constant, that we may accept it as representing the typical result of the application of the bonus system, under certain circumstances. I am inclined to insist that this is so, because I have found it so in other cases which I have not yet had time to work out completely; but wherever a bonus system has been installed,—by that I mean payment to foremen and men—wherever I have been able to work it out, I have found constantly this phenomenon: The rapid decline of minor injury; some increase in cases of severer injury. Now why should that be so; what reason can possibly be offered for severer injury becoming

more frequent when minor injury is declining? I think it is this: The main reliance of safety departments, as to the decline of their accident rating, has been upon the frequency rate; they have followed it. If they have seen it going down rapidly, they have been satisfied, and, being satisfied, they have failed. Thus far all concerns that I have been able to examine have failed in the matter of the reduction of severe injury. Now that does not mean that that is always true, mind you; it means simply that in those cases that I have been able to examine (and those I believe to be a sufficiently large number, over a sufficiently long period of time) there is indicated a tendency against which it is necessary to safeguard yourself. If you are going to use the bonus system, you have to look out and see that you do not fool yourself by noticing a rapid decline in the frequency of minor injury and concluding that that tells you the whole story, because it does not. You are very apt to overlook what may occur right along with that decline in minor injury; an increase in injuries of a more severe character.

We will say, then, that a bonus system applied to foremen will certainly greatly decrease minor injury. Now that is an eminently worthwhile thing to accomplish. Anything which will bring down minor injury deserves the closest and most careful consideration from the safety man, as a means of accomplishing his desired results. He ought to consider it. The bonus system will not necessarily influence satisfactorily the occurrence of severer injury. It has not so affected it in the largest group, over the longest period of time which it has yet been possible to examine. We may find different results with further study. That is the situation as it sizes up with the figures which we have on file in the Bureau of Labor Statistics.

I thought it might be worth while to study another phase of the situation: What sort of things did the foremen in the bonus plants give attention to and get rid of? Could I find anything which would give an indication on that point?

Here is a little table which seems to me rather illuminating, as to what the foremen in bonus plants went after. I grouped the facts under three heads—the whole group is of this character; they are: Accidents against which provision could be made by modifications of structure—what I have called “engineering revision”. All these had some engineering remedy. Then I grouped them, those of minor character, six weeks and under; those over six weeks, and those causing deaths and major mutilation.

I find that in the bonus plants the foremen discovered and had corrected, for cases producing disability of six weeks and under, at the rate of 2.70 per million hours of exposure, whereas the non-bonus plants found and corrected at the rate of .90 per million hours. You will see that the foremen in the bonus plants were clearly getting after the cause of minor injury at a rate surprisingly in excess of the non-bonus plants.

Those over six weeks also showed a marked advantage for the bonus plan. But when we come to those causing death and major mutilation, the bonus plant finds them at the rate of 50 per million hours' exposure

and the non-bonus plant at the rate of 60, and I cannot but believe that this difference in the two cases is due to the fact that the foreman has a greater advantage in the detection and protection of his men against minor injury, whereas major injury is not adequately penalized.

Now I happen to know that in all these plants which I have included here, the penalty for major injury is not more than ten times the penalty for a comparatively minor injury; the penalty for death is not in any case over ten times that for an injury which keeps a man off one day. Now it is perfectly absurd to estimate a death at only ten times as serious as a day's lost time. If anybody is going to use so inadequate a penalty for death as to make it equivalent to the loss of one day's time, they are bound to come out in just this way. What will the foreman do? He will inevitably give attention to the causes of minor injury, which he could easily get out of the way, rather than the causes of major injury, which might require pulling down the mill before he could correct them.

The conclusion which we can fairly draw from this experiment is that every safety man who tries it must look very carefully so that he is not deceived into supposing that his results are satisfactory when he gets rapid decline in frequency of minor injury. He has to go into the situation much more closely, so far as the causes of severe injury are concerned.

Be it understood, of course, that you may have an entirely different experience from this, but the experience of no one of you begins to be as large and as long-continued as this experience which I have presented to you. So I think we may fairly say that this represents the natural inevitable tendency of the application of the bonus system to the reduction of accidents, the bonus system through awards of money to foremen.

CHAIRMAN OARTEL: I now throw the meeting open for a general discussion.

#### GENERAL DISCUSSION

MR. J. R. MULLIGAN (Bethlehem Steel Co.): I am for a cash bonus to safety committeemen for services rendered. I agree with Mr. Smith, first, in giving prizes to get attention and promote interest; and second, in giving cash prizes to get direct tangible results in the real accident prevention game. I disagree with Mr. Stremmel in his paper, because I believe it is idealistic; it sounds good, reads well, but it is not practical.

We have spent about eight years now in the accident prevention game; that is, under direct organization of the National Safety Council, and we have not gotten to the point that we should have reached, considering the time and attention of the great men in the accident prevention work devoted to this particular phase of it. It is about time that we put accident prevention work on a practical business basis and go after it in a practical way, just the same as we do any other thing in which we are engaged.

We who have to do with accident prevention work, are convinced that the point in our program has been reached where we should place the

accident prevention work of our safety committeemen on a compensation basis, and we propose to do it in the near future.

The guarding phase is represented by one-fourth or 25 per cent of the field of accidents, and that is the field where we are practically all working. We are still working in that field. The larger field, which involves the unsafe practices, the bad habits, the carelessness, the recklessness, we still have to enter.

In the plants of the Bethlehem Steel Company, we train our safety committeemen for their work through a four-month course of two hours per week, on company time. The men are trained in First-aid work and accident prevention work. A departmental team of eight men coming from the blast furnace department, is trained along the hazards of their particular department, based upon the accident history of that department. After passing through their graduation exercises in the form of a first-aid meet, they are eligible for safety committee work. These men serve on committees for six months. Our departmental committee is made up of an equal number of foremen and workmen, so that both will work together. The number of committeemen in the department depends upon the number of employees and the number of different or unrelated units of work in that department.

Now in the blast furnace department we have as a committee one man who is known as the Permanent Committeeman; he continues to be the representative of that department while the personnel of the committee changes. He is the Chairman; has charge of all the details of the committee. Then on one side we have three foremen and on the other side three workmen. The superintendent of the department is also a member of that committee, and in our plan of organization the superintendent is held responsible for the accident prevention work in his department.

Our men are trained. The superintendent is responsible. The committee is made up of an equal number of foremen and workmen, giving direct representation both to the management and to the men. These men hold monthly meetings. During the month, as things occur in the department along this line, up in the physical phase of it, the guarding of it, as the committeemen notice this, that and the other thing, they report it to the foreman at once and it is taken care of; instead of waiting until the end of the month at the monthly meeting to report things which need attention, these are given attention from day to day, so that when the committee meets for their monthly meeting, their report is a report of things done rather than things to be done, and the time of that meeting is devoted to the discussion of the things that enter into this field rather than into the field of guarding and so forth.

I maintain that in order to get the direct, personal interest and attention of your Committee every day in the month, there must be a cash compensation or bonus attached to their service, to get direct results; and we have decided, in order to get the personal interest of the committeemen continuously throughout the month, that we will offer such a bonus or cash compensation. To give our plan briefly, let us represent it in this way.

This is the accident scale (illustrating on the blackboard), whether it be frequency of accident or severity, from nothing up to 25 points. Let us say this line here (indicating) represents the hazard or the accident history of any one department in the plant. Let us take the open-hearth, for instance; this line represents the history based on the hazards; things that have actually happened. This line will continue to represent the history of the department if accidents are not prevented, for the reason that the hazard is there and the accidents will result. With this as the starting point, the history of the department for a number of years, several years, two, three, and four, let us drop down on the scale say 10, 15, 20 or 25 per cent, and let this line represent the line to be attained. We say to the committeemen at the beginning of the month, "Boys, reduce your history line for the coming month from this point (indicating) to this point and you will receive as compensation, each one of you (an average of ten men being on the Committee), \$10.00 each, for your definite, detailed attention to this prevention of accidents through unsafe practices, etc."—and the result is that the amount paid for this attention down here, with an average committee of ten, would be ten times ten, or \$100. Now \$100 is about one-fourth the actual cost of a simple fracture of the leg; what is represented in arms, legs, lives, between this line and this line (indicating), not to speak of the amount of money represented here in compensation, outside medical attention and inside medical attention. In other words, we place the line down at a definite point, something that is possible, and when it gets down to that point, the compensation is earned, and the saving is this (indicating).

It resolves itself into this factor: Why not pay the compensation before the accident, in the form of a bonus to committeemen, and save all that is represented between these two lines, rather than pay it out in compensation to the injured after the accident—compensation which never compensates; why pay it out to the doctors, nurses, and everything else involved? Why not pay it on the prevention side rather than on the resultant side?

CHAIRMAN OARTEL: Are there any more questions?

MR. HENRY H. OLMSTEAD (Du Pont Fabrikoid Co., Newburgh, N. Y.): We are trying out a plan something on that order. It has been in force about seven months. We took the total amount of expense due to accidents for two years, and we found that for quite a number of months the expense was practically nothing; some \$10.00 and some \$15.00, so we took the total number and divided it by four, and the Manager agreed that if we kept below the amount of money representing a fourth of the total, he would give in prizes another fourth; in other words, if we could cut them in half for one month, he would give the prizes.

This is the way we give our prizes. Every man and woman on the plan has an equal interest in it. We divide the plan into five areas, under supervisors, and we raffle these prizes off, to the amount of \$10.00 apiece, and so far we have gotten four out of seven months.

MR. J. E. SCHILL (Cleveland Metal Products Co.): I would like to say,

Gentlemen, we are commercializing on everything, we Americans, and it's about time we call a halt! We want to get close to the man, and the way to do it is to study human relations, and get your superintendent and manager and president in with you on the same thing.

I tell you fellows, when you commercialize Safety work, you are doing the wrong thing! Get your superintendents, your factory managers and your executives in and let them study human relations with the men, and you will be far better off.

MR. FRANK E. MORRIS (Secretary, Syracuse Safety Council, Syracuse, N. Y.): We put on a Safety Campaign not so long ago, and one of the stunts put over was to award a prize of \$5.00 to the school child who wrote the best letter on Safety. I went down to one of the school houses to see how this worked out. We saw the school children walking along with these letters in their hands. A gang of boys went over to play a ball game and here came one of these little freckled-faced kids, a little rough boy. One of the boys said to him, "Come on and play ball with the boys", and he replied, "Play ball! Oh, the hell with it; I'm going home and win \$5.00 on Safety!"

I think the cash bonus, offering money for the prevention of accident in safety committee work, sounds too much like the slogan, "A Dollar to Save a Life!" Pay inspectors and First-aid teams by all means; but this thing of paying for safety committee work does not appeal to me. Safety work is a service to your fellow human beings, and I don't think you can buy it with dollars. Let the foreman appoint his safety committee, and let him tell them what to do, as a part of their work. He's the boss, and if he tells them to look out for unsafe practices and conditions, that is their job. If they don't do it, let him fire them, just as he would for any other disobedience.

Mr. Smith gave you a very good elucidation of this subject, and when he got through I thought perhaps I was wrong in this proposition, but I honestly believe that if he had not had his bonus system at all, he would have gotten the results anyhow. This is another form of Safety advertising, I believe. I think that this bonus proposition is just merely getting your men to think about this Safety idea, and when they do that, you have them; they think of Safety, which is the big idea. If you should, instead of having the bonus systems, get all the plant widows at your plant and line them up at the gate for one month, don't you think it would cut accidents? Or, take the cheerful side, and get a lot of sunny-faced, happy, smiling children, and string them along outside of your plant, and have them carry banners with the slogan, "We are happy because our fathers came home from work!" That is better than a bonus system.

CHAIRMAN OARTEL: I am very sorry we have to close this now, but we have a mighty interesting demonstration to follow, by Captain Guy H. Burrell, of the Mine Safety Appliances Company, who did a lot of good research work in the Gas Defense Division during the war, and who is master of his subject.

## CARBON MONOXIDE GAS

RECENT DEVELOPMENTS IN DEVICES FOR DETECTING ITS  
PRESENCE AND AFFORDING PROTECTION

CAPTAIN GUY H. BURRELL, MINE SAFETY APPLIANCES COMPANY,  
PITTSBURGH, PA.

(Outline of Discussion of Technical Principles Involved and Demonstration)

The great war gave tremendous impetus to technical research in a great variety of fields. Problems were solved in a few months' time by virtue of the fact that the most capable technologists in the country were concentrated upon them.

The greatest body of research men ever gathered together in the history of the world was located at the American University Experiment Station, Washington, D. C., in Chemical Warfare Service. Here more than 2,000 of the best-trained technical men in the country were congregated and divided into groups, each group working upon some particular problem having to do with the prosecution of the war.

It is logical that some of the results of this vast research work had application in industrial fields. One important application was that of the gas mask, which has found a broad use in a great variety of industries.

## USE OF STANDARD ARMY MASK IN THE INDUSTRIES

Carbon monoxide gas was not a war gas in that no means was ever found for distributing it effectively over the fighting line. In the first place it was difficult to produce in large quantities, and in the second place it dissipated so rapidly that a toxic concentration could not be maintained.

However, carbon monoxide constituted a distinct hazard in the gun turrets of our men of war, where the gas collected in dangerous quantities when the guns were in heavy action. Carbon monoxide was also likely to be encountered by sappers and by men working in machine gun emplacements, etc.

The standard Army gas mask would not afford protection against this gas, and Chemical Warfare Service was asked to develop a mask similar to the standard army gas mask, which would give adequate protection. The only means heretofore available for protection against carbon monoxide was through the use of the heavy, more cumbersome, oxygen breathing apparatus.

A great amount of work had been done prior to the war on the detection of carbon monoxide gas and means of affording protection, as represented by the canary bird as a detector and the oxygen breathing apparatus as a means of protection. Both of these devices were impracticable so far as the soldier was concerned.

The men in Chemical Warfare Service who were put upon the problem

of developing the carbon monoxide gas mask and detector included Dr. J. C. W. Frazer, of Johns Hopkins University, Col. A. B. Lamb, of Harvard University, Dr. C. R. Hoover, of Wesleyan University, and others of like caliber.

The entire research extended over a period of about one year and in this time a mechanical carbon monoxide detector and a simple type of carbon monoxide gas mask were perfected.

The carbon monoxide detector now comprises a small metal barrel with a rubber bulb on one end and a means for quickly inserting a glass tube filled with a special chemical in a space on top of the barrel. By means of the rubber bulb a sample of the air to be tested is forced through the glass tube and the chemical inside of the tube changes color in contact with the carbon monoxide if any is present, the depth of color depending upon the percentage of carbon monoxide in the air. In the lower percentages of carbon monoxide light green shades of color are produced, while in the heavier percentages deeper greens appear in the tube. By means of a small calibrated color scale, which accompanies the instrument, the approximate amount of carbon monoxide in the air is readily determined by comparing the colors.

The instrument is entirely mechanical in its nature and any one can operate it. It is far more sensitive than a canary bird and has the further advantage that it can be carried through gaseous zones and is always ready for work. The instrument has been thoroughly tried out around blast furnaces and steel mills and in coal mines with most satisfactory results in every case.

It is well known that ordinary tobacco smoke from a cigar, pipe, or cigarette contains a considerable proportion of carbon monoxide. To indicate the action of the detector tube blow a little tobacco smoke through the tube and notice how quickly the color changes to green. (At this point tubes were passed around through the audience, enabling the different smokers to test the carbon monoxide content of their pipes, cigarettes, or cigars, and during the discussion above the details of the instrument were thoroughly explained, the chemistry brought out, etc.)

Nothing that we know of suitable for a gas mask canister will absorb carbon monoxide gas. The standard army canister depends largely for its action in removing ordinary industrial gases upon the fact that the ingredients of the canister absorb the gases. If a substance that would absorb carbon monoxide mechanically could have been produced matters would have been greatly simplified.

However, research to find an ingredient for the gas mask which would protect against carbon monoxide was started out along the line of finding a substance which would, at ordinary temperatures, catalytically convert carbon monoxide to carbon dioxide. It was well known that certain substances such as copper oxide would convert carbon monoxide to carbon dioxide catalytically at high temperatures. After many months of research a combination of metallic oxides was found which would convert carbon monoxide to carbon dioxide at ordinary temperature. This material, placed inside of a gas mask canister, will afford protection against carbon mon-

oxide in that the carbon monoxide in the air that is inhaled through the canister will be converted to carbon dioxide gas.

This material represents a gigantic stride in chemistry and is really one of the great chemical achievements of the war. As stated above, it is catalytic in its nature and as such it neither loses nor gains in weight nor changes physically or chemically while in use. Catalytic reactions are explained by physical chemistry, and a simple definition of a catalytic agent is any substance that will, by its mere presence cause any other two substances to react chemically. The fact that certain substances are catalytic in their nature is taken advantage of for a great many industrial purposes. This catalytic reaction will be thoroughly explained and comparisons made to other catalytic reagents which are being used in the industries.

By means of this special substance then, a simple form of gas mask weighing only 3 to 4 pounds has been developed which will give complete protection against carbon monoxide gas. This particular mask will never take the place of oxygen breathing apparatus in that it cannot be used where there is a deficiency of oxygen, but in places around blast furnaces, steel mills, fighting mine fires, etc., it will be invaluable.

#### DEMONSTRATION APPARATUS

The apparatus for demonstrating the action of the special material for catalytically converting CO to CO<sub>2</sub> consisted essentially of a reservoir containing pure carbon monoxide gas, small glass flow meters for controlling the flow of gas and air, and a glass compartment for containing a white mouse. The demonstration first consisted of passing a carbon monoxide-air mixture through the special substance into the mouse bottle to show how the carbon monoxide is rendered harmless by being converted into CO<sub>2</sub>. The air-gas mixture then was by-passed around the tube containing the special material and the mouse collapsed in several minutes time. In conjunction with this demonstration the audience was invited to come forward and feel the tube containing the special material and to note how it heats up indicating the reaction, etc.

Another experiment was conducted, showing how the material glows at a red heat whenever pure gas is allowed to blow upon it, indicating the very vigorous reaction that takes place and the carbon monoxide detector was demonstrated in the carbon monoxide gas. In addition there were complete instruments for examination and the foregoing talk included full details of all instruments both in their mechanical and technical make-up.

ADJOURNMENT.

## **Mining Section**

**September 28—October 1, 1920**

---

**B. F. TILLSON, Chairman**

Assistant Superintendent, The New Jersey Zinc Company, Franklin, N. J.

## REPORT OF CHAIRMAN

CHAIRMAN TILLSON: Gentlemen, it is a pleasure to renew acquaintance with so many whose faces are familiar and to greet others who for the first time are joining us in our common search for that knowledge and inspiration which will lead to universal safety in our mines.

In welcoming you to this, the Ninth Annual Congress of the Mining Section of the National Safety Council it seems to me fitting to spur you to even greater endeavors in the future by outlining for you your achievements in the past.

The following statistics will indicate to you the relative space which the Mining Section has occupied in the entire proceedings of the National Safety Council Congresses and will show that it has outstripped the other largest section, the Metal Section, in the volume of its transactions and the amount of discussion taking place in its meetings. These are matters of which we may justly be proud for they indicate that we are alive to the opportunities presented to us by such gatherings of experienced mining men as congregate at our annual meetings.

The following tabulation of the space given in our proceedings to the various principal sub-divisions of our mining industry is more or

Number of Addresses and Pages in National Safety Council Proceedings.

NOTES: a—Mining Section organized. No stenographer at meeting to report extemporaneous addresses or discussion.

b—Includes reports on first aid meets during the year.

c—Iron and Steel Section.

d—Iron and Steel and Foundry Section combined.

e—Proceedings condensed as a measure of economy and smaller size type used.

less approximate since it is often hard to make a distinctive classification. Therefore under the "General" heading will be found papers prepared by representatives of the anthracite and bituminous coal and metal mining branches. Under a "Miscellaneous" heading the reports of committees, business meetings, etc., are grouped. The need for reduction of size of the volume of transactions has resulted in the use of finer print, closer spacing, and the elimination of most of the reports of activities throughout the year during the past two years, so there is no absolute comparison.

The number of delegates attending our meetings is naturally smaller than that in many of the other sections, since the mining districts are usually remote from the populous cities in which these Congresses are held, and the correspondingly greater expenses to delegates inhibit their attendance. However, it is clear to me that the benefits accruing to those attending our meetings should (and I think have) warranted expenditures in excess of those required by the majority of the Mining representatives of such companies who are not represented here today. It seems to me that the inspiration and concentrated thought in regard to mine safety which we experience at these meetings makes them the most important service we receive for our membership in the National Safety Council; and if our neighbor companies do not appreciate this we should in all kindness point out to them their error. But let us also remember that we benefit only proportionately as we give, not only in taking the time and thought to prepare addresses but also in entering frankly into the discussions.

But are you all satisfied in having as your ultimate gain such Congress associations, with the added bulletin service, as have been available throughout our past activities? If so, permit me the prediction that you will find yourselves attempting to sow sterile seeds of safety in the barren soil of apathy. I look with hope upon complaints of dissatisfaction with the few activities of our Section throughout the year, for from these must develop the realization that we have indeed a larger service to perform and one in which it is worth our while to invest more of our time, money, and careful thought. It is not enough for any of us to neglect our Section just because we have not been singled out for some particular mission. Your chairman has solicited in the past your voluntary suggestions, criticisms, and support in sending in bulletin material, articles or descriptions of safety devices or methods, and accident statistics. What have you done as your share in this co-operative organization? Have you, "sponged" upon the willing enthusiasm of a few to devote for the common interest such time as they could steal from their regular duties? Be honest with yourselves and if you deserve this scolding consider that it is milder than you deserve and make effective resolutions now not to err again and show your Chairman for next year that you can and will help him as you have never done before.

But who will then have the time to correspond with all of these reformed members who should so co-operate with their ideas and knowledge? It is clear that no volunteer officer could devote the required time if he had any other business and so we are led to the conclusion that this

Section must have a paid Engineer-Secretary to co-ordinate our individual activities and inquiries. This suggestion was made by your Chairman last year and was unanimously endorsed by the delegates present. According to their instructions several inquiries were sent out to the member companies but to date only one-third have replied at all. True enough, in accordance with the following tabulation, the large majority of those replying were in favor of having their dues doubled to pay for such increased service, but your officers and the Executive Committee of the National Safety Council could not neglect the overwhelming number who had not expressed themselves and who might sever their membership if called upon for increased dues. It was not felt, therefore, that the National Safety Council could assume the expenses and risks dependent upon such a contingency.

Your Chairman, therefore, puts the problem squarely before you. It is your problem and you must solve it. Are you going to be contented to drift along as you have or are you sufficiently convinced of your need of a paid secretary so as to labor in the cause of winning one? The summary of our members and their voting is shown herewith.

## Summary.

|               | No.<br>Voting<br>Yes | Dues              | No.<br>Voting<br>No | Dues              | No.<br>Not<br>Voting | Dues              | Total      |                    |
|---------------|----------------------|-------------------|---------------------|-------------------|----------------------|-------------------|------------|--------------------|
|               |                      |                   |                     |                   |                      |                   | No.        | Dues               |

| <b>TOTAL</b>  | <b>58</b>            | <b>\$2,805.00</b> | <b>26</b>           | <b>\$1,132.50</b> | <b>167</b>           | <b>\$6,577.50</b> | <b>251</b> | <b>\$10,515.00</b> |

In closing let me emphasize by true examples the need for this increased service. During the year your Chairman has received a very few complaints but from companies operating respectively bituminous, anthracite, and metal mines. Each complained that the bulletin service dealt chiefly with the type of mining in which they were not engaged. The answer is obvious for actually our service has been equitably proportioned among these three different industries. It is evident that it has not been extensive enough to satisfy any one of them, and it will not be until we invest enough to secure a paid secretary.

MR. J. W. REED (Consolidation Coal Co.): A good many of the companies who have not replied are probably in the same fix that I am in with our company. I tried to get some definite answer, and they said, "Let them do whatever they want to; it won't affect us one way or the other."

CHAIRMAN TILLSON: The first paper on the program is that by C. A. Mitke, Consulting Engineer, Bisbee, Arizona, on "Vocational Training as Influencing Safety and Efficiency in Mining."

Mr. Mitke has not found it possible to come such a long distance east to present his paper, and your Chairman will read it for him.

VOCATIONAL TRAINING AS INFLUENCING  
SAFETY AND EFFICIENCY IN MINING

CHARLES A. MITKE, CONSULTING MINING ENGINEER, BISBEE, ARIZ.

The purpose of vocational training is primarily to equip the man for the job. Besides qualifying him to handle his present work efficiently, it also prepares him for future advancement.

The advantages derived from vocational training by the man himself, are that his efforts become more productive, his earning power is increased, and his view-point broadened. The employer, on the other hand, benefits through increased efficiency on the part of his employees, and also from the fact that better material is available from which to select members of his operating department, and consequently the standard of his entire working force is raised.

With few exceptions, the maintenance of "all American" camps is a thing of the past, and the object of vocational training should be, therefore, not only to instruct the foreign employees in the most efficient method of performing the daily task, but also to train them to become better and safer workmen for the benefit of other employees as well as themselves. The necessity for education along these lines is ably emphasized in the following extract from a report of the late James E. Roderick, chief of the Pennsylvania Department of Mines, 1916:

"The individual must be educated and impressed with the necessity for looking after his own safety and the safety of his fellow workers. There exists a pressing need, therefore, for more thorough education of the worker. The more intelligent the worker, the more careful, other things being equal, is he in his work. The education of the foreign-born workers in the one branch of English alone is said to increase their efficiency about 20 per cent. Just to what extent the conditions of safety are increased is not known, but probably the percentage is as great as in the matter of efficiency."

The Federal Board for Vocational Training in its recent Bulletin on "General Mining" states that 71 per cent of the fatal accidents in the mines of Pennsylvania are among the non-English speaking employees, and 90 per cent of the fatal and non-fatal accidents in Oklahoma occur among foreigners. This bears out Mr. Roderick's statement and emphasizes the need for education along these lines.

Fewer accidents occur among trained workers than where unskilled men are employed. This was especially brought out in 1914 when it became necessary to curtail production in the various copper mines of the Southwest. The newer men were let out at most camps, while the experienced miners were kept on the job. The accident rate dropped immediately. Later on, when the demand for copper increased and it became necessary to hire a great many men, and the companies were forced to take what miners they could get, many of them being foreign, there was a noticeable increase in the accident record.

The fact should be impressed upon the miner that he is responsible for others as well as for himself, and that upon his knowledge frequently

depends not only his own safety but that of his fellow employees. It is a common law in mining that every place where blasting is taking place must be carefully guarded, so that no one can possibly go in before the shots are fired and be injured. Still, accidents of this kind occur time and time again, even in mines where there are a large number of English-speaking miners, and lives are lost needlessly entirely through carelessness and a lack of realization of responsibility for the safety of others. In one of the mines which I visited recently, through the neglect of an English-speaking miner to guard a raise in which blasting was about to take place during the shift, a member of the organization, quite unaware of what was going on, climbed up the raise only to meet his death at the top of the ladder. Such carelessness on the part of an English-speaking employee is criminal and there should be laws on our statute books to punish an individual for gross carelessness of this nature. In the case of a foreign-born employee, his duty to others should be one of the first things to be taught in order to prevent such useless sacrifice of life.

No underground employee can be neglectful of the lives of his fellow workmen. In many instances one careless act may endanger the lives of almost the entire shift. Too much stress cannot be laid on this feature of safety education. Ignorance can no longer be proffered as an excuse when every opportunity is being afforded men to learn not only how to perform efficiently the most ordinary acts of their daily task, but to acquire knowledge of a higher nature which, formerly, was only obtainable in high-class schools and colleges.

During the past few years many of the hazards in mining have been eliminated—no longer is it common practice to bring up a raise or chute directly under the track, and where these are occasionally used, strong grizzlies are made and placed over the opening, in order to prevent the men from falling through. Bars at manways are now the custom; bars and gates at shaft stations and on shaft cages; the guarding of trolley wires, etc. In fact, operators and managers, who are keenly alive to the situation, are sparing neither thought nor money in an effort to do everything possible to safeguard their men. However, no safety device and no large expenditure of money can safeguard a man from accidents which are the result of his own neglect or carelessness, such for instance, as the neglect in barring down the ground immediately when going on shift, rather than take the chance of working under loose rock; or deliberately returning to work in a dead-ended working place without first blowing out the gases produced by blasting. In such instances the only safeguard the operator can provide is to endeavor to educate the men to a keen realization of the dangers resulting from their actions.

#### VOCATIONAL TRAINING ON THE JOB

Incidentally, education develops a more intelligent view-point for the miner of what his employer is endeavoring to do for him, and thus paves the way for better co-operation. The thought and conversation of a man shoveling in a stope are to a large extent limited by his environment. Suppose he is told nothing more than "Muck this waste into a wheelbarrow, tram it into the other chute 50 feet away." This man cannot

possibly take the same interest in his work that he would if the special condition were explained to him. The above order, accompanied by the following explanation was given to miners by a wide-awake shift boss in the presence of the writer:

"See here, this is a heavy stope in which you are working. We have to mine as fast as we can in order to get away from a lot of bad ground. You can see the timbers breaking above your head which were only put in a few days ago. All this needs catching up. After you clear this waste put it into the other chute about 50 feet away, for the purpose of filling up that stope which badly needs waste. 'That stope is just crying for waste.' While the timbers are still holding up it happens to be a stope in which we are away behind with the fill, and I am anxious to have waste put in so that it will soon be producing ore again and help make wages for us all."

Explanations of this character are examples of profitable vocational training on the job. We should have vocational training both underground and in the class room. *More explicit orders should be given and an effort made to give the men a more intelligent understanding of the work they are doing.* Hasty orders, merely giving a few commands, without detailed explanations, are unsatisfactory, both to the miner and to the boss. The modern shift boss should give his instructions in a straightforward manner and thus enable the miner to obtain a *bird's-eye view of the constructive program which is before him.* For example, the commencement of a stope may be the beginning of a certain piece of work which will take anywhere from six months to several years to complete. The miner will take a much greater interest in his work and perform his duties far more intelligently if he knows what he is ultimately working for, rather than knowing only how many tons are to be produced that day. We should have vocational training both underground and in the classroom. There are some instances of classes in mining being actually conducted underground. However, in a great many cases this is impracticable. The instruction given underground by the shift bosses is individual, in a classroom it is collective and is given to groups numbering as high as 200 men.

Among the practical and technical studies taught in the classroom, those should first be taken up which deal with the miner's daily occupation, and should include methods of illustrating the best way of doing things. Simplicity in most cases will be found to be the guide to success, as the common mistake which is being made in most vocational courses is that too great stress is being laid upon the technical side, which is too far advanced for the rank and file of the employees to grasp and can therefore only be taken advantage of by the exceptional few, while the great opportunity of teaching the essentials of mining in the simplest form to the great majority of the men is being overlooked. The teaching of the principles of safety and the essentials of mining might be combined with the teaching of the English language to foreign-born employees, and thus expedite the transition stage through which the worker must pass while being transformed from an unskilled employee to a good safe workman.

# TRAINED MAN WILL OUTDRILL THE UNTRAINED MAN

It has been proved beyond a doubt that vocational training will greatly improve a man's efficiency. Take the miner who consistently drills the cut in the bottom of the face while driving a drift, and compare the results of his footage per day with that of the man who has been trained to drill a standard round, which has been worked out scientifically for the class of ground in which he is drilling, and the results will show that there is no question but that the trained man will greatly outdrill the untrained man, even though the latter may be a good miner.

Many a miner commences work underground without any previous experience in mining and slowly accumulates over a term of years the knowledge which fits him to be a first-class employee. Without instruction he must learn, discard, and re-learn various methods of doing certain work until he develops what he considers to be the best way of doing things. Even this latter may be a very inefficient and crude method. Through vocational training all this preparatory grounding in principles can be covered while the man is working at some of the elementary jobs underground and thus eliminate a great deal of waste time on the part of the man through having to work out these things for himself. He then starts off with the best known methods, and if he is intelligent will try to improve on these and his rise will undoubtedly be quite rapid.

In these days of variable mining methods, it is impossible for the ordinary miner to work long enough at different camps in order to become sufficiently expert at each, and the only solution is that the miner take advantage of the training offered and through this medium gain an insight into the various methods which he may not have an opportunity of seeing in practice. This information, is now available in a great many mining camps, free of charge, both through company classes and also in classes under the supervision of the United States Government.

The common labor at present obtainable for underground purposes is not as intelligent as formerly. Moreover, a large percentage of the labor is not American and has to be educated not only in its duties but in the English language. Americanization is, therefore, one of the most important subjects to be combined with vocational training.

The two great subjects which should come under the heading of vocational training are—Americanization (which includes a study of the English language, and the principles upon which our Government is founded, as well as citizenship); and practical and technical studies in the essentials of mining. Every employee should have loyalty to this country and also to the company by which he is employed. A man is a very poor workman who has not the interest of his country and his company at heart.

CHAIRMAN TILLSON: The subject is now open for discussion. Are there any remarks in regard to vocational training as applied to our mining operations?

## DISCUSSION

MR. E. E. BACH (Pennsylvania Americanization Bureau): I wish to emphasize the Americanization side. I wish to say to the people who are

here from Pennsylvania that they will all be given a chance within the next three months along this line. Pennsylvania has now a program upon Americanization in which every one in the entire state may take part. It is divided into three particular groups: First, the educational; second, the industrial agency; and third, all the co-operative agencies. We will have within your hands within the next three months the names of all the illiterates in Pennsylvania, and we will ask you to get them in contact with the public school system, where they may acquire the English language.

We hold that the American language, working conditions, living conditions, and citizenship are the four principal lines in Americanization for these foreign-born people. We can give you data which will prove to you that merely the learning of the American language increases the efficiency, the labor turnover, and makes for stability of labor. All these things have been worked out scientifically. We now have data by which we can prove these things.

CHAIRMAN TILSON: I am sure that all of us want to know what others here know of the activities of their own companies in regard to their methods of vocational training for mining. It is a subject that is not so well developed as many subjects, and for that reason it is of all the more interest to us.

#### VOCATIONAL TRAINING IN PHELPS-DODGE CORPORATION

MR. W. W. GIDLEY (Phelps-Dodge Corp.): The vocational training has been conducted quite extensively within the last two years by the Phelps-Dodge Corporation, located at Bisbee, and is continually developing to a much larger scale. The vocational classes are run weekly. They are in charge of a person who was formerly connected with the University of Arizona. Papers along practical methods of mining are written by the various members of the Mining organization, for men and bosses. Some papers are written by the superintendents, and some are sent in by the management. One paper on some particular branch of mining operations is read each week and thoroughly discussed and all the students of these vocational classes are required to study these papers and to answer all the questions that are embodied in these various papers, by having standardized methods in that company.

The students at this vocational school are given preference for promotion, etc., depending, of course, upon the examination that they have had. This year they are going to go into the vocational work on a much larger scale, and probably if I am able to be with you next year, I can tell you more about it. But as to the results of the vocational training, there can be no question, and I think it is fast becoming quite a necessity among all corporations. Efficiency is the crying need of the hour, and mining at the present time is advancing with tremendous rapidity. New methods are being introduced constantly.

We have endeavored to standardize every method—standardize in certain ways of raising, drifting, and stoping. All rounds must be drilled the same way, all headings and shaft work—there is one standard method,

and all the students who attend this vocational school are taught these methods.

One feature of the results is this: Many of us who worked in mines and who have handled men in mines probably have had this experience. You hire a man; you put him to work. He has had previous experience in mining. You state to him what you want done and how you want it done. Perhaps you go on then and see your next men throughout the mine. This first man will say, "Well, I know more about this work than the boss does; I have a better way to do that." Perhaps he goes at the work in the opposite direction from the instruction given him by the boss. But when men are taught the one standard method by which to do things in this vocational school, it is of great assistance to the foremen in handling men, because they know the one standard way of doing things and when the boss or foreman goes along and instructs the men along these lines, the men as a usual thing know no other way of doing things.

#### THREE TYPES OF SCHOOLS

Mr. REED: In 1914 I was connected with vocational training. It started at the University of Kentucky and ran in connection with local assistance rendered by the Consolidation Coal Company. Our experience was that where a local man takes care of this work, it requires a great deal of effort on his part to keep it up so it would almost be out of the question to expect it to be carried on by some one who had something else to do unless he is especially paid for it.

That work, as I outlined it to you, was not strictly vocational. We ran three schools; one dealt with the instruction of the foreign born, teaching the non-English-speaking man on conversational English dealing with tools of his trade and things that came up in everyday life so that he could understand the foreman's orders.

The second dealt with the instruction of the American who did not know how to read and write his native language.

The third was a school that I spent most of my time on and that dealt with getting the miners and others who had a little bit of ambition to get ahead and instructing them along the lines of this profession. We started with arithmetic and went through the entire course. You will find among coal miners that their education stops at a very primary point in public schools. In addition to that we taught the subjects that were outlined in the schedule by the University of Kentucky, namely, mine gases, ventilation and drainage, and running throughout the entire ten weeks. We carried a subject which was called "Safety and Dangers", and that was instruction in the safe and dangerous practices inside of coal mines, dealing with how to prevent accidents. We usually start with about forty or fifty men and we finish up with anywhere from eight to ten, so it is a considerable task upon the person who carries on that work to keep it going, but I must say this, that out of those eight or ten men who completed those courses under me, there is not a single one of those men who had ambition enough to go ahead and finish up his work who

has not gone to a pretty high position in our company or in other companies that he has moved to. One of those men is now general manager of a good-sized coal corporation in the Southern part of Kentucky. A great many of the others have reached the position of superintendent, so we have that to show to the men that it does pay. It is an inducement to make them stick to it, but you will find that only the best grade of men will stick through to the end, but I think it is well worth the time and trouble of any person to get those men weeded out and that is about the only way you can get them weeded out, by seeing if they have inside of them that which is necessary to stick to a thing and finish it.

CHAIRMAN TILLSON: If there is no further discussion we will pass on to the next subject.

We will ask Mr. George Martinson, Safety Inspector, Pickands Mather and Company, Gilbert, Minnesota, to give us his paper on "Industrial Nurses in Mining Communities."

#### INDUSTRIAL NURSES IN METAL MINING COMMUNITIES

GEORGE MARTINSON, SAFETY INSPECTOR, PICKANDS, MATHER AND COMPANY,  
HIBBING, MINN.

My experience in the metal mining regions is confined to the Lake Superior district, and particularly to the Minnesota ranges. Therefore, I can deal with this subject as concerning only this district. However, since conditions throughout the metal mining regions of the United States are no doubt similar, there may be some points discussed that may be of interest to all of you.

Before considering the question of Industrial Nurses in Mining Communities, it might be well to describe the conditions under which our employees live. Approximately, one-half of them live in what are commonly called "Locations." Locations are communities in which practically all of the houses are owned by the company. They are, as a rule, located in the vicinity of the mines. Many of these homes have water and electric lights and are rented to the employees at a nominal rate, usually \$1.00 per month, per room. That is, if a family occupies a five-room house, they pay \$5.00 per month. In addition to this, they pay a very low rate for electricity and water. All of these homes have large lots, usually 70 by 125 feet, affording plenty of sunlight and air. The remainder of our employees live in villages near the mine. These villages are much cleaner, and more attention is paid to sanitary features in them than in the average municipality. Given these excellent conditions one ordinarily would assume that the field for the services of a nurse would be limited to caring for the sick, and to first-aid work. We feel, however, that we have found a much larger field for her services.

It has been established beyond any doubt that a contented workman is more efficient than one who is discontented. Inasmuch as the success of an industry depends upon the efficiency of its employees, it is therefore wise to consider their happiness and contentment. If it is within

the power of an organization to remove any causes of inefficiency and unrest, it should be done. There are numerous causes of unrest and they present as many problems and remedies. Not the least of these problems is that of keeping the family contented.

Elbert Hubbard said:

"True life lies in laughter, love, and work."

The metal mining industry is well able to, and has been, furnishing the latter essential to a true life for some time. But what have we done to further the laughter and love?

#### UNHAPPY HOMES MAKE DISCONTENTED WORKMEN

The larger proportion of our miners are of foreign birth. They have settled in our communities with their families. Their wives, being of foreign birth, have come to this country, usually leaving their relatives across the water. They have been brought into our midst and have been left to shift for themselves. Having no warm friends, they have missed the social life to which they were accustomed in the country from whence they came. Finding no social life, it seemed to them that an insurmountable barrier prevented the enjoyment of the social diversions they craved. If this condition existed for a considerable period, what would be more natural than to have them become disgusted with America and its industries which, to their minds, was responsible for their unhappiness. This unhappiness would eventually affect the work of the husband, for instead of finding his helpmate waiting for him with a smile, he would be greeted with a tale of dissatisfaction. With these conditions prevailing, it makes no difference how good the working conditions, or how large the pay check, the man will eventually leave the community for one in which he thinks his family will be satisfied. They will move and find conditions in their new home about the same. After a few more moves, always looking for that better place but never finding it, the workman becomes dissatisfied also, and he begins to feel that the industry is responsible for his unhappiness. When this idea begins to enter his mind, he becomes a comparatively easy prey for the sleek-tongued agitator.

It makes no material difference upon whom the responsibility for this condition rests. It is here. It concerns us as an industry, and we must prevent it. In other words, we must help supply the joy and happiness which will supplant the tears with laughter, the first requisite of the true life. I am reminded of a few lines by C. E. Bowman:

"There is not a place in earth or heaven,  
There is not a task to mankind given,  
There is not a blessing or a woe,  
There is not a whispered yes or no,  
There is not a life, or death, or birth,  
That has a feather's weight of worth—  
Without a woman in it."

There, I believe you have the answer—the industrial nurse.

## NURSE MUST HAVE QUALIFICATIONS OF SOCIAL WORKER

Now, let us assume that we are all agreed that a nurse may prove a profitable investment, and that one or more will be employed. Possibly you may think that a trained social worker would be more satisfactory. Since the adoption of the eighteenth amendment, the liquor question is not acute. There is no great problem of unemployment to deal with and, as I stated before, the housing problem is better taken care of than in most communities. This being true, we can eliminate the idea of a social worker. There is some need, of course, for work of this kind, and it is my opinion that we should have a person who will be able to fulfill the duties of a nurse and social worker as well. By virtue of her professional training, the nurse can be of service to the workers at the time when they are in trouble and most responsive to kindness. After having gained their respect and love in this way, she can begin her social duties.

The foreigner in common with the rest of us has a certain pride about himself and his home, and we should respect the privacy of the home at all times. It is therefore patent that the nurse have tact, in order to get the confidence of the folks with whom she is to deal. Little Joe Krakovich needs a new romper suit, and his mother would love to have him dress like Jim Fisher who lives next door, but she is unable to cut the cloth and make it. On a friendly visit the nurse learns of the mother's wish and assists her. In a few days little Joe is playing with Jim and looks just as much an American. Are the mother and father pleased? Of course they are. When selecting a nurse, don't forget that qualification—she must be able to do plain sewing. She, of course, should be a graduate of some reputable training school and, if possible, one who has had a good education before going into training should be engaged. The nurse should be able to take the lead in the little social gatherings which she must promote. But after all is said, outside of her professional training, tact is really the fundamental requirement.

A brief explanation of our plan might be of interest to you. Our nurses are members of the safety department, and do their work under the direction of the safety inspector. They are also, of course, responsible to the General Superintendent or manager of the group of mines in the district in which they work. Their responsibility to the physician concerns only the cases which he is caring for. That is probably better illustrated in this manner. The physician who is caring for a family where there is illness advises the department of the fact. The nurse visits them, and tries to make the sufferer more comfortable and cheerful, explaining in detail any instructions which the physician may have left. Her responsibility to that physician ends when his case is disposed of. In this way, it is almost impossible for the physician to make use of her as an office assistant, or send her out to apply dressings or do other work for which he is being compensated. The nurse then, being responsible to the company, may feel free to make any suggestions as to the improvements in our medical service, without feeling that she has overstepped the bounds of professional etiquette. Our instructions to our nurses are simply this:

## INSTRUCTIONS TO NURSES

"Here is where our people live. Go out and do your best to help them keep their bodies healthy and their minds free from worry. Sympathize with and help them in their sorrow. Try and leave each home happier because you were there and, finally, try to inculcate in them the spirit of love, not only within the family, but for their neighbors and for America. Remember always, that in their eyes YOU are the company."

The instructions to our nurse may not seem explicit, but it is utterly impossible to lay out a specific plan for her to follow. She, of course, makes weekly and monthly reports of what she has accomplished, but the written and spoken words cannot begin to do her work justice. The real report can only be obtained by going into these communities and noting the changes which have taken place since the advent of the nurse. For example, let us take the case of an ordinary family. One of the children is sick. The nurse calls and helps make the little sufferer comfortable. Before leaving she teaches the mother a few things relating to the care of the child. She calls at this home often during the period of illness, becoming acquainted with the other members of the family and with their immediate neighbors. She learns the birthdays of the children, calls them by their first name, inquires about their school work, in fact she is interested in every affair of their daily lives. Soon she has established herself in the neighborhood. She remembers the birthdays of the children and comes to them on that day with some little gift. Soon the people begin to look forward to her visits with pleasure. The mother of this family has not been in good health and has dreaded to go to the hospital for an examination. Soon, however, the nurse will suggest this and will make an appointment with the hospital, accompanying the mother on her visit. Perhaps a few decayed teeth are the cause of the trouble. She will prevail upon her to have the necessary dental work done. After this work is done, the mother, being again in good health, commences to take a new interest in life. Then comes a desire to improve her home. She will want new curtains and new furniture, and of course the friend of the family, the nurse, is called upon to assist in the selection of this material. She will then wish to associate with her neighbors. The first step in this is usually taken during the canning and preserving season. The folks are brought together in a home, where the nurse has arranged for a demonstration by a person skilled in that work. The friendships formed at this little gathering grow, and probably during the winter they begin to meet at little-neighborhood parties, sponsored by the nurse. After she can associate with Americans, and have the family dress like them, the mother learns to laugh and to live. Then, instead of the workman coming home to a harping, nagging wife, he finds that joy has supplanted gloom and his home is, as it should be, a temple of happiness. In the home where happiness reigns, there you will find love, not only in the family, but also love of America, its institutions and industries. When this attitude prevails among the workmen, and America's industries recognize the blessed trinity of laughter, love, and work, we will have made a real start toward the solution of one of the great problems confronting us.

CHAIRMAN TILLSON: I know your applause indicates that you all greatly appreciate this fine paper that Mr. Martinson has been kind enough to give us, and I feel sure that it isn't out of the way that we should have a paper on such a subject come before our individual Section.

I should like first to have Mr. McIntyre open the discussion on this subject.

#### DISCUSSION

MR. M. D. MCINTYRE (Pickands, Mather & Co., Cleveland): I know of one place in particular where we had a home fitted up for the nurse and our folks provided funds for her to select first-class furniture but by preference she got some old furniture. She wanted to do that because she wanted to show the wives what could be done with old stuff fixed up. I think a whole lot depends on the tact of the nurse.

MR. S. C. REYNOLDS (Aetna Life Insurance Co.): In the anthracite fields one of the large anthracite operators has established just what Mr. Martinson speaks of—community nurses and hospital units in isolated mining communities. It is wonderful what this feature has done in a moral tone for that mining community. It has built up the relationship that should exist—which, unfortunately, we haven't had existing in the past—to the extent that we might have had of which Mr. Martinson speaks, natural love. I thought of it this morning when I was over in one of the other sessions when we were dealing with how to get this safety-first idea across, who was the most responsible, the foreman, the superintendent, the manager or the workmen themselves.

It seems to me that what we want to do is to get a closer relationship, and that is one of the means of doing it. The owner of the mine I am thinking of now told us that they had fixed up that little brick building that had been used primarily as a lamp house until it was too small. The nurse was there in her white uniform. This work leaves the feeling with the workmen who go by and have had their minor injuries attended to that the employer is really interested in their welfare; it brings the workmen and the employer closer together.

CHAIRMAN TILLSON: I would like to know whether or not you take advantage of the services of the visiting nurse to follow up absent employees, to visit the homes of those men who have been absent say three days in succession to find out if they are sick or on a drunk or whether the children are sick or what is the matter that they don't come to work.

MR. MARTINSON: Our nurses are hired primarily for the tact we feel that they have. In fact, we have had authority to put on more nurses for nine months and haven't found a girl that I thought had the qualifications, and rather than put on some one whom I wasn't satisfied with, I let the job go.

MR. RHODES: A visiting nurse went to a house where there were five sick children and the wife thought that the nurse should give her entire time to her family. The husband was making nine dollars and a half a day with the Case Threshing Machine Company. The wife said the Case Threshing Machine Company had inaugurated this thing and had money enough to allow this nurse to take care of those children. She asked her

husband to resign his position, which he did. It aroused resentment in that case.

MR. MARTINSON: We have never had any trouble of that kind. Our people have always felt, I believe, that they have had all the service from the nurse they were, in fairness, entitled to.

MR. RHODES: What would you personally instruct your nurse to do if she came back and reported to you that a family expected her to give her entire time to them?

MR. MARTINSON: I believe I would tell her to do just as she had been instructed before, not to give them any more time than she felt was necessary at that home. We have been working with the nurses for about four years and that question never has come up.

MISS M. MCKAY (Industrial Nurse, Hydro Electric Power Com., Toronto, Ont.): We quite frequently come across cases in visiting where the nurse cannot remain and give her entire time but, as a rule, we know of some one we can put in there and give the help that is needed. We can't always put an experienced person in there but we can put a person in who, with supervision, can give the help that is needed, and that often gets us over the difficulty.

MR. MCINTYRE: In a case of that kind; I think that we wouldn't care to have a visiting nurse devote her entire time there but we could handle that as an individual case. We could hire some one there to take care of the situation, to help the family out before they had a chance to start any resentment.

MR. REYNOLDS: During the last six months our company has installed hospitals and nurses at mining communities, both in the anthracite and bituminous fields on their own initiative and at their own expense. I have in mind a mine where we had three hundred employees and I don't think I have ever heard anything of that sort coming up; and I don't think any one of those non-English speaking families would expect a nurse to devote her whole time to the family. They readily understand that she is covering the whole community, the men and the employees and is giving what service she can.

We don't want her to go into a house uninvited. She approaches that in a roundabout way. She gets acquainted with the children and gets to know the family and the little peculiarities and gives the service we desire.

CHAIRMAN TILLSON: I think we realize that Mr. McIntyres' remarks on that question in a broad sense covers the situation as well as anything can.

I would like to ask Mr. Martinson to consider a former question, and that is as to whether, if the community is large enough, even though only representing one mining county, it might not serve to some advantage for the visiting nurse to be employed by the Borough Council, or whatever form of organization the community has, instead of directly by the mining company, although without doubt the mining company is paying the expense of those things through public taxation, but human nature realizes that they have to play fair to a certain degree where they are dealing with their fellowmen and they get a wrong idea when they

are thinking of something as a corporation, that they can dip their hands into its money-bags, that it is theirs for the asking. That is a psychological impulse that exists in all of us. When we realize that the nurse belongs to the community, we realize that others have just as big a right in that nurse as we do.

MR. R. D. HALL ("Coal Age"): There is a great deal of feeling around the mining camps that the doctor doesn't give enough attention to the individual patient, and there is a great deal of resentment. It is sometimes alleged that the doctor neglects his patients, and sometimes, in fact, he does. That is met very well by the trained nurse who comes in there and takes care of that patient during a period when the doctor can't be there and she is able to make the excuses for the doctor—and sometimes the excuses are perfectly reasonable—and help to avoid the resentment that would otherwise be felt, and there is very little question but what, if she had managed to ingratiate herself sufficiently with that family, her explanations for her own absence would be sufficient. I think in the particular instance mentioned, the man's back was very much to be preferred to his face, and I don't think anything would be lost by his leaving the camp. There are some people who are so unreasonable in their demands on a corporation that if they left it would be a source of joy to the whole community. I think he was probably one of that class.

MR. WILLIAM CONIBEAR (Cleveland-Cliffs Iron Co., Ishpeming, Mich.): My Company has had industrial nurses for ten years. Whenever we find a woman is run down, if it is in the summer months, we have a summer rest house where she can go for from one to three months to rest. If we find a mother is run down and it is necessary for her to go to the hospital, we send her there. If her husband is making eight or nine dollars a day at the mine, he pays for it; if he can't afford it, we pay for it. There has never been any friction or any trouble come up at all and we have employed nurses for ten years.

MR. G. J. JOHNSON (Homestake Mining Co., Lead, S. Dak.): We have established standard nurses all on salary. We have had that for so long the people have gotten used to it and like it quite well. Our nurses don't go out on cases. Whenever there is need of a nurse, the case is brought to the hospital and in that way the individual case can be given more time. Very seldom do we have any overcrowding in the hospital and thus we have found no need of visiting nurses.

MR. GIDLEY: I paid a visit to Mr. Johnson last year and I was very much impressed and very much interested in the method by which the Homestake people conduct their hospital operation. The physicians are allowed absolutely no outside practice, working under a strict salary basis. I know that in a great many mining communities a great deal of dissatisfaction often arises from the fact that where physicians are allowed to do much outside practice (They, of course, like the ordinary run of human nature, are looking after the monetary side of the question) they very often given more attention to the outside patient than to the employee of the company, and that causes much discontentment among the employees; I believe the Homestake people have that problem solved.

MR. JOHNSON: They visit the homes. Not only the employees but the families are covered by these calls. If the case justifies it, we ask them to appear at the hospital; if not, the people are at liberty to call for any specific physician on our staff, but they do not make the calls to the houses to a great extent.

CHAIRMAN TILLSON: How many physicians are on the staff and how many employees have you?

MR. JOHNSON: We have sixteen hundred employees and we have ordinarily five or six physicians. The service is free to employees.

MR. BROWN: What salary is paid the physicians?

MR. JOHNSON: I have never paid any attention to that.

MR. GIDLEY: With reference to the salaries, the Chief Surgeon of the Homestake Company told me last summer that the salary of physicians ranged from \$250 a month up.

MR. ORR WOODBURN (Globe-Miami First Aid, Globe, Ariz.): It is amusing; they come to me in first-aid work and ask me about this and that, and complain of the service they get from the different doctors.

The private physician down town usually has the railroad work and those railroad boys come up to the Mining Company hospitals and pay cash money for their treatments because they get better treatment, and some of the mining boys go off to this same railroad physician and pay cash money because they think they get better treatment. I know of so many instances that it is very amusing, and I doubt, if you would run it down, whether you would find any instance where the doctor was slighting the company patient, as he wouldn't enjoy the respect of the community if he gave that kind of service.

#### SHOULD NURSE BE USED TO LOOK UP ABSENTEES?

CHAIRMAN TILLSON: I haven't heard any one discuss the question in regard to the visiting nurse trying to reduce absentees. I might say that in our experience that is one of the most valuable functions that the visiting nurse has. It means more in dollars returned directly to the company.

MR. MARTINSON: I believe that most of the men have missed the point entirely that I was driving at in my paper. We absolutely divorce the nurse from the doctor. We don't hire the nurse because we want her to help the doctor in his work. We figured that if he wasn't getting enough money or had too much to do, he would have to have an assistant, or if he didn't get enough money we would have to arrange that some other way.

Our idea is this: That the nurse could be of some social service. We could hire a social worker but she wouldn't have the way of worming into these families and getting under their skin, if you want to use that expression, and trying to do something for them in the way of removing some of these ideas that people are getting or have been getting in the last few years concerning industry and capital. That is the point we made. We feel that is the big point in the nursing proposition. We don't provide the nurse with a place to dress injuries; we are paying a doctor to do that and he has to do it.

The nurse has been able to tell us of instances where the doctor has alighted or hasn't done the proper thing by his patients and in such cases we like his back better than his face.

Now, this question of looking up absentees. We have not used our nurse for that to any great extent because we have felt that if the nurse comes into a home and inquires (particularly in a boarding-house) as to where Joe, or Pete, or whoever she is looking for is, they will feel that she is some one sent out by the general superintendent or the mining cabinet at the camp to see what he is doing, and, of course, he resents it. He should. I wouldn't want a nurse to come into my home to find out why I wasn't at work. I feel that my employer should feel that I was honest enough to do the right thing and I think these men would feel the same.

Our absentees are looked up by our local safety inspectors who put in a great deal of time looking up absentees. We have found that has worked out a great deal better.

Now, in regard to the community employing the nurse instead of the mining company, I might say that our communities are particularly fortunate in the fact that they have plenty of money to spend and they all have nurses. Our school districts have nurses; they have a number of them.

We want our people to feel that they are absolutely working for the squarest and best outfit and that is the only way we can keep our operations going properly, that is, to get that idea home to the men, and unless we can give them this little service why they feel that it is a problem of the community and doesn't help us in their eyes, and we want to feel that the people are benefited by the services of the nurse.

MR. R. H. SEIP (The New Jersey Zinc Co.): I would like to take issue with Mr. Martinson. He said he did not feel it was good policy for the nurse to look up absentees, that that would cause resentment, that they should send a man from the safety department.

Now, if the nurse is as tactful as she should be, I don't believe that that would cause as much resentment as it would to send a man from the safety department to find out where this man is. The point I am making is that a great many absences are not due to the sickness of the man himself but it may be due to the sickness of his wife or children. We have found that to be the case and when the nurse goes around to find out why the man is not working, she immediately finds out the other cause for his absence—that he has to stay at home and look after his wife or his children. Now, if that is the case, the nurse takes care of the sickness and arranges with the company to look for some one to take care of the work. Now if there was a man sent around to do that he would have to go back and report that condition and the nurse would then have to go to take care of it. That is one reason why we do send a company nurse out to follow up absentees.

MR. REED: I believe that if nurses go around to find out if it is sickness that is keeping the man from work they will be welcome. I think that when you want to find out just exactly how many men are drunk and lazy and just simply don't want to be on the job that you ought to send around a man in the capacity of a policeman or a safety man.

CHAIRMAN TILLSON: The fact that a nurse goes into the home and finds out the condition that is keeping the man away from work increases the number of men coming out to work, and that is where you make money by having a visiting nurse. I think that wasn't properly emphasized when I mentioned that the visiting nurses could return very materially and directly to companies for their services.

#### THE INDUSTRIAL VISITING NURSE FROM THE DOCTOR'S VIEWPOINT

DR. A. J. LANZA (Medical Director, Hydraulic Pressed Steel Company, Cleveland): Mr. Martinson's paper was very fine. There is no question at all but that a visiting nurse is worth her weight in gold.

I have spent a great deal of time in the mining camps of the Rocky Mountain District and I am perfectly free to say that I could not have accomplished a tenth part of my work if I had not been assisted by able, conscientious, and efficient visiting nurses. There is absolutely nothing like them and nothing to take their place.

On several of these other points I find myself very much at issue with some of the things that have been brought up, particularly in regard to the correction of absentees. I think all of us are inclined perhaps to get away from the fundamentals. In the first place, what is a nurse? A nurse is a woman who has put in three years of her life in getting an education in a first-class hospital in the care of the sick. She has three years of arduous toil and it is a very hard life. She has to take the examination from the State Board of Health to show that she is fit to take care of the sick. Her education and her training, therefore, entitle her to take care of the sick, and they don't entitle her to do anything else. Don't mistake me for a minute when I say that because I am fully aware of the enormous value that a visiting nurse or any other nurse can be, but when you get right down to it, her function is to take care of the sick, and I feel like the gentleman over there, that if you employ a nurse in other departments to run down absentees or the like, you are hiring a person for one thing who is trained in another.

I have in mind a very large corporation not very far from here that employs from ten to twelve nurses in the employment department for the purpose of visiting absentees, their idea being that the nurse, because she had a uniform on and a sweet smile, could go around to John Jones' or Jack Krakovitz's house when he didn't come to work and find out why he didn't come to work and go back and tell the employment department. They take advantage of the fact that the family's first idea when they see a nurse in the nurse's uniform is that she has come to take care of the sick; that is what she is for but instead of that she comes to find out whether Joe is drunk or gone to the baseball game or his mother-in-law's funeral, and the men resent that and they call them "dog-catchers."

Fundamentally, the purpose for which a nurse functions is first in the care of the sick and then in so far as her contact with the people and the families in the care of the sick enable her to be of help and assistance in other lines, and just in so far as she does that, she becomes more and more valuable to the organization that hires her; but I cannot see the

proposition of hiring a trained nurse to be a record clerk or a stenographer or running down absentees or half a dozen other things that you find in the various places.

I can't quite see Mr. Martinson's point when he says he doesn't hire the nurse to be a help to the doctor. If primarily the nurse is educated to help a physician in the case of the sick, which is absolutely appropriate, as it is the only education she gets and is carried out to a very high degree of specialization, why hire her to be other than a help to the doctor? I can't conceive of a first-class medical system in an industry not needing nurses.

In all my wanderings over a great many mining camps and a great many mining corporations where the medical service is handled in many different ways, I have come to certain rather clear-cut conclusions. The system may vary and it is bound to vary in so far as local demands make it necessary. I can't compare a medical system, for instance, in a remote place in Arizona where they have to do everything, with a more settled community in Michigan, or in New Jersey. You can't compare them. Therefore, the thing by which your medical system falls or rises, efficient or not efficient, is the spirit behind it, and where you have a medical system that is run for profit, it is no good. If the medical system is based upon profit for the physician or hospital or corporation running the medical service, why you inevitably get one result—a maximum of price with a minimum of service.

Let us remember in all this talk about the function of the nurse that the fundamental thing is that she is educated through a long and arduous process to take care of the sick and just in so far as she dovetails her duties away from that solid foundation, the proposition falls down.

(The following paper by Mr. Hubbell arrived too late for presentation at the meeting.)

### GETTING THE SAFETY MESSAGE TO THE INDIVIDUAL MINER

N. D. HUBBELL, GENERAL MANAGER, DAVIS AUTOMATIC CRADLE  
MANUFACTURING COMPANY, UNIONTOWN, PA.

The best known safety device is a careful man. Safety appliances and safety rules are of course essential, but their effectiveness is limited by the extent to which the safety idea is a controlling factor in the lives of your workmen. It behooves us then to get the safety idea to our men in such a way that it will make an impression,—an impression vivid enough to dominate their every act, not merely for the time being, but all through their industrial lives. And in order effectively to get the safety message into the minds of our workmen and to keep it there continuously, the whole atmosphere must constantly be kept charged with the safety idea. This called for a comprehensive, well balanced program of safety propaganda; comprehensive in that it effectively reaches all classes of workmen;

well balanced in that it covers all phases of the safety idea and lays the proper emphasis on each.

The safety man then, in order successfully to put across a program of safety propaganda, must study his problem thoroughly and systematically. As I see it, there are six steps or phases of this task:

1. Study your safety problem, especially your Analysis of Accidents by Causes, to determine what ideas you need to instill in the minds of your men to prevent accidents.
2. Study the psychology of all classes of your workmen to learn the best ways of reaching them.
3. Study the other fellow's methods with the purpose of adapting as many of them as possible to your own problem.
4. Work out your safety messages so that they cover the whole field and in addition have enough novelty to attract attention.
5. Send out your safety messages in enough different forms and through different channels to reach all workmen effectively.
6. Change the subject matter and channels of presentation often enough to keep them from going stale.

I now want to outline rather briefly several features, some of them started and some only projected, for a safety campaign in the bituminous coal mining region. Time does not permit me to go into detail regarding the organization and workings of the whole safety department, so I will confine myself to the principal methods or mediums used to get the safety message to the individual miner.

#### I. THROUGH PERSONAL CONTACT WITH OFFICIALS AND SAFETY COMMITTEE MEMBERS

Personal contact is the best way to get any idea across. Consequently the most effective way to get the safety message to the individual miner is through his contact with the local mine officials, foremen, assistants, fire bosses and safety committee members. The officials meet the miners at work in the pit where they can illustrate and drive home safety lessons as the need for them arises. Workmen respect suggestions coming from officials whom they know to be practical men, especially since they can be enforced by disciplinary means if necessary. However just because the foreman has this personal contact with his workmen, you can't simply "pass the buck" to him on safety work and expect permanent results through his efforts. The foreman is primarily a production official, safety is a side line with him and properly so. It is a mistake to try to make the foreman put safety first and production second. The thing to do is to show him how to handle it effectively as a side line and to keep pushing it. There are several ways of keeping the foremen keyed up to safety.

Apply the personal contact principle to your foremen. You as safety men should visit the various foremen at work in the mine and go over with them their specific safety problems. This also gives you a chance to cultivate the acquaintance of your foremen. A little time spent on such missionary work will yield big returns in getting the co-operation of your

local officials. Pass along to them some of the new ideas you get from magazines, meetings, and other sources. Get their opinions and ideas, you will find that they have some good ones which they will give you in conversations, but which they never would express in a meeting.

I don't mean by this to discredit meetings, for they are splendid features. You should hold an informal meeting of your local officials at each mine during the fore part of the month. In addition to being present yourself, arrange to have one of the higher operating officials present. At these meetings give them some facts and figures covering accidents for the preceding month. Give them the standings of the various mines or units figured on some such basis as the number of days lost on account of accidents per average hundred men actually working. This will stimulate the element of competition and works pride. Give them the analysis of accidents by occupations and causes, pointing out any special features, either good or bad. Give them also the cost of accidents and compensation for their mine. Very few foremen have any idea as to what accidents cost, and an insight into it stimulates them to better efforts because they are interested in costs. Take up in detail each accident happening at that mine during the previous month, having the official in immediate charge of the injured workman give a report of his investigation of the accident. No man likes to report that an accident happening under his supervision could have been prevented, consequently this plan is particularly effective in reducing accidents. In addition you can also discuss any accidents happening at the other mines that have a special point of interest. Have an open discussion giving every one a chance to bring up any safety suggestions or ideas that they may have. Occasionally you can give the men a short inspiring safety talk. We all need such inspirations occasionally; that is why we are here.

Supplement these meetings with a weekly letter to all of these officials. These letters can take up peculiar accidents of the previous week, digests of current magazine articles, or other safety topics of general interest. A short letter each week will accomplish wonders in broadening out your foremen and giving them a safety background.

Carry the meeting idea one step farther. Once in a while get the major officials from all local mines together for a dinner meeting. Have a good speaker from the outside give them a talk on some phase of safety. They get tired of home talent no matter how good it is.

Give your foremen the ammunition for the fight against accidents, help them map out their campaigns, show them how to reach their men with the safety message and keep their interest up by the same means that yours is stimulated—facts, figures, new ideas, and inspiring talks. You will find that they will respond by doing their share to permeate the atmosphere with the safety idea.

## II. CONDITION AND CONDUCT OF THE PLANT

The second medium for presenting the safety message is the condition and conduct of the plant. The general impression a workman gets as to the way a plant is run has much to do with his attitude toward safety.

If safety rules are made and enforced, and if everything is kept safe, clean, and orderly, it will be reflected in the workmen. The opposite is also true. It is useless to preach safety to the men if the company is not doing its share to make working conditions safe. I have placed this second in importance, it could be elaborated on to considerable length but I will leave it for you to fill in your own details.

### III. BULLETIN BOARDS

The third medium of presentation is the bulletin board. This topic has several aspects. Location, lighting, arrangement, and changing of bulletins has to be considered but these phases have been quite thoroughly covered in the N. S. C. literature so I will pass on to the main topic,—the bulletins themselves.

In the first place you need a high-class series of general accident bulletins. For this series you naturally want the N. S. C. bulletins because they are the best obtainable. They are the cream of all the accident bulletins produced in the country. But, although each one forcibly drives home a safety lesson, they are necessarily of an impersonal nature and do not draw men to them as a rule.

Consequently in the second place you need a feature series that will draw your men to the bulletin boards. The comic cartoon is the most effective drawing card or headliner. In addition to the comic feature, these cartoons can also be used to drive home some point in connection with the safety or industrial relations program. The house organ exchange list.—Life, Judge, The Literary Digest, and other magazines will furnish good jokes on almost any subject if you are on the lookout for them. These can easily be worked over into themes for cartoons. Have your main characters continuous, running through the entire series and if you are getting a laugh in each issue, it won't be long before your men will be watching to see what has happened to them next. If you don't have both the time and talent for drawing cartoons, you can usually find some one in the organization or in school who will make the drawings for you on tracing cloth at a reasonable cost. They can then be photostated or made up as reverse blue prints for posting. It is surprising how easy they are to work up.

In the third place you need a series of bulletins of your own accidents. Local color is an attraction even if the bulletins are rather crude. If the trouble and expense of making photographs does not justify this method, have sketches made and printed in the same way as I suggested for the cartoons. Use the more serious accidents due to carelessness and you will find that they are very effective.

In addition to the regular bulletin board, you should have a large device of some kind, a safety target, a safety thermometer, a safety race, a safety and accident battlefield, or some unique device for showing inter-departmental or inter-works standings. Advertise this competition feature conspicuously to foster works pride. It may not appeal strongly to every one but it will react the live ones.

## IV. FIRST AID AND MINE RESCUE CLASSES

Your first aid and mine rescue classes include quite a number of your most intelligent and enthusiastic employees. Their classwork is closely allied to safety so if you handle them properly you can get from them some good support for your safety campaign. Give them safety talks, discuss with them some of your plans and scheme. They may not be able to give you many original ideas, but they have the workman's viewpoint and can give you some worth while pointers on his psychology. Give them something to do in connection with the safety program and they will feel a certain responsibility for it and help put it across.

## V. HOUSE ORGAN

The fifth medium of presentation is the internal house organ or employees' magazine. The point that we are interested in is how to dress up the safety message in the house organ so that our employees will read it. We all know that only a small percentage of our employees will read the ordinary, well written, heavy article on safety. There are several methods however, by which the safety message can be put in the house organ so that it will at least be noticed. Use illustrations freely, pictures and cartoons always attract attention. Put in photographs or sketches of some of your accidents, safety devices, or some individuals or groups that have done some real good safety work. Use some good safety cartoons even if you have to make them up to fit your own needs. Use jokes to illustrate points in your safety articles. We all like to read funny stories, so weave appropriate ones into a safety talk and it will be read just to get the stories. The man who can't be reached through his sense of humor is the exception so capitalize this characteristic. Verse is also good. Almost anything written with rhyme and rhythm will be read. Write some short verses on safety themes; if they are funny, so much the better. Write some parodies on popular songs using safety themes and you'll soon hear the kids singing them. Unique wording appeals to the more intelligent, try parables or fables for a change. If you have a number of more intelligent men who are live wires and on whom you can depend to help put it across, try a free for all poem. Take a character like a goat or a mule, let him go into the mine and have some of the more common accidents happen to him. Write up the first installment in a humorous strain, using a simple meter. Then throw the poem open by inviting every one to send in verses for the next installment. It will be pretty generally read and some will do some intensive safety thinking in writing up the verses. Safety slogans can be used to advantage all through the magazine for fillers and in this way you get safety on every page.

## VI. CALENDARS

The sixth medium of presentation is a safety calendar. Take a dozen of your best accident bulletins or cartoons and make up a calendar similar to the N. S. C. calendar only on a smaller scale, and put one in each

home. Calendars are used constantly so they will be continually preaching safety for you.

#### VII. THE SAFETY RULE BOOK

The seventh medium is the handbook of safety rules. Opinions differ as to the effectiveness of such a booklet, but if you have men who can read and understand it, a book of specific safety rules, carefully and concisely compiled, will get the safety message to your men. You should however have some means of checking up to see that they are read and understood.

#### VIII. MEETINGS AND SHOWS

The eighth medium of presentation is meetings and shows. If your workmen understand English well enough to warrant it, hold safety meetings or revivals occasionally for them and their families. Cover public safety in addition to safety as applied to the mine. If most of your men cannot understand English use motion pictures, the universal language. Get one of the Bureau of Mines' films on mine safety, run a comedy in addition to it, and give your workmen tickets for themselves and their families. These shows are good attractions as a rule and you will have no trouble getting a crowd out.

#### IX. THE CHILDREN

The ninth medium of presentation is through the boys and girls. In connection with your playgrounds, boys and girls clubs, boy scouts, juvenile first-aid classes and the regular schools, arrange to have safety taught to the children while their minds are still plastic. They will have a great influence on their parents and then, too, they are the next generation of workmen. Instill the safety idea in their minds and it will bear fruit for years to come.

Now there is just one more thought I want to leave with you, the success of the safety program depends largely on the personality of the safety man. He must be a live wire, energetic, resourceful, diplomatic, and a good organizer. He must have that rare quality of being able to get the whole organization behind him, but not too far behind. I have been able in the time allowed to only hit the high spots, details that I wanted to give have had to be omitted. If any of you are interested in more details regarding any of these ideas I will be glad to give them either in the meeting or outside.

ADJOURNMENT.

### WEDNESDAY MORNING SESSION

**T**HE meeting was called to order at 9:45 by the Chairman, Mr. B. F. Tillson.

**CHAIRMAN TILLSON:** The Chairman of our Committee on Standardization of First-aid Practice, Major Shields, has, during the past year accomplished a piece of work which it had been our desire to get accomplished

for the past three or four years, and we had not been successful in reaching the conclusion which Major Shields has brought about in his Committee this year. I think that we owe a great deal to Major Shields for putting the matter through in its entirety, that is the co-ordination of the National Safety Council with the United States Bureau of Mines and the American Red Cross upon a final, uniform set of standards for training men in first aid and for judging first-aid contests.

Dr. Hunter, of the American Red Cross, who was Secretary for Major Shields' meeting yesterday, will present Major Shields' report which I said would be postponed. It will be really a report of the Secretary of the Committee, and I will ask Dr. Hunter if he will present the resolutions which that Committee voted upon.

REPORT OF COMMITTEE ON STANDARDIZATION OF FIRST-AID PRACTICES

DR. E. R. HUNTER (American Red Cross, Washington): It was recommended:

1. That all classes of employees should be taught first aid and men in supervising positions should be specially trained.
2. Minimum number of hours for a course in first aid to be fifteen.
3. Physicians who have specialized in first-aid work and laymen who have received card of appointment as first-aid instructors from the U. S. Bureau of Mines or Red Cross to teach first aid courses. (Doctor Sayer and Colonel Conner to confer with reference to issuing a list of qualified instructors, etc.)
4. Endorsement is given to the two standard first-aid text-books to be issued with identical text by U. S. Bureau of Mines and the Red Cross Miners' Editions which are now in the course of revision.
5. In the revision of the Bureau of Mines and Red Cross text books standard materials be advised or named for instructive purposes. Also, the triangular bandage be emphasized as preferable for first-aid use as compared to the roller bandage. The teaching of the use of the roller bandage to be confined to special cases.
6. Judges at first-aid contest to act as a committee of three, two physicians and one lay judge. The lay judge to be acquainted with the industry represented in the contest. No contest to be held unless a physician be represented among the judges.
7. Contest to be held in accordance with rules formulated and approved jointly by the U. S. Bureau of Mines and the Red Cross and National Safety Council. Recognition in drawing up rules for first-aid contests to be given to suggestions submitted as to discounts, team rules, etc., as made by Mr. B. F. Tillson of the New Jersey Zinc Company and Dr. H. W. Gentles of Chicago and others.
8. Any first-aid contest to be regular and standard or to be officially recognized shall be first authorized and held under the auspices of either the American Red Cross, the U. S. Bureau of Mines or the National Safety Council, and that a representative of one of these organizations be present at the contest and that no reward of Red Cross medals or U. S.

Bureau of Mines and National Safety Council prizes or awards be given unless the above is complied with.

9. The National Safety Council Mining Section has a permanent first-aid contest committee composed of a representative from the U. S. Bureau of Mines and the American Red Cross to act in co-operation with the Mining Section and the National Safety Council in authorizing and supervising contests and awarding prizes and medals.

CHAIRMAN TILLSON: Having heard the report of the Committee on Standardization of First-Aid, I would suggest that we have Major Shields' paper and any discussion of that report will come in conjunction with the discussion of his paper.

### STANDARDIZATION OF FIRST-AID TRAINING AND FIRST-AID CONTESTS IN MINING

MAJOR M. J. SHIELDS, FIELD DIRECTOR, FIRST-AID DIVISION, AMERICAN RED CROSS, WASHINGTON, D. C.

I was asked by your Chairman, Mr. Tillson, to prepare a paper on Standardization of First-aid Contests, but it is obvious that in order to accomplish anything in regard to Standardizing First-aid Contests, we must first have a broad standardization of the methods of First-aid Training and Instruction.

I fully realize that it would be impossible to make a standard that will apply to every kind of mining and quarry or to fit every condition in each individual mining operation. But there are some basic facts connected with all mining accidents (and for that matter with accidents in other industries) and certain modifications that can be made by the individual plant to apply to their peculiar type of casualties and working conditions without seriously changing the standard method.

There are other important reasons why we should have First-aid Training standardized besides for First-aid Contests. A principal one is the labor turnover; not only miners going from one mine to another, but the changing of instructors whether doctors or laymen. A first-aid man is trained in a certain way at a certain mine or plant. He then goes to another mine or district where they have first-aid technic, materials, and methods that are radically different, although perhaps getting the same results in the end. The man will have to be instructed over again and to be instructed over again will be a loss to both employers.

As I stated above, we have now a few standard practices that are nearly universal such as:

The Schaeffer or Prone Pressure method in artificial respiration.

The universal treatment of open wounds with iodine and a sterile dressing and the condemnation of washing wounds by first-aid men except possibly the use of gasoline in dirty greasy wounds.

The non-interference of the first-aid man in all eye injuries. The first-aid being only to protect the eye on the outside with compresses and bandage and send the injured man to the surgeon.

The treatment of shock by application of external heat, wrapping the patient in blankets and getting him to the doctor or hospital as quickly as possible.

Unfortunately nearly every instructor has a different way of treating burns and scalds. There is a great divergence in the instruction in regard to bleeding and the treatment of fractures.

#### FIRST-AID TEXT-BOOK

Some instructors teach first-aid that is too superficial, others go beyond first-aid. The crux of the whole matter, can be solved I think by a first-aid text-book, that will be adopted and universally used by all mining companies in their first-aid training. I am happy to tell you that such a book is now in the course of revision and will leave the press about January 1, 1921.

Your sub-committee on Standardization of First-aid, of which I have the honor of being Chairman, and the U. S. Bureau of Mines Red Cross Committee on First-aid have agreed to certain changes in the American Red Cross First-aid Text-books, Miner's Edition, and it is now being revised by Colonel Charles Lynch, and when issued, it will be adopted by the U. S. Bureau of Mines, Red Cross, and your committees and a report submitted the N. S. C. Mining Section for approval.

This book will contain the following standard methods of first-aid treatment of the following:

- a. Wounds, Contusions, Sprains and Burns
- b. The Arrest of Hemorrhage or Bleeding
- c. Treatment of Dislocations and Fractures
- d. Rescue and Resuscitation. Methods After Electric Shock, Drowning and Suffocation from Gas, Smoke and Other Fumes
- e. Methods of Handling and Transporting the Injured
- f. Standard First-aid Methods
- g. Standard Methods of Organizing and Maintaining First-aid Classes
- h. Qualification of Instructor
- i. Rules for First-aid Contests

As to the value of first aid in the mining industry little need be said, as its untold value has been proven by actual results years ago. I would like to add just one tribute by quoting from Mr. C. L. Close, Manager of the Bureau of Safety, U. S. Steel Corporation, who states that, since the inauguration of first-aid work, approximately 16,881 men have received this instruction. Mr. Close, speaking of the value of first aid, says: "The primary object of first-aid and rescue work is to have available specially trained men to take immediate charge of the situation where a life is imperiled, as in the case of a serious or extraordinary accident; to give prompt and proper attention to injured men, and to provide clean and aseptic dressings that will prevent infection in the wound. The excellent work of these first-aid and rescue crews has been effectual in reducing the number of infected cases to a minimum. When we consider that infected cases require three and one-half times as long for recovery as non-infected cases, there can be no doubt that the work

of these crews is of the greatest value to the workmen and to the employers.

"The first-aid and rescue crews also render very valuable services in cases of asphyxiation, electric shock, heat exhaustion, freezing, and minor accidents. In cases of cave-ins in the mines and in severe asphyxiations at the blast-furnaces, they render all possible assistance in excavating the injured men and in giving first-aid until they can be moved to an emergency station. Many workers who have been entombed and overcome by gas owe their lives to the splendid work of these crews."

Not only has first-aid training proved its value in actual accidents but it has also demonstrated its worth in "First-aid to the Uninjured or safety. For when you have a trained first-aid man, you have a well rounded out safety man.

#### FIRST-AID CONTESTS

Now as to First-aid contests, "The First First-aid Contest" in the United States was held at Scranton, Pa., on November 6, 1906, and was sponsored by Captain W. A. May, President of the Pennsylvania Coal Company, the Patron Saint of First-aid in Mining. This contest was arranged by me and participated in by first-aid teams from each mining district of the Pennsylvania Coal Company and from the beginning the First-aid Meets have extended to every mining section of the country.

The original idea of first-aid contests came over from England in St. John's Ambulance Association first-aid competitions and are intended to promote, extend, and stimulate interest in first-aid work. Contests are also highly educational both to the participant and the onlooker. A contest takes on somewhat the excitement of a real accident, teaches men to be self-reliant, cool, and collected.

Unfortunately contests in the past have been the cause of a great deal of dissatisfaction and thereby dulled the interest in first-aid work, greatly retarded and in some sections seriously injured first-aid work.

One of the principal causes of this dissatisfaction has been inefficiency and inexperienced judging. Having physicians who have had no experience in either first-aid instruction or first-aid work, who either expect very superficial work or expected highly trained-nurse bandaging, judges who played favorites, etc.

From first-aid teams that have been trained differently by different instructors, the almost universal protest is, "Our doctor told us to do it this way" and in this sentence you have the strongest argument for standard methods of training, and I feel assured that nearly and perhaps all these causes of dissatisfaction can be eliminated by a standard text-book, methods of training, rules and discounts for first-aid contests.

Anticipating the report of our sub-committee in regard to first-aid contests, I submit the following:

All judges of first-aid contests shall have had experience in teaching first-aid work, or previous experience in first-aid contests.

That the judges shall be both physicians and laymen, in the proportion of two physicians to one layman. This layman can be a safety engineer, mine foreman, or any one connected with mining who has taken

a full course of first-aid and holds either a Red Cross or U. S. B. M. First-aid certificate and who has had practical first-aid experience in or around the mine.

That the judges shall work as a committee, two physicians and one layman judge, progressing from team to team in each event or problem.

That contests shall be to the maximum of 50 teams for each day in preliminary contests and in final contests 20 teams. This will prevent the employment of incompetent judges and tiresome prolongation of the contests. When State and National meets are held, a sufficient amount of time or days shall be allotted for the contest so as to prevent hurry in the contest or haste in running off ties. No contesting team will be allowed to wear a spectacular or distinctive uniform; they shall be dressed in ordinary working attire.

That the Standardized American Red Cross First-aid Text-book Miners Edition Revised, should be the authorized book for reference and guidance. That the following table of discounts shall be used. That the judges shall be remunerated at least for their expenses, as this makes for competent and efficient judging.

#### STANDARD TABLE OF DISCOUNTS FOR FIRST AID CONTESTS

|                                                                                                                             |   |
|-----------------------------------------------------------------------------------------------------------------------------|---|
| 1. Not doing the most important thing first:                                                                                |   |
| a Failure temporarily to control hemorrhage previous to application of tourniquet.....                                      | 7 |
| b Failure to remove patient from dangerous gas, roof, electric wire, etc., at proper time.....                              | 4 |
| c Failure to do the most important thing first otherwise than specified in a and b.....                                     | 6 |
| 2. Slow and indifferent work:                                                                                               |   |
| a Slowness in work—Deduct one point for each minute or fraction thereof consumed over time allotted for working problem.... | 1 |
| b Lack of attention on part of one or more team members.....                                                                | 2 |
| c Lack of neatness.....                                                                                                     | 1 |
| 3. Defects in Bandaging:                                                                                                    |   |
| a Failure entirely to cover wound.....                                                                                      | 2 |
| b Bandaging or treating wrong location of injury.....                                                                       | 2 |
| c Tight bandage .....                                                                                                       | 2 |
| d Loose bandage .....                                                                                                       | 2 |
| e Improperly applied bandage.....                                                                                           | 2 |
| f Insecure or granny knot.....                                                                                              | 1 |
| 4. Defects in artificial respiration:                                                                                       |   |
| a Improper or insufficient preparation of patient for artificial resuscitation .....                                        | 3 |
| b Incorrect timing of artificial respiration.....                                                                           | 2 |
| c Ineffective method of artificial respiration.....                                                                         | 9 |
| 5. Splints:                                                                                                                 |   |
| a Splint improperly padded.....                                                                                             | 2 |
| b Splint improperly applied.....                                                                                            | 4 |
| c Use of antiseptic material .....                                                                                          | 3 |

7. Failure to be aseptic.....
8. Failure to have on hand sufficient and proper material to complete dressings .....
9. Awkward handling of patient.....
10. Assistance lent by patient.....
11. Arterial bleeding:
  - a Application of tourniquet so as not to stop bleeding.....
  - b For non-application of tourniquet charge additional to a.....
  - c Tourniquet applied so as to stop bleeding but at wrong points, or in such way as to injure patient.....
12. Not treating shock.....
13. Failure to command properly.....
14. Improper treatment not covered by above, such as wrong dressings, etc. ....

These suggestions and others that I will make to the Sub-committee are based on the fifteen years' experience in holding first-aid contests and on the replies to a questionnaire that was sent out through the Council to a number of mining companies. I have also had access to the report of National First-aid-Standardization Committee appointed by the President, in 1915, and the Sub-committee on Health and Medical Relief report to the Director General of Railroads February 20, 1920.

The following is a preliminary summary to the questionnaire sent out by your Sub-committee on First-aid Standardization, etc.

#### SYNOPSIS FROM 45 REPLIES

Number who have First-aid, 42.

Number who do not have first-aid, 3.

Question No. 2, As to the value of First-aid, the replies are unanimous.

Question No. 6, Which First-aid Text-book do you prefer?

|                                        |    |
|----------------------------------------|----|
| Red Cross Miners Edition.....          | 14 |
| U. S. B. of M. Advanced First-Aid..... | 11 |
| No Preference .....                    | 15 |
| Other Text-books .....                 | 3  |
| No Answer .....                        | 12 |

To Question No. 8. What percentage of your men are trained in First-aid?

|                                          |
|------------------------------------------|
| 5 per cent of Employees in 13 Companies  |
| 10 per cent of Employees in 10 Companies |
| 15 per cent of Employees in 2 Companies  |
| 20 per cent of Employees in 3 Companies  |
| 25 per cent of Employees in 3 Companies  |
| 50 per cent of Employees in 3 Companies  |

Question No. 11, Is First-aid given on the company's time?

|                 |    |
|-----------------|----|
| Yes .....       | 24 |
| No .....        | 10 |
| Part Time ..... | 11 |

**Question No. 13, Who gives your First-aid Instruction?**

|                              |    |
|------------------------------|----|
| Given by non-physicians..... | 21 |
| Given by physicians.....     | 10 |
| No replies .....             | 4  |

**Question No. 15, Do you hold contests?**

I would like to state in closing, that a complete report will be made to your General Committee of the Mining Section at the final meeting of our Sub-committee both in regard to Standardization of First-aid Instruction and First-aid Contests and I would like to add that I have, in an effort to have in future better and more satisfactory and successful contests, collected and arranged by States a roster of the names and addresses of 250 physicians and industrial surgeons who have had experience in judging first-aid contests. The list covers thirteen states. The Red Cross, U. S. Bureau of Mines and the National Safety Council have copies, and copies or a list of judges in your state can be had by addressing either of them.

I shall during the coming winter, make an effort to collect a similar list of competent non-physicians or lay judges.

## DISCUSSION

MR. D. HARRINGTON (U. S. Bureau of Mines, Denver, Colo): In the first place, any engineer or any person that has anything to do with first aid work or training cannot be opposed to standardizing. I have been around in the Bureau of Mines about five or six years, and we have had an immense amount of trouble in the past because our trainers were trained according to different systems. In the last few years we have been trying to standardize our work as far as we are concerned, and at the present time we do not have any difficulty that we had four or five years ago by having one fellow being followed up by another who said his training was all wrong.

As far as the first-aid contests in themselves are concerned, as Major Shields has said, the main trouble in the past has been the method of judging, and the method of judging has ruined first-aid work in a number of instances.

When we had our International Meet recently in Denver, we decided upon a new system of judging, and as far as I can find out we have had a minimum of complaints. We adopted the system of committees. I have heard absolutely no complaint whatever.

Another thing we did was to eliminate the elimination contests. The first-aid contests were held on two days. I would like to suggest that in the future elimination contests be eliminated.

In the past, the success at the National Meet has been largely predicated upon the number of teams attending. I don't think that should be. It seems we would be in better shape if every mining district or even state should have an elimination contest and the winner of that elimination contest should go to the National Meet and not have such an enormous number of teams to handle at the National Meet. In the first place when a Meet is held on the Pacific or the Atlantic Coast, teams sent from the other side find it costs them several thousand dollars. It puts too much burden on them. If you held a state elimination contest, you could state that the winner of that contest would be sent to the National Contest and the expense sustained by the entire mining public of that state, and then the expense would be practically negligible on any one company.

MR. GEORGE MARTINSON (Pickands-Mather Company): I am thoroughly in accord with Major Shields' idea of the standardization of practices. I think it is a fine thing. I believe that the time spent on arranging standard methods for judging contests is not well spent. Personally I am not in favor of first-aid contests for this reason: That before a contest is held, in a certain period during which you do intensive training, you get an over-dose of stimulation, and after the contest is over reaction sets in. We have found that a better way is to have our first-aid classes regularly each month. Then we don't need the stimulant and there is no danger of getting an overdose of it.

MR. ORR WOODBURN (Globe-Miami Dist. First Aid): I take exception to that. The only way that we develop good, extraordinary first-aid work is through contest. As far as there being an over-stimulant and then let

ting it die, it is to be understood that it is just like these safety drives—it does not mean that is the only safety work we do during the year; it means that at one period we pick up speed and get enthusiastic and store up enough energy to go along for another year. We are just simply setting a higher standard and a better standard.

I happened to be instructor of the Old Dominion Company in that line of work and had charge of first-aid work for several years. Our general manager was keen for contests. I used to beg him not to get up contests because they made so much dissatisfaction. But they have developed some wonderful first-aid men, and those men who are the very prominent and reliable men forget all of the unpleasantness of the contest.

About the contests making the game unpopular and causing dissatisfaction: You have one team out of a hundred coming home with first prize. Most of the others have to go home and stand the brunt and take the slurs and kidding of all the other members of the plant for the rest of the year if they get beat. It is hardly fair to take a team that finishes fortieth place and gets a score of ninety and two-tenths, and subject them to that criticism. They have represented their community and their company very well in the National Contest, and yet coming home with fortieth place sounds bad.

To offset that, I made the suggestion that instead of finishing up one, two, three, etc., in order, we finish up in classification. For instance, take the teams that finish between ninety and one hundred per cent and call them Class "A" teams. We will agree that one is as good as another even though the score is different. Put all those between eighty and ninety in Class "B", and below that in Class "C", very poor. There was only one team of the sixty-eight at Denver that fell below eighty. The sixty-seventh team had a score of eighty-two per cent. The first forty teams were above ninety, and yet there were only four or five teams that could go home in good grace. It is all right for the boys who go to the contests; they realize what they are up against; there is nothing unfair about it; but at the same time it is very difficult for a team to go home with fortieth or forty-fourth place and yet have a score of above ninety per cent. I think it could be arranged to grade them in that way and not limit the number in any one class.

MR. J. P. HAWKINS (Clinchfield Coal Corporation, Dante, Va.): I want to bear up what has been said in reference to speeding up the contests. We have done what we think is wonderful work in first-aid contests in one year's time. Last year we sent our team to Pittsburgh and it held forty-ninth place. This year we sent our team to Denver and they got fourth place. Our experience has been that the speeding up of first-aid contests is a good thing. Probably the enthusiasm after the contest is not so great as it was just before, but you find yourselves getting into a rut when there is no contest.

We have had state contests held in Virginia in the last two years, and in neither of these contests have we won first place, but we have sent teams to the National Contests and in both cases we have come out ahead of the teams that won in the state contests, which shows that the stand-

ardizing of judging in contests should be applied not only to the national contests but to the state contests.

Some one has suggested that the winner of the state contests be the only team attending the National Meet, but if such were the case should have been out of the National Meet the past two years; but have sent our team and have come out ahead of the teams that won the state contest.

DR. HUNTER: At the Denver meet I recall a team that took first place at the state meet; there were several teams from that particular state and a team that had made a poor showing at the state meet made better showing there than the team that made the best showing at the state meet. When we first consider that, it may appear to us that it is due to misjudging. At Denver, the team that made such a fine record in the state contest made such a poor showing that it couldn't be compared to the others. It was due to a complete bonehead trick. The things will happen in both state meets and national contests, and, therefore, I don't think we are justified in using the record that was made at the state meet in comparison with the one at the national contest.

MR. WOODBURN: As far as your standardization goes, surely it was working in best form at Denver in all the contests. Never was a contest conducted in any better manner than that. There were sixty-eight teams there two days without any confusion; the contests didn't run until long after dark; there was nothing of that sort, and it was a wonderful exhibition. It just goes to show what can be done in the way of standardization. Those of us interested in mine rescue hope that we can get that up to the high standard reached by the first-aid branch.

There was some propaganda started around the Denver meet to have these national contests every other year instead of each year. We were very much interested in having this meet once in a year at least. It would seem too bad to carry on a national advertising campaign after all these contests—that is what they amount to—and have it only in one issue of the year and then drop down to one every other year. You couldn't expect the advertising to go very far if you did that.

CHAIRMAN TILLSON: Of course, the question of first-aid contests is, to a certain degree, allied with any major sport; it resembles, for instance, baseball, which is a sport which has certain rules, regardless of the reasons why those rules exist. We know that a baseball team may win a series and then lose, and the same thing is likely to happen in first-aid contests. The people have to get used to their misfortunes in first-aid the same as they do in any other sport.

MR. J. W. REED (Consolidation Coal Company): I want to thank Maj. Shields for his excellent paper. We are ordinarily interested in a number of contests each year in different states, and it is quite a problem to supervise and prepare those teams under the various conditions which exist in those states. It is a job to keep track of what the judges want in each state in first-aid work, and I had to make up three sets of standards to train the teams with in order to comply with what I knew they were going up against when they got on the field. It certainly is going

to give relief in not only the national contests but the state, county, and all contests. These rules can be considered standard.

In respect to what was said about first-aid work being boosted up by contests, I feel that is perfectly true, but I want to try and find out if it wouldn't be possible to boost it oftener. I think there should be a national contest at least once each year, and I think that our local contests should be more on the order of our baseball games, that we should not hold an extensive course of training and let it culminate in just one contest. The plan that I want to try and work out for our own team this coming year will be to concentrate our training work pretty well towards the Spring and then try and hold a contest every month, having the winner of the series to represent that section, and have the National Meet take the same place in first-aid work that the National Series used to take in baseball. I believe that if we can get more contests and get them frequently in the small sections where teams are competing and there is considerable rivalry, we will build up an interest in the work a great deal more, and the states will want the standards. The spectators will want to become acquainted with the standards when they know that there is an actual standard, and it will result in their having a better idea and considerable knowledge of some portions of first-aid work which will be of benefit to them. That does not mean they will be first-aid men, but they will have certain knowledge of the essentials such as preventing infection, necessity of protecting wounds, artificial respiration, and a few other things which it would be impossible, in ordinary instruction work, to get scattered around through the mining community.

CHAIRMAN TILLSON: You have a very important proposition before you, of definitely coming to certain standards. In the resolutions of your sub-committee and in Major Shields' paper you have certain definite suggestions. I would like to pin you down and get you to say yes or no, whether you approve of these standards, and I think it would be entirely in keeping with this meeting, after you have finished such discussion, to pass a positive vote of approval of the minutes as they stand and the suggestions made by your sub-committee on which other doctors have co-operated and upon which there has been a good deal of time and attention put by Major Shields. May I ask you to indicate your feeling in regard to these definite proposals that have been made in regard to the nature of the judges, the proportion of the judges, whether lay or physicians, and the adoption of certain practices as proposed by Major Shields?

MR. JAMES THIRTLE (Inland Collieries Company, Indianola, Pa.): We sometimes get competition between teams and the men on the various teams are not working with one mind. The sooner we get down to standardization the better it will be for everybody.

It is impossible to instruct a man fully in five lectures. I would like to see this Council adopt the system of graduated training adopted in England by the St. John's Ambulance. They go through an examination every year. For six years in succession I went through an examination. I think it would be very helpful and it would dispense largely with some of this intensive training that we have to put our teams through to get

them to a contest. This graduated system would keep the men in training the whole of the time.

We have a system of weekly meetings in first-aid and rescue work we have two factions. We train them separately. The course is their own choice and we pass them from one class to another and graduate them from one stage to another. We find that that system is beneficial to us as instructors and to them in learning. I would like to make a suggestion that that be included in the new work of standardization.

CAPT. G. R. G. FISHER (American Red Cross, St. Paul, Minn.): I believe that the vital thing in standardization is a uniform text-book. I spent a year in England and took particular pains to study something of the St. John's Ambulance Association. England is fortunate in this line because there is only one text-book in England, for that matter the British Empire, and that is the handbook of St. John's Ambulance Association.

I really feel, not because I am a member of the Red Cross but after going over the various text-books of this country, that the Red Cross books are the reliable ones to be had.

Along the matter of the contests, I would like to suggest what the people of Britain are doing in first-aid work. Instead of having quarterly contests, the teams have weekly quizzes. I would like to suggest that because it is one way to keep the enthusiasm up and keep before them the correct methods. The quizzes are conducted in this way: A man or woman, as the case may be, would have a distinct question to answer "A man has fallen from the first story. You run to him. He is unconscious and fluid is oozing from the nose and ears. What is wrong?" To answer a question like that you have to be up on first-aid work. That way they keep up the spirit of enthusiasm and particularly correct methods in diagnosing and dealing with accidents.

I would like to urge the adoption of our friend's suggestion, instead of rating from one to one hundred, as the case may be, to classify them as "A," "B" and "C". That would eliminate a great deal of criticism and bantering that naturally comes to an unfortunate team.

MR. E. E. BACH (Pennsylvania Americanization Bureau): I didn't want to say anything because I am a member of the sub-committee, and I was anxious to see what would be said about the committee's report. I think the right procedure would be to vote on the report of the Committee and then have the discussion on the report. It would bring it down to essentials.

DR. W. A. LYNORR (Empire Gas & Fuel Company, Bartlesville, Okla.): I have been very much interested in first aid for years. My connection with the U. S. Bureau of Mines brought me in contact with first-aid contests and the training of people in first-aid work. It is needless to state that every one of us here is familiar with what has been done in first-aid since it was first started in Scranton, Pennsylvania, in 1906, but the contests have become a joke by reason of our incapable or incompetent judging of them by doctors. I am a physician but I have attended first-aid contests where I was positively ashamed of my profession. The

absolutely knew nothing about it. The laymen knew more than they did. I am unalterably opposed to any doctors judging contests unless they are taught themselves in first-aid.

Standardization is an absolute joke to me. We spent two years in the U. S. Bureau of Mines fixing up a standardized work. I am not egotistical in saying it, but I spent two years on that book myself. I wrote every bit of it, and when it had been finished, Dr. Shields and four other doctors were brought in to go over my manuscript and their names were put on as co-authors and I was the third man on the list alphabetically arranged, but they agreed to it that that was the proper work and they standardized it. If that is out of date, let's get the new one that is coming and in two years that will be out of date. I believe we ought to do something and stand by it. If we are going to pull credit for this man or that man because he is the author of it or because the Bureau of Mines has it or the Red Cross, that is foolishness. I say, "Do away with the Bureau of Mines book if the other one coming is going to be all right, but let's stick to what we once do." The railroad men have a book, the Bureau of Mines has one, somebody else has another one. Standardization doesn't amount to anything unless you stand by it. If you are going to use the Bureau of Mines' book, go to the Red Cross and say, "Put your stamp on this," or vice versa.

I believe in contests as an incentive to the men to work all year. They know they are going to be sent to a distant city to see something and they work hard for it.

There are some suggestions made by Major Shields that are wonderful, but there are some that I don't like, but I believe in standardization if we will stand by it.

SECRETARY R. H. SEAR: I realize Dr. Lynott's position in this matter. We have changed books continuously from year to year in the past. In England they have one text-book, but England has had, or the British Empire, if you please, first-aid training for a good many years more than we have. The St. John's Ambulance Corps is certainly a greater work than the first-aid work of the United States, and they have been able to work out a standard of first aid which they can stand by. We haven't got to that stage yet, I believe, and it is going to mean that we will have to continue our work for standardization slowly and surely until we reach a book that we can stand by. I appreciate Dr. Lynott's stand in the matter, and yet I think that we are justified in going ahead until we get to the point where we can't go any farther.

I think one of the biggest things that this committee has done touches upon another of Dr. Lynott's points, that is the judging by physicians. That has been the chief cause for discontent in all contests in the past. I know the judges were more interested in the moving picture machines than in the teams that were working, and yet I believe that the Denver contest has shown what the suggestions made by Major Shields' committee have accomplished. Judging by physicians is of no account if they don't know first aid. You fellows that teach first aid and are called upon to go to some other company and assist them in the judging of their

contests know how difficult it is to judge teams that are not trained under your system. Now, then, can a doctor who doesn't know any system of first aid, not even the principles, judge properly? We are coming to this by combining our lay judges with our physicians and surgeons. It is only a matter of time until we shall have sufficient doctors and surgeons trained so that they will be efficient judges. I believe that when the time comes our judging should be done by physicians.

DR. HUNTER: I want to say a word in behalf of the doctors and I am going through. We have heard a lot of criticism about doctors in judging first aid contests. A lot of it is no doubt true, but I don't think we are hardly fair to the doctors. It is decided to hold a state meet. About two days before the meet is held somebody asks who are going to be the judges. They call in some doctors, there is no preparation made as to the rules or what should be done. Some of the doctors don't know anything about mining conditions and yet you expect them to go there and judge a contest and come away without any criticism.

Dr. Sayers went out to Denver to get the doctors together and go over the rules and the regulations and demonstrate the bandages and bandage forth that would be considered standard. As a result of his work I believe the success of the Denver meet is due, and I think that before we criticize the doctors any further in any of the state meets, it is up to the people that hold the meets to see that the doctors are gathered together in sufficient time and instructed as to what is expected of them. Then if they don't measure up we are justified in criticizing them.

MR. HARRINGTON: I think everybody has lost sight of one point. In the last three or four years, there were very few doctors that knew anything about or cared very much for first aid. During the war period we had a number of doctors that went into the war and they had to learn and teach first aid. Now we have all through the country any number of doctors that are as familiar with first aid and maybe more so than before. In Denver, we canvassed the town to see how many doctors had experience in first aid. We found out we had to have a considerable number of doctors more than probably ever attended before, and we found that we had any number of doctors who had plenty of experience in first aid. We didn't have a doctor on the field who didn't have.

DR. LYNOTT: I perhaps am misunderstood. I said where doctors didn't know first aid they shouldn't be used. In the past we have had too many who didn't know anything about it.

CHAIRMAN TILLSON: The recommendations of the Committee were that doctors or laymen be properly qualified in the knowledge of first aid, making no discrimination in regard to professions but in the qualifications of a man.

DR. R. R. SAYERS (U. S. Bureau of Mines): I would just like to emphasize Dr. Hunter's point. I don't care who you are, doctors or laymen, if you are away from it from two to three years you don't know the method if it is a standard method. You can't remember what to do on if it isn't reviewed for you right there. We went over the rules. Laymen judges had been teaching it recently, therefore they did not

the demonstration, but the doctors that had not been teaching it recently did need the demonstrations. If I had been away from that two years I would know nothing about these dressings. Why? Because I put on so many other dressings in the meantime. An ordinary practicing physician puts on a hundred and one other dressings, and you have to review these dressings that you call standard for him.

Another thing that you have to do is call their attention to all the rules that they are to discount by so they will know what to expect. There are a number of different things that will be taken up, and they are all taken care of by your sub-committee.

MR. WOODBURN: Just preliminary to making a motion, I will say that Dr. Lynott could be very proud of his profession, because the way they handled the contest in Denver was wonderful. They demonstrated the value of the demonstration and how well it had been taken up throughout the country. Here was a team here, there was another—teams from some twenty-two different states, and it didn't make any difference what the problem was, each team was identical no matter what the chances to vary were. You would have thought they had all been instructed by the same instructor even though they used different equipment. That was one of the most remarkable things in the contest.

I would like to make a motion that we accept the report of this Committee and approve of these recommendations as presented. I am quite sure we shall not have a dissenting vote. That, of course, is to include Major Shields' recommendations.

(The motion was seconded.)

MR. REED: I want to ask, in connection with the rules on holding the contests, if there is any provision made as to the selecting and giving out of questions for the contest. In other words, there is a great deal of trouble that arises sometimes due to questions getting in which are in no way covered by the standard and they are of such a nature that each team has to work out individually some method to do it. I wondered if you people, in getting up standards, were making any provision where-by the men that made up the questions would be governed in making them up.

MAJOR SHIELDS: That is a good point and the sub-committee, which will continue its work in regard to the rules and discount tables, will take that matter up. I thank Mr. Reed for bringing up that point; we will certainly make the problems conform with the set of rules that we have.

MR. REED: There was one other thing I wanted to mention. There are two terms used frequently, one in the standards and one in the problems. One is "crushed bone" and the other is "fracture". I wondered whether the new standard would have any information for first-aid men on crushed bone—what to do with them. We get a number of problems about crushed arms, legs, hands, and elbows and the like. We know what to do with a fractured bone, but the question often arises, "Well, this is crushed, what will you do?" We don't have anything definite on it. How are we going to be judged?

**MAJOR SHIELDS:** When we speak medically of a crushed foot or crushed hand, we don't mean a fracture. That, I think, is another point that we can take up so as to specify whether it is a fracture just simply a crushing or contusion of the flesh. The way I understand it is that when you say a crushed hand you don't mean a fracture. It could possibly extend it into a fracture, but we will take that point under advisement, too.

(The question on the motion was called for and the recommendations of the committee were adopted.)

**CHAIRMAN TILLSON:** The next paper on our program is entitled, "Safety Devices on Winding Engines".

## SAFETY DEVICES ON WINDING ENGINES

L. F. MITTEN, VULCAN IRON WORKS, WILKES-BARRE, PA.

Only in comparatively recent years, and entirely within the last decades, have any worth-while attempts been made to apply to mine hoisting engines devices to prevent injury to life or damage to property due to failure of the engines, mistakes of the engine operator, or to accidents to the operator. To realize the importance of adequate safeguards in this respect, one has only to consider that millions of men are now being handled by hoisting and lowering machines operating with danger almost always imminent.

We will not attempt to account for the indifference and neglect of years, for in these days of Safety propaganda and Workmen's Compensation Acts, the necessity of maximum safety in so important a phase of the mining industry is becoming quite generally understood and a live interest in the matter is being taken by responsible mine officials as well as by legislators, inventors, and hoist manufacturers.

Probably the greatest impetus that can be given to the development and use of safety devices on mine hoists are adequate and intelligent laws and Workmen's Compensation Acts. Mine laws should inform mine officials just what is expected of him in the way of safeguards, Compensation Acts make it to his financial advantage to make every possible effort toward safety.

Generally speaking, the inventor and manufacturer have stimulated the interest of the mine officials so that today safety devices for mine hoists are very thoroughly developed and far beyond the laws' requirements and it is possible today to obtain complete protection to life and property in so far as the hoist machine and hoist operator are concerned.

Therefore, in the writer's opinion, the best way to utilize the opportunity afforded by the invitation to prepare a paper on this subject is to outline in concrete form the dangers incident to mine hoisting in general and to show briefly what protection from these dangers is necessary and obtainable.

Almost all accidents in hoisting are due to two general causes, namely: Failure of the hoist machine to function, and Failure of the hoist operator or engineer to act correctly.

Failure of the hoisting machine to function is caused by faults in design, defective material, poor workmanship, overloading and neglect. Of course no safety devices can prevent the failure of a hoist under any of these conditions, but they can prevent to a large extent injury to life and property due to hoist failure from such causes. But in some cases the finest of safety apparatus will be powerless to prevent accident unless backed up by sufficient strength, proper design, and care of the hoisting machine.

It must, therefore, be accepted as of prime necessity that hoisting machines be of ample strength and proper design for the work they are to perform. Just what constitutes ample strength and proper design is usually found to be a matter of opinion of the designer. As to strength, however, a factor of safety of not less than five should be used. As regards design, it will be well to mention a few features that some state laws already require in hoists. Most hoist drums should be provided with an indicator positively driven by chain or gearing from the drum or other hoist part having motion coincident thereto. These indicators should show to the operator the position of the cages or trip throughout the lift or haul, the exactness with which they should show such position being dependent upon the definiteness of the travel limits. Drums should be provided with flanges at each end, extending well above the top of the rope to prevent the rope from winding off. Where multiple layers of rope are wound the flanges should be exceptionally strong to resist outward thrust of rope jamming on the top layers, causing breakage.

Of the utmost importance are adequate brakes, and every hoist should have at least one efficient brake applied to the drum. For long hauls or for deep shafts where heavy loads are lowered by gravity, two brakes are advisable, to be used alternately in order to prevent overheating and probable breakage due thereto. Brakes should be powerful enough to bring the hoist to rest against the maximum load traveling at full speed. Means for adjusting brakes for wear on shoes should be required on all brakes.

Where clutched drums are used their operating mechanism should be such as to prevent slipping out of engagement, and means should always be provided to adjust them for wear.

In the case of steam hoists to prevent breaking of cylinders, large size relief valves should be fitted to both ends of every cylinder to relieve the cylinders of water.

The hoist operator should also be protected as much as possible, and the operating levers should be so placed as to keep him out of the way of a possible flying rope. Safety devices or other mechanism that cause operators' levers to move are dangerous and should be avoided.

The hoist should be designed for the maximum load it will be called upon to handle, and this load should be known to operator and cage tenders. Before men are handled on any hoist, trial trips should be made to test the equipment for possible flaws in materials and workmanship which do not always come to light in the course of manufacture.

Even the best equipment requires care, and laws should require periodic tests and inspections. The laws of some states require that before men

are handled a trial trip be made whenever the steam engine has stood idle for an hour or more, also that there should be definite hoisting signals between hoist operator and cage tender, different signals being used for men than for material, and that all signals for men be given by cage tender and returned by the operator before hoist is started.

In the failure of the operator or engineer to act correctly we have reason for safety devices. It must be understood, however, that the devices are not to be considered as taking the place of the operator. They are intended only to prevent his mistakes causing damage. Only competent men who understand the action and care and use of the entire equipment should be permitted to operate a hoist where damage to life and property may occur. Operators should be given thorough instructions in the operation of a hoist before they are given full responsibility of operating it.

By the foregoing remarks, which are intended to apply to mine hoists in general, it is hoped that the necessity for adequate hoisting equipment and competent operators is duly emphasized.

#### PROTECTION TO LIFE AND PROPERTY PROVIDED BY SAFETY DEVICES

We will now consider the specific protection to life and property, which must be provided by safety devices, so that to as great a degree as possible failure of hoisting equipment and hoist operators may be guarded against and kept from causing damage.

Briefly expressed, the most common dangers incident to hoisting may be enumerated as follows:

1. Cage or trip passing prescribed or safe limits
2. Traveling beyond a prescribed or safe speed
3. Starting the hoist in the wrong direction
4. Improper application of brakes
5. Failure of brake to hold
6. Accidental release of clutched drum
7. Backing away of hoist due to power failure
8. Inability to stop hoist in emergency

Protection from these dangers cannot be had without some form of power-operated brake engine, which automatically applies the brake and brings the hoist to rest through actuation of the safety devices. Such brake engines may be of steam, compressed air, or oil type, according to the power available or preference of the hoist owner. Usually they are of the weighted type, the engine being provided with two cylinders, each having a movable piston, the piston being fitted to a common rod to which, by suitable means, a set of weights is attached, and which also acts to move the brake bell crank. In one cylinder the motive fluid acts to keep the weights in a suspended position ready to be released for application of the brake. The other cylinder contains oil, which is by-passed through an adjustable valve from one end of cylinder to the other, effecting a smooth motion of the piston rod. There is a valve provided at the power end of the brake engine to release the pressure against the piston, allowing the weights to apply the brake. When weighted brakes are not used, the brake is both held in the released position and

applied by direct fluid pressure on the engine cylinder. Either type of brake is normally controlled by the operator by means of hand lever or valve which governs the admission of motive fluid to the brake engine cylinder and its release therefrom. But when the operator fails to act properly, the safety devices take control of the brake from him and use it according to their functions. These two types of brake engines are preferable for high-speed hoists, and on hoists which handle men. On hoists where the rope speed is slow a less expensive form of engine, known usually as the deadweight type, may be used. This engine acts only upon actuation of the safety devices to apply the brake which is normally operated manually, and the weights must be raised to the suspended position by a handcrab after each emergency application. When any weighted type of brake engine is used either to apply or release the brake the arrangement of the weights and the position of brake engine must be such as to preclude the possibility of any obstruction being placed under them, rendering the brake ineffective.

With these introductory remarks concerning the brake engine we will discuss the various dangers enumerated before.

#### I. PASSING PRESCRIBED OR SAFE LIMITS

Practically all hoists have well defined limits of cage or trip travel, movement to any material distance beyond which may result in hoisting the cage into the head sheaves or hauling a trip up to the drum, causing considerable damage to property and injury to life. In balanced hoisting overwinds of this nature, damage is done at the foot of shaft or slope as well as at the top. When self-dumping cages are used to handle material or men, a man-landing is provided usually at the surface, below the cage dumping horns. Should the operator fail to stop the hoist at the man-landing, they will be carried on the cage and somewhat rudely deposited in the chute or hopper, an entirely unpleasant experience and a dangerous one.

For the prevention of this overtraveling or overwinding (as well as for some of its other functions) the safety device usually takes the form of some mechanism positively driven from the drum or other portion of the hoist having movement at all times coincident with the drum. The mechanism moves in ratio with the drum and has a rotating member, which moves from one limit to another and back again, representing the movement of the drum in winding and unwinding the rope in moving cage or trip from bottom to top and from top to bottom. This rotating member is arranged with cams, lugs, or other required projections so arranged that when the cage or trip draws near its travel limits these cams come in contact with switches or catches, which either act to cause the hoist to slow down in approaching the travel limits or force the operator to retard the movement of the hoist under penalty of an automatic application of the brake, which will cause him to have a complete stop of hoist before the cage or trip reaches its travel limit. Should the operator retard the hoist properly, but fail to stop at the limit of travel, the device acts to shut off power and apply the brake, bringing the cage or trip to rest before the safe limit has been passed.

When men are to be handled, where there is a separate man-landing, another set of switches or catches set for the proper limits of travel are automatically brought into effective position when the signal to handle men is given and properly returned. These switches or catches are automatically replaced and rendered ineffective when the signal to handle material is given, bringing the dump limit switches into effective position.

#### II. TRAVELING BEYOND A PRESCRIBED OR SAFE SPEED

Speed limits for handling men are usually set by law, and very often the condition of the hoisting shafts or tracks is such as to limit the speed at which hoisting of men or material can safely be done. Serious damage may also occur to hoisting equipment, especially the motors of electrically operated hoists, if a certain speed is exceeded. The safety device should therefore be capable of preventing the hoist from exceeding a predetermined speed. When the same hoist is used for handling both men and material, it is usual to operate at a much greater speed when hoisting material than when hoisting men. In order to insure the men being handled at reduced or partial speed, the safety device should be such that, when the signal to hoist men is given the operator is prevented from handling men at a greater speed than that prescribed.

For the prevention of overspeeding a centrifugal governor is usually used, so arranged that when the governor balls expand beyond certain limits they lift the governor rod which is provided with means for shutting off the power and applying the brake in case the operator should permit the hoist to travel faster than prescribed.

#### III. STARTING THE HOIST IN WRONG DIRECTION

This mistake in hoists, where no means is provided to prevent it, is quite common and often results in serious accidents as the operator may not notice his mistake until too late. It may happen when beginning to hoist or lower, or after an emergency stopping of the hoist due to overtraveling. On steam hoists it happens when the operator forgets to change the position of the reverse lever, and in electric hoists when the operator carelessly leaves the control level in the wrong position. Safety devices should correct the position of levers or prevent the operator from starting the hoist in any direction until he has corrected the position of the levers.

#### IV. IMPROPER APPLICATION OF BRAKES

By too violent an emergency application of the brake damage often occurs to the brake or hoist mechanism. If such an application occurs when the trip or cages are in rapid motion very serious accidents usually take place. If men are on the cage or trip the sudden stop may cause death or injury. There is a further danger in the case of slope hoists of the trip over running the rope under force of acquired momentum, and then, when the momentum has spent its force, running back and stopping with a jerk, severing the cable or pulling out a drawbar or coupling and allowing the trip to run away and cause great damage on or at the foot of the slope. Emergency application of the brakes through action of the safety devices should therefore be gradual when resulting from overspeed-

ing, causing a gradual slow-down of the moving parts. However, the brake should be completely and immediately applied when travel limits are reached.

#### V. FAILURE OF BRAKE TO HOLD

This may be due to some fault in the brake mechanism, which, of course, no safety device can rectify, but it is usually caused by the operator's neglect to keep the brake adjusted to take up wear of shoes. This danger may be eliminated by mechanical means automatically to take-up brakes as shoes wear, or by a device to cause an emergency action of the brake before wear becomes such as to render the brake useless. This emergency action will prove a rather gentle hint to the operator to adjust the brake, a hint he will probably not require a second time.

#### VI. ACCIDENTAL RELEASE OF CLUTCHED DRUM

Danger due to this cause usually occurs on double drum hoists where one or both drums may be driven by a toothed type of clutch to permit of adjustment of ropes to permit of hoisting in balance from different levels or readily to take up slack rope. The adjustment to hoist from different levels is done by holding one drum, brake applied, clutch disengaged in such position that its cage is at the level from which hoisting is to be done, and then revolving the other drum by action of drum shaft, clutch engaged until its cage is at the desired level. In this operation the operator may fail to apply the brake before he disengages the clutch or neglect to engage the clutch before releasing the brake. Unless he can very quickly stop the drum, which is thus totally released and left without the counterbalance effect of the other drum, rope, and load, it soon acquires a speed that prevents any stopping except the sudden one which comes at the bottom of shaft of slope when the run-away cage or trip gets there. The same thing may occur if the operator pulls the clutch lever instead of the brake lever, or in any other way has the clutch out when it should be in. This recently happened on a large hoist at an anthracite mine near Wilkes-Barre, and the momentum of the run-away drum was so great that it burst to pieces by action of centrifugal force until nothing but the drum spiders with arms broken off close to the hub remained on the drum shaft. Some pieces of the drum have not been found yet. Fortunately no one was injured, but the delay in hoisting and the cost of repairing all damage was rather expensive.

Such occurrences and fatal ones may readily be eliminated by mechanical or electrical interlock between clutch and brake, making it impossible to disengage the clutch from the drum until the brake is applied, or to release the brake until the clutch is fully engaged.

#### VII. POWER FAILURE

This is largely confined to electric hoists and may result, if the hoist is under heavy load, in the hoisting backing away and getting out of control. Means should be provided to apply the brake automatically in case of power failure and keep it applied until the operator has put the control lever in the neutral position.

## VIII. INABILITY TO STOP THE HOIST IN CASE OF EMERGENCY

Regardless of the mechanical perfection of hoists and safety apparatus, something may occasionally happen that will render them non-effective. It is therefore advisable to have some means of last resort when the usual means are non-effective. In the case of steam hoists, an auxiliary throttle to shut off steam is about the only protection in such emergency, and many engines are equipped with two throttles, both levers within easy reach of operator. In electric hoists, however, it is possible to shut off power and apply the brake by the operator's throwing a small switch.

So much for the dangers incident to hoisting and the desirable and obtainable protection therefrom. As it is entirely without the intention of this presentation to discuss in detail the construction and operation of various safety appliances now available, the writer has referred to the construction and action of devices only very generally and briefly. It might be well before closing to make a few remarks about the selection of safety apparatus. It should be as simple in construction as possible and its operation such as not to delay hoisting under normal conditions. It should require the least possible amount of care or adjustment on the part of the operator. The devices should not interfere with movements of the operator nor disturb him unduly—quite the contrary, they should give him confidence in his ability to control and efficiently operate the hoist in his charge. The operator should understand the operation of the devices. The price of the apparatus should be of secondary consideration as the prevention of a single accident may save many times the cost of the best obtainable devices. The protection afforded should be complete.

It might also be advisable for the advantage of any who may desire to pursue this subject further, to mention the most widely known and used safety devices now on the market with a brief statement of the protection they provide.

## SAFETY DEVICES

The "Lilly Hoist Controller" manufactured by the Duro Metal Products Company, 361 East Ohio Street, Chicago, Illinois. Adaptable to steam, air, and electric hoists. Advertised to prevent overspeeding, overtraveling, starting in the wrong direction, to retard the speed for approaching the landings, and to sound alarms to guide operator.

The "Roybel Emergency Governor" manufactured by George F. Royer & Co., 27-31 East North Street, Wilkes-Barre, Pa. Adaptable to steam, air, or electric hoists. Advertised to prevent overspeeding, overtraveling, starting in wrong direction and to compel retardation in approaching landings. This device may also be provided with a trip and signal recording feature, so arranged that the recording instrument will not function if the device is disconnected from the hoist, which insures against the hoist operator detaching the device from the hoist.

The "Nicholson Engine Stop" manufactured by the Vulcan Iron Works, Wilkes-Barre, Pa. Adaptable to steam or air hoists only. Advertised to prevent overspeeding, overtraveling, compel retardation in approaching landings, and prevent starting in wrong direction.

The "Welch Hoisting Engine Controller" manufactured by the Midwest Machine & Tool Co., 1115-1119 Nineteenth St., Denver, Colorado. Adaptable to steam, air, or electric hoists. Advertised to prevent overspeeding, overwinding, retard speed in approaching the landings, and prevent starting in wrong direction.

The "Vulcan Hoist Control" manufactured by the Vulcan Iron Works, Wilkes-Barre, Pa. For electric hoists only. Advertised to prevent overtraveling, overspeeding, starting in wrong direction, accidental release of clutched drum and accident from power failure, to compel retardation when approaching landings, and to compel the handling of men at reduced speed.

In closing, it might be stated that it is not to be inferred that all hoists are subject to the same dangers or are in need of the same protection. Many hoists because of the nature of their operation require no protection. Only a board of mechanical and electrical engineers and manufacturers, expert in mine hoisting problems and equipment, could make a complete classification of hoists and a recommendation of the protection that ought to be provided for each class.

CHAIRMAN TILLSON: Before asking for the discussion, I want to raise one point myself. In reference to the item that was mentioned of having some form of mechanism that would remind the operator if he hadn't kept his brakes in proper adjustment, my experience has been with one type of mechanism to perform that function, the operation being that the brakes had worn too much and had not been taken up and the brake mechanism caused a switch to be opened which really cut off the electric power to the hoist. The idea was then that unless an operator had his brakes normally in proper condition and taken up sufficiently to take care of any previous wear, he would find that he hadn't any current to start the hoist with at all. I want to condemn that particular application. An instance occurred that I know of where the connecting rod, although it looked very heavy and massive between the tops of the two post brakes, failed and the instant that the rod failed there was no brake control of the engine and the same instant that it failed it performed the same function of shutting off all the electric power from this electric hoist. The result was that the operator had no means of stopping the hoist at all. He could not stop it by reverse application of electric power and his brakes were useless. There may be some proper ways of performing that function, and it would then be admirable, but I want to call attention to one that is wrong.

#### DISCUSSION

MR. H. F. LUNT (Colorado State Bureau of Mines): There is one point that I would like to call attention to and that is in the matter of the hoist operator. They have a law in Utah that requires a man to take a physical examination before he is allowed to run a hoist—that is, a large hoist. I think that is a very wise law, and I hope to see it put into effect in other places. In the examination they made in Utah, I think out of several hundred men they only found perhaps three or four who had anything the matter with them that would prevent it, but it does

or occasionally the other way. I know one of my own inspectors in Colorado recently found a man who was quite deaf running a small hoist. They didn't handle over two or three men on the shift, but at the same time this man couldn't hear the signal bell. When he thought it was time for the bell to ring he would simply look at it, and no matter what mechanical device you have, if there is a man of that kind on the hoist you are going to have trouble sooner or later.

Mr. M. J. FLYZIK (Washington State Safety Board): The paper deals with practically modern equipment and there are some very vital suggestions. But what are we going to do with the many concerns that haven't modern equipment? We find that accidents are occurring frequently from lack of exercising proper care with the equipment they handle. We are encouraging in Washington the examination of hoisting equipment before men are hoisted or lowered into the mine. We encourage them, as far as possible, to designate inspectors to go and examine the rope, the cage, or whatever they are using, before men are lowered into the mine. We also try to regulate the speed in most of the mines of the State. We are encouraging the mine companies to provide regular man trips. In many cases we discover that the management use ordinary trips to lower the men. In many cases the cables were found defective and were found to break away while they were lowering the men into the mine. A lot of the companies are providing specially prepared man trips. Those trips are so equipped for safety with devices that in case of a break-away they are derailed. In other cases, they have a cable that they string right around the entire trip and attach it on to the main cable, preventing a break-away; that will, to a certain extent, if properly and constantly used, minimize accidents.

Coming to the question of having engineers properly trained and examined, here is what we are confronted with: There is some opposition, sometimes on the part of the men and sometimes on the part of the management, to putting them through a very strict examination. They say that cuts the incentive for promotion and so forth.

What the gentleman said over here is true. We should not only inquire into their physical ability to run the engine, but we should also endeavor to find out whether or not they are temperamentally fitted to hold such a responsible position. We found out that on one occasion a man came to work and he had had a little family quarrel which he admitted. He took his quarrel to work and he wasn't in the best of humor, and in handling his equipment he attempted to vent his feelings on the engine, which caused a run-away trip and the injury of one or two men.

Mr. WILLIAM CONIBEAR (Cleveland-Cliffs Iron Co.): We are operating twenty-two cages, 3,500 men, four times daily at depths from 600 to 4,000 feet. We pay particular attention to three features. We adopted most of these mechanical devices. All our hoists are electrically driven. No one has access to the engine houses. When the men are handled, going and coming to work morning, noon, and night, as a general rule two men are at the hoist, one man watching the other man. We pay particular attention to our ropes and our cages. No man enters or comes up from

the mine without a cage rider with him, and during the last eight years we haven't had an accident, except with the cage riders, in handling of men. We have had ropes break and hoists fail but we have never had a personal injury case.

CHAIRMAN TILLSON: You notice one question here in particular. I will express an opinion I have heard given in seriousness by men of considerable importance. Mr. Mitten raises the question that the location of the hoisting engineer in his labors should be such as to keep him from being injured providing an over travel of the trip should cause the rope to come over on the engine house.

In a case that happened in South Africa, which was investigated by the South African Governmental Commission, the decision was reached that if they could only locate that hoisting engineer so that the rope would surely hit him, there would be less danger to other men. That is a contrary viewpoint but there is sense in it. If the hoisting engineer realizes that he is going to suffer directly, perhaps there wouldn't be the occasional lapses of care which have happened in the past.

Mr. W. W. TAYLOR (T. L. Smith Company, Milwaukee): I think that hoisting equipment can be fixed nowadays with devices so as to make it almost impossible to have an accident. I have seen two installations recently where if there was any attempt to stop the cage after it was once broken away, it would be found impossible to succeed. I am interested in knowing whether any one has experience with devices which will successfully stop a heavy skip or cage with a load of ten or fifteen tons.

Mr. H. F. LUNT (Colorado State Bureau of Mines): In a vertical shaft I think the ordinary safety dogs will stop a cage. I know several instances where they have been stopped. I don't know of any as heavy as ten tons, but I think if the dogs are kept well oiled so that they work quickly before the cage or skip has a chance to get started, they will stop it. It has happened where a cable has broken high so that the inertia of the cable held the dogs open, a cage has gotten started and simply ripped all the guides out. I don't know of anything that is applicable to incline shafts. I have been looking for something myself and I have talked with a number of the Bureau of Mines engineers to try and find some safety device in a steep incline. There are devices that will work on a slight incline up to forty-five degrees, but when you get from fifty to eighty degrees there doesn't seem to be any device.

Mr. HARRINGTON: I can't give any solution to Mr. Lunt's steep incline problem. On the other hand, I can give an instance of failure of dogs to work in a shaft in Butte. About two or three years ago this happened. The men were ready to be lowered in the morning; there were probably 350 or 400 of them around the collar of the shaft, and in some way or other the engineer lost control of the empties. One cage started to go down and in some unaccountable way the hoist man lost control of the other cage also. Both cages landed at the bottom of the shaft and they picked up pieces of hoist a half a mile away. The cable did not break but the cages got away and went clear to the bottom.

CHAIRMAN TILLSON: A graduated control can be nicely worked out,

particularly with fluid rheostats if they are properly designed for that service.

I would call your attention to the fact that in the past the average custom has not been to take into consideration the desire to stop an unbalanced load by bucking a current against the direction of the motion of the hoist. We should bear that in mind in writing our specifications for hoists, because it can be done if you require people to do it. There is one difficulty that sometimes might arise in doing that, the overload relay would trip on your main circuit brakes because of the large current surge which might be brought into play in such an emergency condition. Of course, that could be taken care of by an entirely separate and emergency oil switch of sufficient capacity to take care of that condition if you install your plant with that in mind.

MR. S. C. REYNOLDS (Aetna Life Insurance Company): The hoisting apparatus problem, so far as it is affecting our mines today, is one of serious thought to mining engineers and men whose work has to do with safety, particularly so in Pennsylvania where we are getting into deep shaft mining right along. We have some splendid devices and splendid controllers and all that sort of thing, but still there remains quite a problem which conditions bring about from time to time. I recall now one of the largest operations in Pennsylvania some few years ago, of which I had charge as chief mine foreman. The hoisting apparatus with its load of coal weighed over twenty-two tons. We made regular inspections of the apparatus. We had a thoroughly modern safety device on the cages. In one shaft we hoisted the coal and in the other shaft our men. Our master mechanic made tests every thirty days of the hoisting apparatus. We placed heavy timbers across the top of the shaft, and by a trigger arrangement the cage was cut loose at a certain distance above the shaft, and it invariably worked. The dogs would catch. It would damage the good heavy guides, but they usually held the cage. On one occasion of which I am thinking on the coal hoists, there were two three-ton cars of coal on the cage, total weight of over twenty-two tons. This was hoisting about midway in the shaft—the shaft was 520 feet deep—and the load broke and it just tore the guides out and everything else in the bottom of the shaft. It went down.

Coming from the anthracite fields the other day, a Bureau of Mines man spoke to me of the steel guide proposition for deep shafts, and he mentioned a recent installation of such guides. We didn't have much opportunity to go into it in detail, but I am wondering if there is anything of that sort applicable at the present time in a practical way and if there is I would like to know of it. The companies I represent are very much interested in apparatus of this sort because in case of accident we always can use them.

We had a recent accident. The supervisor of our department told me we had an accident in New York City on an elevator where we have frequent inspections of the elevators and ropes. However, shortly after the inspection the apparatus failed and the elevator went down and killed three people. On examination of those ropes, the surface indications

were that the ropes were in splendid condition. However, the core, the inside of the rope, broke.

I had occasion, a couple of years ago, to investigate an accident that occurred over in the anthracite fields where eight or ten men, I think, were killed on a hoisting apparatus which was alleged to have been inspected frequently; so the cleavage is a matter of real interest to mining men on hoisting apparatus. We would like to get any enlightenment on this line.

In the different states we have certain standards. We are revising those standards from time to time to use such features as we feel are essential to safety. The standards, of course, are governed by what is most practical.

CHAIRMAN THILSON: Mr. Conibear, could you advise this gentleman of steel guide installations in Michigan?

MR. CONIBEAR: The only one that I know of is on a mine where the shaft was sunk about 240 feet. It was sunk before the days of compressed air, and when the shaft was finally ledged it was so small that we couldn't put in our usual compartments. It was, therefore, necessary to use a long, narrow skip. We were using steel rails as guides. They are not satisfactory. The continual wear of the guides and the skip cause constant repair all the time.

MR. REYNOLDS: Are there tests made to develop whether or not when the cage is cut loose from the top the guides will hold the cage?

MR. CONIBEAR: On the steel runners?

MR. REYNOLDS: Yes, on the hoists.

MR. CONIBEAR: We don't use the cage on them at all. We handle the ore in skips and the men in cages entirely. We use wooden runners; we are using the steel in skip departments but they are very unsatisfactory for they always need repairing and they wear constantly.

MR. J. T. BRADLEY (W. J. Rainey, Inc., Uniontown, Pa.): In our slope mines we had a dummy that we attached to the man trip and this dummy was made of twelve-inch eye-beams, and we had on it a governor and when the speed of the trip exceeded six miles an hour, the governor opened up and dropped the dog and retracted the trip immediately. We don't allow the men to ride in the first three or four cars, and when the trip breaks, the speed is not so great as to cause much damage. Therefore, there is not much danger of anybody getting hurt, whereas, if the trip broke and ran away with the man in it there would be the possibility of some one being killed. This dummy is not very expensive and it works effectively. It will wreck the trip in a few feet after the speed has attained six miles an hour.

MR. M. J. FLYZIK (Washington State Safety Board): At Cleveland when I attended the National Safety Congress, I observed in the exhibit department an arrangement that some one from Kentucky had; it was an equipment of steel on the safety principle as your present arrangement on wooden guide shafts. I do not know how practical it would be on a heavy cage, a rather heavy slope or shaft, but in giving his demonstration there at Cleveland, with a bunch of miners around him, he convinced

most of us that it was very practical. He had a four-ton skip on an incline of about six feet and five degrees. He would take the skip and put it up about three feet and drop it down and it wouldn't move two inches, it would catch. He had a similar equipment on a vertical shaft where he could put up the cage to a distance of about three feet and drop it and it would catch. It was the best thing I had seen.

CHAIRMAN TILLSON: I want to emphasize what Mr. Lunt said. All of those devices which depend upon the severing of the rope close to the cage in order to make them operative are dangerous when the rope breaks, as it usually does, at some point remote so as to cause sufficient inertia on the operation of that device to permit the cage to get to such a high speed that no mechanical strength of materials in the shaft will stop it even though the device attempts to operate. That has been the experience of most mining men, I think, in companies where they make a practice of testing the cage by severing the rope close to the cage every morning before the men go to work to make sure that the dogs operate. That doesn't take care of the rope breaking 100 or so feet away. If the rope breaks between the hoisting engine and the head sheave, you are almost sure to have a wreck in the shaft. The inertia of the rope and the striking of it against the timbers as it comes down will cause the dogs to be held off so that they don't hold the cage up. This should be remembered in regard to all of these devices that somebody demonstrates to you by lifting up the cage three feet and dropping it.

I will ask Mr. Harrington to present Mr. Allen's paper on "Signalling from Moving Cages".

#### SIGNALLING TO AND CONTROLLING MINE HOISTS FROM MOVING CAGES

C. A. ALLEN, MINING ENGINEER, U. S. BUREAU OF MINES, AND CHIEF MINE  
INSPECTOR FOR THE INDUSTRIAL COMMISSION OF UTAH

It is unnecessary for me to try to impress upon the members of the National Safety Council that any new device or method tending to improve methods of signalling in shaft mines is worthy of the most earnest consideration. Approximately 15 per cent of the fatalities in metal mines are shaft accidents and about one-third of the 15 per cent, or 5 per cent of the total fatalities, are caused by the skip or cage. Not only are these occasional fatalities happening but there is always a possibility of the occurrence of a real catastrophe in which all the men riding on the cage might be lost.

In view of these facts, the writer was very much interested in the methods that have been adopted in the metal mines of Utah to signal to the hoisting engineer from the moving cage at any point in the shaft. A summary of these methods was published in the Monthly Reports of the Bureau of Mines and this paper is intended to amplify that report and also present to you sketches of the methods so that they may be better understood, or in case it is desired to adopt the principles in other mines. The methods herein described not only provide for signalling from :

moving cage but they also may be so arranged that the hoist can be stopped by the cage rider, and there is a further element of safety in that the voltage is sufficiently low to eliminate any possibility of danger from electric shock.

The first installation in Utah was at the camp of Eureka in the shaft of the Centennial-Eureka Mine. It was placed in operation, under the management of Mr. C. E. Allen, in the early summer of 1899 and has been in continuous and satisfactory operation for the twenty-one years that have since elapsed.

The arrangement consists of two bare wires down the shaft carrying a current at 60 volts potential, with a device on the cage for making a connection between these two wires, as shown by sketch in Figure No. 1. A similar arrangement

Contact arm carries a wire insulated from the cage, and when it is thrown out by the lever a short circuit is made between the two wires.

FIG. 1. SKETCH PLAN OF ARRANGEMENT FOR SIGNALLING FROM CAGE, CENTENNIAL-EUREKA MINE.

was also made in the Grand Central shaft at Mammoth, Utah, but due to the extreme wetness of this shaft, it was abandoned. At a later date the same plan was adopted in the shaft of the Eagle and Blue Bell Mine, at Eureka, substituting batteries for live current and reducing the voltage to about 10 volts, and this has operated satisfactorily even when the shaft was wet. The Eagle and Blue Bell Mine is under the management of Mr. Imer Pett, of Salt Lake City, and several improvements have been made by the mine electrician, Mr. James Strong, in consultation with Leonard Wilson, Consulting Electrical Engineer of Salt Lake City.

FIG. 2. SKETCH OF ELECTRIC WIRING FOR SAFETY DEVICES ON HOIST. EAGLE AND BLUE BELL MINE, EUREKA, UTAH

## WIRING FOR SAFETY DEVICES—EAGLE AND BLUE BELL HOISTS

In order to give a better idea of the possibilities and application of this system a sketch of the electric wiring for the safety devices on the Eagle and Blue Bell hoist is given in Figure 2. The hoist is double reel modern electric hoist with oil operated clutches and brakes, and with the clutch and brake on each drum operated by different movements of the same control lever.

Whenever the power is cut off, the brakes are automatically applied. The switchboard is equipped with a no-voltage release and a current must be maintained in the control wires of the safety devices or this release will operate, thereby shutting off the power and applying the brakes. As is shown in Figure 2, the control wires pass through limit switches on the headframe through a contact (B-Figure 2 and B-Figure 4) held closed by a Western Union relay, through the governor contact, through clutch switches, and through position switches for each drum or reel. By referring to Figure 2 it will be noticed that if either limit switch in the headframe is opened or the gap at the relay switch (B) is opened the circuit is broken in the control wires and the no-voltage release operated; also, if these connections remain closed but the switches and governor contact are open the same thing happens. The governor contact, however, is wired in parallel with the position switches, so that if the governor contact is closed the position switches may be open. The position switches are operated by the shaft, which operates the indicator, and, in order to allow one drum to operate independent of the other, there are provided two clutch switches which close when the clutches are thrown out, thus short-circuiting the current by the position switches.

This arrangement of wiring for the safety devices is not materially different from that used on other electric hoists, and is only given here in order to show how the hoist can be controlled from the moving cage, with the same wiring that is used for signalling.

## PRESENT WIRING FOR SIGNALLING FROM MOVING CAGE EAGLE AND BLUE BELL SHAFT

In Figure 3 is shown the present diagram for signalling from the moving cage, and, in order to avoid confusion, the method of controlling the hoist by the same wires is omitted in this sketch but is shown in Figure 4.

Discussing the signalling system only as shown in Figure 3, it will be noted that the same wires are used for signalling from the levels as from the moving cage, but there are two sets of dry cells. The wires down the shaft are No. 4 bare copper wires, supported on insulators every 40 feet. To operate the level signal system there are 6 dry cells in the hoist room. Whenever the knife switch for signalling is closed on any level, the circuit is made through the two wires and through an ordinary Western Union relay. The relay closes a contact in the bell circuit and the bell is rung by a separate battery of 30 dry cells, also located in the hoist room. Instead of the 30 dry cells connection could be made to a direct current power or lighting circuit, and by using the 6 dry cells

for the shaft circuit, this is maintained at about 10 volts, which is a voltage that gives no trouble due to grounding in a wet shaft and which is also free from the danger of electric shocks to any person who might come in contact with it.

In order to ring the bell from the moving cage there is a contact, as

FIG. 3. DIAGRAMMATIC SKETCH OF PRESENT WIRING IN SHAFT, SHOWING METHOD OF SIGNALLING FROM THE CAGE. EAGLE AND BLUE BELL MINE, EUREKA, UTAH.

shown, which can be pressed out against one of the wires (the right hand wire shown in the sketch) by means of the lever arm shown by the dotted lines. This contact is simply a curved piece of brass about 5 inches wide, properly insulated from the cage and the lever arm which operates it.

At one time this contact was accidentally pushed out by timbers on the cage, thus giving a signal unintentionally, and to obviate the possibility of this happening again a push button is placed in the circuit on the cage, so that it is necessary to push this button at the same time the contact is pressed out against the bare shaft wire. The current for this circuit is furnished by 6 dry cells placed in a pipe on the cage and they are connected from one terminal with the cable and from the other terminal through the push button to the contact. The bare shaft wire is also grounded, as shown in Figure 3. so that when

the contact is made from the cage the relay closes the bell circuit and the bell is rung exactly the same as when a signal is given from the level.

#### WIRING FOR SIGNALLING FROM MOVING CAGE AND STOPPING THE HOIST

Mr. Strang, the Mine Electrician, informs the writer that, in his opinion, it would be better to have a separate wiring for the level signals and the moving cage signals, with a different bell to be rung from the cage. In order to show the separate wiring for the moving cage signals and also to show how this same arrangement can be used to stop the hoist automatically, Figure 4 is given. The dry cells, and contact (with the push button) on the cage, are arranged in exactly the same manner, but there is only one bare wire down the shaft. It will be noted that when the contact is made from the cage with this bare wire the current will ground through the cable and will also flow through the bare wire through the relay (A) to the ground and through the relay (B) to the ground. The relay (A) is arranged so that the current passing through

it will close the bell circuit and the bell will be rung by the dry cells in the hoist room. The relay (B—see also "B" in Figure 2) is so arranged

FIG. 4. DIAGRAMMATIC SKETCH OF WIRING FOR SIGNALLING AND STOPPING HOIST FROM CAGE AT ANY POINT IN SHAFT.

that the current will open the control circuit on the hoist, which means that the no-voltage release will operate, power will be cut off from the hoist and the brakes automatically applied. In other words, by the arrangement shown in Figure 4, whenever a person on a moving cage completes the circuit with the bare wire, a bell is rung in the hoist room and also the hoist is automatically stopped. Whether it is advisable to make it possible for a person riding on the cage to stop the hoist is a question on which opinions differ; and if such is not desired the relay switch (B) can be removed, which would still leave

it possible to ring the bell from the cage.

PROPOSED MODIFICATIONS OF THE SYSTEM FOR USE AT THE DALY-WEST SHAFT,  
PARK CITY, UTAH

Mr. O. N. Friendly, General Superintendent of the Judge Mining and Smelting Company, is now installing a modification of the Eagle and Blue Bell system for use in the Daly-West shaft at Park City.

By this system it is planned to do all the signalling from the cage and have no signal device on the levels except the flash or buzzer system for calling the cage. A sketch of the arrangement is shown in Figure 5. Double deck cages are being used, and, to make it possible for a cage tender to give signals from the cage while standing on the station at either side of the shaft, four push buttons will be used. Also, in order to avoid using four levers to get contact with the bare wire, there will be one contact maintained at all times. This will be sliding contact, held in place by a spring, or a pantograph type, such as is used on some trolley wires.

GENERAL REMARKS

In looking over the mining papers, the writer has found two articles describing similar signalling devices: One appeared in the E. & M. J. for June 1, 1912, and described a patented device in which a flat strip was used instead of a bare wire. The other article in the Bulletin of the A. I. M. E., February, 1914, describes an arrangement similar to those herein described, which was being used at the Penn Iron Mining Company in Michigan.

As before stated there are two very important safety considerations

involved in the use of those signalling systems, the first being the ability to signal from a moving cage, and the second the low voltage current used. By using such low voltage there is no danger from electric shocks, and, if the bare wires are continuously charged, the danger of a short

to wet timbers is very slight. The Eagle and Blue Bell shaft is 2,000 feet deep and wet in places, yet no trouble has been experienced.

In the method being installed at the Daly-West shaft another danger is also avoided, which is the possibility of a careless or ignorant employee giving a signal from the station when the cage is at some other point in the shaft. Accidents not infrequently happen from this source, despite the fact that signs are placed warning all employees (except the cage tender) to keep their hands off of the hoist signalling system.

The experience which we have gained in Utah, in the matter of signalling, makes us believe that not only are these methods for signalling from the cage, which have been described, very valuable from a safety standpoint but we also feel that it is absolutely neces-

sary to have low voltage on any signal wires with which employees might come in contact. In coal mines there are frequently bare signal wires along the entire length of a slope or incline and, formerly, the voltage on these has been as high as 500. We have records of two men having been killed on 230-volt signal wires. To avoid further accidents of this kind, no bare signal wires are permitted in Utah that carry more than 25 volts, in the metal mines, or 50 volts in the coal mines. The higher voltage being permitted in coal mines on account of the fact that on long slopes—say two miles long—this voltage might be necessary to give proper signals. We have learned from experience, however, that by using a relay at the hoist that this voltage would be sufficient for any distance over which haulage is practicable. It is also required that all shafts placed in operation hereafter, which are over 500 feet deep and through which 50 or more men are hoisted or lowered daily by means of cages, shall have the signalling system so arranged that the hoisting engineer can be signalled from the cage, while it is in motion, at any point in the shaft between levels.

FIG. 5. SKETCH OF WIRING FOR SIGNAL SYSTEM. DALY—WEST SHAFT.

## DISCUSSION

CHAIRMAN TILLSON: Does any electrolysis result from the use of this system as outlined in Mr. Allen's paper? Trolley wires are usually pretty well insulated. It is a little difficult in vertical shafts to maintain the same insulation.

MR. HARRINGTON: I don't know how they are insulated. I don't know exactly how you get that, because trolley wires are extremely bare in some places. They are causing a number of electrocutions.

CHAIRMAN TILLSON: The wires are not insulated, but they are insulated from the ground. How are these wires supported in the shaft so as to avoid the same difficulties?

MR. HARRINGTON: I am not at all familiar with the details of these insulations. I am very much interested in the system, however, and I know of a number of cases where if there had been such a system they would probably have prevented some accidents. I know of one case where a number of men were killed that would probably have come out alive if the shaft had been equipped with a system similar to this.

CHAIRMAN TILLSON: Another thing that came to my mind in this paper was the system which relies on the source of electric energy from a series of batteries on the cages to make it possible to send the signals through to the hoisting engineer. The reason that that appealed to me was that it is very dangerous to have any cage suddenly stopped in its travel, and it should be impossible, in my view-point, for anybody to interfere with the motion of that cage normally except the man who is riding on the cage and is prepared to see it stop. Of course, there may be emergency conditions which make it advisable to stop a cage in travel and have it stopped by somebody who isn't on the cage, as a piece of timber falling across the shaft at a landing point which would cause the cage to be wrecked at that point. Under those conditions the signal system can be so designed with boxes, if you will, similar to fire alarm emergency boxes, whereby a man has to fracture a glass or perform such an operation which is unusual in order to be in a position to stop the moving cage from a station point. That, I think, is very advisable, and I know personally, in systems with which I am familiar, of sixty-two serious accidents that have been avoided by such an emergency station in stopping a cage before it struck something that had fallen across the shaft.

MR. CONIBEAR: The conditions in our mines vary so that it doesn't appeal to me at all. We have very wet shafts. We base the entire responsibility of the manipulation of the cages upon our cage rider. Nobody in any of our mines dares touch a bell. We see no need of stopping a cage once it leaves a shaft station, and personally I do not see that it will improve the conditions existing in our mines at the present time.

## SIGNALLING IN MINE FIRES

MR. HARRINGTON: I am interested in this from the view-point of mine fires. In the Bureau of Mines work a large portion of my time is taken

up in mine fires and a considerable portion of those fires are metal mine fires rather than coal mine fires. In the last four years I have run across probably fifteen or twenty metal mine fires. I know of several cases where men have lost their lives and shafts have become completely lost where if they had a system of this kind the men probably would have been saved and certainly the shafts would have been saved, so it is a very vital thing in places where mines are set afire. Possibly in the Lake Superior region in Michigan and Minnesota they haven't the fires that we have in some places in the West. I know in metal mines in the West that is one of the hardest things we have to combat. Anything we can do to help save lives or shafts is very vital.

MR. SEIP: I would like to ask Mr. Conibear if he has any means whereby he prevents other people from ringing the signals at the landing except the cage man.

MR. CONIBEAR: At each station in addition to the cage rider is the skip tender. All our ore is handled in skips. The skip tender is always there. It is his duty in addition to the cage rider's to prevent men from doing it. But men won't do it because they know the rules and are examined on the rules and regulations.

MR. WOODBURN: As a means of preventing that, one copper mine has put in an arrangement in a new shaft they have constructed; it is an electrical device that works with the indicator on the hoist so that when you are fifty feet above or below a station, anything past that, you cannot signal. We found that if we tried to apply that to many stations it would take so many wires that it wouldn't be practical. But it prevents any one on another level signalling the engineer.

MR. SEIP: Mr. Woodburn, the reason I asked that is because we have a system in our shaft whereby nobody but the cage tender can signal to the engineer. Our signal boxes are so arranged that the cage tender carries a key and he inserts his key in the box and then by turning the key he can signal to the hoisting engineer. When he takes his key out, the hoisting engineer cannot be signalled from any shaft station, but all stations in the shaft can signal to each other. That is, when one signal is sounded all of them are sounded so that if a cage is at any other level the cage tender can be signalled to, but the signal does not go through to the hoist house until the cage tender puts his key in and turns it.

MR. WOODBURN: But that has this disadvantage: If you are on the station and see something is wrong, you have no chance of stepping over and pulling a signal.

MR. SEIP: We can.

CHAIRMAN TILLSON: We have a glass window in the signal box whereby you can make an emergency circuit by breaking the glass. I have done it twice myself to stop wrecks personally.

MR. WOODBURN: Did you avert the wreck?

CHAIRMAN TILLSON: I did, absolutely.

MR. LUNT: I am not very well up in this signalling from the cage, but I know that fifteen or twenty years ago nearly all the shafts were equipped with signals. There were simply two bare wires, and there was

a lever on the cage which, by pulling down, made the contact between these two wires. I don't think there are any of those in use today. I don't know why they took them out. I suppose they got out of order and gave trouble. There is only one shaft that I know of today in Colorado that has a signal system that you can reach from any place. That is a small inferior shaft, a short shaft. They have two bare wires there. They have no device at all. The cage tender carries a little piece of iron, or he could use anything. The wires are only about four inches apart. He just simply touches them with that. It is a very crude apparatus and it wouldn't be practical, probably, in a shaft where there was a great deal of hoisting going on, but this is a very dry shaft, too.

CHAIRMAN TILLSON: I think it is advisable that we should have both sides of the question, and I am going to ask you if you will be kind enough, upon your return to Colorado, to make as rapid an investigation of that surmise of yours and write that to go in the discussions of our transactions so that this will be a matter of complete record. If it has been tried extensively and now isn't, if there was any reasonable reason for its being abandoned outside of those mines being abandoned, we ought to have it in the discussion of the paper.

MR. LUNT: The shafts are still in use. I will do that and I hope that inside of a week from the time I get home I can find out what the reason is that they stopped using that.<sup>1</sup>

MR. REED: I am very much interested in the signalling from the cage. It strikes me as being a very good thing. It was mentioned particularly in a case of mine fires. Although we have had no accidents to people, we have had two accidents to equipment which has shown us how it would be very easy for accidents to happen to people.

It also brings up another question which was not covered in safety devices on shafts. That is the possibility of the cage, where it is supported by an extra set of slides to the guide to hold the cage from rotating—a self-dumping cage—or where it automatically locks at the top and bottom and the lock is damaged so that it does not operate, swinging loose from the guides so that on arrival at either the top or the bottom where there is sufficient room for the cage to turn over it will turn over and dump the car off on to the people at the bottom of the shaft or coming back down the shaft. We had both happen, although the cage when it turned over didn't happen to dump it on top of men as they had just barely got out of the road. If the same thing had happened when we were hoisting men, it would have dumped the men and killed them all. It was due to neglect not to notice a small amount of wear on the guide and to notice that when the cage struck the bottom it struck a little harder than usual and caused it to swing to the side allowing the set of guides which hold the cage simply to jump out of posi-

[From Mr. Lunt's letter to Mr. Tillson, dated October 20, 1920. \* \* \* The method for signalling from the cage, formerly used in some of the mines in Cripple Creek, consisted of two wires, one on each side of one of the guides, and a forked lever attached to the cage, by which connection was made between the two wires. So far as I can learn, there was no difficulty encountered in the operation of this system, but the maintenance of the two trolley wires was expensive and for that reason the use of the system was discontinued.]

tion. If men were going up on that cage they would know at once that the thing would drop, because the cage would tilt over a certain amount and they would be able to signal and stop the cage before it came out of the compartment.

MEMBER: It seems to me that Mr. Reed's trouble might have been avoided by more careful inspection. I think that is a point that could well be brought out. Mr. Reynolds, I think it was, mentioned inspecting the cable and hoisting apparatus generally once a month. I don't consider that often enough. I think that in a well-conducted mine that ought to be done thoroughly once a week, and I think it is usual for the master mechanic or the foreman or somebody to give at least a casual inspection to the cables every day. A great many of these accidents are due to not having any systematic inspection of the hoisting apparatus. If something gets out of order, if they have monthly inspection, it may be several days before the next inspection comes around. Something may get out of order just a few days after the inspection and then it is about twenty-five or twenty-eight days before the next inspection. There ought to be somebody on the job whose business it is to watch that almost constantly where heavy hoisting is done.

MR. REYNOLDS: I would like to make a correction. The inspection that I referred to, or rather the test, was cutting loose the cages. Thorough and complete inspection of the rope, the hoisting apparatus, the safety catches and the cage hoisting apparatus is made regularly and religiously every day and a record kept of such inspection and placed on file at the mine.

MR. W. W. GIDLEY (Phelps-Dodge Corporation): It appears to me that efficient inspection in hoisting shafts has a great deal to do with the accidents. I am rather surprised at these figures quoted here that approximately fifteen per cent of fatalities in metal mines are shaft accidents. Our experience has been this: We are operating nine shafts from 500 to 1,800 feet deep. We have had no fatalities in the shafts for sixteen years, to my knowledge, and personally I think the fewer electric wires installed in the shaft, particularly where the shaft is wet, the better off we are.

Another point with reference to signalling from the cage is this: How many men in case of an accident would have the presence of mind to act on the impulse of the moment? It seems to me that the vital point is very rigid and efficient inspection. We require our cages to be examined thoroughly every twenty-four hours. Our cables are inspected weekly and our cables are built upon a safety factor of seven. The shafts are thoroughly examined every twenty-four hours. In case a cable should break or anything like that, of course the examination of the dogs really doesn't mean anything. The enormous weight, if the cage is in motion, particularly if the cage is loaded, is going to tear out guides and everything in the shaft. If a cage once gets a start, there is hardly any device that could be contrived that would hold that enormous weight. It seems to me that the vital factor lies in efficient and frequent inspection.

MR. WOODBURN: It seems to me that we are discrediting a very valuable suggestion. Mr. Allen is perhaps not putting this out entirely for

operating purposes, but in many shafts we have the advantage of having a good signalling system right on the cage. It is for the unusual condition that this will be of the greatest value.

This case in Butte is of particular importance. Those men went down on that cage with no means of signalling, and I might mention that about the first thing that happens in the case of a mine fire is that your signalling system is out. If any of you have ever been present when the entire mine is threatened with fire and you are limited to signalling by pounding on pipes, you possibly appreciate the value of some system of that sort that might serve, and for that purpose we are arranging to have a field telephone set available to put on the hoisting platform and followed up on the cages. I realize that we have a disadvantage there on the up trip because we have to reel this on the cage as we come up and they have to hoist at a speed that will permit us to do that.

Another thing that could be added to his plan is that instead of making contact by the push button and lever, it could be made so that we have a telephone set for emergency use that could be put on the hoisting engineer's stand and also put on the cage so that they could be in constant conversation and not be dependent entirely upon those signals for unusual conditions.

MR. C. A. HERBERT (U. S. Bureau of Mines): I have a suggestion to offer in regard to the telephone. Locomotives in coal mines have a reel that is operated by a motor and when the cable is unreeled you work against the torque of the motor and it keeps a constant tension on the cable. You might use that for your telephone. When your cage goes down you are pulling your wire down against the torque of the motor; when your cage goes up your motor automatically rewinds your telephone wire.

MR. WOODBURN: We are going to apply this to about twelve open shafts. We cannot break it up in advance to fit.

CHAIRMAN TILLSON: You wouldn't need to. It is like a spring.

MR. HERBERT: The motor acts like a spring to rewind your cable.

CHAIRMAN TILLSON: Where are you going to get the power?

MR. HERBERT: You have your motor on top of your own shaft. If you don't have current you will be up against it naturally.

CHAIRMAN TILLSON: It seems to me it might be a subject of well-merited criticism to have any installation whereby flow of electric current through your hoisting cable could cause electrolysis because it is a dangerous situation to have anything that may influence the nature of the wires in your hoisting cable as something difficult to inspect and make sure of. I would say that it ought to be a subject of very serious consideration before using any signal system whereby you rely upon the flow of electric current through your hoisting cable, but I don't think that is an objection that can't be overcome by some other means of wiring, and I am not sure but what Mr. Allen suggested a system not using a hoisting cable for part of the circuit.

You were speaking of signalling under these conditions. The question of wireless telephony as applied to underground working is something that ought to prove of considerable interest. Some years ago your Chair-

man went into that matter with the wireless companies who were then experimenting, but nothing has been developed. However, I look forward to the opportunity of such a thing being developed and due advantage taken in such a system by making use of return rails in the mines or air lines or any other pipe lines in order to simplify the system of wireless telephony.

MR. WOODBURN: I want to ask if anybody knows anything about such devices. Somebody on a mining trip told one of our mine superintendents of some such apparatus and we tried to get in touch with people that might know about it. So far we have been unsuccessful. We have even corresponded with Belgium and all over the world trying to find out if in connection with this war work some device of that kind had been developed. We are in the market for any information and for any such contrivance of that sort.

MR. CONTIBEAR: In the case of mine fires we don't depend entirely upon our electric bells. We have a pull wire in the cage compartment paralleling the sides of the shaft that the cage rider can always reach. If he is down 2,000 feet he may not be able to pull that wire, but if he takes the handle of a shovel with clamps fastened on it, which is kept on the side of the cage, in two minutes he can clamp that on to the wire and it gives him perfect control and he can pull to the collar of the shaft.

Wherever they find a bad runner they have to stop when inspection is made. They can do that by using this pull wire. There is inspection of pull wires every week and a report is made to me. There are something like twelve reports from each mine, so I have about 300 coming in every day.

CHAIRMAN TILLSON: I want to suggest that Mr. Harrington get in touch with Mr. Allen and that we receive also under discussion of this paper a little clearer description of the emergency conditions under which such an installation is particularly desirable.

One condition that hasn't been mentioned that I might add is in normal inspection and repairing of any shaft or slope shaft, the gang that is working on that can most conveniently and most safely do their work if they have some means like the pull wire or an electric signal system whereby as they move along from one portion to the next they are in absolute contact with the hoisting engineer so far as signalling or telephoning is concerned. That and this fire condition are two conditions. A third condition would be in the operation of sinking a shaft. Under those conditions where men have to light their fuses and make sure that the signal gets up to the hoisting engineer and that they get away in time, it is highly important that they be so that the extension of the signal system is very readily made right down to the bottom where the men are working.

In South Africa the mining laws are very stringent and the laws are that no hoisting engineer shall move a cage under any circumstances without receiving the proper signals. In one instance the hoisting engineer was familiar with the operations of shaft sinking that were going on, and he received the preparatory signal that they were going to light

the fuses and he stood ready to pull the skip away when he received the final signal. He waited and he waited. The final signal did not come and he finally decided that laws or no laws something must have gone wrong with that signal system and he took it upon himself to pull away. He barely saved the lives of those men. They were very seriously injured by the blast that went off before they got far enough away. He got the skip of men to the surface, shut down, put his brakes on the hoisting engine and he disappeared and was no longer seen in the country because he was subject to punishment for criminal action by the laws. There a man had nerve enough to do what he thought was the right thing contrary to the law, but if there were sufficient precaution taken in our signal systems and the extension of our signal systems (so that a man didn't have to climb up a distance to get hold of a signal) we would be safer in shaft sinking operations.

MR. HARRINGTON: I want to suggest that there are any number of cases in which the system could be used to advantage in ordinary operations irrespective of mine fires. I placed emphasis on that because that is the major portion of my work. If a cage is coming to the surface and something goes wrong with one of the cages, the man on the cage has no chance of stopping that cage until the hoist man finds out by a jerk of the rope that something is wrong. If there was a signal system in the cage he could stop it. The same thing is true in hoisting and pulling up cars. A car gets caught in the timber, perhaps. I had a case of a man being killed on a cage. The cage was supposed to be closed and it was not closed. The man got his head in between the side of the cage and the timbers and he was dragged probably 100 feet and dragged to the bottom of the shaft. The man on the cage couldn't do a thing. If there had been some device on the cage, he could have signalled and handled it himself. You might use the pull bell, the pull wire in the shaft, but it is an impossibility to do it if your cage is moving fast. You are helpless when the cage is going.

MR. CONIBEAR: I don't think a man should be driving a cage unless the cage door is closed.

MR. HARRINGTON: They do it all over the country.

MR. CONIBEAR: Not in our mine.

MR. REYNOLDS: If I am right, this problem is one that is being considered pertaining particularly to metal mines. As yet our coal mines haven't, of course, gotten to a depth that makes it so pertinent in matters of this kind, but what experience I have had with metal mines—

CHAIRMAN TILLSON (Interrupting): May I ask you if you see any reason why it isn't equally applicable to coal mines?

MR. REYNOLDS: Yes, the distinction is this: That the average depth of our coal mines is such that the means of communication, even by the voice from the landing points, are very fair.

MR. SEIP: Anthracite?

MR. REYNOLDS: I am thinking now of bituminous. There ought to be some means of communication between the points as outlined in the paper, and I believe it will be worked out. It is bad for a cage to start from a

certain point with no means of communication to the next landing point. I think that it will be worked out and I appreciate the paper.

CHAIRMAN TILLSON: I happen to think of another instance along the lines that I have suggested on which we have more information. It happened to be your Chairman's unpleasant experience once to be riding upon a cage in a vertical shaft when contrary to rules the lander at the bottom had gone in to the sump when the cage was not under his control to clean out some of the rubbish which gradually accumulated in there, and he was ambitious in trying to do things without wasting any time; he was working in there and I was on the cage when it came down upon that man. I realized it and had no way of stopping that cage quickly enough to keep that man from being crushed to death. It was a pull bell system and I did the best I could. That was in a shaft not now in operation and doesn't correspond with our present system, but that is another lesson.

ADJOURNMENT.

#### THURSDAY MORNING SESSION

THE meeting convened at 9:45 a. m., Mr. B. F. Tillson, presiding.

CHAIRMAN TILLSON: The first paper on our program is by Mr. R. A. Walter, "General Rules for Gas Explosion Prevention (Bituminous Coal Mines.)"

(The Chairman read Mr. Walter's paper.)

#### GENERAL RULES FOR GAS EXPLOSION PREVENTION (BITUMINOUS COAL MINES)

R. A. WALTER, SUPERINTENDENT, MULGA WORKS, WOODWARD IRON COMPANY,  
MULGA, ALA.

Instead of giving you a twenty minute talk on the chemistry of "Gases I Have Met in Coal Mines," and on "Ventilating Formulae," I shall endeavor to condense into a few readily understandable rules the results of many years of experience with mines, which prior to the adoption of the methods herein outlined had a continual tendency to blow up, upon the slightest provocation.

The mixture of air, methane, and accompanying gases, commonly known as fire damp, will be intended throughout whenever the word GAS is used. Other explosive gases and mixtures occur, but more frequently as an after accompaniment to explosions and in connection with mine fires. Their presence will be detected by the experienced observer who must decide upon such precautionary measures as may be necessary in addition to those which control methane.

Coal dust in suspension will lower the ignition point of gas-laden mine air to about 1 per cent gas content. As this ignition point is above 5 per cent when no coal dust is present, the importance of humidification

becomes readily apparent. Gassy mines are frequently dry and dusty and the most elaborate system of gas control will not make these explosion proof unless the dust is rendered harmless by sprinkling or other appropriate treatment.

Gas explosions in bituminous coal mines can be prevented by the observance of two rules:

#### VENTILATION

PROVIDE SUCH VENTILATING CURRENT UNDER PROPER CONTROL AS WILL DILUTE TO A HARMLESS MIXTURE, AND CARRY AWAY ALL EXPLOSIVE GASES.

#### PRECAUTIONARY MEASURES

PREVENT ALL CONTACT BETWEEN DANGEROUSLY GAS-LADEN MINE AIR AND FLAMES OR SPARKS SUFFICIENTLY HOT AND SUSTAINED TO CAUSE IGNITION.

Only by faithful observance of these two rules can gas explosions be entirely prevented. Immunity to explosions varies in direct proportion to their observance.

#### VENTILATION

There must be delivered at the working face one hundred and fifty cubic feet of air per minute for every man, and five hundred cubic feet for every mule, with such further volume as may be necessary to dilute to one-half of one per cent the gas content in individual splits, and to one-third of one per cent the gas content in the entire return from the mine.

A fan must be selected that will deliver air to meet the above requirements after due allowance has been made for leakage and friction. The fan wheel must be substantially constructed and well balanced. Bearings and drives must be designed to permit continuous operation.

There must be two separate drives, preferably from entirely different sources of power. Clutches should be located outside the fan chamber. They should be so arranged that not over five minutes will be required to change from one drive to the other.

The fan should normally operate exhausting, but must be reversible. Fan housing and fan house must be of fireproof construction. The fan must be equipped with explosion doors.

The fan must be provided with an accurate continuous recording pressure gauge and with an automatic low pressure alarm signal.

Too much importance cannot be placed on proper proportioning of air courses and the construction of overcasts, stoppings, regulators, brattices, and doors. Splits should be taken off with relation to gas trapped, number of men worked, air velocity, and location of old workings.

If a shaft mine, the entire shaft, or all the shafts, should be concrete-lined, but should this not be feasible, the air compartment at least must be lined with concrete from top to bottom.

Air courses must be of such size and number as will reduce to the minimum, commensurate with cost of driving, the friction on the ventilating current. Local conditions vary too much to give any formulae that will cover all cases, but in every instance this problem can be reduced to simple figures and solved. In old mines this becomes more

difficult, but even then a careful study and calculation of air course construction versus power costs generally results not only in better ventilation, but in an appreciable reduction in operating costs.

Overcasts should be constructed of fireproof material to standard design, and must cause no constriction to either haul-way or airway.

On all headings the inside cross-cut only shall be left open, all others shall be closed with air-tight stoppings constructed of fireproof material. These stoppings should be strong enough to support the roof or it may subside and cause serious leaks through crevices in the roof. These crevices once open, cannot be closed except at prohibitive cost.

Regulators should be constructed of fireproof material. They may be of the sliding or door type, but in either case must be so constructed that they can be locked to any desired opening.

Brattices should be built from all inside working cross-cuts to within fifteen feet of the working face—or nearer if this fails to sweep out the gas. Use only closely-woven brattice cloth of strong texture for this purpose, supporting it at the top and bottom with wooden strips.

Doors must have attendants, or be of the automatic type. They should be arranged in pairs, with room between them for a full trip of cars.

Splits from the main ventilating current must be so proportioned that each individual return will not contain more than one-half of one per cent gas, and so far as possible that the maximum and minimum velocities will not exceed five hundred, or be less than one hundred twenty-five feet per minute.

Not more than seventy men shall be permitted to work on one split.

It is desirable to arrange the splits so that old workings may be ventilated with return air, rendering unnecessary the diversion of fresh air for this purpose.

Abandoned and worked-out sections should be sealed off with heavy, fireproof, air-tight stoppings provided with bleeders opening on return air. Frequent analyses and measurement of the gases escaping from these bleeders will determine the extent to which the sealing off operations shall be carried. Should a large quantity of explosive gas accumulate it must on no account be turned out on men in working sections of the mine. Should gas accumulate in large quantities under pressure, bore holes should be driven from the surface into an open space in the sealed-off section.

In event of total stoppage of fan for an interval sufficiently protracted to permit dangerous accumulations of gas, open all switches to inside power lines. Upon resumption of ventilation every working face must be tested by the fire bosses before the power is again turned on in the mine.

A sufficient number of skilled fire bosses shall be provided so that each can cover the territory assigned to him, in two hours. After making his run each will make his report to the mine foreman, check every man into his section, return to it and utilize the remainder of the shift in hanging brattice cloth and performing such other work as may be necessary to maintain ventilation. This definitely fixes responsibility and invariably results in better work than can be secured where the fire

boss merely tests his section and does not supervise the work necessary to secure ventilation.

The fire boss shall mark out, with a board bearing the word "Gas," in large letters, all places in which gas has accumulated in dangerous quantities, and shall make note of them in his report to the mine foreman. These boards shall be removed by the fire boss only, and then only after the gas has been removed.

Each fire boss shall be provided with a closed electric cap lamp and with a flame safety lamp which will detect a one and one-half per cent to two per cent mixture of gas. Places which will show no gas cap with this lamp are safe if no coal dust is in suspension. Should there be coal dust the safe gas content becomes so low that nothing but a special lamp or detector in the hands of skilled observer can detect it. In ordinary hands the extremely sensitive lamp may become a menace and it is not properly a fire bosses' tool. The best results and greatest speed and safety will be attained by using for testing purposes a flat-wick, naphtha-burning lamp, with double gauze, hood, magnetic lock, and internal relighting device.

At regular intervals analyses shall be made of the air in every return. If any individual split shows gas in excess of one-half of one per cent, analyses should be made daily. If below that sum once a week will be sufficient. For approximate work a Burrell Gas Detector is satisfactory. For more precise results the Haldane type of apparatus is preferred. Both should be part of the equipment of every gaseous mine. The latter is a laboratory instrument and necessitates the use of containers in which to take samples of the mine air and for this purpose nothing should be used except glass pipettes either of the evacuated type or the type provided with two stop-cocks.

When gas readings, or samples are taken, simultaneous observations should be made of volume and humidity, using a properly calibrated anemometer and a wet and dry bulb thermometer in a sling mounting. From this data can be calculated the total amount of gas transpired, its point of origin, and the amount of moisture carried in and out of the mine by the ventilating current. All of which information is essential to efficient control of gas and ventilation. It should be compiled in tabular form for ready reference.

A recording barometer shall be installed at the mine, and comparison made between the barometric chart and the tabulated gas readings. A correspondence will be noted between the two, which will be an invaluable guide in regulating fan speed and special precautions.

#### PRECAUTIONARY MEASURES

Permissible explosives only shall be used and no holes shall be loaded with more than one and one-half pounds of powder.

All shots shall be fired with electric detonators and battery.

All shots shall be loaded, tamped, and fired by men instructed and skilled in the work. All shooting shall be done when none but shot firers are in the mine. All shot firing systems require constant vigilance

and the most careful supervision or they may become sources of real danger.

Use sand or clay for tamping and tamp all holes full to the collar. No dust may be left in the hole, nor shall any hole be shot on the solid.

No open lamps shall be permitted in a gaseous mine. Electric cap lamps are recommended in preference to the flame safety lamp; shift leaders, machine runners, shot firers, and all inside officials to carry in addition, a locked, flame safety lamp of the type standard at the mine.

No machinery driven by internal combustion engines shall be permitted inside the mine.

No fires shall be permitted inside the mine. Smoking is prohibited and matches shall not be carried.

No electric locomotives shall be operated on return air. Electric or air locomotives may be used on intake air, but air locomotives or mules only may be used on the return.

All switches, fuses, and electrical machinery on return air must be enclosed and explosion proof.

Mining machines and controllers must be approved explosion-proof type.

Machine men while cutting must make tests for gas every thirty minutes.

#### ECONOMIC FEATURES

The first question you will ask after a perusal of these rules is, "Will it pay?" I answer most emphatically, "It will." Not only from a humanitarian standpoint and in protection to property, but in lowering operating costs as well.

I have in mind an operation producing half a million tons of coal annually. Twelve thousand dollars expended on two of the main air courses eight years ago would have reduced power costs for fan drive alone six cents per ton. Rather than spend this twelve thousand dollars the owners have thrown away thirty thousand dollars annually for eight years in forcing the ventilating current through inadequate air courses.

Another operation prides itself on erring on the side of safety. Some of their air courses are unnecessarily large and expensive. Twice the necessary amount of air is being delivered at many of the working faces. The available data is insufficient for precise figures, but I conservatively estimate that amortization of excess capital tied up in ventilating accessories, plus excess power costs, adds eight cents per ton to their operating cost.

The first of these operations is merely "getting by." Men are frequently being burned by gas in the working faces. Many places are marked out for gas daily. A serious explosion may occur at any time. Strange to say the second operation is no more safe than the first. Face velocities are too high. During the winter months it is almost a physical impossibility to lay the dust by humidification and sprinkling. Much dust is carried in suspension, there is no shot firing system and some day a blown-out shot may cause fireworks.

In either case revision of the ventilating system in accordance with the

foregoing rules would result in increasing the safety factor and in reducing operating costs.

Another instance—a mine producing fifteen hundred tons of coal per day was using sixty dollars worth of brattice cloth daily, hanging it from prop to prop with no intermediate supports. The cloth sagged away from the roof; shots tore it down; at least ten places were marked out daily on account of gas. It was decided to support this cloth on wooden strips—top and bottom. Within a month the consumption of cloth was cut to thirty dollars per day—a saving of two cents per ton—and not over two or three places were being marked out on account of gas accumulations due to defective brattices.

These are not isolated cases. The ventilating system of seventy-five per cent of the bituminous coal mines in this country are susceptible of improvement. All are not such flagrant instances as those quoted, some are far worse.

Parallel instances can be cited as we go down the list of explosion prevention rules. For example a special man may be needed to take daily gas, air, and humidity readings, but his wages and laboratory expenses can be saved many times over through scaling splits and reducing fan speed and power, as opposed to the common system of supplying excess air in an effort to make the mine safe when there is no knowledge as to the exact requirements.

As to the precautionary measures. With one exception these will show no direct economy in operation. On the contrary they may involve expensive changes if the present practice is very dangerous. Nevertheless all are essential to safety.

The exception noted is that of installing electric cap lamps. These should be installed in every mine generating explosive gases, no matter how small the amount given off. It will be discovered after trial that these lamps cost less to maintain than open, or flame safety lamps; that the light is satisfactory in every way and that increased efficiency will be obtained from all employees because no time need be wasted in filling, or nursing refractory lamps.

#### IN CONCLUSION

Gas explosions can positively be prevented. It is probable, however, that they will increase rather than decrease in number unless radical changes are made in ventilating practices. Mine workings are daily advancing under deeper cover and to greater distances from the outcrop, and the old hit-or-miss ventilating system, which like Topsy, "just grewed," must go.

Take for instance an average mining development. Millions are spent to secure the last word in efficiency of prime movers, haulage, and cutting equipment. More millions in tipples, housing, etc., but the ventilating system is selected by guess, and the fan, through lack of definite knowledge, by performance promised by the salesman. This is a most reprehensible practice the penalty for which is inefficient or unsafe operation and excessive costs for thorough gas control.

The ultimate solution of the problem of efficient gas control will be

found by a new type of mining technician, the ventilating engineer, who will have a thorough knowledge of the chemistry and action of mine gases; of fan design; of the action of the ventilating current under all conditions; of humidification and of the many other items entering into explosion prevention.

Air courses will be designed with as much care as the most complicated electrical installation. The fans installed will be selected as to type and will be designed for the service required. The proper amount of humidification will be added to the mine air. Stone dust will be applied just where needed. Splits will be sealed to the correct volume. Gas contents will be determined by analyses, not by estimation, and finally, half the money now spent for ventilation and gas control will be saved and carried over to the profit side of the operator's ledger, where it properly belongs.

#### DISCUSSION

MR. BRADLEY: Mr. Walter says, "Coal dust in suspension will lower the ignition point of gas-laden mine air to about one per cent gas content." How is it that the coal dust in suspension will lower the ignition point?

MR. HARRINGTON: The Bureau of Mines has gone into this subject pretty thoroughly and in the past it has caused a considerable amount of controversy with the anthracite mines. Anthracite dust is supposed to be non-explosive in itself. The Bureau has tested it out in the experimental mine, and while I am not positive in this statement I think their experiments show that anthracite dust itself is not ignited but as soon as one per cent of gas is admitted to the air the anthracite dust does ignite and propagate an explosion of thirty miles a minute. The anthracite people came back to the Bureau and denied the possibility of anthracite dust exploding and said the dust actually exploded with the ribs of the mine which were Pittsburgh seam. The ribs had been so thoroughly scaled off by about a thousand other explosions that there wasn't much opportunity for the Pittsburgh dust to get in there at all. There is no doubt in my mind that the anthracite dust is exploded with one per cent of gas in the air.

MR. BRADLEY: In a way that answers my question and in another way it does not. It appears as though they do not know specifically if the anthracite dust is explosive or non-explosive, and it is taking a great chance to allow the coal dust to accumulate in dangerous quantities with the idea of diluting the gas in a way.

CHAIRMAN TILLSON: Of course, Mr. Walter's paper deals with bituminous mines. This is all bituminous.

MR. BRADLEY: That increases the danger. Coal dust itself is considered explosive, highly explosive, and having an accumulation of coal dust with a one per cent mixture of gas gives you two dangerous elements right there.

CHAIRMAN TILLSON: I wonder whether in your mind you are thinking of temperature and the author is meaning the percentage ignition point that is present.

MR. BRADLEY: If you have got one per cent you have got two elements that cause considerable damage. You have got the coal dust and you have got the gas even if you only have one per cent.

CHAIRMAN TILLSON: The coal dust forms an explosive mixture with air and with one per cent of methane; that makes a mixture that is dangerous, whereas if the coal dust were not present it would require more methane to make a sufficiently dangerous mixture for explosion.

PROF. H. H. STOEK (University of Illinois): I think that what the author means is that with a percentage of gas in there it becomes more easily ignited. In other words, the methane is simply the match that sets it off as you put sulphur into a mixture of powder to start it more easily. As far as anthracite is concerned, I wish the Bureau would publish the results of some of these tests. A good many of us have been waiting now for about fifteen years for those tests that are said to have been made. No doubt they have been made and the results obtained, but the public does not know anything about it. In the anthracite field, if anthracite were explosive, you would certainly have a great many widespread explosions that you do not have now. No field has more gas in certain of its mines than the anthracite and I suppose there is no other field where men are burned by gas in groups of one, two, three, and so forth. So far as I know, there has never been a widespread explosion in an anthracite mine going over the whole mine as you have so frequently in the bituminous mines.

CHAIRMAN TILLSON: I might add to that that it was only last February that I raised this question with Mr. George S. Rice, Chief Mining Engineer of the U. S. Bureau of Mines, in view of the fact that I was materially interested in the installation of a transport system for pulverized anthracite coal, and I was attempting to determine what were the dangerous ratios of air in anthracite coal dust of less than 200 mesh in size. As near as I could find out from the literature on the subject, Welsh anthracite in the form of coal dust was explosive, and in the presence of methane it was particularly so. The experiments on this side did not seem to have indicated explosibility of anthracite coal dust, and I brought the question up to Mr. Rice. He finally gave me a very definite answer that it was not explosive and that there was an instance of a colliery in the anthracite district which had led to considerable question and criticism as to whether it had not blown up due to the coal dust present within it. He said that the best judgment that could be used in it was that the breaker had been blown up by an explosive charge which had been placed in it and had nothing to do with the coal dust. As I understand from Mr. Rice there is no history to indicate the slightest degree of fear in regard to the explosibility of coal dust, even the Lyken's Valley anthracite coal dust which is the highest in volatile constituents. I was quite interested in that because I was experimenting and built a pulverized anthracite coal establishment right within a boiler house where the dust would surely had been set off had there been any likelihood of it at all.

I would like to suggest that my limited familiarity with the literature

of ventilation gives only too few figures with regard to the proper coefficients of friction to be used in the design of fans to be used for different airways, depending upon the nature of the airways, the amount of timber and the quality of timber and the ratio of area to peripheral surface which you might call hydraulic radius if you were dealing with another branch of engineering.

If those of you here who have experience in laying out those things would only be kind enough to give us the benefit of the factors which you use in your own calculations for certain such conditions, I am certain they would be very valuable to us in our literature and transactions.

MR. HARRINGTON: I can't give you any particular figures of that kind, but as far as ventilation is concerned that is one of the chief kinds of work that I have been doing for the Bureau for about two years in connection with the metal mines chiefly, more than coal mines. The conditions are so vitally different that as far as I am concerned I don't see very much use in trying to apply any one coefficient of friction, because one man's guess is as good as another man's guess as to what the actual conditions may be on the ground.

#### EXPERIMENTS IN THE COPPER MINES AT BUTTE

In the Pennsylvania copper mine at Butte they erected three miniature shafts, one of them the ordinary timber shaft, another a timber shaft with smooth lining, and a third one a circular shaft—circular concrete shaft. They were all about 150 feet in depth. It was all done for experimental purposes. The object was to find out whether the rough-lined or ordinary-lined shaft had enough friction in it to make it any particular object in trying to decrease that friction. They put a small fan at the top of each one of these shafts, operated the fan with a motor of certain size and had a movable canvass pipe connection between the fan and the top of these shafts. All three shafts were in exactly the same cross-sectional area. They found that the ordinary shaft would throw a certain amount of air, would allow a certain amount of air to go through under a certain amount of power; that the same-sized shaft, smooth-lined like the walls of this room, would give one and nine-tenths times as much air as the same shaft without smooth lining; and that the circular concrete shaft, smooth-lined, gave three and three-tenths times as much air as the ordinary shaft unlined. Of course, those are only approximate, but it gave them the idea that by smooth-lining their main air shafts they would be able to increase the flow of air through those shafts at least twice or pretty close to twice in their rectangular shafts, and by sinking circular smooth-lined shafts they would be able to throw at least three times as much air for the same cross-sectional area. They are now preparing to sink a shaft in the Pennsylvania mine 2,800 feet deep—a circular, concrete-lined shaft for the purpose of supplying air to a group of mines and they expect to put in between 315,000 and 415,000 feet of air a minute.

CHAIRMAN TILLSON: Will there be any hoisting or traveling done through that shaft?

MR. HARRINGTON: It will be used for absolutely no other purpose than air.

One engineer will tell you that the use of the cages in the shaft has no influence. Another will tell you that it has extremely vital influence. I have been trying it out for the last three years and you can't convince me it hasn't very vital influence. I think the movement of the cages in the shaft will decrease the air flow as much as fifty per cent.

The Anaconda Company is going into it very definitely. They have figured that the smooth lining of their shafts is of enough benefit that they have decided to smooth line every shaft they have, and they have from twenty-five to thirty shafts.

They have adopted a new system. They drop some ordinary brattice cloth down the side of a shaft on the interior; they cover that with ordinary chicken-wire and then gunite. They claim that lasts for years in a shaft where there is no falling rock.

MR. FLYZIK: I desire to commend Mr. Walter for the able paper he has presented here, and I just wonder whether or not it would be possible for this section to forward that paper to at least all of the mine inspectors in the United States and see that copies are distributed around to different companies. It will furnish food for discussion. I know in Washington there is much suffering from serious explosions. Our fatality rate from that one cause is, I think, fifth on the list. Mexico, Utah, and Colorado are still worse off than Washington, so that in the Northwest this is one thing that is causing the greatest fatality.

I would also take the opportunity to state that I think we would profit very much from these investigations if the Bureau of Mines would publish them not so much in monthly periodicals, outside publications, and the like, but in a mining journal. I readily understand that there was a time when that information couldn't be made public, due to losses, indemnities, and damages, but since we have compensation laws in practically every state, eliminating damage suits between workmen and companies, I think the information should be given out at least to people who are interested as to their findings on dust explosions. The paper contains so many vital suggestions that we should make some effort to send it out to as many of the coal companies as we can. In doing so, I am confident it would tend to increase the activity in this mining department.

CHAIRMAN TILLSON: I think that I can probably be warranted in saying that undoubtedly some of the technical journals such as "Coal Age" will reproduce these papers, or some of them at any rate.

MR. R. D. HALL (Coal Age): There is no doubt we will publish this paper.

CHAIRMAN TILLSON: We have no means of finding out who the mine inspectors are, neither have we the money to distribute them as a mining section. Any funds that we have we ought to spend in a more intensified service ourselves in getting information, but by making them available to the public through technical journals of that sort, which mine in-

spectators should follow up if they don't, they are able to get the information.

MR. HALL: I think Mr. Walter, whom I know very well, is speaking about the conditions in certain sections of the country. My own experience in the West, in Wyoming and Utah, has led me to believe that ventilation there is more than usually good. Mr. Walter's paper would hardly apply. But Illinois and Pennsylvania mines, for the most part, are very well ventilated. While, of course, it is always well to spread such doctrines, I think that in many parts of the country they don't need it very badly. At the same time, I know that there are some, especially in the Southeast, which do need a great deal of this kind of propaganda. Relative to what you say about Wales, you want to remember the difference between the English and the American language. The word "anthracite" has a different meaning in Wales to that which it has in this country. Within the confines of what you would call anthracite in England, you have to include practically the whole of the New River and the Pocahontas fields, which have very bad explosions. It is true that there are parts of the Welsh anthracite fields which are, from what I have been told, as truly anthracite as anything in this country, but they have very narrow limits and only apply to the extreme western end of the field. Much of what is called anthracite in England would not be called anthracite in this country at all. Consequently, it is possible, in their mines, to have severe explosions as we have them in our mines which correspond to their anthracite mines.

MR. H. R. MILLER (Pittsburgh Coal Company): What is the life of the concrete lining of that shaft? What success has any one had with tapping gas with drill holes from the surface?

PROF. STOEK: I can say that in Western Pennsylvania it has been done for a great many years, and this summer, when traveling through, I asked if they had found it successful and they said they had.

MR. HARRINGTON: I went through a number of mines in Oklahoma about four years ago and I was told there that in one of the mines they had to abandon coal mining for a while on account of the excessive amount of gas that was being made in the advancing faces. The problem was so acute that they put down a churn-drill hole from the surface and through that were able to go ahead with the operation of the mine. Whether they put down a series I don't know, but they did put down one.

CHAIRMAN TILLSON: We have another paper on a kindred subject. Mr. Walsh is not here so I will read his paper on "General Rules for Gas Explosion Prevention (Anthracite Coal Mines)".

## RULES FOR PREVENTION OF GAS EXPLOSIONS IN ANTHRACITE MINES

JOSEPH J. WALSH, DISTRICT STATE MINE INSPECTOR, WILKES-BARRE, PA.

Casualties as a result of gas explosions in a coal mine are more nearly inexcusable than those occurring from almost all other causes. When one

considers the means available for the purpose of ventilating a mine, and the many devices and safety appliances invented for the purpose of detecting, and preventing the ignition of explosive gases, there can be only one answer in explanation of the frequency with which explosions take place in certain parts of the Anthracite field of Pennsylvania.

The casualties, as a result of gas explosions, in the Anthracite mines of Pennsylvania, during the past 47 years, were one every working day; the ratio being one fatal to three non-fatal.

Problems involving the element of human life, and particularly that problem influenced by conditions that can not at all times be foreseen, should be so guarded and surrounded by a safety factor that no element of danger can be reasonably seen by the inspector, or the mine manager. In the case of a shaft rope, the factor of safety can be expressed in numbers, but where the applications of the safety factor is for the purpose of preventing accidents from gas explosions, the factor can not be expressed numerically. Neither the intelligence of the workman, nor the action of the elements can be measured in a way that would permit the application of a factor that one could say would act as a barrier against gas explosions under all conditions. Therefore, greater care and a more liberal application of safety devices are required to insure a factor of safety, in the matter of preventing explosions, than would be required if such factor were susceptible to mathematical calculation.

Probably the greatest difficulty in dealing in a general way with the matter of preventing gas explosions is to understand just what is the underlying cause of explosions in a coal mine. Many mining men, ordinarily well informed, are in doubt as to the most effective means by which they might combat the evil. This confusion seems to be brought about by statements to the effect, that the miner is in complete control of the situation, and that his safety is entirely in his own hands, and if he will not exercise caution nothing can be done for him. It is true, the miner has certain statutory duties to perform, and it is also true that he sometimes violates those duties, in consequence of which explosions take place. Explosions also occur because of conditions that are entirely beyond his control.

We are told that the foreign-speaking miner is unskilled, and untrained in mining affairs, as a result of which, the underlying principles of the safety movement are imperilled. It is said he must be educated in order that any degree of efficiency be obtained from a well planned safety movement. While this statement is somewhat in conflict with the actual fact, education is, nevertheless, an essential element in any plan that might be adopted for the prevention of accidents. But in view of the importance of the question the educational scope should be extended to include the inspector, the mine manager, and all other mine officials. A man may be highly efficient in all the technical branches of mining, and at the same time be unable to recognize danger when he meets it.

Great things have been achieved as a result of the educational movement among the miners. Many have left the ranks and are now filling official positions. Regardless of this, there will always be found in every

coal mine the farmer, from European countries, who is unfamiliar with the customs, and who, because of being unskilled and uneducated in the matters of safety, will imperil, not only his own life, but the lives of others as well.

Since a chain is no stronger than its weakest link, likewise a mine will be no safer than the most careless, or the most unskilled man in it, if drastic precautions are not taken in matters that deeply affect its safety.

Therefore, regardless of any practicable effort that might be put forth in an educational way, there will always be unskilled workmen in every mine. This being true, no greater success in the matter of reducing the number of accidents from gas explosions will be achieved in the future than has been recorded in the past, unless those who are unfamiliar with the dangers are surrounded with all the known safety devices. This duty I conceive to be a function of the state and the mine manager.

The greatest impediment to the prospects of success in a safety movement seems to be our failure to draw the danger line at such time or place as would afford the highest degree of safety.

There is a group of mines in a certain part of Pennsylvania, from which 457 tons of methane, or about 4,323 tons of fire-damp are expelled each day; and during a period of four years more than 1,600,000 tons of coal were mined for each casualty as a result of gas explosions.

At a second group of mines bordering those mentioned in which the same conditions prevailed, and from which 390 tons of methane, or about 3,689 tons of fire-damp were expelled daily, the production per accident from explosion of gas was slightly over 300,000 tons.

Still a third group parallel in every respect, and generating about the same volume of gas, produced slightly less than 500,000 tons of coal per accident from the same cause.

In the first group the industrial efficiency which makes it possible to obtain so large a tonnage for each accident, can be attributed to the placing of proper safeguards around the workmen. For instance, safety lamps are used exclusively in a section through which 22,000 cubic feet of air is passing each minute and having a methane content of 0.26 per cent. In another section in which the methane percentage is 0.25, and the volume of air is 16,000 cubic feet, open lights are not used. In still another mine through which a volume of 25,000 cubic feet of air passes each minute, the methane percentage is 0.14, and the only means of illumination is the safety lamp.

In the second group of mines, open lights were used in an air condition containing 1.12 per cent methane; the volume of air being 28,000 cubic feet per minute.

In the third group, haulage was performed by means of trolley motors when the gas percentage was, in one case 1.02, and in another 2.30, the air volumes were 12,000 and 34,000 cubic feet respectively; and thus we may go on citing such extremes in many other instances.

#### CHIEF CAUSES OF ACCUMULATION OF GAS IN A MINE

The chief causes of the accumulation of gas in a coal mine are:

*First.* An insufficient volume of air, due to a weak or improperly located ventilating fan.

*Second.* Loss of the air through leakage, before it reaches the working faces. Conditions of this kind may be found in mines where the stoppings between the intake and return airways are poorly constructed. Likewise, in cases where a mine is developed by the single-entry system, a condition exists that will seriously interfere with the correct ventilating of the mine.

*Third.* The short circuiting of the ventilating current due to a neglected door; the breaking of a brattice, and the driving of openings too far in advance of the air.

*Fourth.* Under this head might be mentioned a cause for the accumulation of gas in a coal mine, that is becoming quite serious; namely, the frequent interruption of the air current on account of electrically driven fans failing to function.

#### IGNITION OF GAS

The ignition of gas takes place in a coal mine, chiefly as a result of the use of open lights; the use of a long flame powder, and the use of electricity. Smoking, defective safety lamps, and the careless striking of matches are also contributing causes of gas ignition.

#### RULES FOR THE PREVENTION OF GAS EXPLOSIONS IN ANTHRACITE MINES

It is not my purpose to enumerate the many rules that have been published from time to time, as precautions to be observed by the 130,000 miners of the Anthracite field of Pennsylvania, but rather to suggest to the 128 mine managers, a means by which they can eliminate, to a large extent, the possibility of an explosion, in case the commonly applied rules are overlooked by some member of the larger group.

1. When about to install a fan, its size and location should be determined with the aid of a ventilating expert. Remember as time goes on your airways will become congested as a result of roof falls. The falls will not be cleaned up, it is not practicable in many cases. Because of this your ventilation will be impaired; to provide against which the power of your ventilating equipment should be at least three times greater than that calculated by means of the volume of air and the ventilating pressure.

2. Build all stoppings between the intake and return airways with stone, brick, or concrete; this can be done regardless of the pitch of the seam.

3. Avoid the use of main doors as far as it is possible.

4. At the more gaseous mines use steam-driven fans for ventilating purposes. They are more reliable than those electrically driven. It was found by an examination of the records of eight steam-driven fans that they stopped without warning, on an average of once in 16 years. Under like conditions it was found by an examination of eight electrically-driven fans that they failed to function, without warning, once every four months. Accidents have occurred as a result of fans stopping.

5. At the moderately gaseous mines, if an electrically-driven fan is operated, the fan should be on an independent circuit. By the term "mod-

erately gaseous" is meant a mine or section of a mine in which is found a gas condition such as appears in paragraph 7.

6. Have the air in each section of your mine analyzed monthly, and remember, the danger lies not so much in the percentage of gas in the current as in the volume of gas generated each minute.

7. Because of the ignition of accumulations of gas by open lights, both fatal and non-fatal accidents have occurred in mines having the following air conditions:

| No. | Quantity of Air<br>Per Minute | Per Cent of<br>Methane | Methane Generated<br>Per Minute, c. f. |
|-----|-------------------------------|------------------------|----------------------------------------|
| 1   | 10,000                        | 0.29                   | 29                                     |
| 2   | 15,000                        | 0.44                   | 66                                     |

With few exceptions safety lamps should be used in mines having an air condition such as indicated in the above table.

8. A mine in which the direction of the air current is controlled by doors is, under like gas conditions, more dangerous than one ventilated without the use of doors. This should be considered in the application of safeguards.

9. Use permissible explosives in all mines where danger is imminent from explosive gases.

10. A section of a mine in which 125 cubic feet of methane, or more, is generated each minute should be classed among the more dangerous mines. By the term "section" is meant that part of a mine defined by the Anthracite Mine Laws, in which 75 persons are permitted to work. Such sections fully manned would comprise an area of about 10 to 12 acres actually being developed.

11. In gaseous mines electricity should be used only in the intake airways.

12. The practice of giving a miner a safety lamp for testing purposes, and at the same time permitting him to work with an open light, is a dangerous custom. Gas may accumulate because of a neglected door, while he is about his duties. It would be unreasonable to expect the most careful workman to avoid accidents in cases of this kind.

Unfortunately, it cannot be said that explosions are things of the past; they continue to occur in spite of all the skill and care of the mine officials, and the miners. It is usually the unexpected that happens, therefore, it will be found to be prudent to surround your workmen with every known safety device, and place in their hands such means as will insure protection in the event of a dangerous condition arising.

## DISCUSSION

MR. HARRINGTON: I notice that both of these gentlemen recommend strongly the use of permissible explosives in the mine. Of course, that is strictly in harmony with what the Bureau of Mines believes, but I would like to call attention to one or two phases about the use of permissible explosives. I am absolutely and totally in favor of the use of permissible explosives almost to the exclusion of any other kind of explosives in coal mines, but people should not get it into their heads that by using permissible explosives they are going to eliminate explosions or troubles coming from explosions. We in the West have had in the past six months three explosions in mines using permissible explosives. The mining companies were extremely concerned about it and called in the U. S. Bureau of Mines men to look into the situation. When we got there we were told that everything was regular, that they were not using more than a pound and a half of the explosives, that everything looked just as though the permissible explosive itself had gone wrong. After we had spent a considerable amount of time sending samples of explosives in for tests, analyses and so on, in all three cases we were told ultimately that the holes instead of being charged with one and a half pounds of explosives were charged—some of them—with seven and eight pounds, and then they expected the explosives to be safe.

MR. BRADLEY: The mining law of Pennsylvania states that an accumulation of explosive gases shall not be allowed to exist in any part of the mine. Should explosive gas be found, electric safety lamps shall be used and also permissible explosives should be used. If you find that element in the mine and use those precautions, I think the dangers from gas explosions will be eliminated.

This appears to be an awful statement—having one gas explosion about every working day in the anthracite region. A gas explosion in the bituminous fields is uncommon occurrence now. I think it has been five or six years since we had one, and we have as much gas to handle down in that region as any other in Pennsylvania, I think.

MR. HERBERT: There is possibly a little difference between an explosion and a man getting burned. The men may be getting burned every day and yet not have what might be termed an explosion.

MR. BRADLEY: What causes the burn?

MR. HERBERT: Of course it is an explosion, but a man might be burned and yet not be able to call the cause an explosion.

MR. BRADLEY: What ignites the gas?

MR. HERBERT: It might be ignited from several causes, electric current or open flame or defective flame safety lamps or explosives or any one of a number of causes.

CHAIRMAN TILLSON: May I correct the wrong impression you have. Mr. Walsh does not say there is a gas explosion in a mine in the anthracite district at the rate of one for every working day. He says there is one casualty for every working day.

MR. BRADLEY: Can't they be prevented? What causes them?

CHAIRMAN TILLSON: Mr. Walsh has been telling us about that.

MR. FLYZIK: That is what we have all been after—to find out as much as possible, but nobody ever came back to tell us what occurred. We theorize considerably about every big dust explosion we have had. We set up a theory. This might have caused it or that might have caused it. We are doing the best we can.

In the State of Washington we have had two serious explosions in the last four years—one causing us to lose thirty-one men. The Bureau of Mines helped the State Department to conduct an investigation. We couldn't exactly determine the cause, but we have set up a theory that the explosion occurred after a shot was fired and the miner went back in with an open lamp. In that particular mine we had mixed lights. From that experience we found out that it is very dangerous practice to permit men to have mixed lights in any vein where gas is generated. The other explosion was caused by what we think was an overloaded charge. The miner tamped the hole about ten minutes before quitting time and shot while they were in there and the supposition is that the charge was too heavy. It ignited the dust and we lost something like nine or ten men in that explosion.

In addition to our mining laws (we recognize that we have some pretty good mining laws in the various states), as a safety booster I am arriving at the conclusion that we have too much repressive legislation. We ought to say, "You don't have to do this but you ought to see that it is done every day of your own free will."

"EDUCATIONAL MINING SAFETY STANDARDS"

In Washington we got out this pamphlet, "Educational Mining Safety Standards," and we distributed it among the workmen. It contains several rules and suggestions on the various tasks; and we make a different appeal to the management. We are not going along and shaking the mining laws before their eyes and saying, "You have got to do this and you have got to do that." We try to appeal to them in a broad manner and try to encourage them to keep safe at the mine 365 days in the year instead of two or three days when the state mine inspector comes along. By pursuing that course I venture to say that we have been successful in reducing our accidents practically forty-six per cent in the year of 1919 over 1918. Thus far in the year of 1920 our accidents will still show a further decrease.

I think that these papers are very valuable and should be given publicity. In doing so we should not pick out technicalities. There was some suggestion that they may be theoretical and put on from a speculative standpoint, but each one of them contains many practical suggestions that are worthy of our consideration.

CHAIRMAN TILLSON: I think we note that Mr. Walsh puts stress upon the point that it is the total quantity of methane released in any working face which he considers of prime importance in consideration with the methods of ventilation and the care of the mine so far as gas explosions

are concerned, and that point is a little new as compared with the other points which Mr. Walter's paper has raised.

We are favored in having the next paper read by Mr. Woodburn, Director of the Globe-Miami District Mine Rescue and First-Aid Association of Globe, Arizona, which is an organization, as I understand it, supported by a group of mines in that district for their mutual welfare.

### MINE RESCUE AND RECOVERY OPERATIONS

ORR WOODBURN, DIRECTOR, GLOBE-MIAMI DISTRICT MINE RESCUE AND  
FIRST AID ASSOCIATION, GLOBE, ARIZ.

In presenting a paper on this subject it would seem pertinent to emphasize only the more important things and also to mention some of the neglected phases of the subject. This subject has been very completely covered from many angles by capable writers, all of whom are in accord on the general principles and many of the details. All that remains to be done in connection with the subject is to arouse sufficient interest and enlist aid in the establishment of, at least, the more important things in the way of preparation. Few mining men have attended or had personal experience with more than a very few mine fires or disasters. Disaster and fire, of course, are the best instructors on the subject but, unfortunately, the instruction is too late to be of much value at the time. As individuals each man must necessarily be dependent upon others who have limited actual experience. This would indicate that the principal source of information on the subject is based largely on opinion rather than fact. The United States Bureau of Mines has done a valuable service in collecting and distributing reliable information on the subject. Standardization of methods and plans is limited on account of the variable conditions and kinds of disasters. These limitations may be offset by each plant studying its own conditions and taking such preventive and preparatory measures as will have application. Such measures serve each other and are without differentiation.

The first thought in case of disaster is—what should be done. Naturally, human life is the first consideration, which is logical, and is followed by the thought of warning the men of the condition and conducting them to safety. Then, to relieve the condition—perhaps by means of facilities that may be meager and equipment that may have been neglected. Without warning, this equipment which was prepared for a battle that might be, and yet never really expected, becomes suddenly of vital importance. Rarely in the history of any mining plant is there a time that the condition of full preparedness exists. All of the local officials should meet frequently, and discuss, and become familiar with the facilities available for handling such exigencies.

Every surface dwelling and building is fully insured and protected by a separate system of fire lines, hose boxes, fire extinguishers, central hose station, and, probably, an alarm system. All of these are inspected by insurance representatives and kept up to the requirements by the operating departments as a part of the regular routine. All of this is to

protect buildings that are fully insured. In the mine insurance is not feasible and yet the hazard of fire is just as great, not to mention the much greater danger to life, and no such complete separate fire system is maintained. Not as much provision is made for the protection of a valuable stope as is made to protect fully insured surface buildings. The Rescue Crews must nearly always depend on water lines that are converted from air lines by cross-connections with a water supply, and probably make openings in the pipe where needed. Pipe lines of proper size must many times be laid and hose carried to the place. The surface building has at least one fire extinguisher and a fire hydrant with available hose at a specified distance.

With these facts in mind and this condition existing, it is hoped that every mining operation face the situation squarely and provide as complete a fire system for the underground workings as is provided on the surface. By so doing, fires could be extinguished at inception and serious fires from accidental means would be of rare occurrence.

#### OXYGEN BREATHING APPARATUS

In this brief paper it is only possible to touch on the more important facts and a few of the common fallacies. Many mining plants rely too completely on oxygen breathing apparatus, expecting much from equipment that has well-defined limitations and, many times, plays only a minor part in the recovery operations. Oxygen apparatus and trained crews are essential and must be maintained on a high plane, but such crews cannot serve except in a limited manner without the best of facilities and equipment as outlined in the many papers and publications on the subject. Oxygen apparatus occupies a most conspicuous place in the field of mine rescue and recovery operations. When such apparatus first came into general use so much reliance was placed in it that many lives were lost needlessly. For a time it appeared that the apparatus only added to the casualty list and its use would have to be abandoned. Then it was that a realization of the lack of knowledge concerning its use came about. The limitations were conceded and regarded together with an improved understanding. It is now an established fact that the use of oxygen apparatus is imperative and will serve within limitations in the same proportion as its condition and proper use will permit.

An almost general belief exists that the purchase of new apparatus eliminates all of the evils of defective or questionable apparatus. The new apparatus will not give the results expected unless it is kept in proper condition and this condition proven by frequent use. No apparatus can be expected to serve as intended unless kept in proper condition. If the old apparatus did not give proper service the same thing can be expected of the new apparatus. Storing the apparatus in a special cabinet and testing at frequent intervals does not insure its safe condition for use. The proof of the condition is the wearing, and the more often it is worn the longer the life of the rubber parts. Recharges and spare parts are often not kept in sufficient amounts. The continuous use of all apparatus for 36 hours would exhaust the recharges of most plants. With the numerous strikes and freight embargoes it is impor-

tant to maintain a high minimum regardless of the geographical location of the plant. A supply that will permit of 100 hours, or better still 150 hours, is advisable especially since the advantage of borrowing from adjacent plants has been limited through the increased number of models of apparatus in use. The high minimum of supplies only requires a greater investment as there is no deterioration or increased consumption.

One of the serious drawbacks in the use of oxygen apparatus is the time required to get the crews equipped and into action. The history of all fires shows that the critical period for life and property is during the first few hours and of that time the first thirty minutes is the most important. Providing cabinets with sets of half-hour oxygen apparatus that can be used by any one without special training, with a complete set of emergency tools, carbon tetrachloride extinguishers, pipe fittings, etc., has proven to be of great value. This will make immediate action possible and if a small fire is encountered it may be extinguished.

The location and extent of the area involved together with the conditions can be ascertained so that when the heavy apparatus crews are ready they can go about the work intelligently. This light equipment is of great value in the further exploration and inspection work. One instance is worthy of mention where the regular operating force controlled and extinguished a serious fire in a raise of a top-slice stope where there was a strong forced draft into a heavy matt. The heavy apparatus crews were ready for service in record time but powerless to help unless the fire gained headway and the situation became worse, necessitating indirect action. This is without doubt the most important, and yet the most overlooked field in the use of oxygen apparatus in metal mines.

#### CENTRAL MINE RESCUE STATION

Mine Rescue, First Aid, and Mine Fire Prevention work is a most important part of mining operations and should be in charge of a man or department of the specialist type to take care of this work exclusively. Where such work is made the part-time duty of some one regardless of his ability only a side line value can be expected when the emergency arises. Where there are several plants within reasonable distances all apparatus should be pooled and a central Mine Rescue Station established. With a large and efficient organization completely equipped at a lower cost per company the best possible service can be depended upon. By distributing the cost per company on the basis of the average number of employees the smallest plant will have just as good protection as the largest and at a cost that is not prohibitive.

Experience around fires has shown that large quantities of fire hose are needed to get sufficient water on the fire without delay. All hose and pipe openings for fire use in the mine should be of the same size as the regular air hose in use and standardized to insure prompt use. If more lines and volume of water are required this can be arranged for in a reasonable time provided a record is kept of all of the surface fire hose as to size and location.

Fire doors should be so placed that fire may be quickly isolated and materials available for the temporary sealing off of the fire area. Cement

guns are of great value in the permanent and efficient sealing off of any area.

All of the labor connected with the fighting of fire should be done as far as possible by the fresh air men who may be assisted and protected by the oxygen apparatus crews. This can be done by building up air pressure with portable blowers.

The value of special trucks with blowers and flexible piping and also large fire extinguishers with long hose cannot be placed too high. When 300 feet of flexible pipe can be installed in an hour and its cost is moderate and it occupies such a small space in storage its use is to be highly recommended. Some of the materials used in making this pipe are highly flammable and this must be considered in purchasing.

Signal systems to call all of the men out of the mine should be provided and it would be well to have such systems standardized at least in each district, and better still nationally. Flashing signals on the electric circuits is apparently the most feasible and common in vogue.

At times of fire and disaster it is of paramount importance to place one man at the scene of operations and another on surface through which all orders must go. Each should keep a complete record of every order, by whom, time, and to whom transmitted, thereby providing a valuable and reliable source of information, saving much duplication and delay. Every boss and official should be instructed and notices posted throughout the mine as to general rules to be followed in case of mine fire.

The danger of smoke and gases from surface fires entering the mine must be considered and provision made to prevent it.

Appended is a brief summary of the equipment and organization of the Globe-Miami District Mine Rescue and First Aid Association and Central Mine Rescue Station at Globe, Arizona.

The purpose of the Association is to provide training and facilities for the employees to render prompt and efficient aid at times of injury, and to aid in every possible way in fire prevention and finally to keep an organization especially trained in the use of oxygen breathing apparatus and mine rescue operations, as well as with the responsibility of keeping the equipment of the station and mines available for immediate use.

The association employs three station attendants and the director. Three shifts are maintained, day shift 8:00 A. M. to 4:00 P. M., night shift 4:00 P. M. to 12:00 midnight; the night shift man sleeps at the station. One day shift man is on the outside inspecting first aid boxes, supply bases, half-hour apparatus, pulmotors and miscellaneous duties. The attendants change shifts every two weeks.

#### STATION EQUIPMENT

Twenty sets Draeger 2-hour, positive pressure, by-pass, mouth-breathing type apparatus, 1 half-hour regular Draeger apparatus, extra oxygen cylinders for each, spare parts, 3 high-pressure refill pumps, 13 150 cu. ft. oxygen storage cylinders, minimum supply of 2-hour regenerator 1,500, 1,000 one-half hour regenerators, 4 basket stretchers, 7 army stretchers, 10 blankets, large supply of 1, 2, and 3-inch roller bandages, absorbent cotton, sterile compresses, made locally and sterilized at the hospital, tri-

angular bandages, iodine, A. S. A., picric acid, 12 canary birds, 1 carbon monoxide gas detector, 1 Globe Geophone, 1 Dodge mine rescue truck, 1 Ford roadster truck, and 1 Ford touring car.

**TIME TO GET TO EACH PLANT WITH RESCUE TRUCK**

|                                         | <b>Miles</b> | <b>Minutes</b> |
|-----------------------------------------|--------------|----------------|
| Inspiration Consolidated Copper Co..... | 7.0          | 25             |
| International Smelting Co.....          | 4.2          | 14             |
| Miami Copper Co.....                    | 5.7          | 17             |
| Old Dominion Co.....                    | 1.0          | 7              |
| Arizona Commercial Mining Co.....       | 3.5          | 14             |
| Iron Cap Copper Co.....                 | 4.0          | 17             |
| Superior & Boston Copper Co.....        | 4.9          | 20             |

**COSTS**

Operating costs of station, first aid and rescue supplies for training average about one cent per shift for each man employed, or \$1.00 per day for each 100 employed. Expenses are carried by the several companies on the basis of the average men employed each month.

**OFFICERS AND DIRECTORS OF THE ASSOCIATION**

At each of the operating shafts and portals of the mines of the district is kept a special cabinet containing six one-half hour oxygen breathing machines, portable fire extinguishers, lineman's belts with emergency tools, flashlights and recharge for the apparatus. This half-hour apparatus can be worn by any one without special training, and is located in a cabinet which has glass doors. It is expected that those present will be able to do work of great value during the important and critical first half-hour, such as getting the men out, locating fires and possibly even fighting the fire in its early stages. These machines only weigh eight

pounds and are of great value in bridging the gap between the time of discovery of fire and the arrival of the rescue trucks and crews. They can be used through the entire operation for exploration work.

#### HALF-HOUR SELF RESCUER CABINETS

**Inspiration Consolidated Copper Co.**—Six self-rescuers with recharges, 6 pyrene fire extinguisher, 7 flashlights and batteries, 5 linemen's belts with emergency tools, 2 hand axes, 1 claw hammer, 1 wood chisel, 2 cold chisels, nails, spikes, 1 hack saw, 1 keyhole saw, 2 three-cornered files, 2 14-inch Stillson wrenches, 3 6-inch Stillsons, 1 12-inch monkey wrench, 1 6-inch monkey wrench, 1 pair side-cutting insulated pliers, 25 feet of 1-inch rope. This equipment is kept in a specially-designed cabinet near the shaft. Two Pulmotors at mine office.

**Old Dominion Co.**—Same equipment kept in the Safety Inspector's office near the shaft. One pulmotor at mine time office, one pulmotor at Grey Shaft.

**Miami Copper Co.**—In addition to the equipment listed above, has special pipe connections, 75 feet of  $\frac{3}{4}$ -inch hose, first-aid box and pulmotor. This equipment is kept on a specially constructed truck that can be taken to any section of the mine; the truck is kept near the main shaft.

**Arizona Commercial Mining Co.**—Has two self-rescuers kept at the supply house near the shaft.

**Iron Cap Copper Co.**—Has four self-rescuers in a cabinet near the shaft.

**Superior and Boston Copper Co.**—Has two self-rescuers in the foreman's change room near the shaft.

#### SPECIAL EQUIPMENT AT INTERNATIONAL SMELTER

Twenty-two army style gas masks with sulphur dioxide canister, 1 by cranemen.

#### RESCUE TRUCK

Dodge, 1-ton, 137-inch wheel base, length over all 17 ft. 6 in, weigh body and load 2,600 pounds, total weight loaded 5,230 pounds.

#### EQUIPMENT OF TRUCK

- 10 2-hour Draeger apparatus
  - 1 ½-hour regular Draeger apparatus
  - 1 Pulmotor
  - 1 High-pressure oxygen refill pump
  - 3 150 cu. ft. oxygen storage tanks
  - 3 Flexible brass tubes
- 10 Extra 2-hour oxygen cylinders
- 12 2-hour regenerators
- 12 ½-hour regenerators
- 24 Eveready flashlights and 40 extra batteries
- 12 Candles
  - 1 Trouble lamp
  - 3 Hand bird cages with seed and water cups
  - 1 Package bird seed
  - Special adapters for pipe lines
  - Life line and reel
  - 3 1-gallon cans pyrene
- 17 Canvas (brattice 6 ft. x 9 ft.)
  - 1 Extra self-rescuer oxygen cylinder
  - 1 Extra regular ½-hour cylinder
- 100 Feet 1-inch rope
  - 2 Basket stretchers, 2 army stretchers
  - 4 Blankets
  - 1 First aid box
  - 1 Set leg splints (padded)
  - 2 Rolls adhesive tape
  - 1 Bottle iodine, 1 bottle A. S. A., 1 bottle picric acid
  - Auto jack, wheel chains, side curtains, 2 extra tires
  - 2 Pyrene extinguishers
  - 6 Flexible tubes (regenerator holder to cooler)
  - 4 2-hour breathing bags
  - 4 Self-rescuer breathing bags
  - 6 Long circulation tubes
  - 6 Short circulation tubes
  - 2 Reducing valves
  - 2 Bypass tubes

- 8 Standard tube couplings
- 4 Bypass tube couplings
- 6 Rubber side straps
- 4 Respiration valve chambers
- 6 Rubber plugs
- 12 Pairs goggles
- 6 Moisture trap tubes
- 4 Moisture traps
- Bag of tools and gaskets

## DISTRICT MINE RESCUE BONUS CREWS

Inspiration Con. Copper Co., 15 men; Miami Copper Co., 15 men; Old Dominion Co., 15 men; Arizona Commercial Mining Co., 5 men; Iron Cap Copper Co., 5 men; Superior & Boston Copper Co., 5 men. These men are paid a bonus of twenty-five cents per day for being on the crew; they are subject to call to any mine in the district in case of disaster, at which time they are paid double time. They receive a minimum of four hours' training every six weeks. Reserve men for crews are on hand, as each company must have the specified number of bonus men at all times. This Association was organized in January, 1918. The station was completed and a full crew put on January 1, 1920.

## OLD DOMINION COMPANY

## GENERAL RULES TO BE OBSERVED FOR MINE FIRES

1. The first consideration must be the safety of all of the men.
2. All air currents are to be maintained as nearly normal condition possible until the men are located.
3. Any one locating a fire and who cannot put it out at once must to the "A" Shaft notifying every one he meets and ring the accident call bell and level for the cage. When the cage arrives he him must go to the engine room and notify the engineer to give the signal.
4. All engineers must be thoroughly familiar in giving the fire signal (which is 3-3-3 on all electric currents).

5. All shift bosses must have a sufficient number of men chosen, instructed, and assigned to certain portions of his run to enable him to get the men assembled as quickly as possible.
6. The powdermen and carmen must be thoroughly instructed regarding fire signals, and should be kept informed at all times as to who the men are that are chosen to make the assemblage and where they are working.
7. When all the men are assembled they will proceed to the "A" shaft if possible. If it is not possible to reach the "A" shaft without danger, take the best available exit.
8. The exit signs along the drifts indicate the way on all levels from "A" shaft to best exits.
9. All abandoned places must be marked by crossed lagging with "closed" sign.
10. Working places such as raises and stopes not connected from one level to the other, also dead end drifts are to be marked "No Emergency Thoroughfare."
11. Regardless of the exit used by you to reach the surface, you must go at once to the mine time office and call for your check, the same as when coming off shift.
12. It shall be the duty of all shift bosses to see that these rules are complied with at all times.

#### INSTRUCTIONS IN CASE OF FIRE IN MINE, MIAMI COPPER CO.

##### DON'T GET EXCITED

##### TIMEKEEPER ON SHIFT

1. On being notified of fire, will learn its location. Also instruct person telephoning to notify assistant foreman on shift.
2. Notify Mr. Woodburn at District Safety Station. Telephone *Globe Main 406*.
3. Send down by cager to assistant foreman on shift the list of trained helmet men on shift and instruct cager to take half-hour helmets and equipment belts from hoist house to the station nearest fire.

##### NOTE

No. 4 shaft fan should be closed off at once. Fans at No. 3 and No. 1 shafts should not be stopped except on special order of person in charge of fire fighting.

4. Telephone—D. G. Scott, Phone No. 41  
C. S. Peyton, Phone No. 53  
F. Kieren, Phone No. 3

Asking them to come to the mine with automobiles. On day shift telephone for cars to:

Garage  
Bucan's Office  
Warehouse  
D. G. Scott  
Mr. Williams

5. Notify Mr. MacLennan, Mr. Hensley, Capt. Wakefield, and Mr. Allen.
6. Notify the helmet men on the following list who can be reached by telephone.
7. On arrival of cars send out for helmet men according to the following list, first checking off the men on shift.
8. Timekeeper will remain in the office to answer calls from the mine, note names and time of arrival of helmet men, and instruct them to report to Mr. Woodburn at the "dry".

**AVOID ALL NEEDLESS PUBLICITY**

**REQUIREMENTS OF RESCUE TRAINING FOR  
METAL MINERS**

R. H. SEIP, SAFETY ENGINEER, THE NEW JERSEY ZINC COMPANY,  
FRANKLIN, N. J.

**INTRODUCTION**

There is no longer any question as to the necessity or desirability of maintaining breathing apparatus at metal mines for use in rescue work, fire fighting, or recovery operations. Neither does any doubt exist in the minds of most mining men as to the equal necessity of properly training men in the use of such apparatus, and the maintenance of the condition of both men and apparatus.

Evidence supporting the first statement is offered in the fact that at present there are comparatively few metal mining companies of appreciable size that have not installed at least two sets of breathing apparatus. In the past few years the tendency has been to give more attention to the proper training of men in the use of the apparatus, and today this phase of the work has reached a fairly high stage of development. This result is due chiefly to the years of effort on the part of the United States Bureau of Mines, and to the employment by the mining companies of men qualified to give sound instructions along these lines. Relative to the maintenance of the apparatus, and the necessary supplementary training of the men who are required to use it, there remains much to be done.

It is not the purpose of this paper to deal with the make, type, or number of breathing machines which should constitute the proper equipment for any mining operation, or of the auxiliary equipment and supplies, as this subject was very thoroughly covered in the paper by Mr. A. J. Moorshead at the Sixth Annual Congress at New York in 1917. The principal aim of the paper is to provoke discussion by the members of the mining section that will tend to increase the efficiency of the rescue crews upon which our mines depend for the saving of life and property in times of emergency or disaster.

Assuming, then, that the proper equipment has been procured, it would seem logical that the subject should be considered as follows:

1. The selection of rescue men
2. The training quarters
3. The schedule of training
4. Supplementary training

#### SELECTION OF RESCUE MEN

Obviously, it is of vast importance that the men to be selected for places on the rescue crews should be given careful consideration. It is just as essential to have physical fitness in rescue or recovery work as it is to have mechanical fitness in the type of apparatus which is used. Each of these factors is dependent on the other, and each without the other is dangerous, not only to the one man but to the entire crew. Therefore, each candidate should be subjected to a thorough physical examination prior to any instruction. An examination given at this time saves not only money for the company, but often embarrassment on the part of a man forced, by physical unfitness, to discontinue the course of training. This examination should, of course, be made by a physician or surgeon. If the surgeon is in the employ of the company he will doubtless be familiar with the nature of the training and will conduct his examination accordingly. In addition to the general physical condition of the candidate, special attention should be paid to the condition of the nose, throat, and lungs. Also, in consideration of the strenuous nature of the work, and the prevalence of hernia among workmen, this important point should not be overlooked in the examination. Systolic blood pressure should also receive careful consideration, as high blood pressure induces vertigo and dizziness.

There are other features also to be considered in the selection of men for training. It would be natural to suppose that men of large stature and corresponding strength would be the best fitted to wear apparatus, yet most of us know that this is not strictly the case. Experience has shown that men of average height and weight are able to handle themselves to a better advantage while wearing apparatus than taller and heavier men.

Inasmuch as a considerable part of actual emergency work with apparatus is dependent upon the absolute understanding and execution of instructions, men who are to be selected for the training should be mentally as well as physically efficient. This statement does not imply that the candidate should be highly educated, but, as Mr. Luke Keating, Mine Rescue Foreman for the Lehigh Valley Coal Company, in his article on "Picking Men for Mine Rescue Training" has stated, "Training in mine rescue work should not be required to include a course of instruction in English."

All candidates should be thoroughly familiar with the mine workings, and should know the conditions existing in each level and ladder-way. It is also important that they should be able to do any of the various kinds of work underground as might be necessary, such as timbering, constructing brattices, drilling, mucking, etc.

There are certain phases of the mental fitness of the men that cannot be determined, sometimes, until later in the training period. These

phases involve the coolness with which they are able to act in dangerous atmospheres, steady nerves, good judgment, and the maintenance of clear faculties. Men who become easily excited or panic stricken should be eliminated from the crews as rapidly as these symptoms become apparent.

Furthermore, rescue work is not the most pleasant occupation that men engage in, and comparatively few men desire to engage in it. At best it is a hazardous occupation, so that men should not be coerced into taking the training. Every man to be trained should be a volunteer in the sense that he does not do the work against his will. The man who is forced into the work may at some time bring disaster to his crew due to mental deficiency which may result from fear or other causes.

#### TAKE TRAINING QUARTERS

With apparatus and men selected, the next thing to be considered is the place of training. Upon this subject there is a diversity of opinion. The preliminary instructions must, of necessity, be given on the surface, so that any room large enough to accommodate the number of men in training will serve this purpose. Also, the first couple of days can be spent in the open air until the men become familiar with the apparatus and "get the feel" of it while wearing it in the preliminary work.

Following this period many instructors then take the crew into the mine for further practice. Whether or not this is advisable is an open question. It is not believed by the writer to be essential. The course of training is for the purpose of teaching the men something entirely new, a phase of mining work that requires courage, and one that is not without hazards. Therefore, the work must be done in a manner and under conditions that will instill in the men absolute confidence in their machines and in their ability to use them. It is of course important that they should be able to carry on their work under the same conditions as exist underground. To this end the training chamber, or smoke room, should be constructed so as to meet these conditions, and most metal mine conditions can, with little work, be represented in the smoke room.

To illustrate this point blue-prints of the training quarters of The New Jersey Zinc Company at Franklin, N. J., have been prepared for reference. Sketch No. 1 indicates the general scheme of layout of the building proper. The ground floor is divided into two rooms: an apparatus and instruction room 13x22 feet in plan and 8 feet in height, from which a door gives access to the smoke room immediately adjacent to it. The smoke room 22x43 feet in plan varies in height from 20 to 28 feet to permit the erection of the necessary timber. Double doors on one side open to the outside of the building. These doors are equipped with electric door openers which may be operated from the apparatus room or the observation chamber. The doors are counter-weighted so that their operation in opening is entirely automatic. This feature, in

addition to a window in the upper part of the building operated by a rope, provides for rapid removal of fumes in emergency. The floor of the smoke room is cinder covered.

Above the apparatus room is a small storage room 8x13 feet in dimensions, and from this room an observation chamber 4x7 feet in cross

FIG. 1. ARRANGEMENT OF APPARATUS IN FIRST AID BUILDING

section projects into the smoke room for a distance of 24 feet and is ventilated by a separate ventilator in the roof. Access to both the storage room and observation chamber is had by a vertical iron ladder from the apparatus room.

One end of the apparatus room is equipped with six vertical closets for the storage of the apparatus, each closet accommodating two sets of apparatus. Above these closets are two horizontal compartments for new first-aid supplies, while below are six drawers for first-aid practice materials, etc. The opposite end of the room is equipped with two copper-lined wash tubs, an antiseptic solution container and a white enamelled sink. The drain boards of all of these receptacles are covered with sheet lead. At each tub and sink hot and cold water faucets are located. A small work bench with additional cupboards above and below the sinks complete the equipment with the exception of the charging pump and six oxygen tanks in a rack.

The smoke room has been constructed to represent as completely as possible actual mine conditions as indicated by sketch No. 2. A standard mine car has been installed on standard mine tracks extending

around the four sides of the room with turnplates at each corner. On one side and end of the room are standard mine timber sets, four sets of which are loose for erection or removal in training. Over the track a vertical cribbed raise has been constructed with a standard chute at the bottom for loading the car. Slightly to one side of the center of the room an inclined timbered raise or manway connects with a platform at

FIG. 2. SKETCH OF FIRST AID BUILDING

Note—Section A.A.—Training room, side walls, and gables to be covered with  $\frac{3}{8}$ -in. sheathing, tar paper, and novelty siding. Roof to be covered with double  $\frac{3}{8}$ -in. sheathing, tar paper and No. 20 corr. galv. iron. Partition double  $\frac{3}{8}$ -in. sheathing and tar paper, make air-tight around all doors and windows. Apparatus room, side walls to be covered with novelty siding. Roof to be covered with  $\frac{3}{8}$ -in. sheathing and No. 20 corr. galv. iron.

the top of the vertical raise. Another means of access to this platform is by a ladder beneath the inclined raise to a trap door at the top. A low timbered passageway directly beneath the inclined raise is reached through a trap door at the bottom of this raise. The opposite end of this passageway is left open. Pipe lines have been installed for practice work, as well as the necessary tools, such as axes, hammers, bars, wrenches, ropes, etc. Smoke or fumes are generated by means of a smudge pot.

It may readily be seen that such an arrangement offers practically all of the mine conditions, eliminates the generation of smoke and fumes in the mine, and, further, establishes confidence in the men during the training period.

## SCHEDULE OF TRAINING

In the study of any subject it is necessary that the fundamental principles of the subject be thoroughly understood. This is no less true of rescue training. Therefore, the instructor can well afford to spend considerable time on this phase of the work, especially on the first and last days of the preliminary course, the last day naturally being by way of review.

It has been generally conceded that five half days, at least, should be allotted for the preliminary training. Six half days are not too many. The following schedule is that used for the preliminary training at Franklin, N. J. (The words "preliminary training" are used to indicate the course of instruction and to differentiate between it and "supplementary training" or additional practice.)

## FIRST DAY

Physical examination

Record Card, filled in for card files

Brief résumé of course of training

Explanation of causes of fires, explosions, etc., which might render use of apparatus necessary

Instruction in gases as to kinds which might be encountered, their effects on man, and the means of detection

Simple explanation of the chemistry of breathing and its relation to the rescue apparatus

Careful and detailed explanation of the apparatus; first by sketch, then by assembly of apparatus

Instruction on various tests to prove mechanical fitness of apparatus

Crew assemble apparatus and test same

Wear apparatus without oxygen one-half hour in fresh air in smoke room

Work schedule—Walk, climb, and crawl around smoke room. Average rate of walking, 3 miles per hour.

Crew disassemble and clean apparatus

Instruction in charging of bottles

Assemble apparatus (as completely as possible) and put into proper place

At this point it might be well to state that, further to insure the confidence of the crew in the apparatus, the instructor should not be merely an instructor, but should participate in all of the work as a member of the crew.

## SECOND DAY

Short review on assembly of apparatus and tests of apparatus

Wear apparatus with oxygen one-half hour in smoke room in fresh air and one-half hour out of doors

Work schedule—Walk, climb, and crawl around smoke room. Average rate of walking, three miles per hour. Walk at same rate to sand pile 1,000 feet away, resting every 250 feet. Fill bag with 50

pounds of sand and carry back to smoke room; same rest intervals. Finish period by walking, climbing, and crawling around smoke room

Dissemble, clean apparatus, and charge bottles

#### THIRD DAY

Assemble, charge and test apparatus

Wear apparatus one and one-half hours in smoke room in fumes of sulphur or formaldehyde and smoke

Work schedule—Walk, crawl, and climb around smoke room at moderate pace for ten minutes. Load car at chute. Tram car around smoke room and dump in front of chute. Replace ore in chute. Carry sand bags and plank to top of inclined raise. Tear up track. Saw six pieces of timber. Finish period by walking, crawling, and climbing around smoke room

Dissemble, clean apparatus, and charge bottles

#### FOURTH DAY

Assemble, charge and test apparatus

Wear apparatus two hours in smoke room in fumes and smoke

Work schedule—Walk, crawl, and climb around smoke room at moderate pace for ten minutes. Take down four sets of timber. Disconnect pipe line along floor and up vertical raise. Relay track taken up on previous day. Carry sand bags and plank down inclined raise and build plank brattice backed with sand bags. Reconnect pipe line. Finish period by walking, climbing, and crawling around smoke room

Dissemble, clean apparatus, and charge bottles

#### FIFTH DAY

Assemble, charge and test apparatus

Instruction in rescue crew organization to include reserve crews and use of life line

Wear apparatus two hours in smoke room in fumes and smoke

Work schedule—Tear down wall built on previous day. Put up four sets of timber. Carry four sand bags to top of inclined raise. Make exploration trip around smoke room, using life line, bird cage, etc. Carry stretcher to top of inclined raise and load with four fifty pound bags of sand. Carry loaded stretcher down incline and around smoke room. Clean up smoke room, and finish period by walking, climbing, and crawling around smoke room

Dissemble, clean apparatus, and charge bottles

#### SIXTH DAY

All apparatus has been completely dissembled and piled in center of floor. Crew required to assemble apparatus completely and test it. Review of construction and circulation system of apparatus and tests

Review of instruction on gases; crew organization, methods of exploration, etc.

Make necessary repairs or replacements on apparatus

Replace apparatus in cupboards

The preliminary course as outlined in the foregoing paragraphs endeavors to carry the candidate gradually from an understanding of the fundamental principles of rescue work to as thorough a knowledge of the details as is possible in the time allotted. It is natural that, in the training period, many unforeseen things will occur that the men will not understand. Reducing valves will require adjustment, by-pass valves will accidentally become opened, men will over-exert themselves, etc. It is the duty of the instructor to explain carefully the reasons for all such occurrences and instruct the men how they may be corrected or prevented. Too much importance cannot be attached to the method of instruction, for the value of the candidate as an efficient rescue man is almost entirely dependent upon the confidence of the man in his instructor and in his apparatus, gained at the beginning of the course.

#### SUPPLEMENTARY TRAINING

The cost of the preliminary training of but five men is not a small item and is increased directly as the number of men trained is increased. Yet, if this preliminary training is to constitute the entire effort on the part of the company, the money spent has been a poor investment.

Most of us know how easy it is to forget simple first-aid training provided we do not continually practice along those lines. For this reason first-aid contests have been inaugurated to stimulate practice in first-aid work.

This paper does not present any argument in favor of contests in rescue work, but it does purpose to lay stress on the necessity of practice or supplementary training in rescue work. The lives of the members of the rescue crew, or of others, depend upon the efficiency and ability of the crew, and such efficiency can be attained only by continual and regular practice.

It would therefore seem advisable that a half-day each month be allotted to each crew for practice. In these periods the apparatus should be worn for at least one and one-half hours and the work should be varied so as not to become monotonous. In case of the loss of members of the crew by resignation new men should be added, but should receive individual instruction, provided there are but one or two vacancies. This method should not be employed if there is any opportunity to train new men as a crew, as better results obtain than from individual training.

It is realized that this subject is not a new one by any means, and that most of the foregoing matter has been discussed at previous meetings of this section. Yet the subject is of much vital importance to the mining industry, to the safety of the men employed, and to the protection of the properties in which millions of dollars have been invested, that this paper has been presented with a view toward stimulating such discussion as will broaden our views of this phase of safety work.

CHAIRMAN TILLSON: These papers are open for discussion.

## DISCUSSION

MR. CONIBEAR: I notice there are some five or six companies. Are the men at one company expected to respond in case of fire at another mine?

MR. WOODBURN: We maintain a crew of sixty men that we call a district crew that are paid extra for that service. They get a small bonus daily and that compensates them for their time. They can be taken to any part of the district. They are all trained men. In addition to that there are reserves or men waiting to get on that crew. In addition to that the engineers and foremen and special men—electricians and so on—in each mine are added to the crew.

MR. BRADLEY: Do you have any trouble relative to getting men to fill these positions on the mine rescue crew?

MR. WOODBURN: No, sir. Each mine has to keep a corps of fifteen men and if they have any vacancies coming up they put a notice on the bulletin board that they will accept applications and we always have enough to recruit probably twice or three times more than we want. We are pretty fussy; we pick out whom we had rather have out of the applications.

MR. CONIBEAR: If it is not too inquisitive or personal, I would like to ask what the extra compensation is to induce men to volunteer and endanger their lives in cases of fire in mines where they do not work.

## COMPENSATION FOR RESCUE WORK

MR. WOODBURN: I might say that we do not have fires and hazards in connection with mine rescue work. In our district we haven't had but one or two mine fires in the last seven or eight years. We pay twenty-five cents a day additional bonus. That is Sunday and every day. That is \$7.50 a month in addition to their regular pay and the time they receive for the practice.

MR. J. T. RYAN (Mine Safety Appliances Company): One of the coal mining companies that maintains a very efficient rescue organization gives an extra compensation to their men for their training work. They train one day a month and do that very religiously, and they pay those men their regular salary or whatever they would make per day and \$5.00 extra and their expenses, which includes their lunch and dinner. They maintain central rescue stations and the crews are made up of men from different mines. Some of the men have to travel possibly two to five miles. They usually provide machines for them. The compensation is regular pay and \$5.00 extra per day. They don't have any trouble in keeping their crews and they have waiting lists.

CHAIRMAN TILLSON: Five dollars for the one day in the month?

MR. RYAN: Yes.

MR. HARRINGTON: In one of the large mines in the West they do a considerable amount of this kind of work. Each mine contains a crew of ten men trained at all times and those men are given a daily rate of twenty-five cents. They have mine fires frequently and they have no difficulty in keeping up their crews. The only difficulty is that the men change around and it requires the training of new men occasionally.

MR. G. J. JOHNSON (Homestake Mining Company): I would like to ask Mr. Woodburn if he had any actual experience with fire extinguishers.

MR. WOODBURN: I am afraid this gentleman misunderstood my reference to that half-hour set in connection with the paper. Each of our main operating shafts has a unit outfit as listed in this paper, and in that there are six pyrenes that we use in small fires. It is surprising how much you can handle in a small place by means of fire extinguishers.

#### FIRE EXTINGUISHERS

Last year I mentioned that we used carbon tetrachlorid in a small slope fire. It was too hot to remain there long and we didn't know whether we could do any good or not, but we put in ten gallons of pyrene. It was about eight months later that we were able to get in, but we could look down the raises and we could see that it burned about half way and then stopped, so we feel that it did some good. Anyway, it was not a costly experiment.

MR. C. E. JULIEN (U. S. Bureau of Mines): I have had some experience with extinguishers, and in one particular case they were valuable in stopping fires. That experience had a bearing on Mr. Conibear's question about what inducement men have to risk their lives for other people's property. I was much impressed by the slight inducement. I have always been astonished at the courage of men when their courage is required. They will rush in and cheerfully try to die on every occasion that presents itself, and then they meet somebody standing at the cross-roads with a club to drive them back. I think that one of the biggest things to remember in mine rescue work is getting the men to the point where they will go into it willingly. It is awfully hard to get the proper attitude behind the lines. If the men are well selected and well supplied they will do everything possible in an emergency. I have been in several difficult situations in every one of which I have been able to analyze defects in performance.

I tried to get a number of companies to combine and have a mine rescue crew. There was one manager who was very narrow in his conceptions and we couldn't do much with him, and consequently our plants had fallen down for lack of joint action. One night I was called up over the telephone and told to get down to my shaft, the men were going down another shaft and we would meet. We didn't know where the fire was. The smoke was coming up from one point. I never did get down to see the fire. I was up on the shaft taking a bath when the fellows all came piling out with dirty faces and said, "Well, you didn't show up at the fire. Where have you been hiding out?" I said, "That is all right, fellows, I've been hiding out in a place where it made it possible for you to be down there." I was up at the top where I was in telephone communication with the service men, I was flying around gathering up these extinguishers and getting the material to fill them and rigging up hoisting equipment that was out of commission and getting the men down to work. That was all I was doing.

MR. FLYZIK: We had rather an unfortunate experience in Washington

some few months ago. We lost three men as the result of a little experimental work being done in an old mine. The rescue team had a double motive in view in undertaking this task. They unsealed this abandoned slope. They had two types of machines in the same crew. They went down to examine some water and, secondly, they thought they would get a little practice in doing that for the Denver meet. They descended to the bottom and spent perhaps more time than they anticipated or realized, because they began to return on their way out a little later and the captain of the team collapsed, and he was considered one of the best first-aid men in the state of Washington. When he collapsed, the rest of the rescue team attempted to pack him out in a pitch of about pretty close to thirty degrees. They packed him out about 200 feet up the slope and then the second man collapsed, so that other three men came to the conclusion that they couldn't carry out the two men and they fixed their machines and proceeded to go out. Just as they got to the fresh air a third man collapsed, but by that time the other two men were successful in dragging him out to the surface. They took their breathing apparatus off and were eventually revived. In the attempt to get out the first two men that collapsed they lost another man. A man that had received the training at one of the other mines and was not in very good shape heard about the incident and went to the mine office and insisted on getting a machine. He was furnished with a machine and the crew reorganized and proceeded to go down the slope to bring out the overcome men. No sooner had they gotten down until this man collapsed. By that time there were several people summoned and sent down and they got out the men. In the investigation it developed that the first men that went into the mine went in with apparatus but half charged and, in fact, placed too much confidence in the machines. The third man wasn't in very good physical shape and should not have been permitted to use the machine. For some six months he had not had a machine on. This goes to prove that we cannot exercise too much precaution in the using of mine rescue apparatus. Our experience has led us to believe that from now on we ought to insist that when men go and use these machines they must take full charges with them and that no man ought to be permitted to use one of those machines unless he is constantly practicing and in excellent shape for the work.

MR. WOODBURN: Mr. Flyzik's recommendations are along the lines we have always been trying to work on. It would seem that it is very easy to have some little oversight occur. Personally I am very much afraid of practice periods in reference to casualties—really more than in actual mine rescue work. In practice work it is very easy to be careless and run into many peculiar things.

I had nineteen men with apparatus in a small prospect tunnel that was pretty well smoked up with burning fuse. It makes a good smudge; it is not particularly deadly but would overcome men in time. These men were in their preliminary training. The farthest man in got in trouble. He had difficulty in breathing. To get back through that small drift through these other eighteen men was a pretty difficult matter. I sensed

the difference in their voices, won my way in, found this man staggering and two men trying to hold him up. Before we got to the portal he collapsed. All that was wrong was that he had filled his bag too full with the by-pass. He was so afraid that he wouldn't get air enough that he would keep sweeping it up; as soon as he got a little fresh air he was all right and insisted upon going back. I made him wait a little while. While he was working around on the outside he did the same thing. We might have got him down inside and had trouble with him again.

I had another man that overlooked giving his machine enough air and he collapsed. We had given him physical examination the day before, had taken him to the chief surgeon after this happened and couldn't find a thing in the world wrong with him, so we figured that was all that could have happened. I would urge everybody to use great care in practice because it is so easy to overlook these precautionary measures. One would feel almost like a murderer getting them into trouble in practice work.

About your fire extinguisher underground, there is a point there in the way of prevention of fires that is worth consideration. I suppose that an average of once a month in our district some incipient fire is put out by a fire extinguisher close at hand and it never gets any attention. We just happen to hear of it in conversation. I highly recommend having these fire extinguishers every place. It would be fine if we would have one within the reach of everybody throughout the mine.

MR. FLYZIK: Mr. Woodburn, would you say that you had some definite rules in your mind about just how far these men should advance? In this particular case they went down 1,200 feet.

MR. WOODBURN: You would have to be governed by the condition entirely. I would say that is far in excess of where they should have traveled. In practice work I wouldn't think of putting men into a highly poisonous atmosphere. In training you can use a dense smudge that isn't so dangerous. I wouldn't put the men into a deadly poisonous gas. I think we discussed that last year at the meeting. The Bureau of Mines puts a distance of traveling on the level of some 2,000 feet.

MR. HARRINGTON: It is according to conditions.

MR. WOODBURN: They set that as a conservative estimate.

MR. HARRINGTON: With respect to that inquiry, Mr. Flyzik, I had some experience about three years ago in a mine fire in Wyoming. There were two Bureau men and another fellow with me there for three weeks, and we found that if we traveled 500 feet at times we had considerable amount of difficulty in getting back. The difficulty is generally this: That when you get into a pitch above twenty degrees, unless there is slack on the floor, if the floor is clean and has had water over it, you have a very difficult time maintaining your foothold even if you have no load on your back, but with a load of forty pounds it is almost impossible to stand. Not only that, but a man can climb a pitch of twenty-five to thirty degrees comparatively easily if he travels light, but the weight of a twenty or twenty-five or forty pound machine on his back has a tendency to cause trouble. I personally made up my mind that in the future if I am present at a fire in a slope mine—a mine of a pitch of

say fifteen degrees or over, the men shall not go down that slope farther than 500 feet. The same is true in a raise. A man climbing a raise of 100 or 200 feet vertically is in grave danger. In most mines you have a situation confronting you that compels you, under the state laws, to have platforms every twenty-five or thirty feet in vertical ladder mines. If those platforms are within twelve or fourteen inches of the ladder, it is almost impossible to take the larger type of apparatus through them. It is an extremely grave and dangerous thing, to my mind, to try to climb any distance on a vertical ladder.

MR. FLYZIK: Would you consider it dangerous for a team to use two types of machines in rescue work?

MR. HARRINGTON: I don't know; I think some of the other men would be better qualified to answer that than I. I think it is a point that is well worth consideration. Personally I am rather inclined to believe that Mr. Bagley is right. He recommended that two types of machines should not be used on the same team. The men who wear the automatic type generally try to speed up. I am inclined to believe that Mr. Bagley's recommendation that the two-trip feed as against the automatic should not be used in the same operation.

MR. JOHNSON: I am not clear on Mr. Woodburn's use of fire extinguishers underground. Is it carbon tetrachlorid?

MR. WOODBURN: The soda acid type is used underground. There are six sets of the tetrachlorid because of their portability.

CHAIRMAN TILLSON: Mr. Seip has attempted to provoke criticism by recommending a definite type of training in a building constructed with appliances to simulate the difficult conditions of a metal mine. He advances an argument in favor of that method of training as opposed to the other methods mentioned of taking teams down in a mine or in a drift and training them there. It seems that some casualties have occurred where you have trained men by taking them down underground, possibly largely because in the darkness underground the supervisor cannot be in perfect control and touch with his men, and what is more, if they have penetrated a distance in an unrespirable atmosphere they have to come back that same distance to get into a respirable atmosphere, whereas with a training building it is possible immediately to get a man into an atmosphere which is respirable although he has been doing his work in an absolutely poisonous atmosphere—poisonous so he will have no tendency to try to slip his mouth-piece and breathe around the corner of it and get into bad habits that he will regret some day. Mr. Seip's recommendations are a little unusual; it strikes me, so far as the practice is concerned. They are either good or bad, and I think we ought to have more discussion in regard to that. If they are good why haven't others adopted them on a larger scale? That is one of the questions. There is another question raised, if you care to discuss it, that I will raise later.

MR. WOODBURN: I would say that I am in hearty accord with Mr. Seip on his work. It is absolutely along the lines of standard practice; it is carried out throughout the metal mines of the country. However, it is not feasible for us to use the training house type or training gallery at

the station because our plants are separated and we can better take our apparatus over on our specially designed truck and conduct the practice at their own plant under their own conditions. We can get any section of the mine that we want that is not in active use, and rig up almost any condition that we care to. Putting the work on a more practical basis is quite essential.

#### DANGER FROM STARTING SMOKE IN A MINE

CHAIRMAN TILLSON: Another feature that I don't think Mr. Seip mentioned in his paper which might be borne in mind by some is the fact that the presence of smoke in a mine is dangerous providing it doesn't indicate a true condition of fire or a dangerous condition. That is, it is dangerous for a man to smell smoke in the mine, be anxious about the presence of a fire there and discover it is only some stunt or practice or something else, because it leads him to be careless in the future.

MR. HARRINGTON: It seems to me that that could be taken care of in almost any mine by building your smudge or having your smoke so that it would not get into the works. In the Butte region, for instance, they use both systems of training. There they give them preliminary training in the outside rescue stations and then take the men underground in a very hot and comparatively dangerous drift which is straight down, but it is really accessible so that if the men should go down and become unconscious they are readily and easily reached by half a minute's walk by any observer. They have to do that in Butte because in fighting their mine fires, of which they have a considerable number, the men have to become accustomed to using the apparatus in extremely hot atmosphere, temperatures of from ninety degrees up to as high as 125 or 130 or 140 degrees. If they are not accustomed to those atmospheres they are absolutely useless in the Butte mines.

CHAIRMAN TILLSON: You can simulate those atmospheres in a rescue building as well as not. Steam temperature can be raised as high as you get in any mine.

I might also add to that, in regard to the criticism of smoke, a little experience I had in the matter. Some years ago at our plant we took some motion picture films in the cause of safety lessons underground, and among the various subjects we photographed were little stories of different causes of mine fires and the development and the work of rescue crews in mine recovery in these fires. In doing that, and to make them realistic, we started actual fires in territories of the mine. That same day I happened to be down late after all the shifts had gone off, and upon coming out to the shaft to go up I discovered a fire in the shaft station. The shaft was the upcast shaft which you say is the return course for the air. Nobody had come down to investigate the possibility of the mine being on fire. The cage tender had smelled the smoke going up the shaft, but they had been building fires in the mine all day and he thought it was some more of the movie stuff going on and he ignored it. It was only by accident that I happened to be present and find the fire that probably would have extended and ruined a shaft and cost hun-

dreds of thousands of dollars. That is the reason that some people object to letting smoke exist in the mine for any reason at all if it isn't a real fire that should be extinguished.

MR. JOHNSON: We carry on our preliminary training outside the building, but the final training is underground. At the same time, the underground working is above the tramway level and has no connection with the mine. We evade the danger of which you speak.

MR. WOODBURN: We have that condition, too. We go off on the hill and have a complete mine all to ourselves. We have our underground galleries, smoke galleries and so forth for our work, but it is very seldom that we use them. More often we take these crews on Sunday and put in an eight-hour shift using about fifteen to twenty apparatus men, working them in four squads. We go in and show them the whole country that they are to work in and give them the lay of the ground to save time and then start smudges at various places throughout that district and ask them to do certain work at certain places. After all, our work in the metal mines is limited to putting up stoppings and isolating fires.

Relative to the smoke: Timber smoke has a very distinctive odor. You will never mistake it. We use no timber smoke in connection with any of our smudges. Concentrated smoke from burning fuses is not to be confused at all with that of timber.

#### SHOULD INSTRUCTOR WEAR APPARATUS WITH CREW

Mr. Seip says that he would like to have the instructor put on an apparatus and wear it right along with the crews. I object to that seriously. I don't know as I would care to do the work that I subject the men to do sometimes. There is another thing: Your foreman is not mucking to set the pace for the muckers. He is not going to run a machine and demonstrate to them how he can run a machine. I am always very closely in touch with them, particularly if they are under actual conditions, by use of the half-hour apparatus. I visit them at least every fifteen minutes. I don't think it is necessary for me to get out there and wear an apparatus right through the training with the crews. I am training sixty men every other week. That would mean I would be putting in six afternoons every other week wearing apparatus.

MR. SEIP: I did not mean in supplementary or additional practice periods. I mean in the preliminary period when you are taking absolutely green men and putting them through the course of training. I know that the men will feel just that way about it and do feel that way about it. You say, "Here is the apparatus. Here is the way to use it. Go in and do all this work." If you go up in the observation chamber on the outside and look in through the window at them, it does not instill the confidence in them that they will have if you say, "Here is the apparatus; you pick out your five and I will take the one that is left." You put that apparatus on and go right in with them and do the work with them for the first week. After that you can run your practice periods with the men as a unit alternating them as captains and they will

then have the confidence in the apparatus that you set out to instill in them.

CHAIRMAN TILLSON: Mention was made of flashing electric signals in a mine as a warning of fire. You remember that last year we had quite a delegation from Butte with us. They had a considerable amount of experience with mine fires out there and had had special investigations which had been made up in regard to signal alarms, warning of catastrophe to get the men out of the mine. They were quite interested in the subject of the use of stenchers as an alarm to get men out of the mines. I think it would be perfectly fitting for us to consider the subject if those here now are interested in regard to the injection of stenchers in the air line of a mine, giving a more widespread warning and a warning closer to the actual working face than can be obtained by the use of the signal flashing system because of the fact that electric illumination cannot be made close to blasting operations.

MR. HARRINGTON: I happened to be living in Butte for about three years and I ran across a number of their mine fires. I was there at the time of the North Butte fire when there were 163 men killed. The question of warning the miners was an extremely difficult one to handle, particularly in that region where they are working levels from the surface at 100 to 3,600 verticals. Some mines had men working at practically every horizon, from, say, 100 feet below the surface down to the very deepest. At the time of the North Butte fire there was ample evidence at the coroner's inquest proceedings to show that men traveled there as far as the 2,400 level down to the 3,000 foot level and then traveled back to the 2,000 foot level warning miners to get out. One man in particular, the assistant foreman at the North Butte mine, had gotten wind of the fire on a 2,400 level, went down to the 3,000 level, climbed back to the 2,000 and was killed. He died just outside the company foundry line after he had warned about fifty or 100 men to get out.

#### USE OF STENCHES FOR WARNING MEN

A question came up as to what would be the best method of handling those warnings. The Butte Superior Mining Company tried out a system of introducing butyric acid into the compressor and found that it was transmitted through the drills and the air hose to the remote parts of the mine in less than five minutes. That was brought to my attention. I put it up to the Bureau of Mines and afterward we took some other stenching materials to the North Butte mine, the same mine that had the fire. We were able to get a very definite signal to remote raises in the lowest parts of the mine in less than five minutes and the North Butte Mining Company has installed and has in readiness for actual use the system of notifying their men by the use of these stenchers. There isn't any doubt on earth about the men getting them, because the stenchers are so bad they would drive the men out of a working place in due time.

## METHYL MERCAPTAN

MR. MARTINSON: We feel that stench is very satisfactory, but I don't feel they are the last thing in warning men of a catastrophe. The plan, of course, in addition to using the stench, is also to have signals with our electric lights in order to get the men who might be working on tramming levels and the places where the air line does not open so that they would get the stench. In that way we take care of the situation a little better than with the stench alone. We found that the methyl mercaptan, of course, was really the best stench, but I don't believe I could recommend that to any one else because we have not been able to buy the chemical, or whatever the stuff is. We have about ten installations on the Mesabi Range and we only have enough chemical to take care of about three of them.

CHAIRMAN TILLSON: Have you ever tried oil of peppermint?

MR. MARTINSON: No.

CHAIRMAN TILLSON: Would it be convenient for you to try that? In the study as presented by the Bureau of Mines that is one of the materials tabulated in one of the tables, and the indication of that tabulation is that it is an effective odor, that a small quantity of it will make itself very noticeable to a large volume of air as compared with some of the other stench which are recommended; and yet in that bulletin it gives no indication of a field test with oil of peppermint; although the analysis of one of the other schedules might seem to the casual observer that it was a favorable stench. Another question raised in contention is as to whether the odor must be a disagreeable one as versus an agreeable one. It might be well to analyze it psychologically. I am convinced that it must not necessarily be offensive in order to be a suitable warning signal when men are trained and instructed that a certain unusual odor is a warning signal. The other viewpoint is brought out that the odor must be so offensive that it naturally drives the man away from the source of the odor to where the air is more agreeable. The other thing I wanted to ask is whether, that is if it would be convenient, you could make a trial of oil of peppermint and permit this section to have the benefit of your experience.

MR. MARTINSON: I should be very glad to do that. We haven't dared to use the methyl mercaptan that we have because we feared that we might need it some time and then not have it. We have tried this artificial banana oil and have got unsatisfactory results, and one of the reasons we discarded it was because we use a great deal of birch timber and the odor from the birch timber, green, is rather sweetish and pleasant and similar, in some respects, to the odor of banana oil.

CHAIRMAN TILLSON: That is anil-acetate?

MR. MARTINSON: Yes.

MR. HARRINGTON: We tried, at one time, anil-acetate also, but it was a failure. I don't think there is any necessity for having any offensive odor. Anything that is distinctive will act as well as anything offensive.

MR. MARTINSON: My point in mentioning the methyl mercaptan was because it is so offensive and on the other hand is not at all dangerous.

## BUTYRIC ACID

CHAIRMAN TILLSON: I believe butyl mercaptan was another strongly favored one. I have never smelled it, but if it is anything like butyric acid or its derivatives, I think I recently smelled it at the chemical exposition in New York. I was wandering around there about a week ago and I struck a corner of the room and I thought, "My gracious! Who left that Limburger cheese out?" I couldn't imagine where this odor came from. I found a large exhibit of some company manufacturing butyric acid products and I imagine that is what it was. Some of these other odors that have been recommended have a garlic odor, and surely the odor of garlic is not at all uncommon to those of us who have been in close contact with our foreign labor. It seems, therefore, that those are not suitable as warning signals, but unusual odors, whether they are pleasant or offensive, might be more valuable.

Another thing that was strongly recommended was something having a skunk-like odor, as it was described. One of our mining men last night said they had too many skunks that hid around the mines to make that effective. I think those things ought to be discussed freely and considered.

## OIL OF PEPPERMINT

I might suggest that I would like very much to know the effect of the oil of peppermint. In 1907, I was the laughing stock of most of the shift bosses and executives in my own company because I suggested and used oil of peppermint not for the purpose of fire alarm but discovering and noting the presence of all the points at which there were air leaks underground in the mine. I found it was very easy to discover leaks which the senses wouldn't otherwise have noticed.

MR. LUNT: I would like to ask how methods have been developed or what methods have been developed for getting these various substances into the air line and how much it takes. If you have a compressor that is developing, say, 1,000 cubic feet of air a minute, how much oil of peppermint or other material is it necessary to put in to get it all over the mine?

MR. HARRINGTON: I cannot give the figures. The Bureau has published figures in connection with this and they give definite data. I don't think that the present stage of the game is practicable in coal mines in the ventilating current, they are too slow. In metal mines, even at times when there is comparatively little compressed air being used, we get very good results. Even at that time we are able to convey the signal within less than five minutes to the furthestmost parts of the mine.

MR. LUNT: How do you get them in?

MR. HARRINGTON: The Bureau also shows how to make connections on your main air current, preferably between your main receiver and the mine. Fill a little cylinder with the material, have air pressure above it, in other words, by-pass the air.

MR. LUNT: Sort of a lubricator?

MR. HARRINGTON: Exactly.

CHAIRMAN TILLSON: Pressure lubricator.

MR. HARRINGTON: It is very inexpensive and you can put it all on for \$25.00 or \$50.00.

MR. MARTINSON: The first one that we tried was one the Bureau of Mines furnished us. We found that we had some difficulty in getting that round cylindrical glass in, so we bought some pint lubricators and installed them and we did the job just as well and didn't have the danger of the glass breaking.

I don't quite see why it is necessary to get this injector between the air receiver and the mine. We have ours in the engine house, in the compressing house. We have considerable cold weather and a lot of snow and we don't want to ask our men to go out there to do the work on the air line. We feel that it is easier to do it in the engine house. Therefore, it saves some time.

CHAIRMAN TILLSON: Your stenchés will volatilize more readily in the engine house than they would outside in the winter time. The only advantage outside is that when you stop feeding your stenchés there is less of the stench left in the system and it cleans away more quickly than if you have a large volume to be cleared out of the receiver. I think that would be Mr. Harrington's contention. That is really a minor point because it is only a matter of a few minutes anyway before it would be cleared out.

#### FLASHING WARNING SIGNALS

PROF. STOEK: What success has been obtained in the flashing signals or telephone for the same purpose, and how have you gotten the messages from the last station to the men who were at the face?

MR. WOODBURN: We have posted all through the mines that they will get a flash of three times three on the light circuit, and every bit of electricity that goes underground is on this one oil switch in the engine room and that is to be used to call the men out at any time necessary. The only time we used it, it worked beautifully. They were all suspicious, they didn't know what was coming, but they came out in good order. We require that those on the level spread the news to the working places. Then our shift bosses have the fire arrangement with the men to get it to certain portions of the mine. Once a month the safety inspector requires the shift boss to notify his men and proceed out of the usual exit from that section of the mine and meet him at some point above.

CHAIRMAN TILLSON: Other suggestions which I have heard made for systems of alarm might be indicated as follows: One is that the compressed air supply is shut off, the reason being that when a man operating a drill finds that the drill stops, he goes back to find where it has been shut off in the line, whether it is a valve near his working face or, if not, his tendency is to go back and investigate. Something is wrong so he goes out and follows his line along to see what is wrong and that is a means of assembling men together.

Another suggestion applicable in shallow mines, but which would probably be less favorably accepted and less practical in deep mines, is

the disconnection of the compressed air mains and the connection of water in the air mains so that automatically when a signal is given it is merely the change from air to water and the man finds water leaking out of his machine. It furnishes a double purpose of being an unusual occurrence to warn the men, especially if they had been told that such a condition was a warning signal, and at the same time it has the advantage of having water present in the air lines for the extinction of any fire and is right at the working faces.

I have also heard the question raised in the coal mines as to whether the shutting off of electric power for coal cutting machinery and so forth would not similarly be a warning to the men working at the face.

MR. WOODBURN: An idea was advanced at Butte to put a test in your air lines at frequent intervals with a whistle. Your compressed air would be shut off at the surface and a vacuum put on the lines which, working against the pressure or sucking on these whistles, would cause them to whistle through the mine. It was found too slow. It takes a little while to develop enough vacuum to blow all the whistles, but there is a possibility there.

#### GONGS NOT SATISFACTORY

PROF. STOEK: There was a law passed in Illinois some time ago requiring gongs to be placed in all inside places. They were taken out within one year. The law was written off of the statute books by the next legislature. You would be surprised how short a distance away you cannot hear a sound. Some tests were made at that time in the northern part of Illinois by simply going around the corner and back a little, and one of those large twelve-inch gongs couldn't be heard at all.

MR. WOODBURN: Two mines adjacent to this one property using the flash signal system, only recently had occasion to call their men out, because they didn't know the seriousness of an alarm and it was surprising to see how they got them out in such good order and in such a remarkably short time. They checked them out and did the job up right without any preliminary instructions or system. They did it the best they could by a messenger passing the word around. They worked just as well as our very elaborate system at the mine next door, and their mines are in the same condition and approximately the same depth.

CHAIRMAN TILLSON: There are other points in the paper that you haven't raised. One of them deals with the danger of relying upon electrically driven ventilating fans in mines. I believe the practice is widespread. The electrically driven fan, I imagine, is generally used, but I think there may be a strong reason in the contentions made to the unreliability of service, power service, transmission line service, and relying upon the electrically driven fans in ventilation of a mine where gases exist. I hope there are people of different opinions here, but if we are all of one opinion we ought to go on record to that effect.

MR. HERBERT: I think it is generally conceded that the steam fan is the more reliable, and I think it is the general custom in all of the mines, in the central field particularly where they are now installing electrically

driven fans, also to make arrangements so that they can be converted to steam driven fans in a few moments.

CHAIRMAN TILLSON: How can they do that if they have not a boiler plant operating?

MR. HERBERT: They put in a separate boiler plant to heat the water for the change houses, and have that of sufficient capacity and keep a small pressure of steam on all the time, large enough, though, to drive the fan engine, possibly not as fast as the motor would drive it but at least fast enough to keep air going through the mine.

CHAIRMAN TILLSON: How about internal combustion engines for such emergencies—gasoline or oil engines?

MR. HERBERT: I have never seen them used.

CHAIRMAN TILLSON: Why wouldn't they be more economical and more subject to instantaneous application than any steam plant, because the amount of water heated in most mine change houses does not require much of a boiler, and the tendency would be to skip the steam engine again.

MR. HERBERT: Those who have used it have used a large enough boiler to attain the purpose for which it was put in.

CHAIRMAN TILLSON: I think it would be more economical, then, to drive the fans entirely by steam than to carry a boiler year after year for that purpose.

MR. HERBERT: In the winter time that heat is used to heat all the buildings around the plant as well as heat the water, so that particularly in the winter time they are not losing a great deal.

CHAIRMAN TILLSON: Does any one know of any internal combustion engine installations for operating fans?

MR. HERBERT: I have seen them used, yes, but not in a joint combination. They were fairly successful, aside from the danger of fire. The fire hazard around a coal mine would be objectionable.

#### STATE LAW REQUIRES TWO SOURCES OF POWER

MR. HARRINGTON: In some states, at mines that are gaseous, the state law requires that there be two sources of power, either steam or electricity or, if electricity is used, two sources of electricity or possibly two kinds of electricity—alternating current and direct current. In one state I know that is the case, and not very long ago, within the last three years, an explosion occurred in a mine that had an electric fan equipped with only one source of power, and it put the mining company up against it very badly because the explosion occurred about an hour after the men went into the mine and it was then discovered that the fan was down and there was no way of starting it before the men could be gotten out.

CHAIRMAN TILLSON: Suppose that in a metal mine what we call a raise for handling rock or ore has become blocked up some distance above a level. It is impossible to get at it from above because it is filled above the block-up with the materials passing down through there. What methods do you know that are safe for starting that raise to running again? Very frequently men having been required, and I personally have

been required, to climb up a distance of forty feet, not knowing what has blocked it above, and place a charge of explosives there with the danger of the whole thing immediately coming down.

MR. GIDLEY: There is one method that can be sometimes used with success. That is turning a hose in at the top and starting it down with a stream of water. That will often start a raise unless the particular point where the raise is hung should be blocked with large boulders. Then, of course, the water will not have the same effect.

CHAIRMAN TILLSON: Sometimes a piece of timber or a couple of pieces of timber will get in there and get crosswise. Have you ever tried to use searchlights of any description to inspect over long distances through a raise of that sort and see what the condition is?

MR. GIDLEY: Some years ago, about twenty, the Anaconda people used to have those raises in the Anaconda mine. They were driven exclusively for ore with no manway along the side, and when the raise was completed they installed a chain, sometimes a wire cable. This was hung at the top of the raise and extended clear down through it. In those days an ore chute was not complete without the chain, and in the case of a chute hanging in any particular place, the loader, by taking hold of the chain and shaking it, could usually start the chute.

CHAIRMAN TILLSON: How long would the chains be, fifty or 100 feet?

MR. GIDLEY: One hundred feet, extending from the level above clear through the chute. Usually around the mine there is always some old cable that can be used for such purposes. They are not very long-lived, of course, but at the same time it is extremely dangerous, even if the chute is only hung up just a short distance above, for a person to get in there to attempt to blast it out. Of course, climbing up thirty or forty feet is out of the question. A chain or cable through the chute is very valuable.

MR. JOHNSON: For lifts which are not too extreme we have a standard 2x2 wooden stock that we have all through the mine, and we first investigate with searchlights and if it is in reach we nail together two or three of these twenty-foot blasting poles, as they are commonly called, around our works, put on a charge and explode it with electric caps, so there is no danger. We use a little storage battery automobile spotlight for a searchlight.

CHAIRMAN TILLSON: Have you tried the Presto-Lite tank for automobile acetylene searchlights?

MR. JOHNSON: No, we haven't used that.

MR. CONIBEAR: This problem is a very serious one with us. We have a large mine in which the ore runs sixteen to eighteen per cent moisture. Whenever any ore is left in the raises—and nearly all our raises are double compartment—we have to keep traveling service crews to take out that ore. Otherwise, it remains over night and it costs more to take it out than it does to mine it. In our hard ore mines we have chunks in the raises. The miners keep poles about eight inches and a half in diameter and fifteen feet long, and they use two of these tied together; a charge is put at the end and one or two shots will usually bring it down.

CHAIRMAN TILLSON: Do you have any difficulty in casting a beam any distance because of the dust or the moisture or the smoke that exists in mining operations reflecting light so as to make a fog that is hard to penetrate the light through?

MR. JOHNSON: We haven't had any particular difficulty, but a yellow beam will throw farther through dust and haze than a silver beam.

ADJOURNMENT.

### FRIDAY MORNING SESSION

THE meeting convened at 9:45, Mr. Tillson presiding.

CHAIRMAN TILLSON: I will read the first paper by Mr. Boardman and Mr. Bates on "Accidents from Falls of Roof and Ground (Metal Mines)".

### ACCIDENTS FROM FALLS OF ROCK OR ORE

JOHN L. BOARDMAN, CHIEF SAFETY ENGINEER, ANACONDA COPPER MINING COMPANY, BUTTE, MONT.

AND

W. S. BATES, SAFETY ENGINEER, MT. VIEW MINE, A. C. M. CO., BUTTE, MONT.

In writing on the subject of Accidents from Falls of Rock or Ore, we must first refer the reader to previous and more complete papers, namely, the yearly "Metal Mine Accidents in the United States," compiled by Albert H. Fay and published by the Bureau of Mines, and "Accident Prevention in the Mines of Butte, Montana," by Daniel Harrington, Mining Engineer of the Bureau.

These writers have had access to accident reports from widely separated mines and mining districts and their papers are more complete than the present one attempts to be. However, we have endeavored to obtain a more detailed study of our subject by confining our attention to the accident reports of the Anaconda Copper Mining Company with which we are familiar.

The importance of this subject will be at once apparent when it is realized that during the five and one-half year period, January 1915 to June 1920, inclusive, of the total underground accidents in the mines of the Anaconda Copper Mining Company at Butte, 37 per cent was due to falls of rock or ore. All accidents from this cause have been tabulated, and the accident rate computed on a basis of 10,000 *underground* shifts. See Table No. 1.

In connection with the accident tabulations used in this paper it must be firmly fixed in the mind of the reader that the Anaconda Copper Mining Company has made a very sincere effort to prevent accidents, and for this purpose has insisted that all accidents from any cause, and regardless of their serious or slight nature, must be fully reported. Therefore the accident rates given show the actual conditions. No comparison of accident rates is made with the Bureau of Mines statistics for the reason

that the Bureau's rates are based on total shifts, surface and underground, while the figures given here are based on underground shifts only, for the reason that surface employees are not exposed to the hazard of falling rock and ore.

Such accidents may be said to be due to three general causes:

1. Natural hazard
2. Faulty methods and materials
3. Carelessness and lack of experience on the part of the miner

and our purpose will be to show how the problem of preventing this class of accidents may best be attacked.

1. *Natural Hazard.* Table No. 2 is a tabulation of accident rates per 10,000 underground shifts based on the method used of mining the ore during a period of 18 months. This table shows conclusively that while a natural hazard is present, it varies in favor of the generally accepted

TABLE No. 3

Showing Total Underground Accident Rate Per 10,000 Underground Shifts Worked. 18 Months, January, 1919, to June, 1920, Inclusive

|                  | Fatal | Serious | Slight | Total  |
|------------------|-------|---------|--------|--------|
| Falls of Ground  | 0.079 | 0.930   | 5.557  | 6.566  |
| All Other Causes | 0.095 | 1.098   | 11.137 | 12.330 |
| Total            | 0.174 | 2.028   | 16.694 | 18.896 |

more hazardous methods of mining. In explanation of this statement we may say that the driving of drifts and crosscuts includes a mining operation which should, on the face of things, be the least hazardous with reference to falling ground. Drifting and Crosscutting is usually done in virgin ground, the back or roof is always within a reasonable distance of the miner and easily reached for barring down. Timbering is simple and easy and all other conditions should tend to make this the safest mining operation. We find however that the very safety of this class of work actually tends to a larger accident rate as shown by the table, drifts and cross-cuts comprising approximately 16 per cent of the underground work having caused 24 per cent of the accidents from falling ground.

Square set stoping which from the nature of the work should be considered more hazardous and which is estimated at 70 per cent of the total mining work, has caused only 63 per cent of the falling ground accidents. Rill stopes where no timber is used, and where the working floor is on a slope corresponding very nearly to the angle of repose of broken ore, which is estimated at 9.5 per cent of mining work, caused only 10.3 per cent of falling ground accidents. Timbered rills and stull stopes which, on account of the timber used should be considered safer are responsible for 3.3 per cent of the underground mining and caused only 1.29 per cent of the accidents. Back filling stopes which are not timbered and where the working floor is on broken ore, are responsible for 1.37 per cent of the mining work and only 0.88 per cent of the falling ground accidents.

From this information we may deduce the fact that in the more dangerous mine workings the miner by increased vigilance renders himself less liable to injury than does the man working in the "safe place," who puts too much trust in the ground holding up. However there is nothing to be wondered at in this. We all know the experienced repairman who is employed in mining through caved ground. He is always to be found around the most dangerous places underground and is rarely if ever caught by a fall. It is a pleasure to watch him work. When he first comes on shift he proceeds to make himself safe, and when he starts mining he is ever on the alert, and as quick as a cat; and if a fall of ground does come he beats the fall to a place of safety by many feet.

2. *Faulty Methods and Material.* In but few cases can a falling ground accident in a mine of the Anaconda Copper Mining Company be laid to this cause, and then only through disobedience to orders on the part of the miner using too light timber, etc. The character of the ground decides the method of mining. No skimping is attempted in the use of timber, and the miners are constantly urged to make themselves safe before proceeding with the shifts work. It is the duty of the shift boss to see that this is done, and in addition there is a safety engineer employed at each mine hoisting ore, whose duty it is to visit every working place as often as possible and to report daily to the mine foreman any unsafe conditions he may encounter. Further, each safety engineer makes a written report every two weeks to Mr. C. W. Goodale, Chairman of the Bureau of Safety, detailing all unsafe conditions and practices he may have encountered in the two weeks' period and stating whether or not they have been remedied. It is the policy of the company to furnish the miners with the best materials for their work. We quote from p. 35 of Mr. Harrington's paper, already referred to, where he speaks of the safety organization of the Anaconda Copper Mining Company. "The writer had occasion during the years 1916 and 1917, also to some extent in 1918, to go underground in more than 20 Butte mines, in many of which he visited every working place (the underground inspection lasting several weeks). It was evident that a sincere, determined effort was being made to keep the mines of the company in a safe condition and to have all employees use safe and sane methods."

3. *Carelessness and Lack of Experience on the Part of the Miner.* Accidents due to lack of experience are of course almost impossible to segregate and no attempt has been made to do so. A man who hires out as a miner always claims to be proficient. No shift boss would knowingly put an inexperienced man in a place for which he was unfitted, and we are satisfied that accidents under this head are a very small percentage of the total.

As to carelessness, a close inspection of underground accident reports, coupled with observations underground, revealed the fact that a very large number of accidents were due to thoughtless or careless actions on the part of the injured. With this idea in view, the company's safety officials thought that a system of competition among the mines might be inaugurated which would interest every man from the foreman down in the prevention of underground accidents.

Realizing that an intense interest might be difficult to maintain for a long period, it was decided to hold a Safety Drive for 4 weeks, and the period July 19 to August 14, inclusive, 27 days, was chosen in order that the results might be tabulated and a prize awarded in connection with the Safety First Field Day exercises, August 16, an annual affair for the miners of the Butte District.

A Safety First pennant 12 ft. by 24 ft. was procured and advertised as the award to the mine having the lowest underground accident rate per 10,000 underground shifts for the period of the Drive. Eighteen mines took part. Twelve of these mines are operated by The Anaconda Copper Mining Company and one each by six other companies in the district.

The Rules of the Drive were:

1. Entries would be limited to mines hoisting ore.
2. All underground accidents resulting in personal injuries regardless of their serious or slight nature should be reported and counted.
3. Any mine found not reporting accidents properly would be disqualified.
4. The winning mine had the exclusive right to display the pennant for one year.

The Drive was a great success and the pennant was won by the Emma Mine of the Anaconda Copper Mining Company with an underground rate of 0.0. With 5,357 shifts worked during the Drive this mine did not have a single accident. Similarly the Alice Mine of the A. C. M. Co. did not have an accident but on account of a greater number of shifts worked, the Emma was declared the winner. The West Colusa Mine of the A. C. M. Co., with 11,428 shifts was third with a total underground accident rate of 2.625. The Black Rock Mine of the Butte and Superior Mining Company was fourth with 20,994 shifts and a total underground accident rate of 4.763.

The results of the Drive in so far as the 12 mines of the Anaconda Copper Mining Company are concerned are shown in Tables No. 4 and No. 5. Table No. 4 is a comparison of underground accident rates, on a basis of 10,000 underground shifts worked, of accidents from falling ground, for the five and one-half year period, January 1915 to June 1920, for July 19 to August 14, 1919, and for July 19 to August 14, 1920—the period of the Safety Drive. Table No. 5 is a tabulation and comparison of the total underground accidents per *ten thousand* underground shifts during the Drive with those at the same mines for the same period last year (July 19 to August 14, 1919, inclusive), and with total underground accidents at all mines of the A. C. M. Co. for the months of July and August, 1919, for the year 1919, and for the first half year of 1920.

It will be noted that the total accident rate was reduced from 23.499 for the same days and mines during 1919 to 9.114 for the Drive, a reduction of 61.3 per cent.

A reduction from 19.210 for July and August 1919 to 9.114, or 52.6 per cent.

When compared with rate for 1919, the Drive shows a reduction of 47.5 per cent.

TABLE NO. 5  
Underground Accident Rates Per 10,000 Underground Shifts

|                                                         | Fatal | Serious | Slight | Total  |
|---------------------------------------------------------|-------|---------|--------|--------|
| During Safety Drive, July 19 to August 14, 1920 .....   | 0.234 | 0.735   | 8.085  | 9.114  |
| Same Mines, July 19 to August 14, 1919, inclusive ..... | 0.671 | 2.014   | 20.814 | 23.499 |
| All Mines during July and August, 1919 .....            | 0.341 | 1.993   | 10.976 | 13.210 |
| All Mines, Year 1919 .....                              | 0.199 | 1.908   | 15.234 | 17.341 |
| All Mines, first half, Year 1920 .....                  | 0.129 | 2.237   | 18.224 | 21.590 |

When compared with rate for first half of 1920 the Drive shows a reduction of 57.8 per cent.

It is especially interesting however to note that the accident rate from falls of rock or ore was reduced 72.3 per cent when compared with the same period of last year, which shows that accidents from this cause are amenable to treatment; and that the prime factor is the human element, even to a greater extent than in accidents from other causes.

Education is the remedy in accident prevention, and when we have taught the miner to concentrate on his daily work for every minute he is underground, all accident rates will show large reductions.

CHAIRMAN TILLSON: Mr. Boardman writes in explanation the following:

"Referring to tables one, two, and four, the accidents shown are all accidents regardless of their serious or slight nature. Any accidental injury in our mines is reportable and many injuries included in these tables are of so slight nature that the injured man lost only a few minutes in having a first-aid bandage applied and did not even leave the plant.

"In classifying injuries we use the ruling of our State Industrial Accident Commission which is that 'serious accidents' are those which cause a loss of more than fourteen days. 'Slight accidents' are those in which the injured was required to leave the plant for one or more days, and 'lost no time' accidents are those when the injured returned to work the following shift."

Table No. 4 shows a remarkable reduction during the safety drive as compared to a similar period compared with their average records. That reduction is without exception in all the sub-divisions of the classification for the total falling ground and rocks.

In table No. 5, the chief reduction is, of course, in the total accidents and in the slight accidents. The question of whether an accident becomes slight or serious is largely a matter of luck. The same piece of ground that falls and hits a fellow on the end of his toe might hit him on the top of his head. In one case it might be a little injury and in another a fatality.

It may be of interest to inject into the minutes of the meeting some comparative statistics of other metal mining operations, as for instance a tabulation of accidents from the New Jersey Zinc Company's mines, tabulated as to the same seriousness of injury based on 10,000 shifts of work—a similar basis to the Anaconda—from 1913 to date. It may be interesting to notice that including the trivial accidents in all cases, that is accidents requiring absolutely no loss of time, the rate has varied anywhere from six down to about three and one-quarter per 10,000 shifts in that period of time. We have here, however, a segregation of the trivial accidents which is not given in Mr. Boardman's report and which is exceedingly interesting because if they are included, as I believe they are in his statistics, that is the point where, as time goes on, you will get a more complete record in following up your accident statistics, that is, as you get your safety organization more fully developed you will have a more complete report of trivial accidents (where a man has just

scratched his finger and had a bandage wound around it). It would be very well worth while, I think, if we could get Mr. Boardman to give us some notes segregating that, because people start in accident prevention work watching statistics and they are likely to get discouraged, because they find the more accident work they do for a few years the poorer they see their statistics appear because they have a more accurate system of reporting and they are catching accidents they didn't catch before.

Mr. Kudlich is not here, so I will read his paper on "Accidents from Falls of Roof and Ground (Coal Mines)".

### ACCIDENTS FROM FALLS OF ROOF AND GROUND (COAL MINES)

H. H. KUDLICH, SAFETY ENGINEER, DELAWARE-HUDSON COAL COMPANY,  
SCRANTON, PA.

Accidents occurring from this cause are responsible for more deaths than any other class of accidents due to mining of coal. While other accident causes may be responsible for a greater number of accidents, approximately 50 per cent of all fatalities are due to falling roof and therefore our greatest efforts are naturally bent toward the reduction of such accidents and more particularly so when the vast majority of all such accidents are potentially a fatality.

In seeking to prevent these accidents our first aim is to seek a true classification in order to ascertain those which can be prevented.

The first natural division is into avoidable and unavoidable accidents. These two classifications naturally overlap depending upon conditions to which they are due.

Accidents avoidable in one field become unavoidable in another due to different working conditions or methods. Where it is customary and permissible to shoot from the solid as is the general practice in the anthracite field, many accidents become unavoidable, which could not be so classed where the coal is sheared or undercut.

Under avoidable accidents must be combined all those which are due to (1) failure by the man in the face to safeguard himself properly, due to ignorance, (2) failure to supervise the man properly in the danger zone, (3) flagrant carelessness or disobedience of rules, (4) willingness to take a chance, (5) improper methods of working.

Under unavoidable accidents must be placed those which it is impossible to safeguard against, whether it be through timbering, removal of dangerous conditions, close official supervision, training of the miner to a realization of the true dangers which threaten him, or due to hidden dangers impossible of detection in advance of the fall.

Of these unavoidable accidents, the great majority are found to occur within ten feet of the face, in the unprotected area which must of necessity be left unpropped where it is the permitted practice to shoot from the solid, and are due to the familiar "horseback," "saddle" or "kettle bottom" which are of such mass as not to be detected by the ordinary

methods employed in detecting dangerous roof conditions, namely, by sound touch or sight.

Again there are occasionally those falls in which an immense mass drops without apparent reason, and with no warning which would be noticeable by the average workman. It has been my misfortune to experience two such within the past few months. In each case a sandstone roof overlaid the seam and a mass 10 feet wide, 8 feet thick, and about 30 feet long, fell without previous indications of danger. Each of these pieces was separated from the main roof on all four edges by a water seam which was not visible before the occurrence of the fall and in each instance, the fall occurred in a 12-foot entry. Such accidents can hardly be classed otherwise than unavoidable.

#### AVOIDABLE ACCIDENTS

Our principal interest is, however, naturally devoted to those accidents which are avoidable and the means which can be employed to prevent their occurrence. We must of necessity include in avoidable accidents all such as can be prevented by any means within our power.

What preventive means then have we available?

#### TRAINING OF MINERS

First and foremost is the training of our miners to a true realization of the dangers which confront them while in the face for it is there that over 90 per cent of our roof fall accidents occur and in the final analysis it is upon the miner that we must depend.

This is well demonstrated in robbing or pillar mining conditions. It is the usual practice to place only experienced and highly-qualified miners at such work as it is realized the greatest dangers exist along the robbing face. As a result for an equal tonnage mined the fatalities occurring under robbing conditions are less than one-half of those occurring in solid mining notwithstanding the greater hazards encountered.

How is the miner to be trained so that he will guard his own safety in so far as possible?

The first step naturally would be the education of the miner to a true realization of the danger to which he is exposed by falling roof.

Since, however, in the anthracite field of Pennsylvania it is compulsory that every miner be granted a certificate of qualification before being allowed to mine coal, it would seem justifiable to assume that he is at least aware of the dangers to which he is under ordinary circumstances exposed.

It then remains to educate the miner so that he may be able to detect possible sources of danger and guard against them.

#### TESTING OF ROOF

The first and most important means of protection is detection of dangerous roof by sound, touch, or visual test. And yet how many miners actually are capable of making such test properly? How often do we

see a miner on entering his working place in the morning do so with his eyes on the roof?

How often do we see a miner sound his roof and at the same time use the sense of touch to assist him in determining dangerous conditions?

As a rule the miner uses but one of his senses, namely, hearing in making his roof tests.

Is it not then part of the employer's duty to see that the miner is properly trained so that he may make use of every faculty in protecting himself?

With this purpose in view, we have found it advisable to make it one of the duties of the supervisory mine force to instruct each and every miner how to test his roof properly, and to continue such instruction until satisfied that the miner thoroughly understands this work.

Each miner is supposed to examine the roof carefully in his working place, at least upon entering his place in the morning and after each shot which he fires during the day, and remove or remedy any dangerous roof conditions which he finds. In addition to this, it is necessary to have examination of roof conditions made by the foreman or his assistant on the daily inspection made by them.

It has been found that on the average each miner fires five holes per day to produce his quota of coal. In other words in a mine having 500 producing faces, 3,000 careful roof examinations would be made each day.

If we can succeed in having every miner test his roof properly as often as mine law requires such test, there will be but very few of the avoidable accidents due to falling roof which will not be eliminated.

Another point of great importance, but which is extremely hard to impress upon the miner is the hazard due to failure to remove dangerous roof, even though it cannot be barred down after continued effort to do so. It seems almost impossible to make the average miner understand that the very attempt which he has made to bar down a dangerous piece of roof has so weakened it that a fall can be expected at any moment.

#### TIMBERING

Another most important means for the prevention of accidents from roof fall, is by proper use of timber.

The most common cause of accidents due to improper timbering is failure by the miner to place sufficient amount of timber. This is particularly true in locations where the roof is, as a rule, considered good. It has been the custom for many years, to place timber only where a dangerous condition is known to exist and as a result, unless the miner is competent and careful, he will not place sufficient timber to protect himself.

As a result, it has been found expedient to place timber along the working face as close as possible, whether there is evidence of its need or not. This brings us back to the question of systematic timbering and develops the weak point in this system—not actually the weak point in it, but rather the failure of the miner to grasp the true meaning of sys-

tematic timbering. In other words, the miner supposes that with timber placed according to set specification, no further support is necessary, not realizing that it is simply the minimum of timber which is to be considered. Here again we have emphasized the necessity for close supervision of the actions of the miners in the face.

Again we have failure to place timber properly, due to the inability of the miner to make proper test and in this way detect the dangerous roof. This failure is, of course, entirely dependent upon the proper training of the miner in the face as I have indicated under that subject and it is quite evident that if we can so train the miner that he will properly test and detect the dangerous roof conditions, he will then naturally take every means to protect his own safety.

Again we have improper setting of timber. The most common fault being the failure on the part of the miners to use cap pieces, to place their cap pieces in the wrong direction, or to make them too small. Occasionally we encounter conditions where the miner will place a prop upon the built-up foundation instead of on the bottom proper.

All of these faults again are naturally dependent upon the training of the miner so that he will realize the dangers which follow improper practices.

Another difficulty met with is the unwillingness of the miner to keep his timber as close to the face as possible. The most usual claim is that the timber will be shot out and if a miner discharges one prop a week, or even one a month, he will advance the claim that it is impossible to keep the timber close to the face due to the shooting out of the props. I have encountered such conditions where no props have been placed within 20 or 30 feet of the face and upon criticising the condition, have been given this as an excuse whereas even though the miner may occasionally discharge a prop when set more closely, we have found it practicable, even under the worst conditions, and shooting from the solid, to maintain timber within 10 feet of the face.

This is another point which can only be enforced by close supervision until such a time as the miner has been educated to the realization of the hazards under which he works, so that he will of his own volition, cut down the unprotected area in the face to a minimum.

#### REMOVAL OF DANGEROUS CONDITIONS

While we must depend upon timbering under many conditions to protect the miner, it should still be borne in mind that it is advisable whenever it is practicable to do so, to remove threatening roof rather than to attempt to support it by timber. It is not at all unusual to find accidents occurring even though props have been placed, for they have proven to be insufficient to sustain the weight, have been displaced by side pressure, or have been shot out causing added hazard. We have, therefore, found it advisable to issue instructions that in all cases where practicable, dangerous roof shall be removed rather than supported by any artificial means.

## CARELESSNESS AND DISREGARD OF RULES

Most accidents arising from this cause are met with in miners of long experience in whom familiarity has bred contempt, or younger miners who have been trained by a careless one.

There is only one means by which we may hope to lessen the accidents arising in this way. If after warning, a miner has been found careless or disobedient and continues in his actions, further warning weakens the effect of rules and the authority of the foreman or sub-foreman issuing them, and it is only possible to eliminate carelessness and enforce obedience by administration of discipline in such a manner as will clearly demonstrate to the miner that he must heed the instructions of the person in authority under whose supervision he is working.

## RULES

In all our actions we are generally assisted by the mine law in effect. In the Anthracite Fields the mine law specifies that the miner shall be held responsible for the safety of his place and shall carefully examine the roof, face, and ribs in order to detect and remove the dangers arising from them. In addition to this requirement of the mine law, we find it advisable to issue and enforce the following rules guiding the miner in protecting both himself and any who may be working with him.

1. Carefully examine your working place before starting in the morning, after each blast, and frequently during the day.
2. You are responsible for your working place. It is up to you to make it safe for yourself and any one who may enter.
3. Never undercut overhanging coal or rock farther than one cut before taking down the overhanging coal or rock.
4. When you have tried to pull down dangerous roof and find you cannot do so, either shoot it down or prop it before going under.
5. Never cut any props or timber while they are in position to support the roof or sides. When it is necessary to remove them, it must be done by blasting.
6. When standing props always wedge securely in place by means of a cap piece driven toward the face and extending over the full width of the prop.
7. If your working place is in a dangerous condition and you have no props, stop working immediately and notify the foreman and do no more work until you have obtained props or timber to safeguard yourself.
8. Notify the foreman immediately in case any unusual or dangerous condition arises.
9. If you notice any movement of the ground indicating a creep or squeeze, immediately put in position danger board across the foot of your place and notify the foreman in charge and do not re-enter the place except by his direction.

These rules cover in a general way all conditions which will be met with by a miner in the course of a day's work.

## SUPERVISION

Until that time arises when every miner or person entering the mine has been educated to the point where he will be able to detect and protect himself against all dangers arising from falls of roof or ribs, we must, to a great extent, depend upon the supervision by the foreman or his assistants and inspectors, to eliminate in so far as possible our accidents from roof fall. Until that time arrives, his duties and responsibility are manifold. We must depend upon him for the proper education and training of the men in the face, so that they will be able to appreciate the hazards of their employment and utilize all means in their power for their own protection. Until the man in the face is able and willing to do this, all of his own volition, we must depend upon the foreman and sub-foreman, etc. to observe all their unsafe conditions which have escaped the attention of the miner and immediately demand that they shall be removed. This cannot be done by the superficial inspection, but requires careful observance of all conditions, careful testing of the roof and instructions to the miners in every case where such are found as to how they may be remedied. This in itself is, however, not sufficient, if the same condition is met with time after time and nothing is done further than the remedying of the same, the miner gradually comes to depend upon the foreman, rather than upon his own observations of test and detection of dangers. This is a condition which must be avoided if we hope to train the miner properly and if he will learn in no other way, we must force him to appreciate the necessity of obeying instructions by disciplining such as fail to do so of their own free will.

Failure to observe rules is either the fault of the foreman who has failed to impress upon the miner the necessity, or is due to unwillingness on the part of the miner to observe them. If due to the first, the fault lies entirely with the foreman and it is another one of his duties to see that every miner under his supervision shall be thoroughly acquainted with the rules formulated for his protection. If he in turn has done his part and there is lack of inclination to obey them, his one recourse is by the administration of discipline.

We must at all times remember that no blame can be attached to a man who makes a mis-step through ignorance, or who has not in his estimation done something which may endanger him—under these conditions the fault lies rather with us in that the man is not properly trained. It is, therefore, our duty in such cases carefully to impress upon our men at all times, the dangers to which they are subjected. On the other hand the workman who shows reluctance to learn, must be given such rules which he will be required to obey without rime or reason and failure on his part to obey them, must be followed by discipline. In short then, our two methods for prevention of accidents can be summed up briefly as follows:

*First:* Education of the minor so that he will use every effort to detect in advance dangerous conditions due to roof falls and use every means in his power to prevent them.

*Second:* The enforcement of certain fundamental rules which through the investigation of many accidents have been found advisable of enforcement upon the miner by supervising forces.

#### METHODS USED IN FOLLOWING OUT THIS PLAN

##### INSTRUCTION

The education of the miners is attempted in a number of different ways—*First*, by direct instruction. This is accomplished by means of the supervising force of the various collieries and the inspectors who make periodical trips covering each colliery in its entirety.

Each of these officials whenever any extraordinary condition or improper practice is encountered, takes the time to instruct the miner carefully as to the proper methods and practices to be used in overcoming the conditions encountered—not only by direct orders but also by a clear explanation as to the reason for each order issued and in case of improper practice, in what point the practice being followed out is improper.

*Second*—By the holding of monthly meetings at each colliery.

At each colliery a Safety Institute has been organized which is attended by all employees. Meetings are held monthly and efforts are made in every case so to interest the employees that it is not necessary for the official force to take any active part in these meetings, rather letting the men understand that the success or failure of this phase of the safety work is up to them, and by placing this responsibility upon them, endeavoring to stimulate additional interest.

At these meetings every accident having special points of interest are taken up when such accidents occur at the colliery in question or at any colliery along the system. Papers are read by various employees upon subjects which will be of interest to the institute.

In addition to this, excellent use is made of the moving picture films on safe practices which are made available by the United States Bureau of Mines and by the National Safety Council.

*Third*—By the issuance of bulletins covering accidents, calling attention of the employees to the method of occurrence and the lesson which is to be derived from such; also by the posting of the bulletins issued by the National Safety Council.

*Fourth*—By the awarding of prizes annually to the employee at each colliery who advanced the suggestion having most value in promotion of safety work.

##### SUPERVISION

The supervision of the working place is dependent upon the foreman and his assistants and is checked up by the periodical inspections made by the safety inspectors.

Regulations are in effect that every working place shall be carefully examined at least once each day and wherever dangerous or unusual conditions are encountered, such places must be re-inspected without

fail during that day in order to see that the instructions issued the foreman or his assistant have been followed out.

The periodical inspection by the safety inspectors serve to check up the practices followed in general at the collieries so that the efficiency of the supervising officials may be kept at a high point.

Any conditions criticized by the inspectors are immediately taken up with the colliery officials so that they may be remedied at once and in addition, the findings of the inspections are referred to the general officials of the company for their attention, so that the efficiency of the colliery force along these lines may be followed up.

The supervising force is also made responsible for the enforcement of their instructions by judicious administration of discipline wherever such is found to be advisable.

#### RESULTS OBTAINED

While the working method as outlined above has not yet reached the highest state of perfection and is not functioning on a 100 per cent basis, it became evident in a short space of time that results were being obtained.

The employees as a whole, were taking considerable interest in the safety movement from the face right back to the breaker, and improvement was noticeable particularly in the departments where hazards were greatest. In the class of accidents with which we are dealing a decrease for the first half of the current year as compared with the same period for the years 1919 and 1918, showed a most satisfactory decrease in roof fall accidents of approximately 20 per cent, in spite of working hazards remaining approximately the same.

#### DISCUSSION

MR. CONIBEAR: The supply of timber in our country is gradually being diminished. I would like to ask if the poor timber that we are forced to use in our mines, has any effect upon our accident rate by falls of ground.

MR. FLYZIK: I come from a country where we have all kinds of timber and the accidents from this one cause are just as numerous as any other place in the United States. Admitting that perhaps defective timber might cause a certain percentage of unavoidable accidents, in my estimation that percentage is so small that it is hardly worth while answering. I really believe that accidents from the fall of timber are worthy of consideration. I should say that actually fifty per cent of our accidents in the United States are caused from that one thing. We kill annually more people in the United States in the mines than Germany and Great Britain combined. One thousand people were killed from the fall of roof; measured in dollars there is an economic loss of \$5,000,000.

In addition to the suggestions offered in these papers, I think it would be advisable for the Bureau of Mines to take a general survey inquiry into the various causes of the fall of roof. Those of us who have worked in the various mines of the United States know that conditions vary.

have worked in mines where we have had to pack our own timber. In those cases, the managers used to unload the timber at the most convenient place to the haulage way and you can readily understand that when we went up to our working place 300 or 400 feet from the main haulage way and encountered a dangerous roof, we didn't feel like coming down; we waited until noon or shooting time or perhaps quitting time in the evening. I am of the firm opinion that it is cheaper to deliver the timber as close to the working place as it is practical to do. In that way I think accidents will be reduced considerably. We must carry on a persistent campaign in educating the miner to the need of properly securing his working place, but in doing that we must also try to remove the human equation that enters into this problem, and that is that if the timber is left at any great distance from his working place he is going to run chances. It is like permitting a machine to be unguarded and expecting all the responsibility to rest with the workman.

Mr. Bagley, the State Mine Inspector of Washington, is about to undertake that sort of a campaign. He is going to take the different parts of the state and go over the various conditions they have there and inquire whether or not accidents are lessened from this one cause in mines where the management delivers the timber to the working place as against those mines where they get paid so much per prop or per set and are expected to pack the timber from 200 to 500 feet up the pitch.

MR. HENRY ROARK (Clinchfield Coal Corporation): Do I understand that in the anthracite region the miners are held responsible for the condition of their working places?

CHAIRMAN TILLSON: I think that is what it said.

MR. ROARK: In the particular mine that I represent, the company is responsible for that. I would like to know if there is any way of finding out the difference where the company is responsible for the setting of the timbers.

CHAIRMAN TILLSON: You mean the difference of timbering on company account or timbering on contract account. That is what it amounts to because the miners in this case are all practically on a contract in their work.

MR. GIDLEY: There is no question but what the scarcity of timber is having a tremendous effect upon the safety of mining operations. We find that down through the South where timber is scarce, we are receiving an inferior grade of timber and, of course, where we have a great deal of heavy ground it has to be supported by various methods of timbering. The quality of timber used is bound to have a decided effect upon accidents. There is no question about that.

This paper is splendid. It gives the reasons and the prevention. Mr. Boardman says that twenty-four per cent of the accidents from falling ground occur in drifts and cross-cuts. In my opinion, accidents due from falling ground in drifts and cross-cuts can be almost eliminated. It depends on the miner absolutely. He doesn't give the percentage of accidents occurring in timber drifts and untimbered drifts, he doesn't make the distinction, but in drifts where no timber is required if the back is

properly dressed down before actual work of shoveling or drilling is begun, it seems to me the hazard could be reduced to the minimum. We have, during the last year, introduced a method of supporting the back in timbered drifts that may be interesting. We have hooks made of inch and a half square iron and the hooks are hung on the cap of the last set of timber that has been put in the drift and those hooks are used for booming purposes. The booms are placed up there. They can be shoved right ahead and the working places can be kept entirely covered. They are very convenient. With this method nothing is in the way and the car can be shoved right up to the working place. Those booms are never taken down. As to rounds of blasting, they are shoved ahead from

*Courtesy Phelps-Dodge Corp.*

**BOOMS SUSPENDED BY IRON HOOKS**

cap to cap and the hooks changed on the cap ahead. It works fine. (See illustration.)

**CHAIRMAN TILLSON:** That is to save the expense of putting false caps on?

**MR. GIDLEY:** Yes. In an ordinary timbered drift after your round is plastered, your first operation is just simply to shove your booms ahead. After that you can place your new cap on top of the boom.

**MR. CONIBEAR:** Suppose you are in cushioning ground?

**MR. GIDLEY:** If you are in cushioning ground where you need more weight, your booms can be supported by a T-piece in a stull in the front if your ground is real heavy.

**MR. CONIBEAR:** Would that hold in real heavy ground?

MR. GIDLEY: Yes.

CHAIRMAN TILLSON: You have been having some little time to glance over these figures. I merely wish to call your attention to the facts that where Mr. Boardman has spoken of percentages of division of accidents that must also be qualified by considering the percentage of work which has been done in those classes whether in drifts or stopes. Where he said that twenty-four per cent of the drifts and cross-cuts have occurred that way, you must realize that only sixteen per cent of the mining work was done that way. This indicates the disproportion of accidents in a place where the causes ought to be very readily correctible.

I think Mr. Kudlik has brought out the same point that in the dangerous and hazardous occupations the accident rate is kept down below the rate in other occupations which are not so hazardous because the men do pay attention in hazardous places to their work. I think both of these papers, written independently, bring that out as the vital point which should be remembered.

MR. CONIBEAR: It has been said that it takes ten to twenty years to get a start in the work of accident prevention. We have had to work ten years and we find that holds true. Our greatest causes of accidents are those falls of ground. The only fatalities that we have suffered the last year are falls of ground, and I think the best prevention is personal contact between the higher officials and the commonest men employed in the mines. We are doing this by periodical and regular examinations by the superintendents of the company and by the safety inspector. These men in positions of authority talk personally to the individual miner in regard to his responsibility, and we find that this is doing more than any other means to educate the men in their own safety and in their own responsibility.

MR. SEIP: I would like to ask those that are here if accidents from falls of roof and ground constitute the largest percentage of their accidents. How many are there who have that condition? There seem to be only about two. That isn't my difficulty. I have two other causes from which I have more accidents. One of those is under the Bureau of Mines classification No. 3, timber and hand tools—accidents resulting from the handling and setting of timber and the use of hand tools. Those are all slight accidents, but the largest number occur there. Another is loading cars at chutes.

MR. GIDLEY: There is no question but what the number of fatal accidents probably are due to fall of ground, that is the largest number, but our experience has been that the majority of minor accidents come from loading from chutes and handling of tools and timbering in square set stopes.

PROF. STOEK: One accident that hasn't been spoken of at all and which in coal mines amounts to about 33½ per cent, is the haulage accident.

MR. MARTINSON: Whenever we have an accident through fall of ground, the first thing that enters our mind in investigating is, has the company provided proper means of preventing this accident in the way of timber made easily accessible to the miner?

The next thing we consider is, has the man been properly instructed by the foreman. We usually find that he has, that is according to the story that we hear after the accident occurs, but I have investigated a large number of these accidents and I have really found, in my experience, that you can easily hang it on the foreman. He comes into the working place and has seen a condition which was dangerous and has no doubt told the men to correct this either by putting in a set of timber or barring down a piece of loose ground; he has walked away; he has not made the impression that he should have made on the man. He doesn't come back to see whether his instructions were carried out. Of course, if the man is killed or severely injured we hear of it; otherwise we don't.

We are starting now to hang it on the foreman. He has to instruct the miner and it is his duty to see that the fellow does it and not go away and say, "I told him to do it."

#### UNRELIABILITY OF STATISTICS

MR. HALL: I think there seems to have been a disposition to explain away statistics. I don't know what good statistics are unless to a certain extent we are guided by them. The statement was made once that rock pillars was the most dangerous work; that is possibly open to question. Perhaps the statistics are right when they suggest that the dangerous thing is to go into new ground. After the roof is subjected to a certain degree of strain, it may, to a certain extent, be relied upon; but when you are going into entirely new ground you come across kettles and slivers of rocks which occasionally cannot be discovered and it may possibly be that the dangers are really as great there as elsewhere. It may be that the statistics may not show the actual hazards, but perhaps we should not be too prone to consider that the statistics do not show the actual facts but to give them the proper weight and question in our own mind whether after all the rawest kind of man should not be allowed to go into breaking new ground and face the dangers which may accompany that work. I really am of the opinion that the most unexpected accidents occur under those circumstances. You can't foresee just exactly what you are going into, whereas when you are drawing back your pillar you are going into the rock which has already underground a certain degree of strain and, therefore, on which certain things can be predicted.

Another thing is the effect of heavy shots usually used in drifting work and the comparatively light shots used in rock pillars.

MR. HARRINGTON: I spent three years in the Butte mining district, and I don't understand Mr. Boardman's figures as to the considerable number of accidents in the face of the drift. The ore there is generally in pretty hard quartz with pyrite, and it requires twelve or fourteen or sixteen holes. The drifts themselves are not very large. The cross-sections are only about five or six feet wide by six or seven feet high and I don't understand why there are such a considerable number of accidents.

Mr. Martinson brought out an idea that I think is one of the vital points in safety, not only in the fall of rock but in all other safety work, underground work, in coal and metal mines. That is placing responsi-

bility on the foreman. I spent a couple of years looking into accident prevention in regions where the companies were devoting a considerable amount of attention to it. I talked to the men and to the safety engineers, to the bosses and to the shift bosses. No doubt, the company was trying to do the best toward reducing accidents. On the other hand, "Well, that sounds fine and dandy, but when the safety engineer is around the shift boss will get after us to make things safe and as soon as the safety engineer gets away he says, 'What we want is the rock in the box.' " I think the fault lies largely in the fact that the mining companies do not get the proper co-operation of the shift bosses. The shift bosses are told to carry out the safety ideas by the management at the top and by the safety engineer, and on the other hand, if the rock doesn't come out, the shift bosses lose their jobs. I think more attention should be paid to the shift bosses.

#### SAFETY ENGINEERS AND BOSSES BREAK SAFETY RULES

Safety engineers and safety men and bosses are only too prone to break their own safety rules. For instance, you see rules against riding on trips, loaded trips particularly; yet you rarely see a safety man who won't get on a trip and ride it out of the mine. A boss will do the same thing.

I investigated a coal mine accident a couple of years ago in which 121 men were killed. They were killed because the safety engineer went into the mine wearing a safety lamp and had the flame extinguished. Gas came out about 100 feet from the face where the flame of the lamp was extinguished, and he deliberately unscrewed the lower portion and the upper portion of the lamp and lighted the gas and killed himself and 120 others.

MR. CONIBEAR: Our accidents prove that the largest percentage occurs in places where we don't expect them, in drifts because of the nature of the ground, etc.

In regard to holding the bosses responsible, when our work started I called attention to the fact that our bosses could not stop at the place to see whether the men did as he instructed them. Immediately in all of our mines the number of shift bosses was doubled and even yet the accidents occur. Our shift bosses have been through a vocational school of two years. They were selected because of their ability, and yet these accidents continue to occur. A boss can't stay in one place all the time. Our bosses are supposed to cover their territory four times a shift, and there isn't a group of men that are better safety inspectors in our mines than our shift bosses. Every six months we select three of them and have them inspect all of our mines.

MR. ROARK: I think there is too much put on the foreman. In our mines, for the last sixty days, we have had two accidents from fall of coal. In the first place, I personally visited the working places and told them not to leave the top coal to the last, but to work the top coal first. The first thing in the morning I would give them that instruction before they had ever shot in many cases, but before I made another trip around they

had shot the bottom coal. On two occasions they had been hurt by the coal falling. The instructions were to shoot the whole cut down but they loaded any coal at all. What are you going to do in a case like that?

CHAIRMAN TILLSON: It seems to me that either by threat or by additional precautions have to be taken, and it depends upon the labor market to a certain degree. If there is plenty of labor and men are working for jobs, discipline works; getting rid of the unsafe man is the obvious thing to do. Where your labor market is not in condition for you to go along without that labor, you have to coax them the best you can and everlastingly keep after them.

There is one other thing that hasn't been mentioned. You speak of barring down ground. Probably that term is used generically, but I want to call attention to the fact that a man will only too frequently take a bar and try to pry down a piece of ground. He can get his bar into the edge of the slip but he can't move forth the piece of ground. Probably he will spall off the edges of the slip in which he has inserted his bar and then give it up. Perhaps seventy per cent of those cases could be handled if he would go and get a wedge and drive that or several of them underneath the piece. In lots of cases where bars won't bring down the ground, wedges will.

#### PAID SECRETARY FOR SECTION

A year ago, your Chairman presented to this Mining Section a report on the need of a paid Secretary or engineer for the Mining Section who would devote his time to furthering the interests of the Mining Section and its members by getting around to the various member companies, collecting data for bulletins, spreading ideas by word of mouth, and in general, running your Mining Section as a business organization similar to the operations of the National Safety Council as a whole and to the engineering societies. For years, now, we have been existing as a volunteer organization relying upon the efforts of a few to spare such as they could from their regular business duties in attempting to further your interests as well as their own mutual interests in the betterment of the mining industry. Your delegates last year voted unanimously to adopt such a procedure, if funds could be raised, as I suggested at the beginning of my remarks, and to send out letter ballots to all members requesting a vote as to whether they were willing to pay double the amount of the dues they had been paying with the understanding that the excess dues should be applied to the direct operations of the Mining Section and should not go to other activities in the National Safety Council. Such ballots were sent out, not only once but four different times in an endeavor to get a complete or authoritative return vote from members. The results have been unsatisfactory in that the members have not responded to these requests for vote. One-third of the members who replied and two-thirds of the third that did reply were in favor of having their dues increased for this service. That leaves us only approximately a quarter of the membership who are in favor of it, and only a small percentage were opposed to it of those who replied. The number in favor

was too few to warrant taking so radical a step with the investment involved and the obligations assumed financially and the possibility of those members who had not replied not favoring the object and dropping their membership from the Council.

Your Chairman, before this Congress, conceived the idea that it would be an advantage to the Mining Section and the National Safety Council through its Mining Section and that there would be a unique field of opportunity involved for the U. S. Bureau of Mines if that Government Bureau should feel that it fell properly within its function to offer the services of one of its employees to act in this technical manner for the Mining Section of the Council. We had a conference with Dr. Cottrell, the Director of the Bureau of Mines, and the general tone was developed that there was a big opportunity for such a co-operative step and that the job of carrying on such work was a job that required a man of very high grade caliber and great ability. Dr. Cottrell also saw some difficulty. He saw the possibility of political interference, congressional committees attempting to cast aspersions upon the good faith of the Bureau of Mines in spending its money in what might be made to appear some outside organization; he, however, felt that possibly that condition could be overcome if the object was truly in accord with the Bureau's policies. On the other hand, he saw the difficulties of finding and applying the right man to the job. Dr. Cottrell, I believe, is willing to give this matter serious consideration and was kind enough to see that a number of delegates from the U. S. Bureau of Mines attended our meetings. In all cases, I think without exception, these delegates have never been to a session of the Mining Section of the National Safety Council before. The objects were new to them.

At the same time, the American Institute of Mining Engineers officially denoted by action of its Executive Committee, a representative to come here to our meetings so as to show the official co-operative spirit of the A. I. M. E. with the activity of this Mining Section, and by very good fortune the man whom they delegated was also more or less the personal delegate of Dr. Cottrell of the U. S. Bureau of Mines. I refer to Mr. C. E. Julihn who is in charge of one of the Bureau of Mines districts and is stationed at the University of Minnesota.

Your Chairman had several conferences with these various representatives of the Bureau of Mines—Mr. Julihn, Mr. Harrington from out West, Mr. Adams who is now Statistician of the Bureau of Mines located at Washington, Dr. Sayers, who is the Bureau of Mines Surgeon, and Mr. Herbert also of the Bureau of Mines, and I hope he is not wrong in saying that these gentlemen view with favor the proposed co-ordination of the Bureau of Mines with the Mining Section of the National Safety Council along these lines.

It is a difficult matter, probably, to express the thought in the short space of time that ought to be devoted to it, but it appears to your Chairman that a field of great vision may be opened up by such activities. To the casual observer it might appear that somebody was trying to put something over, to use a slang expression, on the Bureau of Mines and

get something out of them. To another prejudiced observer, it might appear, "Here is somebody to swing this organization under the control of the Bureau of Mines," so you see the difficulties. Those might be assumed to be extreme and prejudiced views. I think in answer to a question which would arise as to what percentage of time this man would spend working for the Bureau and how much for the National Safety Council, if he did not spend it all with us, and the question might arise, is it satisfactory for a man to serve two masters. That sounds foolish. He should spend 100 per cent of his time working for the interests of the Mining Section of the National Safety Council and he should spend 100 per cent working for the U. S. Bureau of Mines. I see no difference in the interests. They are both out to improve the safety and the efficiency of the mining industry. On the other hand, it seems to me that it is not asking a favor of the Bureau of Mines but it is offering to that organization an opportunity which has great possibilities, an opportunity for them to approach the Mining industry and its operators both from the executives and the workmen with less formality than would be occasioned by its approach from its formal organization which is the Bureau of Mines itself. It further gives them another port of entry to approach them as officers of the Bureau of Mines or to come in as one of the co-operative organizations to which they themselves belong—the National Safety Council.

The other psychological feature that appears is that of course we are all paying individually for the Bureau of Mines; it is ours and it belongs to us and we are a part of its functions and we should be partners in its operations, but do we realize it? We pay our taxes and that is the way we support it. As to how much money we are investing in that Bureau of Mines we don't know. It is so remote that we are not in direct contact with it and our interests are not so drawn toward it as one of our own activities. We do know that we are paying so much in dues to the National Safety Council and it is our organization and if we don't get something out of it it is our fault, and we want to know why. It belongs to us. Therefore, it seems that a more co-operative spirit between the preaching of safety methods would be found in this organization and the Bureau of Mines operating through this organization in this manner than it would be from the more formal organizations.

The general proposal is of this nature: Last year your Chairman suggested that we attempt to have our dues doubled. He would still suggest that that procedure is worth while regardless of this other step. The field is so big that we will need the money before we get through with it. More money will enable us to have more service that we can give no matter how much we can get from the outside. If we can persuade the Director of the Bureau of Mines to delegate a man to us to work in our service as well as their own (it is mutual), and have the Government supply his normal traveling expenses, for which I believe there is a per diem standard rate of \$4.00 per day for expenses on the road, we would be in the position where from our funds we could readily make up the difference to meet the sum which really is required for a man to get

around. As it stands, the government men are restricted by the statutory amounts allowed for expenses for doing the active work in the field that they would like to do. It means that somebody has to supply that extra money. It means we are going to co-operate then, if we adopt this, with the Bureau of Mines, and we are going to invest our money in it and it is going to be ours as much as it is theirs, or more, because there are more of us than there are in the Bureau of Mines.

To get the thing started is the problem. We have to get this balloting. We submitted this list of members around with the request that you note upon the lists those members you would solicit personally and would make a note of their names. We asked that the lists be returned. Some of them have not been returned. The result is that we have to take steps to complete this membership subscription vote. If we can temporarily get from the Bureau of Mines the services of such a man (and the delegates from the Bureau of Mines estimate that in addition to what the government could give it might require a thousand to twelve hundred dollars to canvass the country thoroughly) and if we could obtain a loan from the treasury of the National Safety Council of that sum of \$1,200, then the big "if" would be this: If this idea appeals to these delegates you must all get behind it and work for it, boost it and get all you can out of it. If all that can be done, it is the belief of your Chairman that there are strong possibilities that both the U. S. Bureau of Mines and the Executive Committee of the National Safety Council will look with favor upon this proposition. It is further the belief of your Chairman that if you do adopt this and make a go of it as you must make a go of it if you start it, you are opening up a field of activity for the National Safety Council at large that far surpasses in usefulness anything it has achieved so far. You are opening up possibilities of the general principles of technical paid executive service on a very greatly increased scale being given to all the industries of the country, and you are furthermore aiding the Government Bureau of Mines in a development which I believe will far surpass in possibilities that which it has achieved in the past, and we know that has been considerable.

I am going to ask Mr. Juliñ, who is here from the Bureau of Mines, to just give us his idea regarding this subject.

MR. C. E. JULIÑ: After considering the matter carefully, I can see a very decided room for co-operation suggested. In the first place, under the organic law of the Bureau, we have a right to spend our money in a rather broad way for safety. There should be no difficulty in that connection. The most important feature of the matter, though, in my mind, is the opportunity it may develop for bringing the Bureau's work right home into the mining industry, and that is the thing that appeals to me most strongly. I have not been long in the service, but I have gained an impression that there are a great many governmental agencies that are limited in their usefulness because of a tendency to centralize in Washington to solve questions at distances from the fields they are serving, and so gaps develop between the agency in Washington and the people in the field.

I very much hope to see the Bureau of Mines, which has started in a

way very close to the people, keep going in that direction and build always right into personal contact with the industries. That is the view I take of this, and I am going to recommend its acceptance by the Director.

CHAIRMAN TILLSON: We want to hear from the rest of you.

MR. HALL: I think it would be an excellent idea. I don't think we could arrange anything which will do more to put us on a stable basis and relieve us of many of the difficulties in which we find ourselves. I think the result will make the Mining Section something a great deal more vital than it has ever been in the past.

MR. MARTINSON: I agree that it would certainly prove advantageous to us. Our relations to the Bureau of Mines have always been of the best and we are glad to have those men around. They have done a lot of work for us. I think they can do more for us if they co-operate with the National Safety Council.

MR. GIDLEY: I think that it is vitally essential that we should have the full co-operation of the Bureau of Mines. Personally, I don't think we will experience any difficulty in securing that co-operation provided we all get behind the movement and go at it in the right direction.

MR. REED: I am very favorable to it.

MR. HARRINGTON: I am in favor of it, but I think that there is no reason on earth why the Bureau of Mines should not co-operate with the National Safety Council. Safety work is a large portion of the Bureau's work and is really the work in which the Bureau was first founded and there is every reason that appeals to me why we should get behind it and no reason why we should not.

MR. SULLIVAN (Oliver Iron Mining Co., Duluth, Minn.): I am very much in favor of a technical Secretary. Our company would be in favor of it.

MR. ARTHUR (American Zinc Company of Tennessee, Mascot, Tenn.): I am in favor of it.

PROF. STOEK: First, should this Section have a paid Secretary? Undoubtedly, yes. How is the best way to pay him? If the Section has enough money it ought to pay him. I don't mean by that that there shouldn't be co-operation financially if it cannot raise the money itself. If it has any help it ought to come from an agency already interested in similar work. As most of you know, there is co-operative work being carried on in a number of states in which the Bureau pays for part of the work and the state pays the other part through the universities so that it can be done successfully. Engineering experimentation and such work is being done in perfect harmony. I can testify to that because in Illinois we are carrying on work between the Bureau of Mines and the Geological Survey of the state.

MR. WOODBURN: We are all in accord; I don't see that there is any argument at all.

MR. JOHNSON: I see no possible objection.

MR. BRADLEY: I think it is a good thing and should be pushed to the limit.

MR. L. A. DEBLOIS: (E. I. du Pont de Nemours & Co.): As a hard-headed member of the Executive Committee, I want to get straight on this proposition. Do I understand that the idea now is for the Executive Committee to reach down into its pocket if this thing goes through and come across with \$1,200 to help out the Mining Section in the co-operating and financing of a technical Secretary?

CHAIRMAN TILLSON: A loan of \$1,200.

MR. DEBLOIS: You call it a loan. That is entirely separate from the double-due idea that was undertaken last year or canvassed last year? That is, if you did double the dues of the Mining Section members, the money accruing that way would be used for other purposes, that is purposes other than this?

CHAIRMAN TILLSON: The idea is that if we get a loan of \$1,200 and also get the services of the Bureau of Mines man, we figure that the \$1,200 would be sufficient, with traveling expenses supplied by the Government, to permit him to canvass the situation throughout the country so thoroughly as to succeed in getting member companies to double their dues and repay the loan and continue then with the double dues in all the service that could be given as well as with the services of the man the Bureau of Mines gave us.

MR. DEBLOIS: He is really not selling the National Safety Council idea but he is giving technical service, and you feel that when the members get to realize the value of that service they will be willing to pay more in order to get it?

CHAIRMAN TILLSON: Yes.

MR. DEBLOIS: I have been tremendously interested in the technical development of the sectional work, especially during the past year as Chairman of the Committee on Standardization and Technical Development. We watched the developments in the Mining Section and the Metal Section both very carefully; as you know the Metal Section project fell through. I am personally convinced that although we have a very efficient and I hope more and more useful, Engineering Section created that can serve the sections of the Council in a technical capacity in what might really be termed research work on their problems, still really successful, intimate, technical work of the sections must be done by the sections themselves. Nowhere will you get the interest in the specific problems that each industry or industrial activity has to meet as you will from that industry or its representatives themselves. You may have your problems which you can properly refer to the Engineering Section and in the Engineering Section we will have engineers, mining engineers and others, and technical access to other bodies which will be at your service. But we shall never be able to take keen personal interest nor shall we have the intimate personal touch with your problems that you have. Therefore, I really feel that for the Sections' success their own technical work must be largely done by them, and it will only be a question of time before they will employ technical secretaries or at least paid secretaries who can prosecute technical work—that is the larger sections.

I feel that this thing is certainly a step in advance and I am sure

that if the Executive Committee would approve of such an expenditure they would watch the experiment with a great deal of interest.

CHAIRMAN TILLSON: We have with us our Secretary and Chief Engineer of the National Safety Council, Mr. S. J. Williams, and we would like to know his reaction on this problem.

MR. S. J. WILLIAMS: I have been very much interested in this proposition from the beginning. I was very regretful that the proposition didn't go through immediately. We think we did all we could by correspondence to get replies from the members of the Mining Section voting for or against 100 per cent increase in dues. You have already had the report on the results of that.

As an engineer and officer of the Council, I am very much interested in seeing this thing go through. I hope with all my heart that it will go through. It pleases me more than I can tell you to see that the men in the Section, and especially Mr. Tillson, are sufficiently interested to keep plugging away until they get it through. Anything that I can do personally to help that may be possible will certainly be done, and I think that now with an engineer, Mr. Tolman, as President of the Council, Mr. DeBlois as Second Vice-President, and throwing his influence into the Council's government, there is certainly a chance to get the thing through if ever, and I look for it to go through. I honestly believe that in ten years from now the Safety Council will look on the Mining Section as having pioneered in this field. It seems to me that the development of sections is just as important and inevitable as the development of the local councils which is going on in a very satisfactory degree.

CHAIRMAN TILLSON: Gentlemen, are you ready for the question?

(The members of the Section present were unanimously in favor of the proposition.)

CHAIRMAN TILLSON: The next paper on our program is that by Mr. D. E. A. Charlton, Managing Editor of the "Engineering and Mining Journal," New York.

#### HAZARDS MET IN OPEN-CUT MINING

D. E. A. CHARLTON, MANAGING EDITOR, "ENGINEERING AND MINING JOURNAL,"  
NEW YORK CITY

Some years ago, when I was actively engaged in safety work, I made the statement—I do not admit that it was entirely original—that the best beginning that could be made in the development of an accident prevention program was a careful and systematic study of the accidents which had occurred over a certain period of time at the particular operation or operations where the installation of preventive methods is contemplated. It is to be assumed, of course, that every advantage is to be taken of methods already in practice at similar operations, and for that reason the safety engineer can follow a well defined plan which will apply to his general problems; but his specific problems, those which are peculiar to his individual operation, will be best determined by the study of

the accidents that have occurred about his plant, shop, mine, or whatever the operation engaged in. Having determined the cause, it is then up to the safety engineer to suggest the manner of prevention. Oftentimes it is within his province to put this directly into effect, but at any rate his judgment should be such that possibility of recurrence of a similar accident is reduced to a minimum.

The thoroughness of accident prevention work in all lines of industry needs no comment here, and it is not the intent of this paper to emphasize what has already been done in the different fields. Those engaged in safety work are all working for a common purpose—the elimination of injury. However, there is the great opportunity for co-operation that we should not lose sight of. If we do so, we become provincial and place ourselves in the class of the man who believes himself sufficient to himself, refuses to accept suggestions, and thereby places limitations upon his accomplishments which are bounded by his own often narrow capabilities. There has been, still is, and will continue to be an immense amount of study given to safety work in every branch of industry, so that it behooves the safety engineer not only to give heed to his own type of accidents and the method of prevention but to those conditions in other fields as well. The idea is simply one which is carried out in any line of work, and its application has been largely responsible for the success that has attended America's industrial progress. By way of illustration: During the recent trip of the American Institute of Mining and Metallurgical Engineers to the Lake Superior region it was most noticeable that the visiting engineers were interested in methods which differed from their own, and the comparison of practices was frequently discussed. This example of course applies to the various branches of mining, but it may well be extended to other industries, any one of which includes features common to all of them.

#### OPEN-PIT ACCIDENT PERCENTAGE LOWER THAN OTHER MINING

Open-pit or open-cut mining is free from many of the accidents peculiar to other methods of mining. Although the sources of many open-pit accidents are not present in underground mines, they are, in comparison, in the minority, and it may be said in general that a lower accident rate prevails in open-pit than in underground mines. This is not only true of the average which is based on the number of men employed but also of that obtained on a tonnage basis, for open-pit operations as a rule permit of a greater removal of material than that obtainable through underground methods. The outstanding advantage is, of course, the daylight feature and the relation of this connection with accident prevention is too well known to the safety engineer to require further comment. It is true that night operations are conducted so that perhaps an additional hazard is introduced. The lighting problem, however, does not present such a serious obstacle as is found in other systems of mining, and present practices have reached a high stage of development, so that there is little difference between the number and seriousness of accidents occurring in the night time and the day time.

In order to obtain an idea of the comparison of the accident rate at open-pit mines and that which holds for all other methods I have reproduced a table which appeared in Technical Paper 252 of the Bureau of Mines, "Metal Mine Accidents in the United States During the Calendar Year 1918," compiled by Albert H. Fay. This shows the number killed and injured in open-pit mines where the ore was mined by steam shovel during the years 1914 to 1918 and includes the returns from typical companies employing about 10 000 men and operating open pits in Minnesota, Alabama, Nevada, New Mexico, and Utah. I have also added the number killed and injured in all methods of mining, (including open pits) per 1,000 300-day workers, for the respective years, these figures being obtained from the same source.

The comparison used is entirely an arbitrary one but sufficiently accurate to show that open-pit mining is not so hazardous as other methods.

It should be understood that the term open-pit mining includes not only those operations where steam shovels are used but those in which other methods of excavation are employed. For our purposes, I shall deal with the former, as I believe all of the hazards met with in the latter will be included in such a consideration. It might be well also, in connection with the above explanation, to add that the development of the electrically operated shovel will preclude the designation "steam shovel open pits" in any treatment that may be made of open-pit accidents, for the success which has attended the installation of these excavators has demonstrated that they will play a considerable part in the future of the open pits and earth removal.

#### GENERAL CAUSES OF OPEN-PIT ACCIDENTS

In order to consider the various hazards met in open pits, the following classification of causes may be used and each subject can be treated with its relation to the operation as a whole. The scheme of classification follows the subdivision of accident causes which is used by the Bureau of Mines, and it is to the best of my knowledge adaptable to most open pits. All of the accidents can be traced directly or indirectly to all of these causes and a further elaboration will only complicate the study which will be made from the operative standpoint: Falls or slides of rock or ore; explosives; haulage accidents (locomotives, etc.); steam shovels; falls of persons; falls of derricks, booms, etc.; machinery (other than locomotives or steam shovels); electricity; hand tools; other causes.

Accidents resulting from falls or slides of rock or ore in open pits do not constitute as large a percentage of the total open-pit accidents as do those attributed to a similar cause in a study of those accidents relating to underground mining. The reason for this is quite obvious, inasmuch as the nature of the operation permits better accessibility to the dangerous condition. Not infrequently is ample warning given, the men may be removed to a place of safety, and the necessary steps taken to make the bank safe.

## BANK TRIMMING PREVENTS ACCIDENTS FROM FALLS OF GROUND

I believe the average slope for stripping banks is  $1\frac{1}{2} : 1$  and it is approximately the same for ore, that is where the overburden is composed of glacial till and the ore is soft such as may be found at the open pits on the Mesabi Range. Rock banks or ore which are of denser structure of course permit of steeper slopes unless the pitch of the strata is such that exceptions must be made. In any event the principal preventive measures which must be taken to avoid this type of accident consist of careful inspection of the banks and proper trimming when necessary. Several factors, such as frosts, blasting, removal of rock or ore from other sections of the pit, etc., may influence falls of banks, but all of these must be carefully guarded against. Several companies employ special men on regular bank inspection work and the results have proved that such precautions have entirely justified the expenditures made. Among the rules which are prescribed by many of the companies who are engaged in open-pit operation is to be found a clause relating to workmen at the front and the bank side of a steam shovel. Although perhaps the rule may apply more particularly to steamshovel operation, it is most applicable in connection with falls of rock or ore. By remaining on the free sides of the shovel during its operation, the men are assured of safety, and should their work require them to occupy positions between the shovel and the bank a rigid watch should be kept and the men advised of any movements of ground. Such precautions are easily obtainable during the daytime. During the night shift, unless sufficient illumination is procurable, the difficulty is necessarily increased.

## THE USE OF SHELTER HOUSES IN OPEN PITS

Accidents attributable to explosives are many and varied. Before taking up the subject of the handling and treatment of powder, it may be well to consider the dangers resulting from blasting and some of the precautions necessary. It is most essential at all times that men working in the pit are given adequate protection from flying pieces of rock and ore which often travel considerable distances. There should be ample provision made properly to warn the men, and this is usually done by means of warning whistles which are blown—a series of short blasts from either the steam shovel or locomotive whistles—for some time previous to the blasting. Following this it should be the duty of the foreman and the underbosses to see that all of the men seek proper shelter. There are a number of types of shelter houses which are in use in open pits. These consist of steel frames lined with ties or houses built of steel plate and reinforced. The latter are undoubtedly more serviceable and can be transported from one place to another without much difficulty. In addition to affording protection to the men the shelter also serves as a point from which the blaster may, if he is using an electric battery, explode the charge, and so perform that operation in perfect safety.

## PRIMITIVE THAWING METHODS TABOOED

The lists of "don'ts" which have been given publicity by the manufacturers of blasting powders and which appear in every safety rule book should have adequate perusal and digestion, for they have all been written with a purpose, and apply in open-pit mining as well as in any operation where blasting powder is used.

It is quite essential that proper storage be provided for explosives. Powder magazines must be kept dry and well ventilated, separate houses being maintained for the storage of black powder and dynamite and also for blasting caps, electric fuses and exploders. It is generally specified that these should be located not less than 300 feet from the thawing house or any occupied building. Standard types of thawing houses are provided by powder manufacturers and these are in general use where climatic conditions require that the dynamite be properly prepared before using. Their specifications provide a separate housing for the heating, which is done by hot water, steam, or exhaust steam, and the thawing house proper where the explosives are stored. Certain precautions regarding the proper care of the thawing house, such as the removal of drawers, etc., are stipulated. The many accidents which have resulted from attempts to thaw dynamite by primitive and foolhardy methods have caused rigid rules to be made concerning this particular proceeding, and there are, fortunately, few instances today where attempts are made to thaw powder by methods other than those stipulated by powder manufacturers or operators.

The transportation of powder from the magazine or thawer house to the working place must be accomplished safely and in a convenient manner. At several mines a special slide or lowering device is provided and from the lower end of this the men in special charge of that part of the work convey the powder to the various points where it is to be used. Properly marked boxes should be used and separate boxes provided for dynamite and for caps and exploders.

## GOPHER HOLE PRACTICE ON THE MESABI RANGE

The general practice as relating to the charging of dynamite does not differ appreciably in open-pit work and is too well known to warrant discussion in this paper. The use of black powder is perhaps not as familiar. In this connection, I am sure the following description<sup>1</sup> of "gopher holing" as used in the open pits will be of interest:

"Stripping banks fifteen feet or more in height are shaken up ahead of the shovel by blasting 'gopher' holes. These holes are started at the toe of the bank and are pointed downward at angles of five to ten degrees from the horizontal. 'Gopher' holing, when first used, consisted in making the holes large enough to permit a man to enter and work, but frequent accident caused this method to be abandoned, and 'gopher' holes at the present time have an average diameter of about fifteen

<sup>1</sup>"Steam Shovel Mining on the Mesabi Range," by L. D. Davenport, Engineering and Mining Journal, March 2, 1918.

inches. Loose ground is removed with a No. 2 round-pointed shovel blade, the edges of which are slightly turned up, fitted with a twenty-five foot handle of two or three-inch diameter. When a hard seam is encountered, it is drilled with a long auger or with a moll and one or two sticks of dynamite are pushed in with a pointed loading stick and fired with a blasting machine. The loose ground is then removed with the shovel. If a boulder is struck while the 'gopher' is being driven, repeated blasting with sixty per cent dynamite will often shatter it sufficiently to allow the hole to be continued. Where it is impossible to blast through a boulder, the hole is bottomed against it, or new hole is begun a few feet away, depending on the length attained. The limit of length of a 'gopher' hole is about twenty-five feet."

After the "gopher" has been prepared dynamite is used to chamber the hole, and when sufficient time has been allowed for the interior to cool so that no premature explosion may take place, the hole is loaded with black powder, from five to ten kegs of twenty-five pounds being used. In order to avoid danger from sparks and other sources the powder is poured into the hole by means of a launder device which is provided with a covered hopper. Usually the blasting is done by battery. This and the foregoing description represents Mesabi Range practice and has from a safety standpoint, proved most satisfactory.

#### ROLLING STOCK SHOULD BE CAREFULLY SAFEGUARDED

In considering the hazard which may be involved in the use of locomotives and other rolling stock and the prevention of accidents from those causes, open-pit operators have been guided to a great degree by practices which have been standardized by railroads and other industrial enterprises of a similar nature. The Interstate Commerce Commission in 1910 adopted a number of regulations governing safety appliance standards on locomotives and these are in effect at practically all open pits. They relate to sill steps, hand holds, uncoupling levers, hand rails, hand brakes, running boards and other appurtenances. It is, of course, essential that a well-arranged system of inspection be maintained in order that the proper persons be advised of any breach of regulations in this particular, and constant work is necessary to keep all rolling stock in a safe condition, as the usage to which it is subjected is by no means one that defies wear and tear. There is considerable variety to the equipment used, and the manner of safeguarding locomotives, stripping cars, ore cars, etc., will be governed by the adaptability of safety devices to the certain types. Having specified the mechanical means for the prevention of haulage accidents, it is further necessary to adopt certain regulations and provisions which will make for the avoidance of accident from other than mechanical sources. In Bulletin 751, issued by the Bureau of Mines, the following rules have been suggested as governing safe practices for the operation of locomotives and ore and stripping trains:

"Rules and Regulations for Metal Mines," by W. R. Ingalls, James Douglas, J. R. Finlay, J. Parke Channing and John Hays Hammond. Govt. Ptg. Office, Washington, D. C., 1915.

"Precautions are necessary against collisions, against runaway trains on the steep grades and sharp curves that usually exist, and against the danger of running down men who may be walking on the track. To avoid this last danger trails and walks should be provided apart from the railroad tracks and their use insisted upon. Dangerous methods of coupling and dangerous methods of boarding cars or engines should be forbidden. Nobody should be allowed to ride the ore trains except the train crews. Proper clearances over cars and on the sides should be provided and material should not be allowed to be piled so close to the track as to be dangerous. The men selected to work on the track should be intelligent and alert and should be taught extraordinary caution in looking out for trains. Frogs should be blocked and signs provided at crossings. There should be a strict adherence to safe practice in regard to the use of headlights and rear lights on locomotives and trains, to the sounding of whistles, and the ringing of bells." . . . "There is a certain amount of danger attached to dumping the stripping cars, and somewhat less to discharging the ore cars when the contents are frozen or sticky. Dangerous practices in performing these operations should be specifically prohibited."

These provisions are generally carried out in open-pit practice and modifications to fit specific conditions have been made by the various companies.

It was stated earlier in this paper that the recent advances made in earth excavation practice admitted of a broader term than that of "steam shovel." The steam shovel still holds its own and steam as a motive force remains a dominant feature. With the increasing use of electricity and other forms of power, and the adoption of the drag-line excavator and other mechanical means for earth removal the more general term of "power shovels" or "power excavators" might be more acceptable. However, with a few exceptions, the safeguarding of power excavators is very much the same and follows the lines carried out in any shop scheme wherein all moving parts are covered; that is, where it is possible to do so. It is hardly necessary to state that the construction of guards must be particularly rugged to withstand the hard usage which the machinery must undergo. A regular plan of inspection, such as is carried out in machine shops and other plants where mechanical devices are safeguarded, should be instituted and rigidly followed.

It is quite necessary that the area which is occupied by the shovel be kept clear of material. This is not always possible and particularly so where the shovel is "moving up." but it will be found an excellent rule and one which will be the means of preventing a number of slight accidents. Orderliness in open-pit operation is as necessary for accident prevention as in any other work and should not be neglected.

#### ACCIDENTS FROM FALLS OF PERSONS

The responsibility of mining companies for injuries which occur on their property not only includes the safeguarding of their employees but also extends to those who may have no connection whatever with the com-

pany. For this reason it is not only necessary to maintain a careful watch around the entrances and banks of open pits but also to see that sufficient fencing and guard-railing is done. Stairways should be substantially built and provided with hand rails. Test pits or other openings should be properly covered. The practice of bank trimming, which was referred to in an earlier paragraph, is often carried out under hazardous conditions, as it is sometimes necessary that the men, in order properly to trim a bank or slope, must place themselves in a position where a movement of the ground might cause them to fall or perhaps be buried in a run of rock or ore. To safeguard against this the men are provided with ropes which are placed around their bodies and substantially fastened to some safe point above. This practice is also extensively used in the milling method of mining, which may be regarded as a modification of open-pit operation. In the winter it is especially necessary to keep stairways and other such places free of accumulations of ice which may cause falls of persons.

Under the subject, "Falls of derricks, booms, etc." will be included hazards that are somewhat limited in number. The construction of stripping dumps requires that considerable trestle work be done, and it will be found that accidents result from carelessness in the handling of the timbers used in the trestles. At coal loading stations, water tanks, and other such appurtenances to open-pit mines, arrangements must be made properly to safeguard all devices used, and instructions must be issued as to the proper methods of operation.

There is little machinery used in open-pit mines other than that included under the head of steam shovels and rolling stock. There is, of course, the machine shop, the blacksmith shop, and the other departments at which the necessary repair work must be done, but the hazards to be found at any of these are well known and do not differ from those met with in general shop practice. The same efforts which are applied in the latter should be the rule in the shops of the open pit. Small hoists, compressors, machine drills, or other auxiliary machinery used in open pits should receive the same attention, both as to operation and safeguarding, as in underground or general surface operation.

#### HIGH-VOLTAGE ELECTRICITY NOT GENERAL IN OPEN PITS

Electricity as a motive power, either in driving a shovel or hauling ore or stripping trains, is not as yet in general use, so that the dangers resulting from the transmission of high voltage have not become to any great extent a problem of the safety engineer. In open pits which have reached the stage where steamshovel removal of ore has been replaced by scrambling operations and the ore is removed through a shaft, motor haulage is frequent and here it is necessary that the same precautions used in underground mining be observed. In some instances electricity is used as the motive power for pumps and considerable lighting is done by means of electricity, but in both of these instances methods of safeguarding are well defined and follow the trend of general practice.

**HAND TOOLS: CAUSE MANY SLIGHT ACCIDENTS**

There are few serious accidents which may be attributed to the improper use or condition of hand tools, but as a source of the slight accident they are prolific. The prevention of this type of accident can be brought about mainly by inspection and instruction in the proper use of the tools. There is always the mushroom-head drill to be found, the loose or broken hammer handle, the stillson wrench that is not working properly and any number of small defects which should not be permitted if the men are to do their work safely and properly.

Under "Other Causes" may be included a miscellaneous lot of accidents which result from improper handling of material, explosions (other than those due to blasting powder) and others which do not properly fall into those causes already mentioned. It may be well at this point to mention one factor which has a considerable bearing on the frequency of open-pit accidents. That has to do with labor and, as each operator and engineer knows, with the dependence that can be placed on each workman to look out for his own safety. Open-pit labor, with the exception of the foremen, shovel operators, locomotive engineers, train crews, and such men as are required for certain classes of skilled work, is not required to be of the standard usually employed underground, and it has been drawn largely from foreign fields. In some cases there is, or has been, an unfamiliarity with the English language, a certain sluggishness that has been due to either indifference or timidity, and a rather detrimental effect in so far as the best conditions for obtaining prevention of accidents were concerned. In many instances, this condition has been counteracted by the further employment of such men who would serve as instructors, as bosses, and a lower percentage of accidents to the class of unskilled labor has resulted.

The safety engineer will find much to interest him in the study of accident prevention and the hazards as met with in open-pit mines. The mechanical safeguarding which can be done is limited, but, the opportunity for "safety psychology" presents ever an absorbing problem. Such details as "breaking in" a man on the day shift before he is permitted to work at night, transferring one workman to another place for which he is better fitted and following out other plans which can be determined co-operatively with the foreman, are some of the interesting studies that are open to the safety engineer.

**PRESENT SYSTEM OF LIGHTING IN OPEN PITS IS IMPROVEMENT OVER EARLIER METHODS**

The matter of illumination in open pits is receiving considerable attention. Formerly the practice consisted of obtaining only such light as was possible from the locomotives, lanterns, and gasoline burners on the steam shovels. Later the gasoline burners were discarded as being unsafe and the steam shovels were wired and provided with a small dynamo. This practice exists today and is supplemented by the use of carbide flare lights which provide excellent light. The practice of extending wiring into pits for illumination purposes has not met general acceptance, due

to the fact that frequent blasting causes breakage of the globes and arc lights.

All open-pit mines make use of signals which are given from the shovels or locomotives. A specified code is used and by means of this the men in charge may be notified of any happening at the particular point where the shovel or locomotive is situated. The value of such a system to accident prevention methods as used at open pits is undeniable.

A treatise on the subject of safety in open-pit mining would be incomplete without pointing out the use for warning signs, safety bulletins, and safety rules. These will necessarily be a large part of any safety campaign, but are too well known to warrant further discussion.

In conclusion, the hazards met in open-pit mines are less than those that may be expected from other types of mines. In general it may be said that the three big causes of accidents in open pits are from falls of ground, explosives, and those due to haulage. Similarly these same causes make up the bulk of underground mine accidents, but the manner of prevention in each case is, by reason of the difference in the mode of operation, different.

I realize that much of the information will doubtless be an old story, particularly to those who have had the opportunity to be in touch with open-pit work. The last few years have brought about notable changes. We have today bigger shovels, bigger stripping cars, methods for handling materials on the stripping dumps, compressed air tie tampers, and other devices which are producing more effective results. All of these are given close scrutiny from the safety standpoint, and so far as their mechanical make-up is concerned, the operator may rest assured that the manufacturers have considered the necessary points to make them safe for the workman. With improved machinery and devices must come the higher type of workman, so that as a higher intelligence is demanded the possibility of accident from causes due to ignorance, indifference, and lack of understanding is decreased. And this in short should mean a marked decrease in the number of open-pit accidents.

CHAIRMAN TILLSON: I want to congratulate Mr. Charlton in your name and for myself personally for the excellent presentation he has given of this subject. I would suggest that Mr. Gallus' paper be read before discussion takes place.

(In Mr. Gallus' absence, the Chairman read his paper on "Hazards Met in Anthracite Stripping".)

### THE HAZARDS MET IN ANTHRACITE STRIPPING

F. S. GALLUS, DISTRICT SUPERINTENDENT OF STRIPPINGS, THE LEHIGH COAL AND NAVIGATION COMPANY, LANSFORD, PA.

Impressing upon the mind of every man who toils, the value of Safety and what it really means to him and his, is perhaps the greatest task which this great movement has before it.

It is probably safe to say that the bulk of the mining accidents can be

traced to one of three causes or a combination of all of these causes—RECKLESSNESS, THOUGHTLESSNESS, and LACK OF COMPREHENSION.

As almost every one realizes and statistics have proved, the system of underground mining is one of the most hazardous occupations, yet these dangers are, year by year, being lessened through the tireless efforts of the various companies in promulgating SAFETY.

A new method of mining is coming more in vogue each year in the Anthracite region. This is the open cut or strip pit method of uncovering the veins, in locations where this system is applicable, with steam shovels and loading the coal either by shovel or drawing it down through openings into the mine; and while this system does not present the same hazards and risks which are encountered in underground mining, still there is a certain element of danger ever present which must be guarded against and precaution taken to eliminate it. The bulk of the accidents encountered, independent of blasting dangers, can be placed under the following three captions: Shovel, Transportation, and Dumping of Refuse.

Owing to the somewhat congested condition of the machinery on a steam shovel, too much care cannot be exercised in entering the housing while shovel is in operation, and for this reason and in order to reduce accidents to a minimum, no one but the operator is allowed to enter the shovel while the machinery is in motion. Yet despite precautions of this sort, accidents will happen, as is shown by the following instance: While the shovel was loading, and unobserved by the operator, one of the jackmen had entered the shovel and was at the work bench when in some unaccountable manner his foot became caught between the swinging sheave and cable, tearing off the sole and heel and resulting in the man being laid up in the hospital for a period of five months and leaving him with a stiff foot for life. As will be noted, this accident was entirely unnecessary and would never have occurred had the man observed the rules.

There have been numerous instances of jackmen being struck with the bucket on the back swing to the pit, but in each of these cases it has been due to the fact that the men have entered the pit from the opposite side to the shovel runner, for the purpose of rolling up a stone from the front of the shovel and, not having previously notified the runner of their intentions and being out of his line of vision, have been caught in this manner. Accidents of this sort can be charged to nothing but pure thoughtlessness on the part of the individual. Of course, there are instances of men being hit by the bucket under other conditions. The most frequent of these being while adjusting chains in handling boulders or in using the shovel to retrack cars which have become derailed while loading. Another sort of danger, although happily an infrequent one, is that of the shovel upsetting mainly due to slippage of the blocking, breaking of an arm or brace while the shovel is in operation, or else, the shovel getting beyond control of the runner when the jacks are loosened up while moving up. Accidents of this sort are hard to guard against, and endanger the lives of the entire crew. Probably one of the greatest dangers which is encountered is found where stripping to reclaim an area of coal which has been partially worked years previous. Very often, in a case like this, the exact position of the old chamber or breasts is not

on record and their conditions as to whether they are standing open or have been filled up by a subsidence of the top rock and surface, is absolutely unknown.

In cases of this kind, it may readily be seen that there is the ever present danger of the ground giving away under the weight of the shovel, either drawing it down or upsetting it, and thus causing a very serious accident. Under the conditions mentioned, accidents of this sort have been quite numerous throughout the Anthracite region. Bursting of steam pipes and the blowing out of joints are frequent causes of accidents around the steam shovels. Coincident with an operation of this kind, there are also innumerable minor accidents, such as cut and bruised fingers, hands, and feet caused by hammer blows, pinching with bars, and handling rocks in the pit or in dressing down high banks which the shovel has been unable to reach.

#### TO PREVENT ACCIDENTS IN TRANSPORTATION

In the transportation system as a preventive against accidents, it is essential that the tracks be kept in the best possible condition, although this is very difficult to accomplish due to the fact that the roads in the pit and on the dump are being constantly shifted. Conducive to safety on a rock stripping, only high-set engines with the cab mounted on the top of the frame should be used. This lessens the chance of the cab braces being torn loose from the boiler in case of derailment or by hitting rocks which may accidentally have fallen along the side of track, and probably will prevent the serious injury of the engineer. Several accidents of this sort have occurred during the use of engines with low-slung cabs, by having the braces torn loose from the boiler through derailment, thus allowing the steam to escape, and resulting in the serious scalding of the engineers on each occasion. Runaway trips on the grades due to broken couplings or to the trip getting beyond the control of the engineer on a slippery rail, are the causes of quite a few accidents. As a preventive measure to accidents of this sort, the engineer should be ordered to inspect the couplings on his cars at least once a day and should be cautioned to use care and judgment in handling his train at all times.

Probably the most frequent cause of injury in the transportation end is in men getting their hands and fingers caught while coupling and uncoupling cars as nearly all stripping cars are of the drawhead type with the single link and pin coupling.

There have also been instances of men squeezed around the body while coupling cars, but such accidents have been rare. Retracking cars by means of a pole bumped up with a locomotive is a dangerous practice and should be discountenanced as it has resulted in the injury of quite a few men in trying to adjust the pole. It is better and safer by far to have every locomotive equipped with a pair of good retrackers for this kind of work. Accidents on the spoil dump have been less frequent than in any other section of the operation, and the most serious ones have been directly due to thoughtlessness on the part of the individuals themselves.

## LOADING AND DUMPING

In loading stripping cars, the engineer always endeavors to load the car slightly heavier on the dumping side, so that when the car reaches the dump and the dumping chains are released the car can be more readily tipped. Sometimes, however, cars reach the dump loaded too heavily on the inside and the men are unable to dump them when the chains were opened. In various instances they have been known to clamber on the car to throw off some of the material on the heavy side, but have neglected to hook the side chains before doing so, and consequently the weight of their bodies over tipped the car and precipitated them to the bottom of the dump, resulting in some very serious injuries. The best preventive for accidents of this character is to have a short pointed dumping pole which when placed on an angle between the floor of the car and the sills will permit the car to be tipped by merely moving the trip several feet.

There are also numerous cases of men losing their balance and rolling down the dump, while attempting to bar large rocks which have become lodged on being dumped from the car. Some of the latter have produced permanent injuries and disfigurements. How many needless accidents happen yearly in open cut mining is hard to say, but if every one connected with it would adopt the "Safety First" slogan as their own, it is certain that the number would be cut to a minimum.

CHAIRMAN TILLSON: I think that this is a very able paper. Mr. Gallus has specifically pointed out from his own experience instances of accidents and means whereby they may be prevented.

## DISCUSSION

MR. CHARLTON: I would like to ask either Mr. Sullivan or Mr. Martinson, who I know are familiar with open-cut operations, something with regard to this particular accident that he mentions. I would like to ask them if it isn't customary to have a guard over that swinging shift.

MR. SULLIVAN: Yes, it is.

MR. MARTINSON: There are a couple of things that are being done which might be of interest to some other people, that Mr. Charlton did not touch upon. I might state that some of the companies have been experimenting with flood lighting in smaller places, and I believe that some of them have systems quite satisfactory. The case I have in mind possibly requires a throw of 1,500 feet, and by the installation of flood lighting systems we have been able to make our night operations much more efficient and I believe safer.

I believe this system of having a dog or jack, which is simply a piece of rail about two and a half feet long and sticking it against the side of the car at an angle and trying to catch it against a bolt or something of that kind as the trip goes forward, is causing us to lose about fifty per cent or sixty per cent of our fingers. We have had a very heavy campaign against that as being a very dangerous practice.

MR. CHARLTON: I might say that one practice that I am familiar with

in connection with the dumping of cars is that of having an iron pipe capped at either end and with a small handle protruding at each end so the men will grasp the handle rather than the pole itself, and that gives a much better opportunity for them to fling the pipe in case anything goes wrong and the catch at the bottom doesn't work.

CHAIRMAN TILLSON: Have you found that there were hazards involved in handling it with a pole so equipped?

MR. CHARLTON: As far as I know we have never had any accidents.

MR. REED: A suggestion of that kind was made by some of our men but our safety committees all turned it down and I think they were right in it for the fact that the jack, when they stick it against the side of a car for this purpose, will frequently twist and turn and if there is a handle on the side it would pull the hand against the car and perhaps take the whole hand off in place of just a finger. It is a practice that we felt was unnecessary and dangerous, and it is the opinion of all of our safety committees that it wouldn't be advisable.

CHAIRMAN TILLSON: This is not retracking cars. It is quite a different problem from merely dumping the car. On the other hand, are not the car bottoms more suitable toward the sprag having a proper hold on the car bottom for riding it than would a small mine car which had no provision for it?

MR. CHARLTON: That is right. Of course, in the up-to-date practice as they have today on the Mesabi Range, all those cars are dumped by compressed air, that is to say with twenty and thirty cubic yard cars. This refers particularly to the smaller sized cars, that is twelve-yard cars where they all have wooden bottoms.

CHAIRMAN TILLSON: The best practice is to perform that operation mechanically by power.

PROF. STOKER: I think the paper on the anthracite region has covered that very thoroughly. I might say we do not have the same dangers in the thinner seams and flat seams in Illinois that they do, for instance, in the thick pitching seams of the anthracite region in stripping operations.

#### FEDERAL STATISTICS

MR. W. W. ADAMS (U. S. Bureau of Mines): I want to make a general statement. In a number of the papers read here, use has been made of statistics and I recall a statement made last Monday by the President of the Council that the only industries covered by statistics gathered by the Federal Government were the railways, those statistics being published by the Interstate Commerce Commission, and the statistics covering the mining industry compiled and published by the Bureau of Mines. He made the further statement that those statistics, while they covered the country fairly well, were published so late in the year as to be of considerable annoyance rather than of any use because they came too late to be of value.

I suppose that most of the gentlemen here know that the reports on accidents which are gotten out by the Federal Bureau of Mines are based upon reports voluntarily rendered by the mining companies

throughout the country. The number of companies that we have to send our inquiries to is about 6,000 or 7,000, of which only about half are actually producing. We send out our first request on the first day of the year and follow that up with second, third, and fourth requests at intervals of one month. The fourth request is followed by special letters to delinquent operators so that we find ourselves pretty close to the middle of the year or even later before we can close our figures. Then it is necessary to go through the process of getting that report through the Government Printing Office. I think Mr. Seip will bear me out in the statement that that sometimes is a slow process.

I would like the proceedings of this Council to contain a plea to all of the operators to reply as promptly as possible to the requests that they receive from the Bureau of Mines instead of letting them be put aside from day to day which it is very easy to do. Most of the larger companies report their accidents to us very promptly indeed, and perhaps that would cover seventy-five per cent of the industry; but there are always a sufficient number of delinquents that compel us to keep our figures open because they are so long in replying and yet their figures very materially affect the accident rate in any small locality. If we could get more prompt replies from the operators, it would be possible to get these figures up much more promptly than we do and in that way greatly increase their value.

CHAIRMAN TILLSON: We have a Committee on Standardization of Accident Statistics, and in the past, the statistician of the U. S. Bureau of Mines, Mr. A. H. Fay, while he was in such a position, was Chairman of that Committee. Your Chairman hopes that with the new Statistician of the Bureau of Mines we will be fortunate in having him serve in a similar position if it so pleases the new Chairman of your Mining Section, and that, if so, Mr. Adams will find time unofficially to develop and put before us key figures, if you might call them that, which he does not feel warranted in having brought out in an official publication of the U. S. Bureau of Mines because of their incompleteness, possibly, or because of their being out of line with the statistics which have been produced in the past. I think the membership of this Mining Section can further this object very much by themselves taking home the resolution to specialize a bit more possibly than some of them have in regard to the preparation of accurate mining statistics in regard to accidents and supplying that information to Mr. Adams in a prompt and analytical fashion and giving him the opportunity then of preparing for the Mining Section, if nowhere else, a group of figures interesting to us and indicating the mines that have taken interest in safety and have been enthusiasts in attending these Mining Section meetings and have taken an active part in them. Those figures might be a very interesting group of figures to compare with other groups of figures of the industry in general throughout the country. I should hope that they would show such a marked improvement as to indicate the value of personal interest in this safety propaganda: we ought to be able to show that the National Safety Council is performing a very useful function in the mining industry.

I trust that Mr. Adams will find time to correlate those statistics and present them in a form that would be effective.

MR. ADAMS: I think that could be done.

CHAIRMAN TILLSON: The next item of business that we have is the report of the Nominating Committee. Before this Committee makes its report I should like to say that your Chairman, during the past year, extremely appreciated the opportunity he had to be of service to you and the co-operation he received and the help he received from the Chairmen of other Committees and the officers of the Council and from Mr. Seip who came in when the Secretary you elected last year was forced to resign because of his moving into other fields of endeavor and being remotely located. Mr. Seip has picked up that work and has helped very materially in the functions of our Section in preparing this meeting. Furthermore, the fact of your having a Nominating Committee is purely a matter of form so as to bring some names before your attention, but we hope that you will not feel at all inhibited in bringing forth other nominees directly from the floor in addition to any slate that your Committee may offer.

Mr. Hall was appointed Chairman of the Nominating Committee and we shall be glad to have him make his report.

#### REPORT OF NOMINATING COMMITTEE

MR. HALL: Your Nominating Committee respectfully submits the following names for your consideration as officers of the Mining Section for the ensuing year:

Chairman—B. F. Tillson.

First Vice-Chairman—D. A. F. Knoefel, U. S. Bureau of Mines, Terre Haute, Ind.

Second Vice-Chairman—George Martinson, Pickards, Mathers & Co., Hibbing, Minn.

Third Vice-Chairman—Guy F. Johnson, Homestake Mining Co., Lead, South Dakota.

The Nominating Committee believes that the appointing of a Secretary should be left in the hands of the Chairman of the Section under the present circumstances and, therefore, makes no nomination expressing, however, their hearty appreciation of the good work in the past year by Messrs. Sherman and Seip.

(On motion the Secretary cast the unanimous ballot of the Section for the nominees.)

CHAIRMAN TILLSON: I appreciate very highly your confidence and shall be happy to accept the office, principally in view of the fact that we have in hand a project which has been a pet hobby of your Chairman and which he hopes will materialize in the coming year.

The coming year may bring forward some very ripe possibilities for us. It all depends upon the interest and enthusiasm which you as individuals devote to this Section.

This year we have had the innovation of having four meetings of the Mining Section instead of three as has previously been the case. Do

you consider that the question of having four meeting is a successful one? Has it been too long? Those who believe that we should have four half-day meetings at future meetings will please signify by saying "aye," contrary "no". It seems to be the unanimous opinion that we shall have four half day meetings. That is one practice we will adopt.

As soon as this reorganization can be effected or disposed of, it is hoped that inquiries will be sent out in regard to subject matter for future papers and inquiries for the ideas which you members have in regard to what you would like to have handled by your Mining Section Executive Committee.

The Mining Section is rather completely organized, more so than any other, but we have to get organized in the field now and make this paper organization work as it ought to work and can work if each individual gives his effort to it.

Remember that the Chairmen of any Committees are only Chairmen; they are there to co-ordinate the activities of the Committee members and the initiative must come, to a large degree, from the members.

(The Section went on record as favoring a "Stag Smoker" in place of the "Smile Party" for the next Congress.)

ADJOURNMENT.

## Packers' and Tanners' Section

September 29—October 1, 1920

---

A. B. DRUMMOND, Chairman

Wilson and Company, Union Stock Yards, Chicago, Ill.

W. W. PIERCE, Vice-Chairman

Morris and Company, St. Louis, Mo.

G. L. MALLERY, Secretary

Swift and Company, Chicago, Ill.

---

### WEDNESDAY MORNING SESSION

**T**HE meeting was called to order at 9:30 A. M. by the Chairman,  
Mr. A. B. Drummond.

#### DELEGATES ATTENDING

J. E. Ballentine, A. C. Lawrence Leather Co., Peabody, Mass.  
Henry K. Batchelder, A. C. Lawrence Leather Co., Peabody, Mass.  
G. S. Bixby, The Mechanical Mfg. Co., Chicago, Ill.  
R. S. Bonsib, Tanners' Council of U. S. A., New York City.  
G. A. Brown, Cleveland Provision Co., Cleveland, Ohio.  
Chas. G. F. Coker, National Calfskin Co., Peabody, Mass.  
A. Duncan, Inspector, Industrial Accidents Assn., Toronto.  
Kenneth R. Dunlap, A. F. Gallun and Sons Co., Milwaukee, Wis.  
A. B. Drummond, Wilson and Co., Chicago.  
J. M. Eaton, Libby, McNeill and Libby, Chicago.  
J. C. Gillen, Cudahy Bros. Co., Cudahy, Wis.  
B. Hoffman, Michigan Tanning & Extract Co., Petoskey, Mich.  
H. L. Johnson, N. S. S. Lead Ref. Co., E. Chicago, Ind.  
D. P. Kennedy, Pittsburgh Plate Glass Co., Pittsburgh, Pa.  
George R. Kline, Swift and Co., Chicago, Ill.  
H. J. Kurtz, Plankinton Packing Co., Milwaukee, Wis.  
George Long, Cudahy Brothers Co., Cudahy, Wis.  
W. F. McClellan, Armour and Co., Chicago.  
Leo Rembowski, Solvay Process Co., Detroit, Mich.  
Henry W. Schildt, Plankinton Packing Co., Milwaukee, Wis.  
J. M. Sandel, Swift & Co., Chicago, Ill.

W. W. Williams, Safety Engineer, Ocean Accident and Guarantee Co., Peoria, Ill.

CHAIRMAN DRUMMOND: Last year at the Meat Packers' Section we appointed a number of committees, and a number of officers, and during the year I believe that none of them has functioned quite in the way they should, I myself being equally guilty, of course. We have neither Mr. Pierce, our Vice-Chairman, nor Mr. Mallery, our Secretary, with us, so I believe it will be necessary to appoint some one to sit here, so I will not be so lonesome, and I am going to ask Mr. McClellan to sit up here with me.

(Mr. W. F. McClellan acted as Secretary pro tem.)

CHAIRMAN DRUMMOND: Due to the absence of Mr. Mallery, we will have to dispense with the Secretary's report, but during the year we have gotten out twelve bulletins for the Section. It has been rather hard and difficult to get sufficient material, due to the lack of interest of the people who belong to the Section, and again, I am equally guilty in this. On the reports of the Committees—I think there were six appointed last year—I don't believe anything has been done.

The first paper on the program is "Safety Committees—Value, Organization, Methods Used, and Procedure," by Mr. J. M. Eaton.

### SAFETY COMMITTEES—VALUE, ORGANIZATION, METHODS USED, AND PROCEDURE

J. M. EATON, COMPENSATION DEPARTMENT, LIBBY, MCNEIL, AND LIBBY,  
CHICAGO

The Safety Committees should be classed as the most important part of the Safety Organization in any plant regardless of its size or the number and class of its employees.

The value of a properly organized and efficient committee cannot be fully realized until it has been in operation for at least six months, when a reduction in the number and seriousness of the preventable accidents ought to become apparent.

The Committee at plants where there are only two or three hundred employees, is usually composed of the Superintendent (who acts as chairman), the master mechanic, one or two foremen, the fire marshal, captain of the watch, and the safety inspector.

Committees in larger plants, however, may be composed of three sections, the workmen's, the fire, and the foremen's section, the last in some cases being called The General Committee.

The first section is composed of workmen who are either elected by their fellow workmen by ballot, or appointed by the foreman once every three or six months. The second section or Fire Committee is composed of men selected by the fire marshal, if there is one, otherwise by the Superintendent. These committees meet weekly or semi-monthly and discuss very thoroughly all recommendations made by their members, or those made to the members by other workmen, and draw up favorable reports on all that have merit, submitting them to the general or fore-

men's committees for consideration. The meetings are usually presided over by one of the committeemen selected by the majority, and every member has an equal opportunity to express himself on any questions under discussion. They are held on company time so that no member sustains a financial loss by his attendance.

Sub-committees of these sections, appointed by the chairman each month, make weekly inspections of the plant and draw up reports calling attention to all unguarded hazards found, and submit them at the subsequent meetings.

Each member of The Workmen's Committee, whether on the Sub-committee of Inspection or not, makes a daily inspection of his or her department to locate new hazards, replace misplaced guards, look out for and warn new help of the various hazards of their work, and at all times assume under the supervision of the foreman, the responsibility for the safe operation of the department as a whole.

To do this successfully, however, they must have the enthusiastic co-operation of the foreman.

The General Committee which in the larger plants is composed mostly of foremen with the master mechanic, the fire marshal, chief of police, and the safety inspector present and acting in advisory capacity, meets once a month and considers not only the recommendations of the Workmen's and Fire Committees, but also any other matters brought up by its own members. The superintendent usually acts as chairman, and in his absence, the assistant superintendent.

It goes carefully over a tabulated record of accidents happening since the previous meeting; calling on those in charge of the department where preventable accidents have occurred, to give details. When advisable, and in the presence of the Committee, the superintendent closely questions all parties, with a view to ascertaining the exact cause and the adoption of preventive measures provided efficient ones have not already been adopted.

Weekly inspection reports made by the regular safety inspector are also scrutinized very thoroughly, and his recommendations fully considered with a view to their adoption, if found practical.

A complete record is kept of the proceedings, and later a typewritten copy is submitted to the superintendent for approval or disapproval of those recommendations for the installation of safety devices which have been found practical.

#### MINUTES OF SAFETY COMMITTEE MEETINGS

A copy of the minutes is sent to the safety engineer in charge of all safety work, who, compares or checks them against previous minutes and thus follows up each item in order not only to see that approved recommendations have been carried out, but also that those recommendations which did not meet with the approval of the superintendent, are looked into further as to their merits with a view to using them at other points under different conditions if found practical. If the rejected ones are really practical, he should use every means at his disposal to change the attitude of the superintendent who has disapproved their use

in his particular plant, by suggesting such alterations as appear necessary, provided they do not in any way reduce the efficiency of the device.

The general safety man always, the general superintendent occasionally, and on special occasions at the request of the general safety man, the president, or vice-president, look over the copies of the minutes of the safety committee meetings, and this fact being well advertised among the plants helps to impress the members of the committees with the importance of the work they are doing.

It has been found that increased interest and regular attendance can also be induced by passing out cigars at the monthly meetings of the foremen, and at one or more meetings a month at the other committees.

The question of awards to those making excellent records as safety committeemen has been discussed, and we find the method most popular among workers is a system of promotion for those showing the greatest efficiency in this line.

We can state most emphatically, that through the efforts of the various committees, in co-operation with the superintendents, and the General Safety Department, we have been able to show during the last twelve months a very large decrease in industrial accidents, with corresponding reduction in lost-time cases as well as cost experience; in fact, the results of this work have justified us in asking for and receiving a material reduction in our casualty coverage. This last, with its consequent reduction in operation cost as well as very evident reduction in labor turnover resulting from fewer accidents to efficient operators has helped to make the safety movement popular with the various superintendents heretofore giving it only half-hearted support; thus rendering many difficult problems easier to solve by the safety man.

The whole proposition thus simmers down to the fact that when given an opportunity for self expression through a membership on a safety committee which carries with it the knowledge that the boss recognizes his ability, not only to see and provide against danger to himself but also to his fellow workmen as well, the ordinary laborer or mechanic begins to expand; to realize his capacity, to think and do for himself, and ambition is awakened with the result that where before you had only a human machine, you now have an enthusiastic worker, imbued with the knowledge that he is an integral and necessary part of a great producing industry.

**CHAIRMAN DRUMMOND:** Very valuable points were brought out in Mr. Eaton's paper. Several have been more or less a subject of discussion. There must be some idea, slightly different than Mr. Eaton's way of running a safety organization, whether it would be necessary to have any other than the Foremen's Committee, or a combination of foremen and workmen, or whether the Supervisory Staff Committee would perhaps be the best form of carrying on safety organization work.

#### DISCUSSION

**MR. R. S. BONSB (Tanners' Council of U. S. A.):** By serving on a committee, the workmen come to realize their responsibility and overcome

that inherent instinct to "pass the buck" to the people over their heads. In other words, by getting the workmen on the committees, you are placing the responsibility on the individual. The thing I have found to be one of the best ways of getting really good suggestions is to have the workmen themselves sign their names to the report. Now, the effect of that is this: a man is going to be pretty careful when he signs his name. If he doesn't sign his name, he will make a lot of foolish and senseless suggestions, so if any of you fellows have committees, be sure to have the workmen sign their names to the reports and I think you will get very good results.

MR. G. A. BROWN (Cleveland Provision Co.): Mr. Eaton speaks of rewarding men with promotion. I would like to know what point he makes there.

MR. EATON: Our idea is that if a man shows efficiency in safety work, he is very apt to show efficiency in his own line of work and this is an added merit in his favor. When the foreman is considering promoting a man to Assistant Foreman or some other position, with an increase in pay, the man who is equally efficient with another man and has the added merit of being a good safety man, and has acted on a committee is given the preference.

MR. H. K. BATCHELDER (A. C. Lawrence Leather Co.): I want to outline the Safety Committee at our plant. We have committees composed of both foremen and workmen and we have committees covering main divisions and plants of our business. In addition to these committees, generally made up of three or four, foremen and workmen together, we have what we call a head of each unit, that is, we pick out a bright young man who acts as speaker and head for that unit, and after the inspections are made, that head of the unit gets together with the Inspection Committee and talks. Also, at the monthly safety meeting, the head of the unit is the spokesman for the Committee. We find that plan works out very satisfactorily.

MR. J. M. SANDEL (Swift & Co.): In connection with the organization of the Safety Committees, this point has not been brought out and I should like to hear some comments on what should be the personnel of the committee. Should it be all men who are superintendents and foremen, should it be some foremen and some workmen, a combination committee, so to speak, or should it be all workmen? In Swift and Company's various plants we have all three kinds, and we have made no attempt to have any standard form of safety organization, because we want to see which works out the best and the time which has elapsed since I have been with the company is not sufficient for us to determine which form of committee has given us the best results. I have heard a good many comments at this convention that the combination Foremen and Workmen's Committee has given the best results to other companies and I wonder if any one here has anything to offer along that line.

#### A PROGRESS COMMITTEE

CHAIRMAN DRUMMOND: The Wilson Company have what is commonly called a Safety Committee, but is really a Progress Committee. That

does not touch merely on safety matters, but heating, ventilation, lighting, efficiency, and almost everything you could ask a man to take an interest in. Safety, as a rule, where men don't have any greater responsibilities, gets monotonous, so we give them something else to think about. They are getting some mighty fine results. We have on these Progress Committees one man or woman from each department throughout the plant to meet once a month and discuss every subject in their minds. There is nobody from the Executive Board, except one representative from the Superintendent's office and myself. We generally arrange to hold the meetings as I get around to the different plants and we are getting results in this way, because we have given them something else to think about, except the one safety idea and I think something along those lines will work out well.

In our local "No Accidents Week," the last week in August, in the 153 different locations around the country, only four reported accidents in the entire time, so I think we are getting results. I think it is working out for us very satisfactorily. There must be some other thought, however, on the Safety Committee idea. I know some people feel rather strongly on not having the working men and others on them and some on combinations of workmen and foremen, but there must be a plan in each different plant that has proven successful and this is the place to discuss it.

MR. BROWN: It seems to me, by having the foremen on this Committee, that the workmen might fear to make suggestions because they might get in bad with the head of the department and I have seen it often result that way. I think, myself, that the Committee ought to be composed of the workmen in the different departments.

MR. EATON: Answering Mr. Sandel, I believe that a large plant requires two committees; a small plant does not. In a small plant, the Committee could be composed of foremen and workmen, but in a larger plant, especially where there are various nationalities working, you will get better results by allowing them to have their own workmen's committees, with their own foreman as a member, as it enables them to give free expression to anything they wish to discuss. I have found in one of our plants that we get very good results where we have the workmen's committee. In another plant we don't, on account of nationality. In one of our plants the Irishmen predominate; they want to talk and don't want any interference. In another plant the Polish predominate; they are very timid and don't have much to say, so conditions of nationality, as well as living conditions, have to be taken into consideration when figuring on the committees. You can't have a fixed rule for any committee at any particular plant or location. You have to take into consideration the number of people and the work they do, whether it is hazardous or not.

MR. SANDEL: Along the line of who should compose the personnel, I have heard quite a few persons make the statement that the foremen make the best members of committees; because when your educational work gets under way, it is necessary, first of all, to convert your foremen and, if the foremen in committee meeting determine any operating prac-

tices which make for safety and follow them out, your workmen will follow those practices when they see the foremen doing it. That is one argument that has almost converted me to foremen committees, and foremen committees are doing good work in various plants.

MR. W. F. McCLELLAN (Armour & Co.): I might add that we have a plant executive at our place and four divisions, one for athletics, one for safety, one for education, and one for Americanization. Under our Americanization Committee we went through the plant with a series of lectures on Safety, starting in February and not ending until July and we also took the Entertainment Committee on that and each afternoon, three days a week, in our various departments we have a safety meeting. We have a sign in advance, notifying them to this effect. In a large department, we would knock off ten minutes of twelve and would go in to the entertainment and put on our "Safety Talk," and I want to tell you we derived more good out of those meetings than all the committees we ever had on the plant, because the men came forward and told about various little things going on in the department that they would not tell the foremen about. We got in and cleaned them up.

CHAIRMAN DRUMMOND: I will ask Mr. Bonsib, Director, Industrial Bureau, National Tanners' Council, New York City, to read his paper on "Tanning Industry Hazards."

## HAZARDS IN THE TANNING INDUSTRY AND THEIR REMEDIES

R. S. BONSI, DIRECTOR, INDUSTRIAL BUREAU, TANNERS' COUNCIL OF THE  
U. S. A., NEW YORK CITY

### INTRODUCTION

Contrary to the general opinion, the converting of hides and skins into leather is not a hazardous occupation. Considering the large number of people engaged in this industry the number of serious injuries is surprisingly small. I say "surprisingly" because it has only been within the last few years that any concerted effort has been made along accident-prevention lines. Although the leather industry ranks as the fourth largest manufacturing industry in the United States and the tanning of hides and skins is man's oldest art, this industry has been backward in accident prevention only when compared to those industries which have become the most efficient along these lines. Since the establishment of the Industrial Bureau of the Tanner's Council there has been an active campaign in accident prevention propaganda and advice on the most effective methods of complying with the requirements of insurance companies and state factory laws. However, it must be remembered that the leather industry, which because of the character of its operations requires the employment of unskilled labor almost entirely, necessitated the use of immigrant labor of the lower type. This in itself imposed a hardship upon the industry because the employee is very largely unable

to understand instructions issued in the English language, besides being innately careless in his habits.

Hazards of the tanning industry may be divided into two general heads—occupational hazard and accident hazards.

*Occupational Hazards*—Occupational hazards will simply be touched upon lightly in this paper, as this is a subject more in the realm of the medical world than in that of the safety engineer. Taken as a whole, the health of tannery workers is remarkably good in spite of the fact that in some departments very large quantities of water are used in the process, but the workers are protected very well through the use of clogs, leather aprons, and other necessary clothing. These conditions are apt to cause rheumatic and catarrhal affections, also skin diseases, unless proper precautions are adopted. In the old days there was a little trouble among patent leather workers, due to naphtha and amyl-acetate poisoning, but with the improvement of methods, this hazard has been practically eliminated.

An occupational hazard, which has been given the greatest notoriety, but unjustly, is that of anthrax. Anthrax is a disease to which tanners who handle infected hides, especially the dry ones from China, Russia, and Asia Minor, are liable. With the enforced disinfection of hides by the Bureau of Animal Industry and precautions which are now being used by tanners of the above mentioned skins, anthrax is gradually disappearing.

*Accident Hazards*—Accident hazards are due to machinery, plant conditions, and the human element. Owing to the absence of detailed records, it is impossible to determine the frequency and severity of rates for the tanning industry but, generally speaking, unguarded or improperly guarded machinery is the cause of probably about 40 per cent of the accidents, the remainder being due to the human element.

#### PART I—UNGUARDED OR IMPROPERLY GUARDED MACHINERY

There are a great many machines, peculiar to tanning operations, which are not found outside a tannery. It will be impossible in the limited time allotted me to discuss all of these machines or to go very much into detail as to their operation or safeguarding, consequently only a few of the more important ones will be discussed.

##### SHERIDAN PRESS

This machine is considered one of the most efficient embossing and plating presses available, especially in the finishing of upholstering leather. It has, however caused some serious accidents.

Two types of guards have been developed which have proved satisfactory. As a basis for proper protection to the operator a fixed guard should be provided in front of the press plates on both of the "operating" and "take-up" sides of the machine, which will enable the operator who feeds the machine to insert the leather but prevent him from getting

his hands between the plates, and also allow the man on the other side to catch the emerging leather without being caught. This type of guard simply fences in the machine, making it impossible for the operator to get his hand caught. The principle above mentioned is now in practical operation in a number of large tanneries. A more convenient form of guard has recently been developed which has several advantages over the above mentioned type, although it is not entirely "fool-proof." The guard consists of a thrust frame attached to the rocker arm. This frame is so arranged that it descends slightly in advance of the plate of the press, so that if a man should have his hand in the press, this warning frame would come down upon his hand and enable him to withdraw it before the press descends.

There are two or three other types of guards which either force the frames away from the machine through the raising of a table or bar, or which require the operator to pull down a lever so arranged that both hands must be used. I do not believe that these types are effective, because in the first mentioned class the table or bar "gets broke." In other words, a large part of the men would rather take a chance of losing their hands than use the device; consequently, they disconnect it or bend it so that it will not operate as it should. In the other type (levers), both of the handles are usually tied together and operated by one hand, thus exposing the other hand to injury.

I would, therefore, most strongly recommend the fence type as first choice and the warning frame as second. The fence guard should be securely fastened to the machine, but arranged so that it can be readily opened up in case repairs to the press are required.

In connection with the prevention of accidents on presses, it is highly important that the attention of the operator be kept on his work. Therefore, there should be a strict rule that no one should talk to the operator. It is also important that he should not be suddenly approached from the rear but from the front so that he can sense the approach and not have his mind suddenly distracted. Flat sticks should also be provided to help straighten out the leather placed on the press and the operator required to use this stick.

#### REVOLVING DRUMS

Many serious accidents have been caused by revolving drums, due to the accidental starting of the drum and also due to the projecting lugs and other projections catching the employee's clothing and whirling him around the drum.

*Accidental Starting of Drums*—In the more up-to-date plants where individual motor drives or friction clutches have been adopted, this danger has been eliminated. In all other cases, however, the belt shifters should be provided with a lock to avoid any possibility of the belt shifting from loose to tight pulley and thus starting the machine. A prominent New England tanner has developed a spring lock which is purely automatic in its action and securely holds the shifter in a safe position, thus eliminating accidents which might occur if the operator were

depended upon to fasten the shifter in place by a wooden pin or rope. Some companies have adopted a lock arrangement in which the drum is securely fastened in position by means of a chain hooked to the wheel. This method has two disadvantages due to the fact that there is danger of the chain breaking if the wheel is started accidentally and also to the fact that the workman might neglect to attach the chain. Another tanner fastens his drums by means of a lock, consisting of a hand screw and sliding block. Whenever the drum is stopped and is to remain stationary while the workmen are placing and removing the hides, the hand screw is turned which forces the sliding block against the end of the staves. This is, I believe, more safe than the chain arrangement, but it is also subject to the liability of the workmen forgetting to make use of it.

A belt tightening arrangement has been adopted in several tanning districts in place of belt shifters. The belt is allowed to run loose when the drums are being filled or emptied. When it is desired to start them in motion, the belt is tightened by turning a wheel which moves out the belt by a ratchet and pinion arrangement. This is apparently a very successful method.

To guard against the possibility of a loose pulley "seizing" from lack of lubrication or other causes and turning the drum, a mechanical lock should be provided. There is practically no danger, however, of pulleys "seizing" if the loose pulleys are provided with bronze bushings and oiled every morning. When bronze bushings get dry, they do not stick, but give out squeaky noises whereas the cast-iron bushings stick without giving any warning.

#### UNHAIRING AND FLESHING MACHINES

Improperly protected unhairing and fleshing machines have occasionally caused the loss of hands, and arms. Probably the best method of guarding this machine is by means of a wire mesh guard. The cylindrical knives of the machine operate downward and remain clamped to the bolster, holding the hide in place while the revolving cylinder makes its return trip upward and automatically releases the gate at the front of the machine and allows the same to move upward, permitting the hide to be removed and a new hide to be placed on the bolster. Fine mesh wire should also be placed over the top of the gate to prevent the operator from reaching over the gate to smooth out the hide while the machine is in operation. The gears at the side of the machine should also be protected with a standard angle iron and wire mesh guard.

#### SHAVING MACHINES

This type of machine frequently causes the loss of tips of fingers, but it is not as serious a hazard as previously discussed machines. One of the simplest guards consists of a curved piece of heavy sheet metal attached on either side of the cylinder wheel hood in front of the rubber bolster. This prevents the operator's hands from being drawn into the

revolving cylinder from the side of the machine. A  $\frac{1}{4}$ -inch bar should also be placed over the bolster as an additional protection against the hands of the operator being drawn into the revolving cylinder.

#### STONING AND GLAZING JACKS

Accidents on these machines are rare. There are several types of guards, but they interfere with production. The type which has proven most popular is a finger guard which has a "D" shaped attachment set as close to the bed of the machine as will make it practicable to operate. This guard may be adjusted to various heights, but should not be higher than  $1\frac{1}{4}$  inches from the bed of the machine.

#### STAKING MACHINES

Accidents on this type of machine are also rare. There is no danger so long as the operator keeps his mind on the work and attends strictly to business. I know of no guard that could be installed which would not interfere with production and which might also increase the hazard rather than eliminate it. It is advisable to equip these machines with a rotary belt shift to prevent the accidental starting or stopping of the machine.

#### SPLITTING MACHINES

There have been a few accidents on splitting machines, especially of the belt or band knife type, due to the operator coming into accidental contact with the blade of the knife. Consequently, the area between the rolls and the pulley should be protected by wire mesh, both at the top and bottom.

#### MISCELLANEOUS MACHINES

There are several types of machines used in tanneries, such as rolls, brushing wheels, and buffing wheels which, although not particularly dangerous, may be effectively guarded by special types of guard. However, it will be impossible to go into these in detail, due to lack of time.

### PART II. PLANT CONDITIONS

#### PROPER LIGHTING

It has been proven conclusively that there is a direct relation between light, safety, and efficiency. In the older plants comparatively little attention has been paid to proper lighting, but this subject has been fully recognized in the construction of the newer plants. Great care should be taken in placing lights, or equipping them with shades, so that there will be no glare or chance of light shining directly in the eyes of the workmen. Glare not only interferes with the efficiency of the workmen, but is apt to be the cause of serious accidents.

## FLOORS AND FLOORING

Due to the great amount of trucking in this industry, thereby requiring the full maintenance of floors, poorly maintained floors appear to be one of the inherent evils in the tanning industry as there seems to be a tendency not to pay any attention to this subject until the floor gets into a very poor condition. In the construction of the newer plants, more attention has been paid to proper drainage systems and the selection of floor materials, so that the tripping and stumbling hazard has been greatly reduced. This is a very vital subject which unfortunately cannot be discussed more in detail on account of limited time.

## STAIRS AND STAIRWAYS

Falling downstairs has been the cause of some serious accidents which could have been prevented by proper construction, proper lighting, and the installation of hand-rails. Since the greater proportion of people are right-handed and since there is more danger of injury to people falling downstairs than there is of people falling up, I believe that the hand-rail should be placed on the righthand side going down. When a person stumbles or falls, he instinctively throws out his right hand, and, when there is no hand-rail to catch him, he falls and is injured. These hand-rails should be built to comply with the standards adopted by the Compensation Board.

## PART III. PERSONAL CONSIDERATIONS

## CLOTHING

As a whole tannery employees are very careless about their clothing while on the job. A study of statistics shows that ragged sleeve ends, loose ties, and open jackets have again and again wound around a part in motion and frightful, sometimes fatal, injuries have resulted. The union type of overalls is the safest to wear, but if these are not available, then the overall coat or jacket should be worn inside the trousers. Under no consideration should loose jackets or torn clothing be worn.

Whenever women are employed for work on machines, they should be instructed to wear some type of overalls. This is not only a life-saver, but will add greatly to their working efficiency. Women and men with long hair should wear a cap or some other means for keeping their hair from being caught by moving machinery. Many fingers have been lost on account of rings catching on projecting parts of machinery, and rings should, therefore, be prohibited. One of the most glaring instances of improper clothing is the shoes worn by men and women. Some of these shoes are simply a mass of tatters, which are apt to get caught on projecting corners, causing the employee to be thrown and more or less seriously injured. The wearing of improper shoes is especially dangerous in the tacking room where there is danger of stepping on tacks which may cause wounds leading to serious infections, lock-jaw, or even the loss of a leg.

**HANDLING ACIDS**

Acid burns are injuries which commonly occur and are doubtless due to the men not being properly warned of the dangers of the acid, but clinator reduces the acid-burn hazard and also greatly facilitates the work.

**HANDLING LIME**

Men working in and about the lime house or lime vats get burns, which are more or less painful, and, unless proper treatment is given, particularly to improper methods of handling. The use of a carboy in are apt to become infected. Most tanneries provide rubber gloves for their employees but sometimes the lime gets down into the gloves and causes trouble. Lime burns may positively be prevented by the following method:

Before starting to work have the men cover their hands and wrists with a half and half mixture of fish oil and pine tar, and then slip on a pair of canvas gloves, covered with the same mixture. Fish oil may be used in removing the tar from the hands, although kerosene is equally effective.

**PROJECTING NAILS**

Stepping on nails is one of the common causes of injuries around any industrial plant. There is a tendency to swear at the nail and kick the board aside. The wound seems to be apparently an insignificant one, but it is often followed with serious results. Every man should be made to realize the importance of going immediately to the First-Aid room or plant physician and have his injury given prompt and proper attention. Projecting nails around the tops of kegs and boxes cause more injuries than stepping on nails. A rule should be adopted compelling the person opening any keg or box either to remove the nails or bend them down in a horizontal position.

**CONSTRUCTION AND PLACEMENT OF LADDERS**

The construction and placement of ladders is an important consideration as there have been several injuries due to ladders breaking or falling when they are used. In the first place, ladders should be built strong enough to support more than an average man without breaking or the rungs coming off. They should also be properly placed so that there would be no danger of slipping or falling down. The men should be instructed always to face the ladder when ascending or descending, also not to go up or down the ladder without the free use of both hands.

**NEGLECTING MINOR INJURIES**

Infections cause one of the most painful injuries which the average tannery employee experiences. Prompt attention at the time of the injury will positively eliminate any chance of infection. Every man

should be made to realize that no matter how slight the injury, he should have it attended to promptly. I believe that every plant should have an experienced First-Aid man right on the job; and, in case the number of employees is sufficient, a capable doctor should be in charge of a well equipped First-Aid Room.

#### CONCLUSION

In this rather brief survey of a very broad subject, it has not been possible to go very much into detail. An effort, however, has been made to give a general idea of some of the main hazards in the tanning industry and methods whereby they may be remedied or eliminated. The Industrial Bureau of the Tanners' Council is carrying on an active, accident-prevention campaign by means of a weekly bulletin, which we have called a "Safetygram", in which the methods of eliminating various hazards is gone into in minute detail, in most cases photographs and drawings of the most effective devices being given, also by plant inspections and illustrated lectures. Interest in this subject is rapidly growing, and I am happy to state that the tanning industry is gradually being made one of the least hazardous of the great manufacturing industries of this country.

CHAIRMAN DRUMMOND: I am sure that Mr. Bonsib has covered the matter of the tanning industry very thoroughly, but I don't think we should close the subject without hearing further from some other men. I am going to ask Mr. Hoffman, of the Michigan Tanning and Extract Company, to say something in connection with the tanning industry.

#### DISCUSSION

MR. B. HOFFMAN: I think Mr. Bonsib has truly said that in the tanning industry the number of accidents is small. In our plants practically nothing was done until this last year. In fact, the real organization is even less than a year old. I listened with some interest to the discussion here about the types of committees at these plants. The time elapsed has not yet been sufficient to say whether we should have an all foremen's committee or a mixed committee. I am under the impression at the present time, for the average tanner, the type we have, that the mixed committee will get the best results.

In regard to the matter of safety devices, our machines, most of them, are not such complicated machines and the matter of safety devices is not so hard to take care of, but in practically every case they are different and I believe it is entirely a matter of local concern as to the type of device that should be used. In this connection, our safety committees are doing some very good work and I am pleased to say that many of our best suggestions have come from the workmen and not from the foremen.

CHAIRMAN DRUMMOND: I feel quite sure that Mr. Batchelder will have something to say on the hazards of the tanning industry.

MR. BATCHELDER: I might say, if you want a word about our work in Peabody, that we have thoroughly guarded all machinery, belting, and

every hazard that we could find and we are looking hard for hazards all the time, through our various safety committees. We go into the safety work, I think, in a whole-hearted way. We have a monthly meeting of our foremen. We have a dinner and light up the cigars and then go to it. We have a report from the head of each Safety Unit on the accidents, which are thoroughly discussed, to take up every means possible to prevent similar accidents. We have meetings at other periods of the head of our Safety Units. We put out propaganda in our pay envelopes, through our factory magazines, the A. C. L. and through bulletins and various other ways we try to keep the safety idea constantly before our workmen. I think we have accomplished good results in reducing accidents. I think on the embossing machine alone, previous to the time we went into the safety work, there were a good many accidents. We have fixed the table so the man can't reach under the plate if he wants to and since that time we have not had one accident. We have a living example of those accidents in our plant. One man has both hands off and I think the fact that we have eliminated the accidents on that machine alone will repay us for our work. I will be glad to answer any question.

CHAIRMAN DRUMMOND: The purpose, Mr. Batchelder, of getting additional talks would be to see if we can't arouse some discussion on some point, something a little different from the idea expressed before. Our entire idea of gathering here was to get new ideas. I am going to ask Mr. Charles Coker of the National Calfskin Company, Peabody, Mass., to speak to us.

MR. C. G. F. COKER: I don't know that I can add anything. Our company is an allied industry and Mr. Batchelder has covered it pretty well on the safety work. I felt, while sitting here, that in connection with this sectional conference we are like the tail of the cow, we seem to be tacked on the packers' industry, although Mr. Bonsib told us it was the fourth largest manufacturing industry in the country.

However, I think the line of safety work that we are pursuing has accomplished great results. We have, I might say, just one thing in connection with the prevention of lime burns which was spoken of and the solution which was mentioned as a preventive. We have tried out that solution and are following out the suggestion in the pamphlet issued by the United States Department of Labor, and although undoubtedly it is a help, we have found that it is a hindrance in the man's work, for the reason that the solution makes the inside of his gloves slippery and he cannot handle the tools necessary to perform the operation in the lime house. I would like to have Mr. Bonsib, or perhaps some other gentleman, tell us how that can be overcome.

MR. BONSBIB: In answering that question, it is very important in applying this mixture to rub it thoroughly into the hands. I should have mentioned in my paper that the great trouble is that they plaster it on too thickly—the whole thing is to have the epidermis thoroughly saturated with the half and half mixture. If you have it too thick, there will be slipping, but if you get a good creamy consistency of your mixture, rub it into the hands and put the gloves over, it will be all right. We

say half and half, but it all depends on the thickness of the liquid you use. However, if you have a great excess, there will be slipping, but the idea is to saturate the epidermis with this mixture and I know it will prevent lime burns. I know a man working in the lime house for fifteen years and his hands are as soft as anybody's and, where it has been used that way, I have never heard any complaint of it interfering with the efficiency of the man. As I say, I have been in 299 tanneries and I would be glad to answer any questions along this line.

#### TANNING INDUSTRY IN THE HAZARDOUS CLASS

MR. BATCHELDER: I would like to ask Mr. Bonsib if I understood him to say that the tanning industry was not hazardous.

MR. BONSI: Not particularly.

MR. BATCHELDER: I have not known so many different industries, but it seems to me that in the tanning industries there are a good many machines, that is, more than in any of the industries I have visited. I think we have in our twelve plants twelve hundred machines and, of course, that in itself seems to me rather hazardous.

MR. BONSI: When I say hazardous, I mean compared to other manufacturing industries. That is a comparative statement. Of course, any industry that has machines is more hazardous than one that does not have machines, but the common impression is that the tanning industry is especially hazardous. In fact, our insurance brethren inform us it is among the hazardous industries. However, when compared with other industries, it is not particularly hazardous, although we do use a large number of machines, and, as I point out in my paper, we have a number of machines not used in any other industry. I would like to have the Chairman call on Mr. Pope.

MR. POPE: I have only been with the Pfister Vogel Company for about two years and previous to going there I did not dig into past history in reference to the tanning industry and why it should be classed as it was classed by the insurance companies as an extra hazardous occupation. I did not come here with any definite figures or percentage, but I might say that we employ in the Pfister Vogel plant in Milwaukee about twenty-five hundred men and, for the year 1920, up to the present time, we have had nine lost time accidents, that is, lost time of over a week. After the beginning of the eighth day we count it a compensation case and, up to the present time, of the twenty-five hundred employees, we have had nine lost time accidents, and the largest limit of time has been seven weeks. That occurred from a bad scald from hot water. As far as our machinery accidents are concerned, operating accidents, I will simply give you the figures of the Industrial Commission, compared to the metal trades. We had 33½ per cent as many machine accidents as the metal trades had, regardless of the fact that we were classed as an extra-hazardous occupation. Our experience has been such that a year ago we put into our plant group insurance and we had some trouble. Two of the largest and oldest companies in the country positively refused to take us. However, we were accepted at a very moderate rate by one of the large insurance

companies of the country and our experience was such that at the expiration of the first year we got a decided decrease in the cost of insurance, based on their experience, which of course is about the most reliable authority we have.

I might offer a suggestion to Mr. Hoffman on his Committee proposition. I don't know whether you can take advantage of this idea the way we have but we have found it very satisfactory. We have four plants in the city and in appointing the Safety, Sanitation, and Inspection Committee, I take three foremen from the three plants and they inspect the fourth, and the next week the fourth man, with two of the others, inspects the plant of the remaining man, and so on. This has brought very good results, as there is a rivalry between the fellows and one says, "That fellow jacked us up pretty hard this week. If there is anything wrong in his plant next week, we will get it," and they do get it. If there is anything loose around the place, an unguarded machine or insanitary condition, they find it. Those reports are handed in to me and I copy them and send a copy to each foreman and the superintendent of the plant inspected by the other three. It seems to me if you are not situated where you can have plant compete with plant, you can have department compete with department. We change our Inspection Committee every week—we don't have the same men on it at all—it is not a permanent position. We make our selection of different foremen, because I find that where one foreman will find some one particular fault, another will miss it, and the next month he goes around the other fellow will find the one the other fellow missed the previous month and, in that way, I think we get very good service.

CHAIRMAN DRUMMOND: I think your system is a rather good idea, for the reason that (all the insurance men in the audience will bear me out in this) some men can find set screws and nothing else and another a defective elevator, so by changing your men from time to time you are going to get better results.

#### ANTHRAX IN TANNERIES

MR. POPE: Regarding the hazardous part of it, in twelve years' experience with twenty-five hundred men, we have not had one case of anthrax and our Chicago plant in twelve years had only one case of it.

MR. BONSIE: May I say a word? Somehow or other, as soon as a man gets a little sore around a tannery he goes to a doctor and it is immediately anthrax. I have talked to a large number of physicians regarding how to differentiate anthrax. At a certain stage it looks very much like carbuncle, but if you press the pustule of a carbuncle it is very painful. Pressure on the pustule of anthrax is absolutely painless. It is a very simple way to tell. We are not denying that we have it. We have a few cases, but it is rare. It is not a common thing in the tanning industry any more, but it is something I wish the doctors would take the time to study up on so they can tell a case and not call up the editor of the town paper and say, "We found a case of anthrax in such and such a tannery." That is a good front page story, but if the doctors

would take the trouble to tell the difference it would help matters. The disease is not so hard to differentiate and it should be a proven case. Anthrax kills a person in three or four days, and they should be able to tell exactly what it is and not get the industry in bad when it is a case of lack of diagnosis on the part of the physician.

MR. COKER: We have never had a case of anthrax in twenty years and we have handled a good many of the skins about which Mr. Bonsib spoke, skins coming from the other side, so I think it is largely, as Mr. Bonsib has indicated, a case of bugaboo on the part of some people, although the disease is a real disease, but it is not so hazardous in the tanning industry as some people would have you believe. I wish that the gentlemen would tell us what experience they have had with their lime burns.

#### LIME BURNS

MR. POPE: We don't take any extra precaution in guarding the lime burns, with the exception of rubber gloves and insist on the men wearing them. We don't use the fish oil that Mr. Bonsib speaks about, for the reason that you can tell the man to take the time to rub it on his hands and he won't do it. If you rub it in for him and pay him for the time, he will have it done, otherwise he won't. However, we have a very strict rule that a man absolutely must report to his foreman the moment he has a sore of any kind and when it has the appearance of a burn, we send him to the first-aid house and the record is kept, and he comes back every day. If he does not, the nurse calls for him. That is the only thing to do.

CHAIRMAN DRUMMOND: Mr. Batchelder is going to read his paper tomorrow on "Burns and Scalds" and I think we are stealing some of his thunder.

#### DISCUSSION REGARDING A JOINT ORGANIZATION OF PACKERS AND TANNERS

Mr. Coker brought up a question a while back about the tanners being more or less the tail of the packers' cow. I don't think that is quite the right position. We had intended to put it to the members of the organization at this time whether or not we could make a joint section, that is, a tanners' and packers' section, rather than have the tanners, as he expressed it, as the tail of the packers' section and I think, as long as the question came up, we should have some discussion on that as to whether or not it is advisable, whether you feel there is any value in joining up the two. I rather feel we have too many things in common not to derive much benefit from each other and it would be a desirable proposition, but I am going to ask you to give it a free discussion. I hesitated in appointing a Nominating Committee, because I did not know whether it was the desire of the members to combine and, therefore, we would want a representation from both sections on the official staff, so I am going to ask Mr. Bonsib to start the discussion.

MR. BONSI: What I say is as an individual, not as a representative of the Tanners' Council, because I have no authority to speak for them as an organization. For some reason or other, the National Safety Council has not been able to get a very large percentage of our members into the

Council. The tanning industry is in its infancy and, if we could get every one of our members to become members of the Safety Council, the work of the Industrial Bureau would be wonderfully facilitated. At the present time, some of our smaller members are just beginning to realize that safety is a good thing, as a paying proposition. It will take a little time to sell the idea to them, but they are beginning to realize it, but at the present time, under the present circumstances, it might be a good idea to form a joint organization of the packers and tanners, and later on, when safety becomes a big factor in the tanning industry, as it should be, we can divorce the packers' section and have a little section of our own; but personally I would be very glad to see it come about, although I am talking as an individual and not as an industry.

CHAIRMAN DRUMMOND: I would like to have some more discussion.

MR. GEORGE LONG (Cudahy Brothers Co., Cudahy, Wis.): Some time ago I was asked to join a certain organization and I feel that my company ought to pay my expenses in joining that organization, so I went to them and the first question they asked me was, "Have they got a tanners' section?" and that same question will be asked here. If you make it packers' and tanners', at least you put our name up there, it will be much easier for you to get the co-operation of the tanners all over the country. They will begin to feel that they are being represented and there is some section in which they can bring up their troubles and some section in which their particular problems can receive special attention. I believe there is hardly enough representation from the tanners alone at the present time to make a good section and, so far as I am concerned, I would feel well satisfied to be tied up with the packers at the present time, but I certainly want to see that the name "Tanners" is added.

CHAIRMAN DRUMMOND: How do you feel, Mr. Batchelder?

MR. BATCHELDER: It is my personal opinion that if the tanners were represented by name, more tanners would attend the national conferences and, of course, the value of attending a conference is in meeting members of your own trade and getting together and talking over things and I think if the tanners were represented by name they would be more agreeable to sending some one to the conference, thinking they would get more good from it. I am heartily in favor of seeing the tanners represented. I think it would help both the packers and tanners.

CHAIRMAN DRUMMOND: Mr. Coker started this. How do you feel about it?

MR. COKER: I was wondering how many things in common the tanners and packers did have. The tanners handle the product which a number of years ago was supposed to be a by-product of the packers. At present the tanners' industry is not sufficiently represented to have a section of its own and I think the combination of the two trades is a grand idea. You might go a step farther, although I don't know whether it would be desirable or not, and consider the boot and shoe industry, which is considered an allied industry, to put us well on our feet. Perhaps that is not to be considered at this time, but the boot and shoe industry should be represented in the National Safety Council some way or other and I think it is not now.

CHAIRMAN DRUMMOND: As I see it, it is a constructive proposition entirely. The boot and shoe people are not represented, the packers and tanners are in small numbers. It seems to me we have to do something constructive and get the thing started. If necessary later, there could be a Boot and Shoe and Tanners' Section.

MR. COKER: I simply brought it up as a possibility of the future.

MR. BONSBIB: There are a large number of industries that work up the leather. On the other hand, you are complicating your program and it would be pretty hard to get something where the conditions are common. That is another thing we want to look out for, to get something where the interests are partly allied. For example, this morning I imagine the packers are bored while we are talking about tanning hazards and some of the tanners will be bored when talking about the hazards peculiar to the packers' industry. That is one of the things we want to look out for.

CHAIRMAN DRUMMOND: I think it is a mistake at this time to take in too much of the leather section. That should be future development. I don't think anybody has been bored by listening to things that are not closely allied to his own trade, because after all 98 per cent of the accidents that happen in one trade are common in another trade. You will notice I have been very careful to call on tanners. Now, I am going to ask Mr. Eaton his idea.

MR. EATON: As I am really representing the food canning industry, I have not very much to say. I think the larger we get this section, even though we take in the leather industry as a whole, will produce more interest and we will have more members coming in. As it is, we are very small and the more we get the better off we shall be. We are bound to get good information no matter who talks. I was listening to the A. B. C. and the Round Table discussions which had nothing to do with packing, but I got a lot of stuff I am taking back with me.

CHAIRMAN DRUMMOND: How do you feel about it, Mr. Brown?

MR. BROWN: I think the idea is a very good one. I think the tanners will in a short time have a session of their own and I think the general knowledge we shall all derive will be beneficial to all.

MR. SANDEL: I welcome the tanners into this section, as long as they wish to stay, and I think that this would be an opportunity for the tanners to boost their membership in the National Safety Council which Mr. Bonsib says he would like to see. There are some hazards common to them both and while Mr. Bonsib was speaking this morning there occurred to me one which is common to both the tanning and the packing business, that is, it applies to the packing business just in part. I refer to the method used in protecting the vats where the skins are soaked in the tanning liquor. We have the same proposition in our glue houses and so far our experience has been very good. The vats in our houses are not very deep, but we have found that the men would be injured more by the falls than the lime and I wonder whether the tanners could give us any suggestion or information whether it is necessary to take special precaution.

CHAIRMAN DRUMMOND: We have not heard from Mr. Long, I wonder how he feels on the proposition of the joint section.

MR. LONG: We are not very well represented here, considering the number of packers in the country and I believe personally that a joint section would be the thing, until it grew to a point where segregation would be the proper thing.

In answer to Mr. Sandel's point, there are many other open vats besides the glue vats, particularly in older plants where there are slush vats. They are very dangerous things and most houses have the old vats, where they discharge from the side of the tank and it is necessary to lift the platform off the top and discharge the tank, and the men don't take the necessary steps to protect themselves.

CHAIRMAN DRUMMOND: How do you feel, Mr. McClellan?

MR. MCCLELLAN: I am heartily in favor of having the tanners come with us. When we started here a year ago, we had a very small meeting, but today I think we have a few more than we had last year. As has been expressed, there were only a few of each, but we ought to stay together until we get started and then we can divorce one another.

I highly enjoyed Mr. Bonsib's paper, because lots of things really struck home. We handle lime and have machines and I think both of us are in common on the one object.

CHAIRMAN DRUMMOND: Of course, you realize that in order to put this over as a Packers and Tanners' Section, the entire matter will have to be referred to the Executive Board of the National Safety Council, but I think we have thoroughly agreed that the proper thing to do would be to make a combination of the two sections and join them together and they will come through and give us their support on boosting the thing, but it seems to me that we will have to do a lot more work in the coming year than in the past, in order to make the section as it should be. With the large number of each in the country, there is no reason why we should not grow and I believe the time has arrived for some one to make a motion that the combination go through, so we will put it before them officially with the approval of everybody present.

NAME CHANGED TO PACKERS' AND TANNERS' SECTION

(The motion was made by Mr. Coker, seconded by Mr. Sandel, and carried unanimously, that the name of this section be changed to the "Tanners' and Packers' Section".)

CHAIRMAN DRUMMOND: Now that the benediction has been placed on the Section of the Packers and Tanners, it will be in order for the Chairman to appoint the Nominating Committee. Mr. Coker was the man who started the discussion, so I will place him on the Nominating Committee as Chairman.

MR. COKER: I should prefer that a packers' representative be appointed. I would rather give way to one of them.

APPOINTMENT OF NOMINATING COMMITTEE

CHAIRMAN DRUMMOND: In view of Mr. Coker's declination of the Chairmanship of the Nominating Committee and his suggestion that we appoint a representative of the packers, I will appoint Mr. Brown, of the Cleveland Provision Company, as Chairman of the Nominating Com-

mittee. I will appoint Mr. Coker, of the National Calfskin Company, and Mr. Long, of Cudahy Brothers, as the other members.

The Chairman has been given the pleasure of speaking on the "Hazards of Conveying Machinery."

#### HAZARDS OF CONVEYING MACHINERY

A. B. DRUMMOND, MANAGER, SAFETY BUREAU, WILSON AND COMPANY,  
CHICAGO

Without conveying and hosting machinery, we should still be sleeping on the banks of the Nile. Without elevators, for instance, the factories of the present day could not be more than two stories in height and, without hoisting and conveying machinery, many of the things we use from day to day would be absolutely impossible to get hold of.

In the main, the conveying machinery hazard is due to mechanical defects. I mean by that they are not placed properly; or the engineering department has not considered the accident hazards in placing box hoists, chutes, barrel hoists, or other conveying and elevating machinery. They are not given the proper consideration and I think it is necessary for a man to consult, from time to time, with his engineering department to see that everything is considered from a safety standpoint. There is such a varied amount of conveying machinery it would be rather impossible to go into the hazards of all, but the one most common is the hazard in connection with elevators, something we have in all our places, regardless of whether we are meat packers or any other line of manufacture or industry.

It is true that very few accidents happen on elevators due to mechanical defects which can be exposed by very careful inspection by competent people. In our plant we have a series of inspections made, at least one every two weeks, by a different man, and a report in detail must be filled out covering all possible mechanical defects. The most common source of accidents on elevators is the gate. In the packing industry, it is almost impossible to get a gate which will fit all the situations that are peculiar to the packing industry. The semi-automatic types of gate in use on most elevators, where feasible, can never be kept in such shape that they are truly a safe proposition. This is the experience of those of us in the packing game and I think obtains in most industries. I have not prepared a paper on this, and I am merely saying some things you people may not agree with, in the hope that it will arouse a discussion.

You undoubtedly have all been solicited from time to time by men who have gates supposed to be accident-proof, to be applied by mechanical interlock, or electric, or electric and mechanical, but due to the conditions in most packing houses we have found that most of them are not workable. I am not going to state my opinion on this, with the hope that it will arouse a further discussion.

#### DISCUSSION

MR. SANDEL: I have been searching hard for some kind of mechanical interlock, which will make safe the horizontal opening door and I have

not found anything which shows any real results. It is only lately that I have been able to get on the track of an installation with an interlock used in connection with the type of door or gate where half of the door is above the hatchway opening and half below. I have not seen the details of that yet, but if anybody here can give me any information on a mechanical interlock, which can be used on the horizontal opening door, I will be mighty glad to have it.

CHAIRMAN DRUMMOND: It is a really vital subject and I would like to hear it discussed all the way through, because we will all agree that most of the accidents are due to so-called gate accidents, and I know in the packing industry, due to the almost general use of the friction hoist elevator in the enclosed hatchway, some device is necessary and I feel that so many people have had experience on those things that we ought to get a discussion valuable to all of us. Can you give us some idea, Mr. McClellan?

MR. McCLELLAN: I cannot say that I can give you any ideas on friction elevators. We can't overcome these ourselves. We placed an order a short time ago with the Otis people for a new gate they have and when we get it in Mr. Sandel can come over and look at it.

CHAIRMAN DRUMMOND: Mr. Bonsib, you must have some elevator gates or other elevator apparatus in mind.

MR. BONSI: They have few gates in the tanneries, with the exception of the very large ones. Most of the smaller tanneries are in buildings not more than two or three stories high. In a lot of those places chutes are used, in conveying things downward. As far as I know, we have not had so very many accidents through elevators, nor have we developed any particular gate, other than that ordinarily used. It isn't as in the packing industry, where you have to go through areas—we don't have that.

CHAIRMAN DRUMMOND: We are talking both from the packers' and tanner's viewpoint, rather than just the packers'. It is true that the elevator accident is not the most common one in any of our plants, but it is a costly one and I know we have all given a lot of thought to it. I am sure there must be a little more discussion on this to make it worth while. Is Mr. Duncan with us?

MR. DUNCAN: Well, it depends how you run your elevator. We have packing houses where there is an interlock. The door has to be closed before you can move the elevator. No one can interfere with the elevator at all—you can't open the door. I know you must be familiar with that kind of lock.

MR. BATCHELDER: In regard to elevator accidents, I have made out a good many reports of elevator accidents and the majority of them read like this: "The man was riding up on the elevator and caught his foot between the elevator and the frame of the elevator." We have had a good many accidents that happened in just that manner. We have had many since the time that help was changed from American, or English-speaking help, to the foreign-speaking help from abroad, several years ago. We were running fine at one time and a man was caught in this manner and caught his legs and we had to chop out the frame work

of the elevator well and it resulted in a fatal accident. Up to that time there was nothing that we could think of that would prevent such an accident, but our Master Mechanic, Mr. Ballentine, (I think he is here now) thought of the very simple idea of hinging a part of the floor, cutting away and setting in a heavy plank, so when the elevator came up, if a man's foot stuck out the side, it would hit the plank and the plank would go up over it and the man would not be crushed. I think that has worked out very satisfactorily.

MR. BALLENTINE: I can say we have never had an accident of any kind on the elevators equipped that way. It does not open the space between the car and the floor; it simply requires a plank hinge, ten to twelve inches wide, supported by brackets outside the platform of the car. The man can sit in front of the car and go up without any injury.

MR. BATCHELDER: If a man is going up the elevator and this is the floor and he sticks one foot over and comes up to the next floor, he is going to get caught, but instead of coming against the edge, he comes against this hinged plank and this hinged plank goes up and lets him by.

MR. W. W. WILLIAMS (Ocean Accident and Guarantee Corporation, Peoria, Ill.): We have seen the device and it works very well.

CHAIRMAN DRUMMOND: The time for adjournment is twelve o'clock. If there is anything still fresh in your minds, or if you feel that more information is desired, we still have a few minutes to bring that out.

MR. G. S. BIXBY (Mechanical Mfg. Co.): We are not members but are manufacturers of machinery, of course some tanning machinery, so we are taking an interest. We feel that this safety movement affects us as well as it does you. I want to ask Mr. Bonsib if the photographs and cuts he spoke of having on file are available.

MR. BONSI: Did I speak of having any on file? The only way of getting anything from the Tanners' Council would be to be a member or make a special request to the Board of Directors, stating the reason. I have no authority whatever. You might take this up with the Directors.

MR. BIXBY: I want to say that if anything comes up in the way of safety appliances that can be applied on the machine when being built and we can co-operate with you, we will be glad to do so, if you will only put it to us.

MR. BONSI: I might say there is a book in which there are a large number of drawings which I think you can get from the Department of Labor if you will apply to them.

CHAIRMAN DRUMMOND: I am rather glad that Mr. Bixby spoke as he did, because I think the Nominating Committee should arrange for some one whose duty it would be to communicate with the manufacturers and tanning industry, to the end that they may incorporate any ideas at the time the machine is manufactured. All of us have been more or less lax in not seeing that our Engineering Department bought guarded machinery as we should do.

MR. BIXBY: May I add a word to bring it out as strong as I can? We have followed this policy for the past three or four years and, as you stated, it does add to the cost of machinery, but not in proportion to

what you have to do in the end, and it is hard to make a Purchasing Agent realize this, unless it is particularly brought to his attention.

CHAIRMAN DRUMMOND: Is there anything further for discussion? If not, the meeting is adjourned until tomorrow morning at 9:30.

ADJOURNMENT.

#### THURSDAY MORNING SESSION

**T**HE meeting convened at 9:30 a. m., Mr. A. B. Drummond presiding.

CHAIRMAN DRUMMOND: Mr. Sanford has been kind enough to come to give us his views on fire protection, and I think we ought to give him the courtesy of letting him start in and put on his show and not detain him any longer than necessary.

#### FIRE DRILLS AND FIRE ALARM AND DRILL SIGNAL SYSTEMS

G. E. SANFORD, GENERAL ELECTRIC COMPANY, LYNN, MASS.

In considering the subject of fire drills and fire alarm and drill signal systems it must be assumed that you represent industries, some of which occupy one or more buildings, and some of which occupy only a portion of a single building. The employer with a whole building under his control can easily develop a drill system, but it is also highly advisable for the man who has a small factory in a portion of a building only to be able properly to drill his employees to leave without confusion, in case of emergency, as he has no way of controlling the situation in the other parts of the same building.

##### SIGNAL SYSTEMS

With these two factors in mind it is necessary to consider more than one type of signalling system. The system best adapted to the building occupied by more than one manufacturer is often used by the General Electric Company in large buildings, but it is complicated and in some places too elaborate considering the fire hazard and the building construction. For example, a one-floor factory building, particularly a machine shop or foundry, is very easy to leave at time of emergency and although a fire signal system is desirable, fire exit drills seem to me to be unnecessary, especially where the bulk of the employees are males.

The practice commonly used where a manufacturer occupies the entire building is a signal which sounds throughout the entire building and all employees of the building leave at once. Where more than one manufacturer occupies the same building, such a signal while highly desirable in the case of fire is not desirable in case of fire exit drills, as no individual manufacturer would sound the fire signal without incurring the enmity of other occupants of the building and if all of the manu-

facturers occupying the building agreed upon some one time to hold the drill, the chances are that the bulk of the employees would know ahead of time that a drill was to be given at such and such a time. Furthermore where the responsibility is divided the fire drill is very liable to become slighted.

The General Electric Company have had a signal system in use in their plant at Newark, N. J., for the past few years and which has proven so satisfactory that it is being adopted in other plants of the Company. This signal system is there used in a plant of about five buildings, but is equally adapted to a building containing a number of factories, as it will allow any manufacturer to drill his people without disturbing any others, but in the case of actual fire will sound complete alarm throughout the building. This signal system was developed by engineers of the General Electric Company in conjunction with engineers of two fire alarm signal system companies. This system has a box on each floor of each building. The first figure of the number indicates the building number, the second number indicates the floor, No. 1 being the first or ground floor, No. 2 the second, and so on up, using the figure next higher than the highest floor of any building in the plant as the basement number. In a large building where more than one box per floor is desired, the first figure of the box number should be in the same relative position on each floor of the building.

In addition to the usual connections with factory whistle, if there is one, there should be a sufficient number of electro-mechanical gongs, so that a gong may be located at or near each box. Other gongs not located at the boxes are desirable in places where there is any extremely noisy machinery which would drown the sound of the gong at the box. The boxes on this system have inside a set of buttons with a sliding arm. When box door is closed, the sliding arm is on the alarm button only. If arm is on any other button, the closing of the door will automatically throw it on to the alarm button. For drill purposes when the box is opened, the arm may be moved to one of the other buttons as desired on that particular drill.

The wiring connections allow the striking on the gongs, blowing of the whistle, and recording on the register the number of the box pulled for fire. A box pulled for brigade drill is repeated on the whistle only; a box pulled for employees' drill is repeated on all the gongs of the system, but not on the whistle. A box pulled for local floor drill sounds only the gong in the immediate vicinity of that particular box.

The reliability of this system is, that if floor drill is being held and a fire breaks out during such drill, the pulling of another box for fire would cause its number to be blown on the whistle and sounded on all the gongs, except the one being used for local floor drill. If a drill is being held with all gongs in use, the pulling of another box for fire will interrupt the drill box on all gongs and sound the fire number. If the whistle is being blown for brigade drill, no other box will come in until after the brigade signal is sounded four times, after which the box pulled for fire will cut in and sound its number four times on all gongs and whistle. In case two boxes were pulled for fire at the same instant, the internal

operation of this particular case would be that both boxes would start together and work in unison until the smallest digit number wheel holds the line open longer than the other. This causes the largest digit number box to drop out without confusion; then when the control box finishes its four rounds, the other box will in turn signal its four rounds.

#### DRILLS

The system to be followed in drilling employees out from any building follows in general the same plan; although in some particular instances it is necessary to add to or subtract from the average plan. On the sounding of the alarm signal, employees should first shut off the power from their machines and those who are seated should rise and push their chairs underneath or close to the benches. This last is a very important point as it at once leaves side aisle clear for passageways (firemen entering). Lines should be formed in the nearest main or side aisle and should march under the direction of leaders to a designated exit. Each side aisle should have its leader in addition to those for room in general. A marching signal for a room can well be given by the man in charge of drills on that floor, using a loud sounding whistle. One of the policeman's type is recommended.

While the line is forming certain men employees should be assigned to stations on stairways to keep the line orderly, also to assist any girl who might fall. Other employees either men or women should be assigned to the task of closing windows, opening main power switches and turning off gas from ovens or heaters. Those employees as soon as their individual tasks are done should fall into the line passing out. It is highly advisable for every individual who has any task whatsoever in connection with the drill other than marching out on command, to be provided with an understudy. Each understudy should be thoroughly competent to handle his or her part of the drill in the absence of the regular employee whose duty it is to assume this work.

I would recommend that employees be frequently given what is known by us as a local floor drill or assembly, the idea being for them to form in column the same as if passing out for a fire and then at the signal from the leaders go back to work. The signal in each room is the same for floor drill as for fire, and by pre-arrangement with leaders, the employees can be sent back to work without loss of more than a minute's time.

A plant should not get in the habit of holding fire drills in the middle of the forenoon or in the middle of the afternoon, but they should be held at widely different periods of the day, as the operatives will soon become accustomed to drills at specified times and if an alarm came in at any other time, might have a tendency to throw the room into confusion under the impression that there was actual danger of fire. I visited one factory some few months ago where I was told that the fire drills were always held at four o'clock in the afternoon. Such practice ought not to be allowed. Every fire drill should be treated the same as if there were actual fire conditions present, and I would strongly recom-

mend that the time of the drill be changed in every instance. Drills might be held occasionally five minutes after employees come in to work, or five minutes before closing time. Furthermore, when a drill alarm is pulled, the fewest number of persons possible should know that the drill is to be held.

(Lantern slides were then shown, with explanatory remarks by Mr. Sanford, in which the following additional suggestions were made.)

It is desirable a good many times to have doors in your factory that you don't want to have the employees passing through, although in cases of emergency it is highly desirable to have the door opening in the shortest possible time. In such cases, we place a key to the door inside a glass covered box and use an emergency sign on the door showing that it can be opened in a very few seconds, if necessary, to allow passing in case of fire or any other emergency.

One person should be assigned in each department to visit the women's rest and toilet rooms to see that persons there are also notified of fire alarms, and it is called "fire alarm" in all cases and not "drill."

On the signal for going out in any one direction, certain employees hold open any double swinging doors which may be necessary to pass through. After passing through the doors, those holding the doors open fall into line.

The stair towers provide a double hand-rail and are wide enough to allow four persons to pass down abreast. In the multi-story buildings, one file coming out goes to one side of the stairway and the file coming from the floor below goes to the other and the two of them practically parallel each other without confusion. The girls next to the hand-rail are required to keep hold of the rail and be ready to take care of the girls next to them in case of any slip.

#### DRILL THE FIRE BRIGADE

The training of the fire brigade is one thing that is advisable. Carrying hose up the ladder, the correct method for carrying a nozzle is over the back of the shoulder. Another thing, too, on training fire brigades: I believe in sending a brigade over a ladder every time it is called out. I visited a plant not long ago, in looking up these various practices of brigade drill, where they very proudly told me that their fire brigade had won all the championships around there for fast work in laying hose. I told them I would like to see them lay the hose in the second story window. They put up the ladder; the man leading carried the nozzle in the proper position, but his foot slipped three times. The man behind him went up holding a loop of hose straight up over his shoulder with one hand and having only one hand for the ladder rungs, so it is advisable to give them plenty of ladder practice.

The General Electric buildings frequently have different roof levels and in such cases we use a particular ladder which is about halfway between an ordinary ladder and step-ladder, for the convenience of the firemen in going over from one roof to another.

In case the clothing of the occupants should happen to catch fire, we

have heavy woolen blankets, ordinary army blankets, which are located in departments where the hazard of catching the clothing is more or less possible. These are kept in containers or sometimes in wooden boxes with paper or glass ends.

At the end of the fire drill, each drill foreman is required to make out his report, giving the number of employees present, time for dismissal, number of exits used, time of drill, and time of recall. In one case it took 195 employees two minutes and twenty-five seconds; I don't know why it took so long, unless it was the considerable number of floors. I am not familiar with that building, but I saw a drill at one of the General Electric Lamp Factories last week, in which 635 employees, mostly women, were taken out of three floors in two minutes and forty-one seconds. That came without any warning whatsoever. They were not even thinking of a drill.

There may be some doubt in the minds of some people as to whether or not fire drills amount to enough in the long run to repay the employer for the loss of time in the holding of such drills. In this connection I wish to quote from a Newark, N. J. newspaper in reference to a statement by a woman employee of a factory in that city which had been destroyed by fire with loss of eleven lives.

"It was the worst fire I ever saw. It did not seem to be a minute after the fire bell rang before a cloud of black, stifling smoke spread over one end of the top floor. I heard tapping of the bell and immediately started for the exit. Before taking this job, I worked for eight or nine years with the Edison Lamp Works of the General Electric Company. They have the best kind of protection for their employees, and fire drills there are so rigidly carried out that to hesitate a moment when you hear the gong, even if you know it is only a drill, is almost as much as your job is worth.

"At the button factory, I was one of the aisle leaders. When the gong struck, I had to drop everything on the instant and take my place at the head of the line. Before I reached the door, I saw the dense pall of smoke and the next moment tongues of flame began to shoot through it. Every girl, however, kept her place in line, and not one of them lost her head as we tore down the stairs."

The example of bravery and coolness in the face of danger set by this young woman saved a dozen lives. With the first clang of the fire gong, she instinctively dropped her work, called to the other girls to follow, and went immediately to the nearest exit. Thanks to the years of rigid training in fire drills received in the Lamp Works, she knew just what to do when the alarm sounded, and so her own life and the lives of her companion workers were saved.

At the inquest, half a dozen employees testified that no fire drills had been held for over a year. On this point the superintendent and the girls differed, but the testimony tended to show that even if the drills were held, they were conducted at such widely separated intervals and so carelessly, that they made no lasting impression on the employees. When the fire confronted them, they were utterly helpless; panic seized them

and they jumped from windows or ran hither and thither without knowing why. If those who were trapped by the flames at the other end of the third floor had had the benefit of fire drills, they would have instinctively sought the stairs at the first alarm and so escaped as did the others on the same floor who were led only by one girl who had received her training in the General Electric Company's factory.

In the General Electric Company's plant at Schenectady, New York, there is a large building, three floors in height with a fourth floor for about one-fourth the length of the building. This fourth floor had an exit in a stair tower at one corner on the end of the building, the other a fire emergency exit consisting of a door opening from the other side of the room out on to the roof of the main building across which it was necessary to walk for 300 to 400 feet to a stairway near an elevator pent-house on the side of the building. The bulk of the employees on this upper floor were women. During working hours a few months ago a heavy wind storm blew in the end wall of this upper floor and blew out the side wall, leaving the stairway inaccessible. A fire drill signal was sounded, the girls in that room formed in line, marched out across that open room despite the wind, and down to the stairway in perfect order.

It may be stated by persons objecting to taking the time for practicing fire drill that the chance of a fire in a factory is very remote. Let us hope so, but if we can be the means of saving lives, not only in our own factories but in others through the training received by our former employees, I believe it is money well invested.

#### DISCUSSION

MR. BROWN: Have you ever had any experience with sending the fire call through the factories? For instance, we use the call system for calling them out.

MR. SANFORD: I don't think that is used in any of the factories. We have that call system in some of our plants, but I don't recall any plant that uses that as a fire signal. There has been some talk of it in places, but I don't think it has ever been carried out.

MR. BROWN: I think there will come a time when laws will be passed and enacted in every state, compelling them to have fire drills and fire alarm systems throughout the plants. That law is now in effect in Ohio.

MR. SANFORD: It is in New Jersey and some other states.

MR. BROWN: Just recently it has gone into effect in Ohio and we have received notice that we have to have fire drills in buildings of three stories or more. We are about to install one in our plant and I was wondering whether to use the system in our plant.

MR. SANFORD: I don't see why it could not be.

MR. BROWN: The reason I state that is because there are so many whistles blowing at times that it might be mistaken and they might not hear. For instance, you could have one blast for one house and two for another and all the way up to five blasts and it doesn't mean anything at all to the average employees.

MR. EATON: Mr. Sanford, do you have a Fire Committee as part of your Safety Committee? We have in all of our plants a special Committee, which inspects all alarm apparatus.

MR. SANFORD: We have the Fire Committee in some cases in the small plant. They may be part of the Safety Committee, but the large plants are entirely separate. At the Lynn plant we have two men who spend all their time inspecting fire apparatus.

MR. EATON: Making recommendations, etc.?

MR. SANFORD: It is a case not so much of making recommendations as seeing that the equipment is kept up.

MR. EATON: Ours is a little different. The Committee consists of about three men, whether it is a large or small plant, three men assigned out of the fire squad, one used as a fire marshal, with two assistants. They inspect and recommend to the General Safety Committee any addition they think necessary.

MR. BONSB: I would like to ask three questions. First, how often should the fire hose be inspected and should it be inspected under water pressure or not?

MR. SANFORD: I think you had better put that up to the company carrying your fire insurance.

MR. BONSB: I wanted to get a practical man's view. I will change my question. How often are the hose in the General Electric Plant inspected and is it under water pressure?

MR. SANFORD: Very seldom under pressure.

MR. BONSB: Don't you think hose should be inspected under pressure?

MR. SANFORD: That is a matter I would rather you would refer to the people that carry your fire insurance. Opinions differ.

MR. SANDEL: Do you think the question as to whether or not you should inspect hose under pressure depends on your facility for drying the hose afterward? In some places where there are the fire brigades and they have fire towers for drying the hose properly it is all right, but without that your hose is more liable to deteriorate and mildew.

MR. BONSB: My purpose in asking the question was that I noticed some time ago a fire in which pressure was put on the hose and it burst, although the hose had been inspected at regular intervals. Of course, I don't think a hose should be inspected under pressure during the winter time when it would freeze, as that would naturally cause cracking.

Another question I wanted to ask was do you think in connection with the ordinary word "exit" an arrow should be used pointing to the exit, thereby eliminating the mental effort of locating the word?

MR. SANFORD: Where the sign is immediately over the door I don't see any need of it. With that large illuminated sign which I showed, there is the smaller sign over the door and that small sign is plainly visible twenty or more feet away.

On that other proposition, I think it might be a little difficult to test the hose under the water pressure, because an unlined hose will at first leak in all directions, but as soon as the fibre swells up, the leaking stops, and a good deal of the hose commonly used is unlined.

MR. LONG: At our plant at Cudahy Brothers, we make it a rule to test once a year under higher pressures, run it up to 100 or 110 and if it doesn't leak, we use it for another year. We find if you get the cotton hose dried, it will be all right. The little dampness in the rubber won't hurt. It seems to prolong the life of the rubber. That seems to be the opinion of the manufacturers of hose and the insurance companies.

MR. BROWN: How often do you inspect fire apparatus?

MR. SANFORD: Where chemical extinguishers are used, they are re-filled at least yearly. Most of our plants, however, use pails of water or pails of sand, and those are inspected weekly. There is always some evaporation from the water pail and those are inspected every week. The man who inspects does not say, "Here is a pail that needs filling, some one fill it," but carries a pail of water right along. The fire pail system is used in more cases than the other. We have another combination which is used where we are liable to have an oil fire and that is bicarbonate of soda and sawdust in large bins with long-handled shovels to throw it on the fire. Those bins when filled are sealed over with heavy brown paper, the shovel left with handle projecting through a hole in the paper and that is considered to be all right until it is wanted. If the paper is torn, it means immediate inspection to find out why it is torn and to replace it.

MR. BONSIB: What proportions do you use of the sawdust and bicarbonate of soda?

MR. SANFORD: Ten pounds bicarbonate of soda to one bushel of dry sawdust.

MR. BONSIB: It is mixed dry, of course?

MR. SANFORD: Yes.

MR. SANDEL: Are your exit lights on an electric circuit or gas?

MR. SANFORD: Electric.

MR. SANDEL: Is that circuit different from the floor circuit?

MR. SANFORD: Yes, the lighting circuit and the power circuit are different.

MR. SANDEL: But the circuit for lighting the floor generally is the same as the one you use on the exits?

MR. SANFORD: It is the same circuit from the power house, but in case of a fire drill the lighting is never touched. The power circuits are pulled pulled off on each floor, but that has nothing to do with exit lighting or the elevators. The elevators are left in commission as long as anybody wants them.

CHAIRMAN DRUMMOND: Does the Building Code in your vicinity demand that power for exit signs be from outside source?

MR. SANFORD: In some cases. You see I am interested in the General Electric Company factories in all states. Some have rules and some don't have any.

CHAIRMAN DRUMMOND: I am sure we are mighty grateful to Mr. Sanford for his explanation of the General Electric Fire Equipment.

CHAIRMAN DRUMMOND: "The Value of Foremen's Instructions to New Employees," by Mr. McClellan, Safety Inspector of Armour and Company, Chicago, is the next paper on our program.

**VALUE OF FOREMAN'S INSTRUCTIONS TO NEW  
EMPLOYEE**

W. F. MCCLELLAN. SAFETY INSPECTOR, ARMOUR AND COMPANY, CHICAGO

No analogy can be found for the position of the foreman in modern industry. The foreman of today is typically the product of this age, the age of gigantic achievement, tremendous ventures, and delegation of duties. As there is no time in the world's history which is a counterpart with this in industrial life so there is no figure in history who takes the place of this key man of the factory and shop, the foreman.

**THE FOREMAN THE PIVOT OF PRODUCTION**

For the foreman is the pivot of all production. Sometimes we safety men and others who are not concerned with the actual work of getting out material forget, or at least gloss over the fact, that business exists for its ability to serve the world by getting out the product. Society would not allow business to exist as it is today were it not for its efficiency; and if society would permit it (a thing which is impossible) such a business would crumble of its own weight.

I want to define the position of the foreman so I can demonstrate the value of his instructions. With the development of big industry, the owner,—the man who has a dollars and cents interest in production, the man of whom society demands results,—has been driven by force of circumstances away from his employees. I will not attempt to go into the reasons. You know them as well as any one. At first he appointed a superintendent to represent him but the advent of highly specialized methods, the more complicated machinery, forced the superintendent away from the man on the job and then the industrial relations manager had to come in to fill the vacant place.

When the industrial relations manager took his job he was soon forced to recognize that he could do nothing without the aid of the foreman because he did not have an actual job-work-a-day contact with the wage earner. I understand the leading industrial relations men of the country are now bending their utmost efforts to delegate their work to foremen. This is the irreducible level and I think it is the logical working scheme.

As mentioned above, the foreman has no counterpart in the world's history. You might say he stood somewhere between the learned doctor of the Old World and the chancellor, the keeper of the king's conscience. The foreman today is the instructor of youth in industry, and the keeper of the employer's conscience in the shop. In every day English he is the teacher of the new employee and the man who hands out a square deal to every one be he either old or new in the employ of the company.

**THE OLD TYPE OF FOREMAN**

Let us first take up the foreman as a teacher. You all know how it is if any of you started in the ranks, the first job you applied for you came to the gate and waited until some foreman yelled out, "six truckers

for the storeroom." You happened to be nearest that foreman and you rushed forward. After going through the necessary preliminaries of being put on the payroll, the foreman bit off a chew of tobacco, told you to find a truck and "follow that fellow over there out into the next room and do what he is doing." In the old days you were supposed to have been sufficiently instructed when the foreman or "boss" as we used to call him, gave you this careful and painstaking apprenticeship. You found a truck, too, if you wanted the job, for if you came back to this foreman and told him you couldn't find one you were informed there was no further use for your services, only he used more vigorous language. If you found a truck the chances were it belonged to some one else and you had to fight for it and later this would result in your being discharged for quarrelsomeness.

To a group of safety men and women, this may seem a little strange that an employee could come and go without being given a course of instructions in safety by the foreman, but as a man who has been in an industry for a long time, I want to tell you there was no instruction in safety in the old days, for the very good reason there wasn't anything to instruct about. If you got hurt there was another man to take your job. If you didn't, well that wasn't any of the foreman's business either.

It would be a waste of time for me to tell you how things have changed; it is sufficient to say now we regard man-power and human life and limb as things we have a moral obligation to preserve. We safety men were hired to supplant this old regime. We were put in to do away with such scenes as the one I have just described, but we all know that if we started out by ignoring the foreman we were quickly brought to the realization of the fact we were getting no place. The foreman was the man who had the actual job contact with the help. He was indifferent to our work either through old-fashioned prejudices or through our fault in not securing his co-operation at first and we were not making more than a dent in the big accident problem. We had to teach the foreman to teach his men and, we might as well admit it now, the foreman taught us a great deal.

If our foremen are not given proper instructions on safety and other matters connected with the business it is our fault. We are the men who see the foreman on the job with the new employee and our task is something bigger than the mere preparation of an accident report and assuring the superintendent that a guard is on a machine.

Let us take a typical case of a foreman doing his full duty in the instructions of a new employee. The man is hired at the employment office and taken by a guide to the Packing and Shipping Department. On the way the guide starts the instructions. He shows him the various exits, tells him the best car lines to take to get to his home, and gives him general information concerning the lay out of the plant and the rules of conduct for employees. The pair arrive in the Packing and Shipping Department and go to the foreman's office. If the guide is on the job, he will say: "Foreman Jones, here is Frank Smith, a man Mr. White has just hired. We think he will fit in your department very nicely." "I am glad to meet you, Mr. Smith," says the foreman. Right here the ice is broken.

The new employee is put on the basis of a human being and not No. 8251; he knows the foreman's name, the foreman has called him "Mister" extending to him the courtesy to which every man is entitled. The guide leaves, and the next five or ten minutes conversation between the foreman and the new employee determine to a large extent the future usefulness of Frank Smith.

#### THE UP-TO-DATE FOREMAN

If Foreman Jones is thoroughly up-to-date in his methods, he walks to the time clock with Mr. Smith and on the way his instructions go something like this: "I want you to understand our method of time keeping here. As a matter of fact, it is your method because you keep your own time. You see this clock? Have you ever used one like it before? You have. Well perhaps some of our rules are a little different and the clock slightly different in construction so I will explain it to you thoroughly. Your number is 8251. You had better write that down so you won't forget it. You will find your card in the rack to the left of the clock. When you come each morning pull it from the rack and stick it in this slot in the clock. When you get it clear down pull the lever and you will see it registers the exact time you started to work. If you are more than two minutes late it will register the time in red. After you have punched the card put it in the rack to the right in the slot with your number at the top. Be sure you punch your card before starting to work and as soon as you are through. Never punch any one's card but your own and never allow any one to punch yours. A violation of this rule will mean your discharge. The hour of starting is 7 A. M. unless you are notified differently by this blackboard here. You work eight hours a day, half an hour for lunch time. Your rate is so much an hour and you receive time-and-a-half for overtime. You will find all these instructions concerning punching the clock on the back of your time card; read them carefully."

As they walk away from the clock the foreman tells him that he is on trial and his permanent connection with the firm will be determined by the interest he shows in his work. As they go to the place of work the foreman points out the various exits, shows him how to get to the lunch room, giving him some idea of the prices charged for the food. Next the man is instructed in any machinery which may be in the department, with full instructions that he is not to operate a machine unless told to do so by the foreman himself but, in the meantime, it is up to him to try and learn the working of the machine by the present operator. Strict instruction is given that the guards are not to be taken from the machine because they are put on for his protection as well as for the company. He is then taken to the elevator and the methods explained about the signals, and also told that he is never to get on or off while it is in motion, and never under any circumstances to go into the pit while the elevator is above him. If any article falls off the truck into the pit he is to notify the operator and not get in there himself.

Last, but perhaps most important because it makes a man feel at home, is the introducing of a new employee to an old hand. It could be done

something like this: "Mike, I want to introduce Mr. Smith. Mr. McGuire knows how everything should be done around here, as he has been in this department for twelve years, and the fact that he has been here twelve years shows that he does things right. I am going to ask our friend McGuire to look after you until you get well started. Anything you want to know, no matter how trivial, don't hesitate to ask Mike because he takes great pride in the fact that the men he shows the ropes always stay here a long time, and of course we hope you will be with us too."

After the introduction comes the specific instructions as to the exact work the man is to do. These should be thorough and clear. A man who is introduced to the job in this way immediately becomes an asset to the company because he feels that he is a part of the business and the spirit of loyalty has been instilled and he is a better accident risk than the employee who says, "I've been working here eight years and never had an accident. I don't think there is sense in this here safety stuff."

The foreman who has given a series of instructions similar to these has turned a green hand who is potentially a liability to a concern into a potential asset. The foreman determines on which side of the ledger the man's account should be kept. The new employee who feels that he is a stranger in a strange land has to search for the lunch room, the drinking fountains, the toilet rooms, and exits; who makes mistakes in recording his time because he does not understand the mechanism of the clock is on the road to becoming one of the firm's liabilities.

We safety men know that not only the man who has an accident, but the man that is always nearly having an accident is a liability. We know that the man who is forced to spend five or ten minutes of each half-day explaining to his fellow-workers what a great risk he took, and how he just escaped an accident or losing an arm, really is not making much money for the company. The man who, because of carelessness either on his part or on the part of the foreman who is charged with the duty of instructing him, has a string of trivial accidents causing repeated trips to the doctor's office, should have his account with the company entered in red ink. The foreman is charged with the duty of securing production, and he cannot secure a maximum from his men if they are always discussing accidents or near accidents and he always has a man or two absent for medical treatment.

At the first of this paper, I said the foreman held a position which was a cross between a teacher and a chancellor. He is the keeper of the employer's conscience. The human element of a large corporation is in his hand. It is upon his recommendation and upon his judgment that men are advanced, discharged, or transferred. He is the arbitrator of their petty squabbles and he must see that they not only get paid for every hour they work but that the company gets an hour's work for every unit of pay.

This paper is not devoted to the discussion of the foreman's duties along this line. We are concerned here only with his instructions and their values. I am mentioning this aside from his work merely because it dove-tails in with his duties as an instructor. There could not be any

happier combination than that the teacher should be the arbitrator and dealer out of a square deal. The value of his instructions to any individual is based on the faith that man has in him and no employee could be expected to have faith in a man who does not perform his administrative duties intelligently and judiciously.

The foreman is interested in the production because that is the thing that shows up to his credit at the end of the week or month as the case may be, and when he instructs a new man on safety, he reaps the benefit for it keeps every one on the job. The foreman is in favor of safety from a human standpoint. He knows that he has been in the other fellow's job or came up from the ranks after starting in as a new man and he knows something of the suffering that would be caused by an accident, not alone to the injured but also to his family. He realizes that injury destroys the morale of the unit because the strength of a chain is the weakest link. So it is true of the unit or gang. The speed is indicated by the slowest man in the gang, which may be brought about by accident.

From the beginning, the foreman should understand and present safety to the new man as a business proposition and a part of the company's work. Loss of time by perhaps the best man in the gang means replacing him by a much slower man and perhaps a green hand entirely. Inferior work which is due to the new man not being up on the quality of work and if he takes time to do the job properly that means cutting down the volume or the production end of it which counts so much to the foreman's credit. I believe that both the new man and the foreman benefit by this instruction, but especially more by an actual demonstration in the safe way to do their work, i. e., how to stop machinery, motors, etc., how and when to clean the machinery, and how to reach the nearest fire exits in case of fire. To be specific and show the man what to look out for and point out the danger that is in each operation will add to production, and keep down his medical expense and the labor turnover.

CHAIRMAN DRUMMOND: I know personally that Mr. McClellan knows whereof he speaks and has proven the things he said in his paper, to the complete satisfaction of his superiors. There may be some disagreement or further enlightenment desired by the members of the audience and I am sure he will be glad to either defend his position or give more information.

MR. BROWN: Mr. McClellan, have you had physical examinations in your plants?

MR. MCCLELLAN: Yes, up to the last two months.

MR. BROWN: When is a man examined; when hired or after he has worked a while?

MR. MCCLELLAN: After he has worked a while. He is hired and put through the employment office and later notified to go to the doctor's office.

MR. BROWN: Have you ever had any trouble about a man refusing to be examined?

MR. MCCLELLAN: Not to speak of.

MR. EATON: Where your foreman does not speak a foreign language, is he assigned to some man who does, to give him instructions?

MR. MCCLELLAN: We generally have some man in the department who speaks his language to explain the operations to him. Generally some man from the gang can explain to him. The foreman stands there while he is being instructed.

MEMBER: How do you handle men that are temporarily disabled.

MR. MCCLELLAN: That all depends on the doctor's report. If he is fit for work, he is sent back to the employment department. If the work in the department he is in is too heavy for him, he is transferred to some department where he can have a lighter job.

MR. EATON: I would like to bring up the point I mentioned to you at the Round Table. I would like to get the opinion of various men here as to the advisability of taking an injured man, not seriously injured yet through his own carelessness, through the department with the bandage and every time he goes to the doctor's office for redressing have him go through the department and thereby keep in the minds of the balance of the employees the penalty of carelessness. They usually know this man was careless or he would not have had his fingers injured. I would like to have some opinions on that.

CHAIRMAN DRUMMOND: I should say that a plan of that kind would result more or less in the loss of time among the men of the department and you would have some objections from your operating men on that. You might get good results if you printed a man's hand and picture on a bulletin in the department, outlining the accident, but I believe if you made a man an object show every time he went to the doctor's office, it would result in such a loss of time that the Operating Department would be hindered on their work all the way through. I am not opposed to the horrible example idea—it is a mighty good stunt, but it does not agree with every one's viewpoint. Some people think we are making a mistake in holding up the horrible example.

MR. SANDEL: I know of a case where they had a "No Accident" campaign at the plant. The safety engineer secured the co-operation of several of the men, injured severely enough to have bandages, had them stand at the entrance to the plant, getting there in time for the men coming to work to see them. Nothing was said, but the plant employed about a thousand men, so the news of any accidents would be pretty generally known. They claimed to receive good results during the week from the exhibit of those men and it seems to me that would be a better plan than parading the men through the departments. I personally do not feel it is a good thing to take an injured man through the department where the machinery operates. It is my policy in discussing an operation of a machine or any dangerous machine to get away from the operator, because it makes him nervous, when he realizes that somebody near him is discussing the machine he is operating. There may be a chance of an accident, because of the way he feels.

MR. COKER: I think in most cases the injured employee resents that.

MR. EATON: I just wanted to get an opinion. I agree with most of you fellows.

**MR. ROSSELAND:** You will probably remember having read in one of our publications of the scheme pulled off by one of the Du Pont plants. They had a man injured carry a large sign on his shoulder, telling how he was injured and, as I recall it, how long he had been off. This is in line with the idea you speak of. If I may venture my personal opinion, it seems to me that wherever you have a man fairly well known, a good sport, whom you can get to do so, taking him through the plant would have a good effect, once in a while. I am inclined to agree with the other speakers who thought that as a general thing it might interfere too much with production.

**MR. BATCHELDER:** At times we have had an accident in a certain department and sent the man around to the particular machine the accident occurred at, to explain the accident. I think that had some very good effects.

**CHAIRMAN DRUMMOND:** The success of a safety man all depends on the co-operation of the operating departments and any time you put in too much effort which results in loss of time you cannot expect a lot of co-operation. I have in mind an object lesson. One of the largest locomotive companies in this section had been rather opposed to the safety idea. I was up in the office one morning and looked in the yard and a man had his leg broken and he lay in the watchman's shanty for two hours. I could see out the window and there was not a time during the two hours that there were not at least two hundred men coming and going. The Works Manager saw what the stoppage meant in lost time. Everybody knows that when an accident happens in a department you generally find a lot of people immediately around the accident, and all those things mean such a loss in time that I am afraid if you go too strong on the idea of stopping the work, these lessons instead of contributing to the income of the company will become a liability.

**MR. EATON:** The whole department is interested, stops or does not keep up its efficiency for quite a while, and I have adopted a plan of sending out a report immediately, if a man is only slightly hurt, advising that he is O. K. and it reassures those around and they go back to work in better spirits.

**CHAIRMAN DRUMMOND:** We shall now pass to the report of the Nominating Committee.

#### REPORT OF NOMINATING COMMITTEE

**MR. G. A. BROWN:** The Nominating Committee beg to submit for your consideration and approval the following:

For Chairman—Mr. A. B. Drummond, Wilson & Co., Chicago.

Vice-Chairman—Mr. Henry Batchelder, A. C. Lawrence Leather Co., Peabody, Mass.

Secretary—Mr. W. F. McClellan, Armour & Co., Chicago.

We recommend that the following gentlemen be appointed chairmen of the following committees and in addition thereto, that they have the power to select their own committeemen for their respective committees and in

so doing, take into consideration the advisability of having equal representation of both packers and tanners on their committees:

**Educational Committee**—Mr. B. Hoffman, Michigan Tannery & Extract Co., Petoskey, Mich.

**Standardization**—Mr. J. M. Sandel, Swift & Co., Chicago.

**Entertainment and Program**—Mr. J. M. Eaton, Libby, McNeil & Libby, Chicago.

**Membership and Program**—Mr. F. E. Pope, Pfister & Vogel Leather Co., Milwaukee.

**Bulletin**—Mr. R. S. Bonsib, Tanners' Council, New York, 41 Park Row and A. A. Bureau, Morris & Co, Chicago.

(The report of the Nominating Committee was unanimously approved.)

**CHAIRMAN DRUMMOND:** I feel quite sure that the Nominating Committee had several things in mind for the upbuilding of the Section. I know they have given careful consideration to many of the phases that will result in an upbuilding of the work and they have attempted to place men on the different committees that could do the work required of them, but did not tie their hands as to the number of men on the Committees. I think it is a good plan for the Chairman of each Committee to have the right to appoint as many men as he pleases and, with the progress made last year, I don't think the Committees can be too large. I think the Section should grow much faster than last year with the new interest shown and the combination.

Mr. J. S. Marks of the Security Mutual Casualty Company, Chicago, was to deliver a paper on "Preventing Stub Knife Cuts." Mr. Marks is not present, but his paper will be published in the Proceedings.

## PREVENTION OF KNIFE CUTS IN THE PACKING INDUSTRY

JOHN S. MARKS, CHIEF INSPECTOR, SECURITY MUTUAL CASUALTY COMPANY,  
CHICAGO

Experience has shown that about 30 per cent of packing house accidents are the result of knife cuts. These accidents can be divided in two classes:

**First:** Accidents where knife slips and cuts the workman's hand with which he is holding the product being worked on.

**Second:** Stub knife cuts caused by knife being forced back through workman's hand in which he is using the knife.

Many experiments have been made in an attempt to prevent the first class of knife injuries but up to the present time no method has been devised or used with any degree of success. This class of knife accidents is much larger in number but much less serious than cuts to the right hand.

Cuts to the right hand are caused by knife slipping, due to greasy hands, or when workmen are cutting frozen product knife frequently glances from material being worked on, striking hand. The majority of these cuts are superficial. In an attempt to prevent this type of cuts, leather finger stalls have been worn by workmen and while they have

not, in all cases, prevented the workman's thumb or finger from being cut, they have materially reduced the seriousness of the injury.

Leather finger stalls reinforced with metal staples have also been worn by workman and were found impractical as they were too cumbersome. Canvas finger stalls reinforced with metal staples were worn by workmen and these also proved impractical as the workmen complained about their interfering with the free movement of their fingers.

The second group of accidents are caused by point of knife blade coming in contact with hard object such as bone in meat being cut, forcing the knife blade back through the workman's hand, causing a severe cut. A great number of these stub knife cuts are due to the point of knife blade striking the edge of the hot water box when the workman is in the act of dipping his knife in hot water.

A number of stub knife cuts have left a permanent loss of use of one or more fingers. To prevent this type of accident, there has been invented a guard for every type of knife used, in the various branches of the packing industry where cutting is done.

#### GUARDS FOR KNIVES

Guard used on Specimen No. 1 is made of No. 12 gauge iron, wire coppered, and is attached to the forward part of knife handle by means of looping wire around knife handle, leaving the lower part of wire looped for the purpose of inserting the first finger of hand in which knife is being held. This type of knife is used in the Pork Department, sticking hogs.

Guard used on Specimen No. 2 is made of a small piece of galvanized iron attached to the right side of knife handle by two small screws. That part of the guard toward the point of knife is slightly bevelled at right angle to prevent workman's hand being forced up on to the knife blade. Knives equipped with this type of guard are used by hog string cutters, ham shavers, shoulder shavers, re-shavers, bung gut trimmers and by workmen engaged in cutting off bladders, facing hams, hog marking, cutting off heads, shaving heads, trimming out gullets, trimming plucks, cutting out caul fat, trimming livers, cutting off snouts, shaving snouts, skinning heads, cutting off lips, skinning jaws, cheeking, trimming heads, cutting tonsils, trimming gut ends, boning beef, trimming pellets, tripe inspector, tonguer, fat inspector, tongue trimmer, and pluck trimmer.

Guard used on Specimen No. 3 is made of a galvanized wire loop which is attached to right side of knife handle by drilling two holes through knife and cleating ends of wire on opposite side of handle. Knives equipped with this type of guard are used by the men engaged in the following operations: trimming bellies and trimming, skinning, and cutting off hams.

Guard used on Specimen No. 4 is made of a small galvanized wire loop placed on right side of knife handle, and used between the first and second fingers, the handle of knife being wrapped with burlap. Knives equipped with this type of guard are used in place of Specimen No. 3, i. e., for trimming bellies, neck bones, back fat, ham fat, belly strips, plates, pig feet, diamond bones, and for skirting ribs.

Guard used on Specimen No. 5 is made of a galvanized wire loop attached to the right side of knife handle extending up over top of knife blade and rests against thumb. Guard is attached to knife handle by drilling two holes through knife handle, cleating ends of wire on opposite side of handle. The knife handle is then wrapped with burlap. Knives equipped with this type of guard are used for trimming and boning shoulders, trimming loins, slitting sides, raising spare ribs, ribbing, and cutting down.

Guard used on Specimen No. 6 is made of scrap Babbit metal and is attached to the knife in the following manner: One-half inch of the knife handle on both sides is sawed off; the knife blade is then notched on both top and lower parts, after which a mould is placed around this part of knife and Babbit metal poured into it. After metal becomes cold and mould is removed, it is necessary to file off sharp edges. This operation requires very little time. Knives equipped with this type of guard are used exclusively in the beef and sheep fancy meat department and for general floor work, such as beef killing and sticking cattle.

Guard used on Specimen No. 7 is made of No. 12 gauge iron wire coppered, and is attached to forward part of knife handle by means of a loop. The lower loop is used over the first finger of hand in which knife is being used. This type of guarded knife is used on the Hog Killing floor and in the Fancy Meat Department.

Guard used on Specimen No. 8 is made of tape wrapped around knife blade in front of handle. This type of guarded knife is used in Sheep Dressing Department.

Guard used on Specimen No. 9 is made of No. 12 gauge iron wire coppered and is attached to forward part of knife handle by means of looping wire around knife handle leaving the lower part of wire looped for the purpose of inserting the first finger of hand in which knife is held. This type of guarded knife is used as skinning knife on Cattle Killing Floor, also for sticking cattle.

Guard used on Specimen No. 10 is made of aluminum and is manipulated with the thumb of hand in which knife is being used. This type of guarded knife is used for opening hogs and the guard not only protects the workman's hand but also prevents the gut from being cut.

There are also a number of very serious cuts to the arms and wrists of butchers engaged in boning shoulders and like operations which have been prevented by wearing a heavy leather cuff. The specimen of cuff shown was worn by a butcher boning shoulders, for a period of about four months. The numerous gashes that it contains is the best evidence of its usefulness in protecting the arm and wrist from knife cuts. Since these cuffs have been in use there has been but one cut on the wrist of a man boning shoulders and this occurred when another butcher was relieving the regular man and failed to use the cuff.

#### REPORT OF INJURIES CAUSED BY KNIFE ACCIDENTS

A close study of the injuries caused by knife accidents, covering a period of one year, at a plant employing about 2,000 men shows as follows:

|                      | May       | June      | July      | August    | September | October   | November  | December  | January   | February  | March     | April     | Total     |
|----------------------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|
|                      | Cuts—Days | Cuts—Days | Cuts—Days | Cuts—Days | Cuts—Days | Cuts—Days | Cuts—Days | Cuts—Days | Cuts—Days | Cuts—Days | Cuts—Days | Cuts—Days | Cuts—Days |
| Left hand.....       | 3 0       | 4 5       | 7 55      | 2 4       | 3 0       | 9 8       | 4 0       | 5 0       | 4 0       | 7 2       | 4 14      | 4 7       | 56 96     |

---

Total 510 cuts.....743 days lost time

Of this total, 419 cuts occurred while using knife in the other hand from the one cut and entailed a loss of 448 days, or a little over one day for each cut; 74 cuts entailing 210 days lost time occurred while using the knife in the same hand that was cut, an average of three days to each cut. These 74 cuts, of course, are what we term "stub cuts," and this shows clearly that while not so numerous as the other cuts, they are more severe.

An interesting feature of the above knife cut report is that on the left hand 377 cuts happened to the hand, thumb, first, and second fingers, and caused 433 days disability; 57 cuts happened to the third and fourth fingers and caused 87 days disability. On the right hand, 64 cuts happened to the hand, thumb, first and second fingers, causing 191 days disability and eleven cuts happened to the third and fourth fingers, causing 32 days disability. It is apparent, then, if a suitable guard could be devised for the thumb, first and second fingers of the hand opposite to the one in which the knife is used, it would eliminate approximately 60 per cent of the lost time due to knife cuts.

It is apparent from the foregoing that knife guards are practical and are doing a great deal in preventing serious knife injuries.

The success plants have in inducing employees to use guarded knives depends entirely on the co-operation between the workmen and the foremen and the latter's insistence that guarded knives be used.

While much has been accomplished in preventing accidents by knife guards, we feel much remains to be done and we are constantly seeking to develop new devices which will overcome all objections of those who may be prejudiced against their use.

Swift and Company, one of our largest assured, we think, were the pioneers in this phase of safety work and, using as an argument the excellent results obtained by them, we have been able to induce all of our assured engaged in the same business to follow their example with similar results.

The guards referred to in this paper are fitted to the knives without cost to the employees and arm cuffs are also provided free of charge.

CHAIRMAN DRUMMOND: Stub knife cuts are something that worry the men in the packing industry considerably, and I am wondering if Mr. Sandel can tell us something from his experience. Mr. Marks has sent up a number of guarded knives which you might use in your explanation, Mr. Sandel.

#### DISCUSSION

MR. SANDEL: I can't tell a whole lot about the subject, because it is one that I have not given so very much time to, but I think some one could derive some benefit from the samples if the knives were passed around and they were given a chance to examine them. I know in the South St. Joseph plant, we have had more success in using knives which could be termed "Guarded knives" than in any other plant. Several times there have been 100 per cent guarded knives throughout the plant, but the success of the movement depends on supervision. A man dislikes to use a knife with any protection; he takes off the guard at the first opportunity and it was always a case of the foreman being on the job and the Safety Inspector following up the situation very closely.

At the South St. Joseph plant we get periodic reports as to how they stand and if in the Safety Inspectors' report it was found that knives were not 100 per cent guarded, the foreman would be called into the Committee meeting and asked to explain why that condition prevailed. The people in our different plants feel that the use of the guarded knives prevents accidents. At the same time we have quite a number of accidents to the other hand, but I do not know if there are quite as many as would prevail without guarded knives. It seems to me at various times we might get along a whole lot further in our work on this knife question if we would not use the term "Guarded knives." There is a pronounced repulsion, you might say, to the use of a guard and, in one of our plants, we stopped using that term and instead use the term "Improved knife handles." It is simple camouflage, but we think we are getting somewhere with it.

CHAIRMAN DRUMMOND: Has an effort been made to carry the knife with the improved handle into the store rooms where the employees may purchase them?

MR. SANDEL: All those handles and guarded knives are carried in stock.

MR. ROSSELAND: I am interested in what Mr. Sandel said about the aversion to the name "Guarded." It seems to me there is considerable ground for that aversion and I wonder if it would not be more truthful for the packers generally to adopt some such description as Mr. Sandel suggested, as "Improved Knife Handles" or "Swift and Company Standard," or something of that sort? Take for example this knife, from the standpoint of accident prevention, that is probably guarded but, inasmuch as the guarding consists of this stop, it does not quite come up to the definition of "guarded." You might very properly call it "Swift and Company's Standard Knife" or "Improved Knife Handle," it seems to me, and get away from this objection that Mr. Sandel mentioned.

MR. SANDEL: Our South St. Joseph place has issued a blueprint on these different handles.

(Mr. Sandel then explained the use of various guarded knives, in connection with the blueprint.)

MR. BROWN: What do you do to protect your steel?

MR. SANDEL: The only protection for steel is to put a round guard into the handle; fibre works out better than rubber.

MR. BROWN: What do you do to carry your knives to the dressing room.

MR. SANDEL: The men of the killing section are more or less going from place to place as they do their work and those men are provided with pouches, which hold four or five knives. They carry the pouch on the belt and usually at their back. We have very little trouble with those men getting them to carry the knives in the pouches to and from the dressing room, but we do have some trouble getting them to return the knife to the pouch as soon as they have finished. That is one point we are making a special drive on now. The men on the killing floor, however, have not been carrying any pouches, due to the fact that they use only two knives at the most and most of them use only one knife. That is the point we have taken up in several of our plants and will soon furnish all those men with pouches.

MR. BROWN: How about the girls in the trimming room?

MR. SANDEL: The girls in the trimming room we have furnished with a canvas bag large enough to hold all the knives they will use and a whetstone and we make one pocket in the bag for the whetstone and one for the knives. The pockets are deeper than the blades of the knife, so when the knife is put into the pocket, the handle is held at the top and the point of it does not touch the bottom, so that there is no chance of the knife cutting any person or hurting her by projecting through.

MR. BROWN: Has anybody else any ideas on carrying knives to and fro?

MR. McCLELLAN: Mr. Sandel, what guard do you use for ham boning and legging sheep?

MR. SANDEL: I am sorry I cannot tell you about the ham boning, because there we have not been able to get anything that works out satisfactorily.

MR. EATON: That is just my trouble.

MR. SANDEL: The same way on the beef boning, although the men at South St. Joseph believe that this is a guard which will work out satisfactorily on beef boning. That was the idea of putting that ring on the handle, so they could use it in this way and when they change the hand, the ring would be there to guard.

MR. McCLELLAN: Do you furnish these pouches?

MR. SANDEL: No, they furnish their own. At East St. Louis they have purchased those canvas sacks for the girls in the trimming room, I believe.

MR. BROWN: Mack, how do you carry your knives?

MR. McCLELLAN: They are furnished with little wooden boxes to put the knives in.

MR. BONSIB: I would like to say a few words about knife cuts in the tanning industry. In cutting sole leather especially, there have been several accidents, due to the knife slipping and cutting the tendons. One of the plants conducted a number of experiments with various types of

guards. It was found that the use of wire irritated the hands, which might lead to infection, so they developed a guard something like this. That prong is not curved enough to give a real good hold; the thing is apt to slip out and scratch the fingers, but this type of knife has been found to increase the efficiency of the man by giving him a stronger hold, as well as decreasing accidents. Since they have introduced this type of guard, they have never had any knife cut injuries. They make them for right-handed and left-handed men, by simply changing the guard.

CHAIRMAN DRUMMOND: I am wondering, Mr. Bonsib, whether the use of copper would not increase the chance of infection, rather than decrease it.

MR. BONSI: Copper is the germicide. The only trouble is that copper might corrode under the influence of some acid, such as sulphur, but copper itself is a germicide. You have seen the green film on copper, which is disastrous to the internal organs, but from an infectional standpoint, you have never heard of an infection caused by copper—at least I never have. In fact, I am under the impression that copper is one of the few metals that has a germicidal action.

CHAIRMAN DRUMMOND: That is rather important information. I rather felt the other way about it.

MR. BONSI: That is the common impression. You have heard of people being poisoned by eating this, but that is the action of acetic acid on copper, but regarding an infection, or anything of that sort, I have never heard of a case. I may be wrong, but judging from my own experience, this is so.

CHAIRMAN DRUMMOND: I don't want to terminate this mighty interesting discussion, but Mr. Batchelder has prepared a paper on "Burns and Scalds" and can probably give us some good information along those lines.

#### BURNS AND SCALDS—TANNING INDUSTRY

HENRY K. BATCHELDER, A. C. LAWRENCE LEATHER COMPANY, PEABODY, MASS.

In the tanning industry the A. C. Lawrence Leather Company was quick to realize the importance of the safety movement, and as one of the pioneers in accident prevention work in Massachusetts took up the task in their usual whole-hearted way. At first we shared the thought, then prevalent, that all accidents in our factories were caused by machinery, but after the thorough guarding of machinery, and taking all precautionary means to make our buildings safe, we realized the importance of the education of our employees, and we turned toward this phase of safety work.

A study of the industrial accident hazards shows conclusively that every industry has a particular occupational hazard—so the manufacture of leather-tanning has its burns and scalds. These occur in numerous ways and may be classified as follows: lime burns; acid burns; scalds; friction burns; steam pipe burns.

## LIME BURNS

Lime burns are most frequent and in our experience most severe. Lime burns are of two types, the first being a surface burn which readily responds to treatment, the second which is at first superficial, but rapidly develops into a deep-seated affair having all the characteristics of a boil and is treated not as a burn but by incision and drainage. We have had a fatal case as the result of a man getting a solution of lime in his rubber boot. He carelessly neglected bringing the matter to the attention of his foreman and continued to work throughout the day in this condition in spite of the burning sensation which he must have felt. Blood poisoning set in and this man died after a period of intense suffering. Lime burns are caused by the use of slacked lime in conjunction with other chemicals to remove hair from hides preparatory to tanning. It is a fact that some men are more susceptible to lime burns than others, especially new men until such time as they become "seasoned on the job." Among Beamhouse men who have been following the trade for years lime burns are almost negligible.

Our company furnishes each employee engaged on this work with rubber gauntlets, gloves, sleevelets, and aprons, also insists that they wear rubber boots in good condition, and not wear imperfect gloves, but in spite of constant warnings they allow the finger tips of gloves to break open, with the result that the chemical action of the lime attacks the epidermis of the exposed members, and with the usual neglect of slight burns on the part of the average man, the constant rubbing causes the skin to break open and become infected.

Our experience over the past few years proves conclusively that lime burns can be reduced to a minimum by education of employees in protecting their hands, arms, and feet with proper rubber covering. In the past two years this class of injury has been reduced 50 per cent, and our statistics just completed for 6 months ending July 1, 1920, show that we have reduced this hazard 30 per cent over the year 1919. The reason for the improvement we feel to be in a great measure due to the attention given to this feature of safety work.

## ACID BURNS

Sulphuric and muriatic acid are extensively used in the tanning industry and when carelessly handled cause burns of a most severe kind. A few drops spattered in the eyes may result in partial or complete blindness. When the carboys of acid are received the metal cap over the top of the carboy is fastened on with plaster of Paris. The action of the acid sometimes causes this top to become loosened and in order that an accident may not occur from this cause in unloading and moving all carboys, a piece of burlap is thrown over the top of the carboy so that if the top does become loose it will not spatter on the man handling it. We have also installed in all departments a pyrene acid pump which we find has been of great service in reducing the hazard of acid spattering on a man while transferring it from the carboy to a measure in its use in the factory.

**SCALDS**

One of the most frequent reasons for a man to be scalded was that the cold water and steam valves being generally placed together for convenience in the work men in haste frequently opened the steam valve instead of the cold water valve with the consequent result of a severe scald. These scalds have been reduced to almost nil by the use of metal tags on the wheel of the valves.

**EMBOSSING MACHINE BURNS**

Up to a few years ago (or to be more explicit, up to the time when our company first gave serious consideration to the safety movement) embossing machine burns were quite frequent. At that time little or no attention was paid to the guarding of the embossing machine and although the burns were insignificant as compared with the loss of hands and arms, however the burns caused by the hot plates closing in on these members which were withdrawn before being crushed, were both numerous and severe.

A study of the hazard of the embossing machine was made and in order to combat this hazard a table was installed on each machine which automatically rises when the machine is tripped as the machine closes, pushing the body, hands, and arms of the man away from the machine. This device has almost entirely eliminated the major hazard and likewise reduced the burns.

**FRICTION BURNS ON BUFFING WHEELS**

The buffing of leather on an emery wheel requires considerable skill and as the skin or hide must be passed directly over the exposed surface of the wheel by the operator's hands regulating the pressure according to the condition of the stock, sometimes while buffing a shank or the edge of the skin, the skin breaks or the operator's hands slip over the skin onto the surface of the wheel. This causes a friction burn generally on the under side of the wrist. We do not know at present of any guard that would be practical to prevent these burns that could be used without seriously interfering with the operation.

**STEAM PIPE BURNS**

In the old days this was quite some hazard but steam pipe burns have been reduced in recent years due to improved methods of drying leather by machinery, also to covering of all exposed piping with wire guards both for safety and the elimination of the fire hazard, also the better covering of main and branch lines with asbestos.

**TREATMENT OF BURNS AND SCALDS**

Burns and scalds are injuries due to the action of heat. Scalds are due to heated fluids or vapors. There is no pathological difference between burns and scalds. Burns have been classified into six degrees as follows.

1. Characterized by redness

2. Characterized by inflammation with formation of blisters
3. Characterized by partial destruction of the skin which structure is not, however, entirely burned through
4. Characterized by destruction of the skin to the tissue beneath
5. Characterized by destruction of the skin and part of the muscular layer
6. Characterized by destruction of the whole thickness of the muscles

The local treatment varies with the degree of the burn. In burns of the first and second degrees a bland ointment (such as 3 per cent soda bi-carb. in vaseline) though not antiseptic, makes a comfortable dressing. The 1 per cent picric acid solution treatment, which consists in applying gauze moistened in the solution, is good. It greatly decreases the pain, but should be used only in limited burns of the first and second degrees. If used in a large or deep burn it may poison the patient. When extensive destruction of tissue has taken place, skin grafting should be begun as early as possible. This, of course, is a hospital measure. The greatest advance in treatment of burns was brought about by a Frenchman in the early part of the late war. This consisted in the application of a hot wax compound directly to the burned area. The method is as follows:

The part is freed from any foreign matter and cleansed with a 2 per cent solution of chloramine T. It is then thoroughly dried with a hot-air dryer, or by gently mopping with wads of soft gauze. The wax which is heated to a temperature of 140° to 150° is applied with a cotton swab over the entire area. The part is then covered with a thin sheet of absorbent cotton and another coat of wax applied. Over this the usual gauze and bandage dressing. This is repeated daily.

This treatment has many advantages in that it is painless to apply, quickly hardens and so seals the area from outside air, is readily removed (as easily as a glove from the hand) without injury to the new forming tissue and seems to promote the growth of new skin with a minimum of scarring.

The treatment as outlined is the usual procedure at our plants. Our medical staff consists of a full-time physician, one trained nurse, together with several first aid workers. These first aid workers are stationed at each of our three plants in Peabody where we have at each plant well fitted hospital rooms.

#### ORGANIZATION

Our organization is probably similar in many respects to that of other companies engaged in safety work. We appoint a safety committee made up of five members, each selected from a unit manufacturing different lines. Each unit has a leader who is given the title of safety director of his unit and is responsible for the results of his unit. This committee plan and execute all safety activities with the chairman of the safety committee. A few of the main features of activity are our monthly foremen's meetings, monthly workmen's inspections of all plants, bulletin boards, articles published twice monthly in our Factory Magazine the "A. C. L.," pay envelope publicity and blue-print charts of statistics showing severity, frequency, and costs monthly.

The monthly foremen's meeting is the most potent factor in effecting a reduction in accidents and hazards. At these meetings we have some of the foremost speakers on this subject in our section. The Safety Directors make a report on all accidents in their unit for the past month showing how they occurred, who was responsible and what has been done to prevent a repetition. Next the plant physician makes his report from a medical standpoint on the same accidents and his recommendation covering same.

The phases of each accident are then threshed out with the particular foremen in the department where the accidents occurred so that the foremen are fully conversant with their responsibilities as safety supervisors.

In our factories we have achieved wonders in the reduction of the number and seriousness of accidents since the formation of safety committees and educational propaganda of the past few years. The reduction which has been increased with each year is a great source of gratification to us, for it surely indicates that our people are all co-operating for a "safe place to work."

#### DISCUSSION

MR. McCLELLAN: Not being familiar with leather, I would like to take up a moment to explain something we have in our plant. For the ripping, which is done on the cutting floor, we have a leather wristlet. The thought occurred to me that if the leather was brought over the hand, it might stop the friction.

MR. BATCHELDER: They lay their hands on the leather. They have to have the feel of the hand to do the work properly. It might cover the wrist all right.

MR. BONSIB: In connection with burns, I found that tags are not nearly so effective as brilliant colors to distinguish cold and hot water, etc. We tried that out at the Pacific Coast in one of the shipyards. We found that tags did not work at all and there were occasions when those tags disappeared for one reason or another, but by painting it some brilliant color, they will take more precaution. In one plant we painted the hot water a real brilliant red and that was so prominent that a fellow could not possibly make a mistake and, if he could not read a tag, the fact that red is usually a danger color would appeal to him. We have started a plan in our plant of using standardized colors for each of our pipes.

There has always been a number of burns on account of the shower bath not provided with proper regulators and I would like to emphasize the fact that if any of you have shower baths in your plants that you be sure and get some form of regulator that works, so it is not possible for a man to get under a shower and think it is cold and then have the water scalding hot. That has happened and I want to emphasize that. There are several good regulators on the market now; they don't cost very much and it is impossible for a man to get scalded. A regulator should not be where a man can get to it. It should be set by the engineer. Man is essentially a curious creature. I have never seen a man who did not want to investigate how a thing is put together, so put the regulator where

the man can't get it and have it in charge of the Master Mechanic, or somebody who understands it.

In connection with acid burns, I think it is very important to have the supply of running water near where acid is handled. At some plants I find that they have tablets in which ammonia carbonate is used for the body and soda bicarbonate for the eyes, but there is nothing which will come up to a bountiful supply of running water to wash out, rather than treating it. That is something important which I would like to emphasize, a bountiful supply of running water near places where accidents happen.

In connection with the rocker, somehow or other unless the foreman or somebody is on the job when the new carboy is put on, it gets loose. The pump seems to be popular with people—they seem to like to play with it, although I am inclined to think the pump is better.

CHAIRMAN DRUMMOND: I went through a large acid plant recently and I noticed they had a shower and would rush the man right in and get plenty of cold water to wash everything off as soon as possible and the treatment followed that.

ADJOURNMENT.

## FRIDAY MORNING SESSION

THE meeting convened at 9:30 a. m., Mr. A. B. Drummond presiding.

CHAIRMAN DRUMMOND: We have a new member who has not been with us on the previous meetings, Mr. A. A. Bureau, Safety Engineer of Morris and Company, Chicago. Mr. Bureau is going to read a paper on "Value of Physical Examinations and Reconstruction".

MR. BUREAU: Gentlemen, we have found in our plant substantially what I have noted here and if you want to ask anything about any of these details, have us furnish any charts or anything of the sort, we will be glad to do so.

## PHYSICAL EXAMINATIONS AND RECONSTRUCTION

A. A. BUREAU, SAFETY ENGINEER, MORRIS AND COMPANY, CHICAGO

One of the great problems today before the Industrial Committees of big industry is the finding of the exact place physical examinations should occupy in the selection of employees. In the past we have hired men upon the basis of education or skill. In this day when physical examinations (army and industrial) are so common, we are beginning to realize that there is still another great factor in the hiring and placing of men. A man's mental alertness, soundness of judgment, or efficiency and skill in his trade depend, to a large extent, upon his physical condition. A man in poor health is like a dirty machine. He cannot make his body respond quickly in the face of impending danger. Also, he cannot do his best regardless of how good the working conditions may be. As to

safety, an abnormal man is never 100 per cent mentally or physically alert. As such, he decreases the safety of his fellow workers. Accidents are costly misfortunes, both in human suffering and cold cash. As to efficiency, anything less than his best is a decrease in the production of that department. The loss in production caused by the physical health of one man, when multiplied by many such men, soon can make a marked difference in the total amount of production for the plant. Therefore, the physical condition of the employees is an important factor; first, in the reduction of accidents, and second, in the cost of production.

Looking upon physical examinations as one means of controlling the number of accidents and the cost of production, I believe that the place of the physical examination department shall be looked upon more and more as an absolutely essential part in any well-regulated industrial organization. Also there will, as time goes on, be more emphasis laid upon the grading of workers as to their physical fitness to perform the work of the particular job for which they are hired. In industries where there are no physical examinations, they will be required, and in industries now conducting such, the work will be done with more care and precision.

Physical examinations as now conducted in army, civil, or industrial life, are to keep out the physically unfit from that particular organization. The army refused the imperfect man, the life insurance company rejects the poor risk, and the industrial organization turns down the man liable to be injured at his work. Then we have the just-passable class in industry which may be in the unfit class of tomorrow. Our physical examinations accordingly in the future must take on a broader scope—in other words, if they are to serve the community and industry as a whole they must build up some form of reconstruction work to be followed among their employees.

In this brief introduction, we have seen the reasons why physical examinations have a place in industry, a glimpse of what their future must be, and a bird's-eye view of their present status. Now let us examine step by step how we provide for the safety of our employees in the elimination of the unfit and in medical reconstruction.

EMPLOYMENT MANAGER MUST BE HELD ACCOUNTABLE FOR CLASS OF MEN  
HE HIRES

The first step in the elimination of the unfit takes place in the Employment Office. It is the duty of the employment manager to hire those he deems good risks of industry—that is, men who have the necessary strength and energy to perform safely the duties of the jobs open and to pass up the run-down and the physically unfit otherwise. This may seem a divergence from the subject, but it is a very important step and must not be overlooked. The doctor's office is not then made a weeding out station. The doctor must ever stand as the friend of the plant worker. In fact, he must take the place of the employer, as the caretaker of his injured employees. In the olden days in case of an accident, the boss went personally and looked after his hired man. But the times and conditions

have changed with the rise of big industry. In his examinations, the examining physician must stand as a reconstructionist, if confidence is to be placed upon his advice for the physical upbuilding of the one examined. If the doctor's office is seen as their true friend in the time of their physical disability, there can be no more powerful influence in the getting of the good will of the employees. Therefore, the doctors should be called upon to reject very few men; in fact, only in case where the disabilities are hidden. The employment manager must be held strictly accountable for the class of men he hires. It makes a much better impression with labor to pass up a man than to have him rejected because he cannot come up to the company's set rule. Under no circumstances, should the employment man be allowed to pass the buck to the doctor's office for the rejection of all the unfit.

#### EXAMINE MEN AFTER THEY HAVE GONE TO WORK

After the hiring of the applicant ultimately comes the physical test for fitness. The examination may be conducted immediately and before the man goes to his job or after he has been on his job for a few days. We examine our men after they have gone to work. Several obvious reasons present themselves for this procedure. First it is easier to induce the men to go to work. They do not have ever in their mind that immediately following the acceptance of the job they will have to be subjected to a physical examination—a thing ever repulsive to the workers. This way they will be given a chance to see if they like their job and want to stay with it. Our experience is that the men don't mind the physical examinations so much after they are hired. In fact, a refusal is a rare thing. These are usually among the ignorant whites.

Second, the examinations can be made more thorough and will be of greater benefit to the employees. Our big hiring day is Monday. The rest of the week is slow in comparison. Thus, if the doctor had to examine all of Monday's applicants on Monday, he could do nothing else but give them a very superficial examination. In very few cases could he actually take time to give advice. If the doctor has more time, he can advise each one personally. Also, he will have only as many as he can handle by calling the applicants from their work.

Third, examinations on which the doctor can spend time and give adequate counsel create loyalty to the company, and will give the man a view that the company's doctor is a real friend, not one who does just as little as possible because he is a company doctor.

The calling of the men up to the doctor's office is an ordinary matter of routine. First, the time office furnishes a list of additions, transfers, and take-offs from the payroll to the examining physician's clerk. Then he makes up a list of the men required for examination. The record card of those transferred is automatically renumbered and refilled. The record cards of the take-offs are removed from the live file and placed in the dead file. The list of the unexamined is sent to the different foremen by a messenger boy who goes to each and notifies him of the men he is to send to the doctor's office that day. The foreman gets a duplicate copy of the

list and puts his name on the original list to show that he has been duly notified, and he is thus held responsible for sending those men to the examining room that day as he can spare his men. With each man is returned an O. K. card to show the foreman that the man has been to the doctor's office, examined, and accepted.

The examinations are conducted more or less on the army style. We have the applicant remove his clothing. Every irregularity is diagnosed and noted on his record card. The examinations are thorough in every respect. Then at the bottom of the card we note our opinion of the safety risk and fitness of the applicant.

#### STUDIES OF PHYSICAL EXAMINATION FINDINGS

During the month of July we made some rather broad studies of our physical examination findings, based upon the record cards of 855 men. It rather startled us at first to find so many defective men; however, in a study made by a Life Insurance Company, it reported only a little over two per cent of the men they examined were found perfect. Out of this 855, we found sixty-eight men, or 8 per cent had some defect of the hand or arm, such as amputated fingers, stiff joints, rheumatism, cut tendons, etc. Thirty-three men, or approximately 4 per cent, had some defects of the feet, as bunions, deformed toes, amputations, etc. Fifty-eight men, or about 7 per cent, possessed some varicose veins which, in most cases, are not now serious but will in old age be a very serious annoyance. Two hundred and sixty-two, or 30 per cent, were afflicted with flat feet. This includes from slight to extreme flat feet. One hundred and fourteen men, or 13.4 per cent, had some form of organic heart disease. Seventy-seven, or 9 per cent, possessed a hernia, either umbilical, single or double inguinal hernia. Seventy-six men, or 9 per cent, had piles. Nine men, or 1 per cent, were found to be blind in one eye. Taking 20/40 as a basis for poor vision, sixty-five were found to have poor vision in one eye and ninety-seven, or 11 per cent, to have poor vision in both eyes. Also, we found sixteen other defects of the eyes, such as strabismus, cataracts, nystagmus, ulcers of the eye, etc. Six men were found with some form of venereal disease. In most of the cases, the defects were minor and did not affect the efficiency of the worker to any great extent. However, they make him liable to accidents.

In a more recent examination at our car shops of 182 men, we found 55 defects which made the men employed more or less of a risk to the company. Of this number of men we classed 142 men as good safety risks, 34 men as fair safety risks—that is, they were passable—and 6 were classed as poor risks, or below the standard to be employed.

The causes for which we reject men are: First, contagious diseases of various sorts, such as venereal diseases, tuberculosis, and skin rashes, and eye diseases; second, poor safety risks. This includes those who are more or less a safety risk to the plant, endangering their own well being or that of their fellow employees. In this class are hernias, very poor vision, paralysis, fits, and the like. When possible, we place this class of men in positions that do not require the same energy or strength as

the ordinary job. Third, the physically undesirable, those who should not work at some particular classes of work. This includes the weak lunged in the fertilizer or hair house, rheumatic people in the pork room, tripe room, or freezers, where there are wet and cold conditions. In most of these cases we try to find something else open in our plant where these men may work without injury to their health.

#### PHYSICAL RECONSTRUCTION WORK

Our physical reconstruction work may be divided into three different classes: First, medical advice (a) advice regarding simple medical treatment which they can do for themselves, and (b) advice as to the work which they can and cannot perform to their physical well being; Second, medical and surgical aid; Third, advice and instruction as to free dispensaries.

For minor medical cases we often write a prescription. In many cases we recommend something that the man can buy at the drug store at a very small cost. This applies to skin rashes of a non-contagious nature, bronchitis, colds, etc.

In the case of bad varicose veins we either recommend that the man have an operation for the same or wear a rubber elastic stocking.

In the heart cases we give these men advice as to what kind of work they can do with safety to their health and also general advice such as to avoid running upstairs and the like.

Our venereal cases are simply directed to go to a good physician and get a permanent cure or go to a government or city dispensary and get the proper medical treatment there; also to avoid quacks. In no case do we allow them in the food producing departments.

For hernias we advise operations. To the young man we especially recommend an immediate operation while he is young and can easily undergo the operation. In the case of an old man we recommend that he get a truss. In all cases, we require either an operation or the wearing of a truss before they come back to work.

Also we find a lot of men who have not been vaccinated, especially among the colored. Here we require vaccination either by their own doctors or the examining physician.

In case of failing vision we lay strong emphasis upon securing of the proper glasses for their eyes. If they haven't the money to purchase glasses, we send them to a certain eye dispensary where they only have to pay for the lenses.

The amount of ignorance prevailing among the ordinary workman, as to where he can get free medical attention without cost or expense to himself, is appalling. In most cases, this free medical attention is far better than he could afford. In the large cities there are hundreds of free dispensaries for every kind of an ailment, dental, eye, operative, skin, lung, medical, etc.

Many workmen have serious defects often unsuspected by themselves. Many come in who have no idea as to the condition of their lungs, others as to their heart, etc. Most workmen do not realize the seriousness of

having a hernia. We question them about it and advise the proper treatment, and they will come back invariably with the statement that it has never bothered them. Many would rather quit their job than buy and wear a truss. Many do not suspect at all that they have a hernia,—in fact, good sized hernia,—until it is brought to their attention. One case especially, the old colored man said to the doctor, "I got a swelling and I've been putting everything on it, salve and poultices, and it won't go away." What he had was a hernia.

Then there should be physical examinations of the old employees at intervals to reveal if there is an approaching disease. Many a disease, if caught at the beginning, can be forestalled or warded off. The great trouble is that most workmen allow the disease to get a great hold upon them before seeking proper medical service. In fact, statistics show that 650,000 workmen die every year from preventable disease.

The finding of the unsuspected defects is the greatest good that can be derived from a physical examination department. Only in this way can the man, his company, or the community be able to help him in maintaining his good health. If for no other reason, this aid to the individual employee will justify the existence of physical examinations in every industrial organization. Then the placing of men in jobs according to their strength and energy often saves the loss of life and limb. The saving of one life is worth the necessary expense of a whole department.

In conclusion, I wish to say first, that the hiring of men under a physical examination system is the only way of intelligently employing men. When the employer does not know the fitness of his men or the men do not know their own fitness, it is as though the blind hired the blind. Second, that physical examinations are not conducted to bar men from industry, but to place them where the safety of their own well being is not endangered. Third, that by the examination system only can the employer get at his men to carry on any kind of physical reconstruction work among his employees. Fourth, from the view-point of efficiency, physical examinations are essential. To industries where they do not place their men according to their physical fitness, weak help is paid for very heavily. Fifth and last, from the view-point of safety to the employees, physical examinations are not only absolutely essential, but should be required by the community for its own protection. No industry, because of its lack of oversight over its employees' physical condition, has a right to turn out men upon the community crippled and inefficient to be more or less a public charge.

Physical examinations pay from every point of view—safety, efficiency, humanitarian, and cold cash.

CHAIRMAN DRUMMOND: Are there any questions?

#### DISCUSSION

MR. BONSIB: I believe in the very near future every company is going to adopt physical examinations. I know during the stress of war, labor was scarce and they were glad to get any kind of help, but with increased cost it will be necessary to economize and the best economy is getting an

efficient man on the job, who can produce. I would like to ask Mr. Bureau just how thoroughly the men are examined. Is it a thorough examination such as the Life Extension Institute gives; or general?

MR. BUREAU: An absolutely complete examination, from head to toe, lungs, eyes, and everything that can be taken in in the examination.

MR. BONSB: Is a copy of that report placed in the hands of the superintendent of the department or is that sent to the doctor?

MR. BUREAU: It is held in the doctor's office and the superintendent is notified that the man has been accepted for the work.

MR. BONSB: Do you think it would be of any benefit to have a copy sent to the superintendent? Don't you think that would give the superintendent a better chance to understand the men individually and not ask them, in a burst of enthusiasm, to do things they are not fit to do.

MR. BUREAU: A man can't be changed from one job to another without a re-examination for the work.

CHAIRMAN DRUMMOND: I should think the record of a man's physical condition is a thing between his physician and himself. There is enough opposition by the labor organizations against physical examination to make it more or less of a matter between the man and the doctor. The labor organizations are opposed to physical examination, because in the past it has been used to weed out.

MR. BONSB: I did not mean the complete examination should be given, but if the man would know an employees' principal defect (not make it public) I am wondering if it would be advisable. Of course, I think the complete examination should be confidential between the medical officer and the man.

CHAIRMAN DRUMMOND: I think your idea is good and might be worked out on a code system. For instance, a man in Class "A" might have a defective heart, in Class "B" defective lungs, and so on.

MR. BUREAU: We have a series of charts covering that exact thing. We haven't got it in practice yet, but are working up the chart.

CHAIRMAN DRUMMOND: Regarding the thoroughness of examination, would it cover urinalysis and would you make a Wassermann test on each man?

MR. BUREAU: No, the examination is nothing further than what you can give a man on his general physical condition, including eyes, lungs, and any venereal disease that is shown.

CHAIRMAN DRUMMOND: In other words, nothing except the ordinary physical examination, with the aid of the stethoscope? They don't make a urinalysis test in each case?

MR. BUREAU: In cases we suspect, but not in all cases.

MR. SANDEL: I have an idea that you might incur considerable opposition from a good many men, if you attempt to perform this Wassermann test. We had this point up at our East St. Louis plant some time ago and because of the fact that we have so many colored people there and the doctor's attitude toward the help was not quite right, there was opposition.

CHAIRMAN DRUMMOND: I did not mean to give the impression that I

was in favor of the Wassermann test, but I was trying to assist Mr. Bonsib to see how complete the examination was.

MR. BONSIK: A question of urinalysis, of course, is something that has to be determined by the doctors and we are not doctors, but it seems to me that is a very important thing that should receive more attention than the others, because that is indicating a hidden condition, which you can't determine any other way. I know a case where a man was apparently all right; he was hired and it turned out later that he was not as good as he looked to be. In other words, we have all some time during our lives bought a nice rosy apple on a fruit stand and biting into it found that it had a hollow core. That is my reason for mentioning that. It is a good thing for us to think about, because in lots of places the medical department is in close connection with the safety department.

MR. SANDEL: I would like to ask Mr. Bureau if his company carries any group insurance and if the time of physical examinations is determined in any way by insurance features.

MR. BUREAU: We conduct our physical examinations as we see fit.

CHAIRMAN DRUMMOND: I believe that Morris and Company has an employees' mutual benefit fund, in connection with their work.

MR. BUREAU: We have.

MR. SCHMIDT: I have been connected with one of the large packing house concerns in Buffalo, New York, and there was quite a little opposition shown first to the physical examination of the employees.

CHAIRMAN DRUMMOND: I wonder if Mr. Bureau would tell us of the method used in making examination of women employees?

MR. BUREAU: We have not yet started to make the actual examination of women employees, but we are working on that now.

CHAIRMAN DRUMMOND: Is it the intention to use the same doctor for examination of women as you are using for the men?

MR. BUREAU: I think we shall have to employ a woman for the women.

MR. McCLELLAN: Armour and Company has employed a woman.

MR. BONSIK: I would like to ask if you insist on a physical examination of the foreman. That is a point the men raise with respect to physical examination, "If they examine us, why not the bosses?"

MR. SCHMIDT: The superintendent at our plant is firmly determined to have all examined and says "All," and I was included in that examination. He says we must make no distinction. We are all examined and he was the first one that went up to the doctor and said, "Here I am," and the President of the organization said, "I want my record in this office, to show whether I will live fifty years more or not."

CHAIRMAN DRUMMOND: At our plant we make examinations of every one on the operating end. We have not yet got in the office, except in those cases where the members of the employees' mutual benefit fund are office workers, and then they have the examination, too. I think it is mighty wise to have every one included in the examination. It removed a lot of objection.

Any further discussion on physical examinations? It is a mighty important subject and some things that haven't been disclosed yet might be asked.

If not, Mr. Squires of the White Motor Company, Chicago, will read his paper on "Motor Truck Accidents." In Chicago quite recently they attempted to organize, and have been very successful, an automobile section, the main idea being to create a greater interest in the public, especially among the drivers of automobile trucks that you can't control, so twenty-five or thirty large corporations with large fleets of motor cars, including the street car companies, have become very much interested and have prepared a series of lessons that I think are mighty fine.

### MOTOR TRUCK ACCIDENTS

F. H. SQUIRES, WHITE MOTOR CAR COMPANY, CHICAGO

I have not had time really to write on the things I would say. I had one thought, however, that this "Motor Truck Accident" topic probably might be introduced, carried through, and closed by a suggestion, that wherever motor trucks are handled, we imitate the soap ad by "Good morning, have you tested your brakes?"

#### MENTAL ATTITUDE AND PHYSICAL DEFECTS OF OPERATOR

The brake system of any motor vehicle is probably one of the most important things about it and keeping them in proper shape and operating them properly means much toward the prevention of accidents. In thinking over this subject, it appears that the causes of motor truck accidents may be practically listed under the four heads, first the mental attitude of the operator of the motor vehicle; that is, as to whether he is careless or reckless, has a bad temper or criminal disposition, whether he is revengeful, considerate of other people, whether he is discourteous, lazy, whether he has poor judgment,—all mental conditions which in the negative mean sooner or later that something will happen, something that is not right.

Second, physical defects in the operator. The paper just read has been very interesting, the discussion also; right along that line, indicating that the physical well being of the individual employee means much toward efficiency in any kind of work he does. It means much toward prevention of accidents, of the spreading of disease. In the operation of motor vehicles, physical defects may have much to do with the safe or unsafe operation of vehicles. For example, bad sight, bad hearing, physical weakness, make a fellow unable to handle the vehicle of which he is put in charge. If the fellow is tired or sleepy, if he spends a lot of time off duty out on the street, or somewhere where he is not getting the proper rest, he can not do his work properly. A man who goes to sleep at the wheel is a rather dangerous operator. I know—I tried it once, but fortunately did not have a serious accident, but awakened up very suddenly. I have noticed a number of operators with deformed limbs who have attempted to handle trucks. The other day I saw a man with his left foot bandaged up and he could not put pressure on it. It is a very unsafe proposition.

## MECHANICAL DEFECTS AND HAZARDS OF OPERATING CONDITIONS

Third, mechanical shortcomings in the vehicle itself; if your brakes are out of order, will not stop the vehicle or control it, if your clutches are slipping, if your engine is out of order, missing cylinders and not working right, if the wheels and the tires of the vehicle are not in proper condition, not properly set, these things will all lead to accidents. If the steering mechanism, next to the brakes, is bad or weak, that is a mighty dangerous thing. I can think of nothing more awful than a wild motor truck, that is, one that can't be steered. Then if the lubrication system is bad, something happens that causes accidents.

Fourth, conditions under which motor vehicles are operated. Just a little misty rain on the street will make the pavement like a glass surface—heavy rain is a more satisfactory driving condition. Water on the pavement sometimes makes your brakes refuse to work and in checking up the statistics of the Police Department and the Coroner's Department, many, many times you will find the testimony "My brake refused to work". A man charged with manslaughter or criminal negligence, or that sort of thing, said, "I tried to stop the vehicle and the brakes would not work." The obscure causes are bad corners, bad grades and congested traffic conditions.

## ACCIDENT STATISTICS

Last year in Chicago the total number of people injured in accidents, in which motor vehicles were concerned, was 5,299 persons; 274 of these were fatal. Of this number motor trucks were responsible for a total of 962, of which 91 were fatal. This year, up to September 1, there were 109 deaths chargeable to motor trucks. This morning's *Tribune* says that three died from motor vehicle accidents in Chicago. There seems to be quite a considerable increase in the number of accidents, but naturally there would be because there is such a tremendous number of vehicles in operation and that accounts for it.

In New York City, the total number of deaths in 1919 was 767, not quite double the number in Chicago. The total number of deaths for the first seven months in 1920 was 298.

So much for statistics. They give one some idea of why there should be desperate efforts along the line of preventing such sacrifices and I would suggest as a slogan along this line that you put before your chauffeurs or operators of your vehicles a printed slogan, on the windshield, that it is better to be safe than sorry.

## N. S. C. LESSON OUTLINES

A reference to the lessons gotten out by the Safety Council will give you a better idea of what they are doing and through these lessons you can get tremendous help, wonderful ideas of how to promote safety in the operation of motor trucks. For example, they have twelve lessons outlined.

In checking over these things, this is one thing that appealed to me. I have been interested a good deal in the past, and still am, in rifle

shooting, hunting, and that sort of thing. I have given some thought and a little time to this and it occurred to me to check up what a motor truck means on the street as a projectile. Did you ever think of it in that way? Take a five ton truck, for example. You have about a ten thousand pound weight and, if traveling down the street at ten miles an hour, you have there about 300,000 foot pounds of energy. That energy, concentrated on an object, would bring ruin to anything short of a very thick concrete wall. Now, if you increase that speed, you increase your damage accordingly. I just suggest this as a thought that you might carry with you and I would recommend still further another old adage as a slogan. That is, when it comes to the handling of motor trucks, we shall always find that an ounce of prevention is worth a pound of cure. That is true in handling the brakes, in handling the power plant, the lubrication and that sort of thing. It is just a little tiny step in taking care of the vehicle in proper shape so it is in position to operate.

"GOOD MORNING, HAVE YOU TESTED YOUR BRAKES?"

Use the slogan, "Good morning, have you tested your brakes?" If the brakes are not right or out of adjustment, the control rod broken or anything of that sort when you leave the garage, turn around and go back to the garage, and make that a last thought. "Go back and fix the brakes." If you have a knock in the motor and it sounds like a connecting rod bearing, your lubrication is not right—don't run another foot. For example, a man operating a truck on the south side of Chicago called at our service station one day and said, "This truck has a kind of knock in it and I don't know whether I should run it or not." The service man said, "Describe it." He said, "I had been driving along pretty good and it started knocking more than it was." The service man said, "If it has a knock like that, I imagine it is a bearing knock, although I can't tell from what you say to me, but find out what it is and get it fixed." The next morning he came up with parts of the crank case connecting rod and said, "On the crossing the connecting rod went out through the crank case and smashed it to pieces." Well, it meant an expense of several hundred dollars. We had the whole thing fixed up, new tank, rod bearings, new motor, because the whole thing exploded, it was a wreck. That is just one of those careless things, in which the ounce of prevention is worth a pound of cure, and so on down through the line.

Another thing I had in mind was a passenger car (I happened to be in the car) and my brother-in-law was operating it. He had a knock in the car and it was losing power. I said, "George, I would not run it if it was my car. I am positive it is a connecting rod and you are taking a chance every foot you run. Every time the motor turns over, it may reach the point where it will not hold any longer." He said, "Oh, we will go a little farther." I said, "You do as you like, but if it were my car, I would not run it." The next morning we went to get it, opened it up and found that the oil pipe had broken next to the pump and the oil had been pumped out of the motor so we were running the motor without lubrication and three bearings were badly burned. One was gone entirely.

If we had stopped in the first place, we might have saved all but the one bearing, so an ounce of prevention is worth a pound of cure. In other words, one can't be too careful.

CHAIRMAN DRUMMOND: Mr. Squires, I was just wondering whether you could not read a few little lines out of the lessons, just one or two little things that strike you on the lubrication as being worth while.

(Mr. Squires read from the lessons prepared by the Safety Council several paragraphs regarding lubrication. Lesson No. 2, "Safety Lessons for Automobile Drivers." This may be obtained from N. S. C. headquarters.)

CHAIRMAN DRUMMOND: There has not been sufficient attention paid by the majority of people to street accidents and it became necessary that something be done to arouse a little more interest and I don't know where it could be more properly aroused and to a better advantage than in the National Safety Council and I believe street accidents are as much part of the work as anything, as nearly all of us have motor trucks or other vehicles running around the street, that we should look over. Insurance costs, of course, interest quite a few of us. If there is any question you have to ask on anything that may come to your mind, in regard to the accident prevention on motor trucks, I am sure Mr. Squires will be glad to answer it.

#### DISCUSSION

MEMBER: I might say that I came to the convention to hear his paper, as far as getting something from the convention is concerned. I would like to ask what method Mr. Squires is using in dealing with the human element, that is, seeing that rules and instructions are carried out by the man.

MR. SQUIRES: That is one of the hardest things to do. About the only way you can accomplish that is to deal with the psychological side of the thing, the mental condition of the driver. Personally, I am greatly in favor of the small bulletins that have been discussed in the committee meetings on this series of lessons—small poster bulletins illustrating the human side. For example, a recent bulletin published by the Safety Council showed a picture of a street car, and truck rushing down the wrong side of the street, a woman with a little boy in her arms and a little boy on her hand, trying to hurry her across the street, and here is the truck bearing down on her and the whole thing is labeled "Too late." It is hard to bring the same kind of feeling and sentiment to all individuals alike, but I imagine to a man who has a home of his own and wife and children, that very thing would stir within him a tremendous desire to be safe rather than sorry. The idea was suggested that a lot of these bulletins, pictorially illustrating the terrible things that happen when a man does not use his judgment, be posted right in front of him on the windshield, and it is everlastingly before him. Then he won't do a lot of things he might otherwise do. I believe in getting sessions together and talking things over and that is what these lessons do. It is considered here from the mechanical side and the human side. It is always better to be safe than sorry.

MEMBER: One more point I would like to ask Mr. Squire's opinion on is this: There is a manager of a large truck concern in Detroit, who lays great emphasis on the rule that the truck driver must never have anybody with him on the seat. They make that a primary requisite and, in fact, enforce the rule strictly. If the driver is found breaking that rule, he is liable to immediate discharge. I would like to ask Mr. Squires how universally that rule is adopted and what he thinks of it.

MR. SQUIRES: On that score, I could not give you the statistics, but it is my impression, from general observation, that it is not universally adopted. In many instances it could not be adopted very well, because heavy duty trucks, especially, require a helper, that is, the driver and helper, and where a helper is necessary he always wants to be on the seat. Then, I have met this condition also, that many concerns are requiring a cab built on the truck, wide enough to accommodate three people on the seat, instead of two. One concern I have in mind a few months ago bought some trucks and the men complained because they were not as wide as they wanted, that is, wide enough for three men on the seat.

MR. SANDEL: Not so very long ago a peculiar set of circumstances arose, in connection with the investigation of an automobile accident in Cleveland. One chauffeur was involved in three accidents and a careful inquiry of witnesses and examination of the truck, and his own story all tallied to the extent that this chauffeur was not responsible for the accident. It seems to the branch house manager and to our insurance department that this man was a victim of circumstances. The insurance department manager said that he was a carrier of bad luck and we thought the best thing in that case was to lay off the man, rather than keep him. The branch house manager said he was the best chauffeur he had and he hated to do so, but ever since that the experience in Cleveland has been quite good.

MR. BUREAU: We had a chauffeurs' efficiency contest. We awarded five prizes, first, second, third, fourth and fifth, for efficiency shown in handling trucks and it is working out first rate. Before long, we will probably have something to say about the benefit of that experience.

CHAIRMAN DRUMMOND: Mr. Turley of the Wilson and Company Automobile Service Department has a system which awards prizes in two ways. One is a tire saving contest and the other a no-accident contest—a bonus proposition—and five prizes are given.

Out of 97 accidents at railroad crossings, 45 of them were occasioned by the vehicle attempting to cross, hitting the train, rather than the train hitting the vehicle.

MR. BUREAU: What does this show, lack of control?

MR. SQUIRES: It may be that the brakes were not properly tested before they went out. I think, however, that the mental attitude of the driver has more to do with it, whether he is careless, reckless, or uses bad judgment.

MR. SANDEL: I would like to ask Mr. Squires if there is a real honest-to-goodness non-skid tire on the market.

MR. SQUIRES: We have had a good many discussions with our men and members of the committee. There is no such thing as a non-skid tire, except the cog wheel. I should say it could be made a non-skid device. In handling motor vehicles, I think you safety engineers would do well to make as much of that point as any other, that the chauffeur should understand how to control his vehicle with the brakes and power plant. Personally, I believe that thing ought to be developed or taught more than any one thing. It is easy to lock brakes of vehicles and it is easy to slide into things, as most folks do. In other words, the average operator gets excited, jams on his brakes and slides.

MR. SANDEL: Don't you think, Mr. Squires, that a good many drivers should blow the horn oftener than they do? It seems they neglect blowing the horn at street intersections, and this is not fair to the other man.

MR. SQUIRES: Frankly, I have been as sore at the fellows who keep screeching all the time as at the one who does not signal enough, but I think that signalling ought to be done more.

MR. BONSIB: I had occasion to call down a motor truck driver about not using his horn and he said that anybody who blew a horn was an amateur, it was not professional, and I think it would be important to show him that it is necessary to blow his horn.

MR. SQUIRES: Let me cite conditions. I realize the feeling, but take the middle-aged, or elderly woman who is standing in the street, or rather crossing the street. The expert automobile operator who does not blow his horn may be thoroughly conversant with all conditions surrounding this traffic jam and go through all right, but suppose he does not blow his horn and gets close to the individual who suddenly realizes the situation, the tendency is to get nervous and she may step in front of another vehicle. Many street accidents are recorded because of that and I believe it is only fair to the other party for the driver to blow his horn, to give the other fellow a fair chance.

MR. SANDEL: On the subject of blowing horns, it is rather amusing down South, on some of the country roads. The drivers, when they come across some colored people, blow their horns and step on the gas, and let the other fellow take care of himself.

CHAIRMAN DRUMMOND: Mr. Sandel, from Swift and Company, has some very valuable information on the "Value of Comparative Accident Statistics."

#### VALUE OF COMPARATIVE ACCIDENT STATISTICS

J. M. SANDEL, SAFETY AND EQUIPMENT ENGINEER, SWIFT AND COMPANY,  
CHICAGO

The chief reason justifying a safety engineer's use of accident statistics is that a means for prevention of accidents can readily be found. Every plant will have its individual accident problems dependent on the nature of the work, the conditions of work, and the character of the workers. The means of meeting these problems adequately can be discovered only by carefully compiled accident statistics. The proportion of accidents

which are due indirectly to poor physical condition, overwork, and inadequate wages with the accompanying indifference and lowered vitality of the workers, or directly to ill-guarded machinery or inability to understand English may be developed in any statistical analysis.

No doubt the greatest booster for statistics of any kind is Mr. Roger W. Babson. I suppose that Mr. Babson has statistics for every meal in the day and even dreams them for the greater part of his merchandise is information of a statistical nature. According to Mr. Babson, most anything can be foretold in part if the statistical records of the past are complete; and the best argument that safety engineers can use at any time and at any place is successful past experience and successful past practice. I think many of you will agree with me on that point for no doubt all of you have been asked when proposing action along any line, "What has been our past experience?"

Having no statistics of accident experience is like operating a business without an inventory. While figures can be made to lie as well as to tell the truth, within your own organization they should serve the purpose of clinching an argument for action where it is a question of facts. Without accurate records of the past, it is so much harder to get action, for there are no facts to support contention. Likewise it is impossible to tell if any progress is being made in safety work or along what line it is preferable that the safety work be concentrated. No executive will consent to even a moderate expenditure without definite reasons for doing so, and it has been my experience that an accurate array of figures will get approval with a minimum amount of verbal argument.

Briefly, statistics should show the safety engineer:

- 1 The department or operation which has the most severe accidents
- 2 The section of the plant where consistent work is needed
- 3 The operations or equipment which are involved in the largest number of accidents

Contrast a plant where no accident statistics are kept with one of the same size keeping statistics. In the first instance, we have nothing but a memory of the past which all of us recognize that, although valuable, is very inaccurate; especially if we would like knowledge for a long period of time. We would know of accidents where the loss both in life and money was heavy while those accidents which cause only temporary disability would hold no place at all. It would be possible that some of the men who have been in the establishment a long time could tell of several who were injured in one department or one location but a report of the extent of those injured would not be found to be very satisfactory for presentation. An operating man in a plant will consequently earnestly believe that work under his supervision is not hazardous. If he should send a man to the Doctor's Office to be treated for an injury, that is very often the last thing which causes him to have anything to do with the case so that he proceeds to forget about it until the next man is sent. The more trifling the injuries are, the less is he liable to give them further consideration and the danger is that he may fail to realize the necessity of sending men for proper treatment. On the other hand, such a

state of inaccuracy would not exist in the presence of statistics however simple or complex they may be. As a means of dismissing a condition of lethargy they are the safety engineer's right arm.

Statistical study is quite inexhaustible. As one of my good safety engineering friends has very often said, "You can go in for and work with accident statistics until you are blue in the face, and then you find that you do not get anywhere." The biggest problem, therefore, is to decide what to use and then how to use it. Usually there are other departments than the safety department interested in the figures we would publish as well as the data from which they are obtainable, so that their wishes should be considered. The form of presentations will sometimes be governed by practice in other departments. Sometimes this is not a very easy thing to do as the units used by the production men and accountants are not readily applicable for advantageous presentation by safety engineer.

Most of our information regarding an accident is written on an accident report form; other information is in the form of statements and conclusions. None of this information is valuable unless it is accurate. Because it is desirable to present the information on the prescribed forms, those forms should be arranged so that we have accuracy in concentrated form, so to speak. Insurance companies have simplified their forms considerably since carrying compensation risks. The character of this change is from purely legal information to that which is of greater assistance to the safety engineer.

Four parties are interested in every accident. They are the injured man, the employer, the doctor, and the safety engineer. The necessary information regarding every accident is the place of employment when injured, the experience and service records of the man, the nature of the injury, and the cause of the injury. There is no hard and fast rule as to where this data should come from but, in order to obtain accuracy, a good rule for the safety engineer is to turn to the Employment Office, the foreman of the man, and the Doctor's Office for what he needs.

The Employment Office should be able to give the correct name and address of the man; the names, ages, relationship, and addresses of his dependents, if any; his conjugal condition, his length of service, and his service record.

The foreman should be able to give us the length of time the man worked on the job where he was injured and if that particular work was a part of his job; a description of the work place which should include conditions such as light, ventilation, floors, equipment, and machinery, and enable the determination of primary and secondary causes.

The doctor should tell us the nature of the injury which very often would include the part of the body injured.

When investigating the accident, the safety engineer usually sees the foreman of the man injured. Very often these two men can determine the best remedy. At any rate when the safety engineer gets all of the information mentioned above, he is well equipped to determine the next necessary step to prevent repetition of an accident.

These details are doubtless familiar to all of you but I have included them to emphasize the necessity of two things in all statistical work—accuracy and thoroughness. Many of the sections of an accident report are more useful to others than the safety engineer, but in order to be certain that any one bit of information is correct, thoroughness in all work on the report is necessary. We can easily get this by requiring a signature on the report from those who supply various information. The necessity of signing gives a hint of responsibility, and at the same time is a reminder that an accident has occurred and that an accurate accident report must be compiled.

The next step is to get all statistics in a form that they can be compared. The methods for doing so are numerous and I shall pass over that phase of the problem. What we want more than anything else is the cause of injury. The nationality of the man, his experience, the time of day, and day of the week that accident occurred, part of the body injured, and nature of the injury are all minor considerations to the cause, but those features give us much information that is useful.

It may be the thought of some persons present that cause of injuries in any one plant would be well known to the management. That is quite true but without any statistics no one would be able to tell how many accidents occurred from any one cause during a period or how many different causes can be assigned even the most outstanding accidents in a given period. As mentioned previously, it is easy for a person to remember when a severe accident took place and very likely what caused it, but there can readily be many accidents of a minor injury costing in time lost, wages lost, and compensation paid, fully as much as the severe injury and yet these accidents are not given their due consideration. As you carry your statistics over a period of time it becomes readily apparent which causes are the ones desirable to expend the efforts of prevention of accidents. Usually we conclude to direct our attention to the accidents resulting in the greatest severity. By the term "severity" we mean, loss of time by the employee, loss of wages by the employee, and loss of compensation by the employer. The first two figures are the most useful in promoting safety among the men of the plant and the latter is useful in insuring action by the company.

Desirable sections of an accident report which were mentioned previously, include information from the Employment Office. From there we get the length of service and service records which are sometimes very important considerations for the safety engineer. At some operations a new man is very liable to be injured while at others the new employee is far less liable to injury than the older man. That may be one answer to the cause of the accident. Service record, whether with the present employer or former, may give us some information that would assist us in determining a secondary cause if not a primary cause.

In most instances we inquire if a man is single, married, or widowed. It seems to me that the Employment Office should ascertain, upon hiring, those who are divorced or separated. Domestic trouble very frequently is one cause of inattention and thoughtlessness, and in some accidents I

have investigated in the past, it appears to be very close to the primary cause.

Several times I have mentioned the terms "primary" and "secondary" causes. In many accidents we find that there is more than one thing that is definitely the cause. Probably a better term would be "direct and indirect causes" but the fact remains that more than one feature merits consideration. Often the poor testimony of witnesses and frequently the injured man himself does not enable us to determine accurately both primary and secondary causes but I believe that there is such a thing.

What should be included as causes? I receive quite a few accident reports where the cause is stated: handling material, knife cut, knife slip, and sometimes sore eyes. Because it seems to me that the cause of an accident is the most valuable part of the report, stating the cause in any of those ways reduces the value of the report to less than the paper it is written on. Handling material, whether you specify the material handled or not, cannot be considered the cause. That term more accurately describes the work the man was doing. Mishandling material, however, is a cause and in order to get anywhere, it is better to state to what extent and how the material was mishandled. The expression "knife cut" and "knife slip" more accurately describes what occurred but is not the cause of the accident. They are inaccurate expressions which have grown up with our business, but a more accurate term would be "handle slipped".

After the causes have been determined, the information can be used in foremen's and employees' meetings and on safety bulletins. Take for example, an operation which has produced several accidents. When you discuss this with the foremen and other parties interested and arrive at a remedy for it, make it up into a bulletin preferably illustrated by showing the safe and unsafe methods of performing an operation and what will result if the unsafe way is used. Quote some accident figures on the same bulletin which will back up your argument for safe practices and safe operation. From a number of causes a good subject for a moving picture film can be secured. That is a method used by several large corporations in producing safety films.

There is only one feature which should govern the use of statistics and that is the results which can be obtained from their presentation. All forms of statistics are not desirable for display. The two methods commonly used are an illustration or a curve. More than two subjects treated on one graph cause confusion to the reader, and no subject is thoroughly "driven home". A detailed analysis covering all of the important sections of accident reports is valuable only as a source of material for the presentation of one of those subjects. In order to ascertain what to use, individual idiosyncrasies of those receiving the information sometimes must be subject to change so that the most effective method will be used.

#### DISCUSSION

MR. BONSB: I would like to ask Mr. Sandel if he does not think it is advisable to keep a record of the most minute accidents.

**MR. SANDEL:** Absolutely. One reason is that if you have a record of very minute injuries, and something more serious develops later, your case is complete and there is no chance for anybody putting anything over the company.

**MR. BONSB:** I am a firm believer in reporting injuries, and I have had a lot of opposition from the foreman because they say it takes time, but the point is this: It shows there is something wrong. If a man gets hurt, it shows there is something wrong, and it is only a potential injury and might have been worse than it was. It also gives you an idea of the kind of man he is. A man continually getting injured in a minor way you don't want to have around, and you don't have to be much of a prophet to say that some day he is going to be injured by a major injury.

**CHAIRMAN DRUMMOND:** I don't think the importance of having your small accidents recorded, as well as the large ones, can be overlooked. I remember distinctly one man in our general room had been involved in an accident and he said that all he had received was a scratch on the shoulder and bruise on the hip. A few days later he said that he was not feeling well, and I said, "Jim, how did this thing come on?" He said, "I am not going to tell you, I will show you." He had a huge dynamo with an open pit on two sides and around the pit was a railing that had been removed, and he went down into the eighteen foot pit with a dynamo running at full tilt. He should have been dead, but the report only showed a scratch on the shoulder.

**MR. BUREAU:** I agree with Mr. Bonsb, that we should report all accidents. In all our plants at the end of the month we get out a straight line chart showing each plant how the others stand with reference to accidents, and the psychological effect of that is that they are all on their toes to get the least number of accidents and it keeps them keyed up.

**CHAIRMAN DRUMMOND:** This concludes the program we had prepared. We have about ten minutes left. There may be some suggestions in the minds of the members, as to the best way to get results for larger membership for the Section during the coming year.

**MR. BUREAU:** I would suggest, Mr. Drummond, that some of the smaller packers be canvassed, and also the smaller tanners.

**CHAIRMAN DRUMMOND:** The National Safety Council is willing to do everything in the way of carrying on educational work, but they are going to depend on us to give them the information on the way we want it done. I wonder, Mr. Bonsb, if it will be possible to get a complete list of the members of the National Tanners' Council, for the purpose of solicitation.

**MR. BONSB:** Mr. Drummond, there is a directory published by the Boot and Shoe Recorder, giving a complete list of the tanners of the United States and Canada, issued by the Boot and Shoe Recorder in Boston. It will be impossible to give out a list of membership of the Tanners' Council, for the simple reason that we did it during the war and we were simply besieged with requests for copies, which were used as mailing lists, and our members were simply deluged with all sorts of circulars and other material, so we have taken the stand not to give our list

to any one and I think about a third of my time in the office is used explaining to the various societies and organizations and companies why I cannot give them a list and not give other people lists. On the other hand, I am very much interested in seeing our members become members of the Safety Council, but I can't break that rule.

MR. SANDEL: Are we entirely agreed as to what the name of this Section should be? I personally have no special name I think we should go under, whether "Tanners' and Packers'" or "Packers' and Tanners'" but that is a subject, with which I think we should close the day.

NAME OF SECTION

CHAIRMAN DRUMMOND: I want to leave this to the members for discussion, as to what they think would be the proper heading for the Section.

(It was voted unanimously that the name should be "Packers' and Tanners' Section.")

CHAIRMAN DRUMMOND: I do believe that the combination of packers and tanners is going to make this Section a great deal larger next year. I am particularly pleased with the men from the tanners' section coming in, representing the larger interests, and I know from their past history that they will be perfectly willing to devote a lot of time to building up their own end, and it should result in a healthy condition. I think the packers will have to stand up on their guns and fight pretty hard to retain their laurels, and I think that is as it should be. This competition is going to make us bigger, stronger and better in every way and a close relationship will bring out information at our next meeting that will be very valuable.

ADJOURNMENT.

# **Paper and Pulp Section**

**September 29 and 30, 1920**

---

**ROBERT M. ALTMAN, Chairman**

**Marathon Paper Mills Company, Rothschild, Wis.**

**G. W. DICKSON, Vice-Chairman**

**Riordon Pulp and Paper Company, Montreal, Quebec, Canada**

**N. S. STONE, Secretary**

**Wausau Sulphate Fibre Company, Mosinee, Wis.**

---

## **WEDNESDAY MORNING SESSION**

**T**HE first session of the Paper and Pulp Section was called to order at 10 A. M., Wednesday, September 29, by Robert M. Altman, Chairman.

### **REPORT OF CHAIRMAN**

**CHAIRMAN ALTMAN:** It gives me great pleasure to bid you welcome to the sessions of the Pulp and Paper Section of the National Safety Council; in fact, I wish to extend to you a double welcome; one, on behalf of the National Safety Council and in the capacity of Chairman of this Section; the other on behalf of the State of Wisconsin, of which state I am a resident.

A great deal of this pleasure is due, no doubt, to the fact that we have so large an attendance. I am certain that our sessions will prove interesting and to the point, for programs which tend to draw so large an attendance surely cannot prove otherwise.

There are but three new lines of action which were undertaken by our Section during the past year. As to the success of these, I can refer you to the attendance this morning, to the special paper by Mr. Guerrant to-morrow, and to the fact that this section has been assigned the sponsorship of a national safety code for the pulp and paper industry. Perhaps it will be best to explain in more detail.

First we made a special effort to bring together to these sessions as large a representation as possible. It is for that reason that we had a Congress Representation Committee. In addition to the work of this committee Mr. Asche of the Thilmany Pulp and Paper Company, Mr. Shattuck of

the Kimberly-Clark Company, Mr. Stone of the Wausau Sulphate Fibre Company, and your Chairman sent out letters to both members and non-members of the industry advising them of this Congress and urging the sending of representatives. Your Chairman also corresponded with the Chairmen of the various Divisions of the American Pulp and Paper Mill Superintendents Association and enlisted their services in spreading the advice. You see the result.

Regarding the second line of action, with the help of Mr. R. H. Guerant of the headquarters staff, National Safety Council, we began the establishing of data which would give us a standard accident frequency and severity rate in the pulp and paper industry. In this way it will be possible for any one to determine whether an accident rate for a given plant is high or low as compared with the average for the industry. Some very interesting data covering the first six months of 1920 is in our possession but it is not necessary to go into detail at this time as Mr. Guerant has made this the subject of his paper to be presented to-morrow. I strongly urge you to be present for there is quite a treat in store for you.

And last but not least, the matter of formulating a standard safety code for the pulp and paper industry of the United States. Through the National Safety Council, the Pulp and Paper Section is made responsible for the sponsorship of a standard safety code, the basis of which is to be the Safe Practices Pamphlets worked out by previous committees of this Section. It is a splendid opportunity which has been granted us to continue the good work which has already been done and to gain national recognition as the authors of a safety standard for the industry. This is to be approved by the American Engineering Standards Committee, representing all the big engineering societies, and will serve as the basis for safety regulations which may hereafter be adopted by various states.

The members of this Section will be called upon for assistance by the committee working on this code. I sincerely trust that you will all show the same courtesy, the same co-operation which was the chief factor in the success of our previous work on safe practices.

In closing, I hope that the three lines of action which I have mentioned will be developed to such an extent that we will all get the greatest amount of good possible. There should be one more point undertaken during the coming year and that is an increase in membership. While our membership is about 185 today it should be increased. The Pulp and Paper Section should be the section of the National Safety Council and its members should work toward that end.

We will now proceed with the program as outlined, and listen to the report of the Secretary, Mr. N. S. Stone of the Wausau Sulphate Fibre Company, Mosinee, Wisconsin.

#### REPORT OF THE SECRETARY

**MR. STONE:** The past year has been an encouraging one in every respect. The membership list at this time shows a healthy increase over last year. Fewer cancellations have been made, indicating that industries are being

benefited by association with this organization and value their membership.

A mid-year meeting of the Sectional Chairman, the Chairman of the Program Committee, and the Secretary was held at Neenah, Wisconsin, at which time plans were made to send out follow-up letters impressing on executives the importance of being represented at these meetings. Paper mills in the Middle West not holding membership were likewise invited to send their representatives, as we felt that having once attended our meetings they would better understand the scope and importance of the safety movement and become active members.

I would suggest to the Nominating Committee that if possible the Chairman and Secretary should again be selected from the same locality. During the past year your Chairman and Secretary have been able to consult with each other at frequent intervals and to better co-ordinate their work.

CHAIRMAN ALTMAN: Mr. Shattuck, Chairman of the Program Committee will give us his report.

#### REPORT OF THE PROGRAM COMMITTEE

MR. S. F. SHATTUCK: Although the program provided for the two sessions of the Paper and Pulp Section of the National Safety Council might be considered report enough from the Program Committee, the necessity of a report offers the opportunity to express the Chairman's obligation to those whose ideas made the program possible.

The building of this program provided an excuse for two very pleasant meetings around the dinner table for certain congenial spirits, such as Al Kroes of the Employers' Mutual of Wausau, Mr. Asche of the Thilmany Company, Miss Baker and Mr. Hoyman of the Kimberly-Clark Company, Mr. Stone of the Wausau Sulphate Fibre Company of Mosinee, Wisconsin, and our Chairman, Mr. Altman of the Marathon Paper Mills Company, Rothschild.

Our invitations to contribute to the program of the Milwaukee meeting met with a prompt and hearty response and if the members of the section enjoy the program as much as the committee did getting it up, it will be voted a success.

CHAIRMAN ALTMAN: We will next hear the report of the Representation Committee of which Mr. E. C. Gildenzopf is the Chairman.

#### REPORT OF THE REPRESENTATION COMMITTEE

MR. E. C. GILDENZOPF: Each and every member of the Paper and Pulp Section of the National Safety Council was notified by a special letter on or about August 3, 1920, to send one or more representatives to the Ninth Annual Safety Council to be held at Milwaukee, Wis., September 27 to October 1, inclusive, and the chairman also personally called on three of the members, asking them to be represented.

CHAIRMAN ALTMAN: I wonder if Mr. Kroes, the Chairman of the Bulletin Committee, has a report for us this morning.

MR. AL KROES: I haven't any report to make because the Bulletin Com-

mittee hasn't done any work. They are waiting for standardization. If there is any concrete work to be done on that committee it may be possible to get out some bulletins which will be useful to all the mills of the paper industry. I think that the Chairman has put it very well when he said that the future work of this association will be accomplished chiefly through co-operation. I believe there is going to be something done in getting together on the bulletin proposition.

I believe that when we get the code on this paper mill work that we will have a better opportunity to get these bulletins out than we have at the present time, and I will be very glad at that time to give what little assistance I can to the work along that line.

CHAIRMAN ALTMAN: I hope that from the report of the Chairman of the Bulletin Committee, you did not get a wrong impression. We have had, during the year, our regular Sectional Bulletins, but the officers of the Section had to go back to the members of the Section for help, and I am glad to say that quite a number of you responded nicely, and we were able to keep on with the regular issue of bulletins during the entire year.

I really believe that there should be another method adopted for the issuance of bulletins because it seems that there are only three or four, perhaps a half dozen, that give active attention to any requests on the part of either the Bulletin Committee or on the part of the Chairman of the Section.

I appoint as a nominating committee Messrs. F. H. Eberhardt of the Consolidated Water Power and Paper Company, Wisconsin Rapids, Wisconsin; A. P. Costigane, of the Ontario Paper and Pulp Makers Safety Association, Toronto, Ontario, Canada, and S. F. Shattuck of the Kimberly-Clark Company, Neenah, Wisconsin.

I understand that Mr. Shattuck is not here and Mr. Rosebush of the Nekoosa-Edwards Paper Company will act in his place. Will you please get together sometime today and give us a list of the nominees tomorrow morning so that we can go through the regular form of election?

CHAIRMAN ALTMAN: Now we come to the main procedure. We always enjoy any program that helps us in our work and there is no doubt of it that the program as outlined today should help us all because we are getting the view-points of all the departments, we can say from all standpoints, in the mill. For that reason we will be able to judge just exactly how far the safety game in the paper industry has advanced.

The Kimberly-Clark Company has been instrumental in giving us quite a number of good things heretofore, and I am sure it is giving us something very good this morning.

### THE SAFETY GAME AS PLAYED IN ONE PLANT

All of the following speakers are drawn from the Kimberly Mill of the Kimberly-Clark Company, Neenah, Wisconsin.

1. The Employment Secretary—Miss Mary Baker
2. The Man on the Job—Mike Corcoran

3. The Foreman—Henry Bongers
4. The General Superintendent—F. G. Wheeler
5. The Safety Director—M. G. Hoyman

#### THE EMPLOYMENT SECRETARY

MISS MARY BAKER

There is the conviction in the minds of the members of our firm that the tragedy of industrial accidents should be eliminated. They realize the industrial hazard in handling the material and human element of the industry, and that the Safety game could not be won by one leader nor yet by one single thrilling action, but that it would follow observation, deep conviction, and conscientious, enthusiastic team-work. As a result of that the spirit of safety is flourishing in our plant. Every one on our payroll takes part.

Five of us were chosen by the firm today to come down and tell how we play the Safety game in the Kimberly-Clark mill. Our stories will have neither thrills nor frills. They simply will picture the every-day doings and I have been chosen to speak first not because of my ability or talent, but simply because I am at the entrance of the plant: the Employment Manager.

#### ONLY SAFETY-FIRST FOLKS SHOULD APPLY

There is a sign that hangs over the entrance in black and white, which says that only Safety First folks should apply, and if signs came true, then my work would be done before it was begun, but funny papers delegate the intelligent work of sign reading to old, long-whiskered hayseeds, so all classes of people slip under, safe and unsafe, and gather in the waiting room. Here the first work in safety instruction begins. We have safety pictures on the wall, safety pamphlets and booklets with safety rules are upon the table, and we don't claim that our applicants seize upon them avidly, but some facts are bound to register and the fact that a great deal of this literature disappears proves that people become interested and carry it away to study.

When the applicants come in for the interview, the first work of the Employment Secretary begins, the first safety work. I never labor under the delusion that any applicant comes in one hundred per cent safety, since all men are subject to fatigue, diseases, worry, and anxiety. Just as that is true, then all men are hazard risks. We do not claim, either, that we can absolutely detect all the risks that our applicants are apt to bring with them.

Our object is not to bar the people who are subject to accidents from our industry, but to save them for the industry and place them so wisely that their employment will not be to the detriment of themselves or the plant. If we have to quarantine a person from the industry we let them know why and they are reasonable about it. Unless you can make the person interviewed feel that you are not trying to bar him but to safe-

guard him, unless you can make him feel that, he will give you little information. The more friendly and informal an interview can be, the more likely you are to get revelations that will help you make your decisions.

#### HOW TO DETERMINE RISKS

For instance, you would be perhaps interested to know how we determine risks. If you watch an applicant enter a room, stand up, sit down, answer questions, you can't help but detect the outstanding hazards. You find out whether or not he is slow of comprehension, whether his vision is poor, his hearing poor, or his joints stiff, and when you have determined these things, you commence to think where you can place that man. Say for instance a man with poor vision, you wouldn't want to make him a driver of a tractor, but he could shovel clay. If his hearing is poor, you wouldn't want him to operate an elevator, but such a man could safely pile pulp or pitch stock, or something like that. If any man has a slightly mutilated hand, you can put him on some machine where he doesn't have to handle complicated machinery, or if it is a bad mutilation, you might put him to work as a watchman; so, I say, that it is not with the idea of barring, but placing them wisely when you find out their points of weakness.

In carrying out the interview one shouldn't be in too much of a hurry. We should let our applicants talk. You get valuable leads in that way.

#### DEFECTS IN DISPOSITION

The other day a bright, sturdy-looking chap applied for a job as electrician. When signing his name I noticed that a bone in his wrist protruded. I commented on it and he went on to tell me how he had had the accident, and as he narrated the story he told every detail and seemed to be having such a good time that I determined he was a venturesome chap, and I commented that if I had such an accident I would be afraid of machines, but he laughed at the idea and told two more accidents he had had. When he finished the stories I made up my mind that he was a dare-devil, and when that type gets in they sometimes try to do stunts like they do in the movies and throw a scare into the workmen. Such people are the greatest hazards in industry. After all, a great many people seem to feel that physical defects are the only hazards, but defects in disposition are worse than defects in body, and if you are getting people who are nervous, excitable, and emotional, you are getting in the type which is much more likely to bring about accidents than if you were getting in people with physical defects.

Before we hire any man we give him a trip through the mill, and we generally try to arrange it so that two or three will go at the same time. We have several reasons for giving this trip. When a man is being interviewed, he is more or less on his guard and you can't detect much about his disposition, but when they start to visit with each other and talk about the process going on they forget their restraint. They become friendly and fall into their natural traits and we get many suggestions

during that trip that help us to place a man wisely. If you go through a wood room and the man watches some one lifting heavy boxes he might say, "I couldn't work here I have a rupture." Or in another room the light may affect his eyes. Or, he may mention the fact that he is subject to sore throat or rheumatism, and so you get many suggestions as you go along. Another thing; you discover which ones are grouchy, which are daring, which are stupid, which seem to lack all comprehension, and which seem to register facts slowly. This trip through the mill, I think, is one of the greatest methods of preventing misfits, and after all they are the breeders of accidents.

As I said before, the placing of people with defective dispositions is one of the greatest tasks. An employment secretary cannot hope to do that unless he is pretty well acquainted with the bosses, the foremen. For instance, you might have a man with a quick temper. If you put him to work with a man of similar disposition you would probably have disaster, but, if you know the bosses well, you can place your men as safety first additions to the firm.

We have in our firm one man who is the father of a good-sized family of normal, active, frisky boys, and he is one of the best men in the world to handle young chaps. He knows when and how to reprimand them and I give him most of the frisky boys to handle. Then we have other foremen who are very patient. You can give them nervous men or foreigners and they can handle them all in first-class shape. We have still another man who is a genius for handling people who are aggressive or quarrelsome. He can handle them so that the risk of disposition is eliminated.

You often find temperaments that surprise you. I remember one man who appeared very stupid and placid. He didn't seem to register intelligence, and when we were going through one of the rooms he saw a burly looking man in charge. He turned to me and said, "If he were my boss I'd trim him, all right," and there was such a glint of ill-will in his eyes that I saw I had mis-read his disposition.

Another thing we do is to tell the foremen the nature of the risk. For instance, I write a note and tell the foreman that I am sending him Bill Jones who has a splendid work record but a hot temper and I ask him if he has a one-man job where he can place this man, or a job with a partner who would be sure to get along with him.

Our chief aim is, of course, to build up defectives physically and mentally, so that they may become safety-first men.

In our plant I think each month there are about 300 men who call upon the plant nurses, the plant dentists, and the plant doctors, and we have discovered that in our plant the time lost on account of sickness has been reduced two-thirds. You can imagine that if all the conditions that are associated with sickness have been reduced that much, safety must have been improved wonderfully, and I feel sure that the good safety record we are building up should be credited to our medical corps. Another thing is true of them, they keep a record of all minor accidents, near accidents, and slight accidents, and those records are the barometers which will guide us in our plant protection. For instance, there is a

condition which would bring about a slight accident, that condition, if neglected, will eventually bring about a major accident.

#### HOME-MADE BULLETINS

I can remember one month that there were some twelve or thirteen jack-knife accidents reported. We got out hand bulletins on that subject. The boys were using the jack-knife for screw-drivers, hammers, and so forth, and as a result of these bulletins the jack-knife accidents disappeared. I don't know whether the boys used more caution or the foremen provided more tools, but the fact is that any safety bulletin based on local accidents makes a greater appeal than bulletins that come in and tell of things which happen in far-off plants to far-off people.

Not only must we build up physical, but mental conditions. I think the slogan we had last night, "Keep Smiling" is the best slogan in the world. If you keep your men in such a mental state you needn't worry much about safety records, and so, when men come to our office with all sorts of grievances, we listen with sympathy, and sometimes a little sympathy will blow the trouble away. Sometimes you have to change the man's partner, and you sometimes even have to put him under a different foreman, but when there is a grievance, we consider that something ought to be done because it is the clearing up of these grievances that keeps the plant smiling.

Last year we were able to keep our labor turn-over down to fifty per cent. We were delighted to keep old friends on old jobs. If you can succeed in this you will succeed in keeping your safety records much better. For instance, when we cut our labor turn-over fifty per cent that meant that we had half as many new men to break in, and twice as much time to spend on each man, so that it wasn't very much wonder that the same year we cut the turn-over fifty per cent we cut our accident record fifty per cent.

Non-English speaking people are a great hazard. We have to study them carefully and we try as far as possible to put them under foremen who can understand their language but you can well imagine that when you get a whole department that has to be instructed by gestures and signs instead of orally, you are getting a condition that is really hazardous. In the first place we wouldn't think of putting a non-English speaking person on a job where he has to give directions or receive them, but we turn him over on work where that is not necessary until he can learn English. If he has friends who have introduced him to us we tell them that he has been put on that job because he cannot understand English. We tell them to advise him to go to an English-speaking school and learn the language so that he can protect himself and get promoted.

We keep statistics because just as all other types of work have to be handled scientifically, the Safety work has to be handled scientifically.

#### VALUE OF STATISTICS IN SAFETY WORK

Before we kept statistics we used to have impressions of what the most dangerous accidents were and thought them absolutely true but when we

began to keep statistics we found they weren't true at all. A machine we thought to be the most dangerous one in the mill because a certain very bad accident had occurred on it, we found when we went back over records, we had been doing an injustice to because it was a really well behaved machine. So when you know the relative dangers of different machines, you know whether or not to place people on those machines.

We had always been under the impression too, at one time, that the man past forty was a dangerous hazard but we were very much surprised when we took our files for two or three years past to find that our men past forty had lost less time because of accidents and sickness than those younger.

We also found what people are accident repeaters and we can either discipline those people or quarantine them out of the plant, or we can place them on work where there is less hazard. Not only do we find individuals, but whole families that seem to flourish along that line of risk. We have also by keeping records, detected fakers who try to get insurance and state compensation by supposed injuries which they received.

#### VALUABLE SUGGESTIONS TO BE OBTAINED FROM EMPLOYEES QUITTING

We like to get criticism in the line of safety from the people entering the plant and from visitors, and from people quitting us. Those who quit are likely to be very critical and we get valuable suggestions from them.

We try to act as safety inspectors when we go down to the mill to visit the men. If there are broken steps or rails out of place we tell the safety director. We also watch out for safety slogans and pictures so that we can send them into our plant or put them on the bulletin board.

We find that visitors are a risk in a plant. They get so interested in the process that they just seem to be oblivious to sounds about them; they see no pillars or signals or signs and if anything unusual happens they get very panicky and do all sorts of things.

We feel that another great part that can be played by the employment managers is to keep a full payroll. When we have eliminated the problem of overtime and double shifts, which are sources of fatigue, and fatigue dulls the senses—and after all man's senses are his personal safety guards—so that it behooves the Employment Department just as far as possible, to keep a well equipped payroll.

We have made great strides in our safety work, not, however, because of any miracle workers and not because we have some strange improvement schemes. We are in the market for suggestions and new ideas all the time, and we hope that the story of the task that we carry on and its successes and failures may bring a few pointers and suggestions to the rest of our paper mill friends so that when they go back they will be able to conserve the human material at their plants.

CHAIRMAN ALTMAN: The next man, the one that we try to reach and all work for and sometimes with very little thanks is the Man on the Job, and Mike Corcoran of the Kimberly-Clark people will tell us his viewpoint and the viewpoint of his fellow-workers.

## THE MAN ON THE JOB

MIKE CORCORAN

I entered the employment of the Kimberly-Clark Company about five years ago, it being my first job in a paper mill. I walked boldly up to the employment office where a sign stared me in the face, "If you are a Safety Man we Want You, if not Just Keep on Traveling."

I walked into the employment office and it seemed strange to me that the employment agent spent so much time finding out my safety record. He didn't seem to want to know whether I was worth a dollar a week as a workman or not but he had to know my safety record. When I got in the mill, however, it was altogether different. The mill was far from being dangerous, yet it was far from being safe. I could then see their point of view. They were putting in a safety guard.

I kept my eyes open and when I saw something unsafe I would tell them. When one tries to find another's mistakes it is much easier than to find one's own. When I saw an unsafe place I would call the foreman's attention to it and if he would say nobody ever got hurt there before, I would ask him if that would stop anybody from getting hurt there now, but usually the thing was taken care of at once and believe me it would make me feel good to see three or four men working on a piece of safety work I had suggested. There is no greater credit to man than to see a fellow workman saved by a safety guard he has had installed.

Any man may forget himself for a minute and it is the duty of some man standing by to show him his mistake.

We always notice that the new men are anxious to find and report unsafe conditions. If an unsafe man comes in, his chance of remaining is very slim.

I remember last year we were running safety rules and the first couple of days there wasn't much doing. Then I got busy and put up some cards on the bulletin board telling the men what we were going to show them in the way of safety. I sure did start something. In about an hour they all had what they were going to do. They pulled the mill through one, two, three, four, five days without an accident, but at night of the last day a large shaft fell on one of our millwright's feet and the whole place went up in smoke. Talk about a sore bunch the next morning! That only lasted a week, and the fellows decided that if they could pull through one week without accidents they could pull through three weeks, and they did. Then came the challenge from our friends of Niagara to an eighteen-day safety race.

Watch the new man, help him along, show him his mistakes and if he thinks there is some one with him, he is always sure to keep safe.

I've noticed that the men in our department not only help in safety but are right on the job to help in ventilation and sanitation and tips taken from new men have helped our case wonderfully. One man alone can do nothing, but get your men organized into a safety union and they will show you what they can do. When a man suggests a piece of safety, don't figure out and point out what that is going to cost; give it a chance.

If it proves a success, tell him it is a good stunt, go up to him and pat him on the back, don't be reaching out for all the credit yourself. Tell him what he has done has been wonderful. If it hasn't tell him anyway, and he will do more for your plant than all the safety literature you could buy.

The next thing that seems to me to be the greatest safety factor of all is the satisfaction of the men in the department, to have satisfied men. You don't want them to come trailing in to punch the clock in the morning with a frown. Have them come in with a smile. Have them come in to a foreman who is a man among men, a man to whom they can come with their troubles or with their jokes. Just watch the safety percentage of the department which is in such a foreman's charge.

When your safety director comes into the plant, let your men be at liberty to come up and talk with him. They can give him tips, some little guard that is needed which he has passed up. When your accidents start dropping off, you will find that it is due to the co-operation of the foremen, the safety director, and the man on the job. They have brought about something that the mere spending of millions could not bring.

CHAIRMAN ALTMAN: I knew there was a treat in store for you. Our program is not nearly complete until we hear from the Foreman of the gang, the man who as Mr. Corcoran says, comes along and slaps you on the back and says, "Mike how are the kids today?" We will hear from Henry Bongers.

#### THE FOREMAN

##### HENRY BONGERS

My work consists chiefly in loading and unloading cars of material such as pulp, clay, soda ash, and so forth. When we unload pulp I am generally with the men when they open the cars, and first of all we find many wood cleats that have nails in them to keep the doors from coming open, or to keep cinders from flying in which have to be removed. This is where I give them their first lesson. They are to take an iron bar and jam it against the door nails sticking up. They never throw down cleats without first bending the nails. Some one might easily step on a nail or fall over them causing an injury.

After the door is open we place a runway to the truck. We use a piece of sheet metal with holes through which to drive spikes to keep the runway from shifting as the truck passes over it. If it is not nailed, it is very dangerous and I watch that very closely. If the boys start unloading and I come along and find that it is not spiked, I immediately call their attention to it and make them spike it.

I am reminded of what might have been a serious accident. Last winter one day, it was very cold and the men were unloading a car of pulp. They were using a runway about four or five feet long and the platform was frozen over with ice. There were three men to a truck, one pulling and two pushing. The boys started to pull out but they had forgotten to nail the runway and as the truck came out the runway slid and pinned the fellow at the pole between the truck and the runway. That the life

wasn't squeezed out of him was a mystery. We took him to the first-aid room and to our surprise found no bones broken, but he was badly squeezed and numb. He lay there a few hours and was finally taken home and laid off for about two weeks.

Believe me the fellows that helped him and saw that accident don't need to be told any more to nail down the runways for trucking.

The next thing is the loading of the trucks. We generally put on three tiers of pulp two lengthwise and one crosswise. The front tier has to be watched closely for if it is piled a little forward and the man who is trucking it goes along with his hand on his back, the pile falls on the handle and it hits him in back of the knees and might cause a very painful accident.

Piling pulp into storage is also very dangerous. We generally select two or three pretty careful men to make straight piles and give proper instructions to bind the sides and corners of the pulp as it is bound to settle. It may look safe, but if it stays there any length of time it will fall over.

Taking down pulp piles is just as dangerous. Men sometimes come along and dig in here and there, then the whole pile is very likely to lean and fall. We always instruct them to take down piles two or three tiers back before they take them down from the floor or it is liable to fall. Taking it back two or three tiers avoids that. Then I also give them instructions, if they happen to notice a pile leaning a little, to go up and shove it rather than to wait until it falls and catches their fellow-workmen.

In loading dry pulp we generally put on eight rolls, six on end and two over the top, but that front roll is dangerous and liable to roll forward and injure a man.

Unloading of clay is dangerous in that car doors are narrow and you have to arrange to have one right hand and one left hand shoveler. If you take two shovels going the same way they are liable to hit each other and the man's hands are apt to be injured.

When unloading barrels of resin or alum in opening the doors, we have to watch very carefully for when the barrels are piled in two and three high, when they jerk the door open, one is very liable to fall out. I have seen that happen and luckily the man wasn't under it or there might have been a very serious accident.

#### LOADING OF CAUSTICS

Very few people realize the strength of caustic. It is poured into cans boiling hot and some are liable to burst open. As the caustic is poured in, naturally some of it gets on the floor and the men cannot load these cans without stepping into the caustic. You have to watch them to see that they have on proper shoes or it will eat through their shoes and into their feet. It is so strong that it may cause two or three months lay-off if it happens to get into a man's feet. Be sure to see that the men have heavy boots on for this work and so do away with that danger.

Good trucks are also necessary. A two-wheel truck, on which one cotter-

pin is nearly worn through, wobbles and the paper is going to fall off. If it doesn't injure the trucker, it will probably injure a passerby.

Sitting in the cars while they are being switched is also very dangerous. I never allow that. Should there be a man in the car near the pulp or paper and the engine gives it a bump he might be buried underneath the pile.

Cleaning out the converse is sometimes necessary and when a man is doing that he should always tell one of his fellow workmen to stay at the switch until he gets out and gives him permission to start the converse.

Riding on crane platforms in the warehouses is a dangerous practice. Some of the men even try to go as far as to ride the hooks that hook onto the platform. I have rules put up forbidding any man to hang on these very dangerous places.

#### PLACING OF NEW MEN IS DIFFICULT

The placing of new men is also a very difficult task. You take men in who have probably never seen the inside of a paper mill and don't know anything about the working conditions of it. You have to manage to place him with a man who will teach him the safe way and who will be able to get along with the new man. We sometimes find that a man will not listen. He has been cautioned and warned and he is either a daredevil or a dangerous man. We had an accident happen about a year ago to a man by the name of Tony Horn. If I had warned him once I had warned him a hundred times to be careful, but he didn't seem to pay any heed. He got hurt once and twice, and the third time he was trying to ride the elevator gate. He had tried to ride up with it and then he tried to let himself drop, but didn't drop soon enough, and got a very nasty wound across the fingers of his hand. We don't like to do it very often, but a man like that has to be discharged.

We have from forty to sixty-five men working in the yards. Sometimes the freight gets bunched up and we have to manage to get the cars off in time to avoid demurrage. Then if work is slack we have to reduce our crew. This works as a sort of a training camp for these men. They come in and learn the safety way of working and are now ready to be shifted and transferred to some other department. I am only too glad when I can transfer a man and put him in the mill and say he is a safe and honest workman, although I don't like the idea of picking out our best men for other departments, but as I say, it would be an injustice to hold him down.

My department was once known as the worst department in the mill. Workmen were coming in by the dozens and going out by the dozens. There were sometimes as high as twenty in one day. But today it is different. The men have a sort of department pride. They have nice wash-rooms, bath-towels, lockers, they have games and spend the noon-hour playing basket ball and so forth. So you see the foreman can do a whole lot towards the happiness and safety movement by cautioning the men and it will not take long before he will have a lot of followers only too anxious to help co-operate and boost safety.

CHAIRMAN ALTMAN: Perhaps next to the point of view of the Man on the Job, that of the Foreman is the most important, and I am mighty glad, in fact all of us are glad to have had the opportunity of hearing Mr. Bongers cover in detail a part of the accident frequency which we call the two-thirds we ought to eliminate. We know that a certain amount of that can be covered by safety guards, but we also know that a greater portion of it is due entirely to carelessness on the part of employees and by employees I don't mean the man on the job only, but I include the foreman who is also an employee. If we can reach the foreman so that he will not allow carelessness to predominate there is no reason why we cannot eliminate a great amount of the two-thirds which we, as safety engineers have undertaken to eliminate.

Of course, without the superintendent, who is after all the head of all, neither the foreman nor the men on the job will be inspired to do safe work, and in order to get the safe employees, safe foremen, safe men on the jobs, it is up to the superintendent to be a safety enthusiast.

We will now hear from F. G. Wheeler, the General Superintendent, whose point of view should prove interesting and valuable.

#### THE SUPERINTENDENT

F. G. WHEELER

As you all know, the superintendent is usually responsible for the production and cost. When the safety movement first came in and we were told that it was Safety First, it led me to believe that Safety was ahead of production and cost. In other words that it was more important. After considering this and its application with regard to the machines in the mill I was sold to the idea to the extent that everything which came up and everything which was done should be considered first from the safety standpoint. Supposing, for instance, that there was a special job done and it was completed very quickly. My first thought was not how quickly the work was completed, but was any one hurt while it was being done? Looked at from this standpoint one always has in the back part of his head the question of safety and whether each job is absolutely safe not only from the material standpoint of having the machines guarded but from the attitude which the men themselves have toward safety.

With this in mind I started first deliberately to create in the minds of the foremen who were under me the idea that safety was really ahead of production. In doing that as I have said, one has to be sold to the idea absolutely because the studied phrase or the thought-out question will not convince a foreman nor will it convince the men, that you really mean that safety is ahead of production. It is the small unthought question which will produce the atmosphere of safety in a plant and the superintendent must produce that atmosphere. Not only will he work through his foremen but as our good friend, Mr. Corcoran has said, he will work with the men to the end that they will think and live safety.

In that matter the guarding of machines is the first point that we consider. The second point is that a man must not drive his men at a speed

which prevents safety. When a foreman is in a hurry to get out the work and he pushes the men for results it oftens happens that the men will not see the danger of an accident and in that respect the foreman must let up on his men to the degree that they will not hesitate to slow down a little bit if there is danger of an accident. That was brought out particularly by Mr. Bongers when he spoke about the nailing down of planks in unloading cars. The men must not be hurried to the point where they will not do that because they are in a hurry to get that car unloaded.

The next point to be considered is that the men must realize as Mr. Corcoran also brought out that they can protect their fellow-workmen. We all know that the human mind is so made that the imagination pictures to a man what his senses have given him, and the sense which is used the most in imagination is that of sight. In a man's imagination he will not see a danger which the other man will because he has never seen himself as he is working and to a great extent one man must be taught to protect the others.

There is a most noteworthy case in my mind in which a man was working near a pump. The piping had been disconnected, that is the piping which was above, and in that which led down there was caustic. As the man reached down to lift the pump, a fellow-workman, seeing the danger of the caustic, slipped a piece of wire felt over the other man's shoulder. Naturally the man who was lifting the pump did not see the danger, and it seems to me if that whole atmosphere can be conveyed through the foremen, we have one of the most potent forces that there is toward safety.

CHAIRMAN ALTMAN: Last but not least, the man who is held responsible for the safety not only of the Man on the Job, but the Foreman and the Superintendent—the Safety Director.

#### THE SAFETY DIRECTOR

M. G. HOYMAN

I wish to preface my few remarks by saying that the course outlined here as applying to this one particular mill is identical with that pursued in the six other mills of this Company in which I have charge of Safety.

A little over a year ago when I had the good fortune to become connected with the Kimberly-Clark Company as Safety Director, I brought with me the idea that the foreman is the biggest safety factor in the plant, and that if he were given the responsibility he would make good. Now, up to that time I had never seen that plan put into practical operation. I think quite a few were skeptical when, as we put it, the old Safety Committee was disbanded temporarily. I immediately put it up to the foremen in about this fashion: If an accident occurs in your department I am coming to you for the explanation; if you do not have accidents in your department you get the credit. I wish to say at this point that the members of our firm and the superintendents of the various departments co-operated most splendidly.

Immediately I started getting out posters showing especially the long no-accident runs of the different foremen. This developed later into what is now known as our weekly Bulletin. This bulletin, of which I have a few samples here, gives the foreman's name, the department in which he works, the number of men under him, and his record for the past week, and is posted on the Safety boards each Monday.

I made it my business to try and see the foremen at least once or twice a week at his work and talk over the safety situation with him. At the monthly foremen's meeting I or some one would give them a little talk on the progress we were making. Everything I could think of was done to assist him and get it home to him that we were not only depending upon him, but watching his records very closely. It soon became a known fact that these weekly bulletins got on the desks of the officials every Monday morning, and that they read them and were interested was proven by special letters of commendation for some particular long no-accident run.

With the old Safety Committee in force the foreman felt no responsibility for accidents. He reasoned somewhat like this: Safety is not my job, why should I worry, let the committee take care of that. On the other hand, the committee making their trips of inspection once a month were in no position to keep very close tab on affairs, and besides, after each one got out of the department he was working in, he was at sea in so far as understanding the hazards involved. On the other hand with the foreman as the safety man, he is on the job 24 hours a day, knows the men under him, the work they must do and all the various hazards involved. Consequently, when he understood that the safety of his department was up to him, I got some action.

I make systematic inspections of the entire mill as often as I can, but I am going to confess that most of the danger spots are called to my attention by one or the other of my safety workers, which includes in its list the entire personnel of the plant. This has been brought about, I believe, first by my earnestly asking every one to call my attention to anything that needed guarding or repairing. Second, the way I receive the suggestions. I am never too busy to listen or to go with a man and look at the particular spot he has in mind, without showing any impatience no matter how big a rush I am in. I always take him seriously, be the matter great or small. Usually, unless it is very apparent, I ask him how he would have it done, showing him that I value his opinion, leaving him with the assurance that I will have it repaired as soon as possible, and thanking him for calling my attention to it. I might say that many things along safety lines are taken care of by the foremen or superintendent without waiting for me to come around.

Next, we do endeavor to follow up suggestions by repairing or guarding, as the case may be, just as soon as possible; in fact, we stretch a point in this matter for both the superintendents and I realize that nothing will discourage a man so easily as to come to you bubbling over with a crack safety suggestion and then have things drag along for weeks and no action taken on the matter. Another thing, while I am talking about the men of our mill, I do not confine my interest solely to their safety. I

am interested in their homes, troubles, children, sports, and whatever is vital to them, and that I have become one of them is often proven by the conversations they hold in my presence. The same thing applies to the foremen—I know every one by name. I attend their meetings and mix with them on a regular man to man basis.

Our superintendents have a weekly meeting. I attend these and few go by that something pertaining to safety is not discussed.

We try to keep our plant so that it will be mechanically safe, following out the rules of the Industrial Commission as relating to guarding very closely. I do not believe we have had an accident due to lack of mechanical guards in any of our mills in the past year. Any new installation of machinery is guarded and we believe, well. For example, after a new paper machine in this plant was set up I talked with the superintendent about guarding the pulleys on the main floor. He said he believed the best guard was a solid sheet-iron guard completely enclosing the pulleys. The same being installed certainly makes a fine looking job and absolutely fool-proof.

The way I get the work done incidental to guarding is as follows: Whenever anything is brought to my attention, I try to determine first just what is needed and what will be necessary to make the place safe. Then I go to the superintendent of the department and if the job is of some moment I ask him to go with me and look it over. There we discuss the need, and ways and means of making the place safe. If I can convince him of the need he immediately takes steps to have the work done. Quite often on small jobs such as repairing broken railings or steps and the like, I ask the superintendent for a carpenter or millwright and show him just what I want done.

We have a regular form for making recommendations relative to guarding. This form is made out in triplicate and on it is written the specific recommendations covering the work I wish done. The superintendent signs all three. One copy he retains, one goes to the main office, and one is for myself. The superintendent also must write "yes" or "no" in regard to his intentions of doing the work. If he writes "yes" I need bother no further with the matter except to check up now and then and see that it is not forgotten; if the superintendent writes "no" on the recommendation, meaning that he does not think the work necessary, I can, if I feel he is mistaken, refer the matter directly to one of the directors of the company who will make the final decision. I have, however, used this method very little, probably for the reason that it is only necessary for me to bring to their attention any condition whereby the safety of the worker is not fully guarded to have their instant co-operation in eliminating the hazard, whatever it may be.

Construction work has its problems for the safety director. At best it is a hazardous line of work and requires much attention. Large jobs quite frequently are let out on contract; then again your own crew does the work. Whichever it may be, you will have many uneasy moments until it is finished unless you have a construction crew like the Kimberly Mill boasts of. This crew consists of 41 men and during the past year

has had three minor accidents, causing a total loss of 24 days. This, in spite of the fact that these men are probably given the most hazardous work we have. The explanation is simple—just the foreman who takes great pride in his record and sees to it that his men play doubly safe. He is proud of his record, so am I, and I have not made a secret of it either.

Then probably our next greatest risk is the new man. Volumes have been written on how to handle the difficult problem of getting him started in the right atmosphere, as you might say. In our plant he must first pass through the employment office, and here let me say, a mighty efficient one, too, as you no doubt concluded if you heard the first talk of this series. If he can pass the employment office he is turned over to his foreman, and the vital problem confronts us—who is going to train this man? A knocker? Or a booster? A man who is an expert and interested in his work or one whose interest is gone and who is only waiting for his check?

Supposing this new man has been hired to work on some machine, that the present operator has, for some reason, decided to quit and given his notice. Wouldn't it be the policy of a great many to place this new man alongside the old timer who was going to quit, to learn how to operate the machine and get acquainted? I do not know how extensively this practice is being used these times, but I can assure you it is a poor one.

The reason is this: When a man has made up his mind to quit, it matters not what the reason, his interest lags, and probably through some real or fancied grievance, he becomes a knocker; he shows the new man just enough so that he can get by with the work, failing to mention anything about the dangers that may accompany the work and, if a knocker, winds up his time telling the new man what a bum company he has signed up with. Under these circumstances would it be surprising if the new man got hurt within the first two weeks, as so many do, or could you blame him if he was rather slow in picking up plant spirit and loyalty?

In our plant, if the situation is such that the foreman cannot personally instruct the new man, he is placed with the best man in the department, insuring him expert training from an interested instructor, and one whose mind is not on so many more days or hours until he can get his check and be gone. Personally, I do not believe in keeping a man after he has signified his desire to leave the employ of the company, unless he desires to work his notice out, for, with few exceptions, you will get poor and indifferent service the balance of his stay. Before I pass on from the new man and his trainer I wish to say that I believe the trainer's make-up should embody these four indispensable characteristics, namely: patience, skill, safety, and loyalty.

I am now going to outline some of the more pronounced methods used to keep safety constantly before our men. First come the *Safety Bulletin Boards*. In the Kimberly Mill we have twenty-two, all painted a dark green with Safety Bulletins stenciled in white as a heading. These boards are painted often so as to keep them clean and are placed in the most prominent places in each department where they will not interfere with

the labor performed there and yet be readily accessible, both for reading the bulletins placed thereon and the replacing with fresh ones.

As to the bulletins used, our weekly bulletin referred to in the beginning of this paper is placed on these Safety Boards every Monday, then we use a great number of illustrated bulletins, some from the Mutual Liability Company of Warsaw, some from the Traveler Insurance Company, but our chief supply, by far, comes from the National Safety Council. These last-named bulletins are changed every week, and as consistently as I can, I change the size each week, first a large and then a small one, and so on, with the idea of making the change just as pronounced as possible, thus attracting attention. I am not very strong for bulletins with just reading matter on them, for very few men will take time to read them, whereas if accompanied by a good illustration they stop to look at the picture and then, if not too much, will read the printed matter.

Last year we tried for a NO ACCIDENT week, not but what we have lots of weeks without a single accident, but we, and not chance, wished to say when we would have that week. We failed last year largely through over-confidence, but I believe that sufficient interest was aroused through the failure to put it across this year, for of course we will try again. All our mills take part in NO ACCIDENT week.

Then, we have contests between mills, and have just finished one lately between the mill at Kimberly and the Niagara Mill. I will describe one of the methods used to keep the men informed as to the progress of the contest. I want to say here the most gratifying part of this contest to me was the fact that it originated through the foremen of one mill challenging the foremen of the other mill to a 24 day safety contest, which challenge was promptly accepted. In order to keep the progress before every one in a graphic manner I put it in the form of a horse race. I had built a straight race track of lumber, 24 feet long to correspond with the contest of 24 days, or a foot a day. I then had a chap who is rather handy, paint two very nice horses about 14 inches long by 10 or 11 inches high on one inch lumber. The horses were then carefully cut out, and were fitted into grooves in the race track one above the other; on the sides of the horses, which were painted brown and black respectively, were the names of the mill they represented. The horses were moved ahead each morning 12 inches if no accident occurred the previous day. If an accident did occur the horse belonging to that mill was retarded several inches as agreed upon before the contest. This horse race probably created more interest than anything in the way of prizes we might have offered; in other words it was a winner. I might add that this race track was placed out in front of the main entrance where the men could see it both going to and coming from the mill. The contest developed into a real neck and neck race clean to the finish. Who the winner was could be decided only through the fact that one mill had a few more employees than the other, the number of accidents being the same, three minor accidents each. The losers are now planning to challenge for a longer period of time.

Then I have a large monthly Safety board about 4 x 17 feet in size

and placed by the main entrance to the mill. On this board the record for each department is shown day by day for the entire month. This board is covered with white oil cloth upon which is painted in the first 3 feet in large letters, the following: "Help make your department safe by being a safe and careful workman." Then come the names of the various departments, the balance being laid out in little squares about 3 inches in diameter, one row of squares in line with each department. Along the top are placed figures corresponding with the squares up to 31. These are for the days of the month with a place for the name of the month. Then I have little round tin discs about 2½ inches in diameter with a small hole in the center for a tack. These discs are all painted on one side either a deep green or bright red. Each morning these discs are put up for the preceding day, a green disc for Safety, a red one for an Accident. This board is well lighted at night and any one can tell at a glance just how each department stands to date. The board is so large and the colors make such a contrast you can hardly help noticing it, and once you notice it, you will probably look to see how your department stands and how it compares with the others, entailing some thought of safety. It is just one more way to make sure it is not forgotten.

We have a plant publication called "Co-operation" issued once a month, and a good one, we all believe. Always one, and usually two pages are devoted to safety. Safety records, history, sayings, jokes, and some good articles written by our own men as well as some of the best gleaned from others find their way to these pages and make them well worth reading.

Then each Fall we have what is known as our Mass Safety meeting, where not only the workers but their families are invited. Last year we preceded this meeting, which is usually held on Sunday, by a Children's meeting which was held on Saturday afternoon. In this children's meeting, composed of about 1400 children, ages limited from seven to fourteen years, I think we got in some real Safety seeds. We had the City Fire Chief address them briefly on fire hazards around the home, the police chief on traffic hazards, a talk by Miss Edwards, a little demonstration by youngsters on how accidents happen, a safety movie picture, and songs. It sure was a dandy, and I know the homes they represented heard considerable about safety for some time. The adult mass meeting the following day was equally successful, free transportation coupled with a good program brought out a large crowd. We expect to hold another one in about a month, also to repeat the children's meeting. The children of today are the men and women of tomorrow, so it behooves us to get started early with them, and besides that is just one more way to reach the men.

This paper would not be complete without some mention of our First Aid Department. We have two very able and efficient nurses, one who acts in the capacity of visiting nurse, visiting the sick and injured, and getting them back on the job as soon as they are able. The other tends the office, caring for the injured or sick. There can be no doubt that we

are saved many days of lost time through their prompt and careful treatment of the smallest injury. On top of their efficiency they are two of my best safety boosters, taking as much pride in the mill safety record as I do. They keep an accurate record of all accidents, the cause, and kind so that I have at all times available for my information the trend of things. By that I mean the particular kind of injuries that happen the most frequently, and it is not infrequent that they bring to my attention some safety job that needs doing badly.

In concluding this paper I wish to leave with you these thoughts: To get Safety across we must keep everlastingly at it, presenting it in new garb, new stunts, but always keeping it before the men 365 days a year.

I have not tried to give in detail just what I do every day, but have simply presented a few of my ideas and stunts that have been successful in interesting the men and getting them to think, for when men think, accidents rarely happen. In the Kimberly Mill last year, accidents were reduced 41 per cent and days lost due to same, 47 per cent. The figures for our entire seven mills total 49 per cent reduction in accidents and 51 per cent in days lost.

This, I believe you will agree, is a nice reduction, bearing in mind that Safety is not a new thing with the Kimberly-Clark Company, but has been pressed vigorously for years.

I believe it simmers down to this: Every plant represented in this gathering has, without doubt, the material with which to build up a real live progressive Safety organization. Employment secretaries, workmen, foremen, and superintendents are to be found in almost every plant, each and every one having a vital and prominent part to play in the safety game, and the job of the Safety Director is to co-ordinate these Safety factors into a real active, working group.

CHAIRMAN ALTMAN: Conditions in various plants bring about different problems and we are ready for a discussion of these problems. Perhaps these people will be able to help you out with your particular problem.

#### DISCUSSION

MR. ROSEBUSH: I would like to ask the Safety Engineer one question, and that is if the millwrights who do the safety work are directly under his charge or if they do that work at his suggestion, but are in charge of the superintendent or foreman?

MR. HOYMAN: They are under the superintendent and foremen.

MR. D. P. KENNEDY (Pittsburgh Plate Glass Co.): I wanted to ask three questions. Do you have medical examinations, what percentage are turned away, and what sort of bulletins are posted every Monday?

MISS BAKER: The medical examination does not precede employment but we have medical examinations when we enter our man on our company's insurance, and if the medical examination shows the man has a defect that hasn't been mentioned, we have to transfer and replace him. The percentage turned away is very low.

We have no particular day for posting bulletins. We have a bulletin

board at the entrance of the mill and among other things we keep our safety records posted on it.

CHAIRMAN ALTMAN: I am going to ask if there is any one in the audience here who has a medical examination preceding employment?

DR. CARR (Richardson Co., Cincinnati.): We have a medical examination of every employee.

A. KROES (Empl. Mut. Lias. Ins., Wausau, Wis.): I would like to ask the doctor if they find these a success?

DR. CARR: Just what do you mean?

MR. KROES: Do the men object to the examination?

DR. CARR: When they make their first application for employment they are told that they must have a medical examination.

MR. KROES: Then I suppose you have a method whereby a man not fitted for one job is given another job?

DR. CARR: That is what we are trying to do.

CHAIRMAN ALTMAN: How long has this plan been in operation?

DR. CARR: Since February.

MR. SPEAR (Oxford Paper Co., Rumford, Me.): I would like to ask Mr. Bongers if when there is a fall in the yard his men are assimilated by the rest of the mill, and what he does when there is a sudden rush of work, how he increases his force in the yard.

MR. BONGERS: I have about sixty men and when my work slackens we try to give them a chance to work in some other department in the mill. Sometimes the other departments have a scarcity when we have an over-supply and we send our men to them. At other times the other departments are slow when we are rushed and they lend us some of their men. We find that works out very well.

CHAIRMAN ALTMAN: At the Marathon we have a similar system. We have what we call the "Chain Gang," that is a department that does the loading and unloading either of the raw material or the finished product and we use the same method when we have a congestion of freight. When there is a great deal of raw material we have a larger crew but as soon as the cars stop coming in so fast we put them off into different departments and give them a chance to learn something about those departments.

MR. BEAUDOIN (Robert Gair Co., Brooklyn, N. Y.): I would like to ask Mr. Bongers what per cent of foreign labor is used in his gang, what the nationality is, and the percentage of accidents in their particular department.

MR. BONGERS: I should judge that in my department the foreigners were about fifty per cent. Is that right Miss Baker?

MISS BAKER: Well fifty per cent can't speak English.

MR. BONGERS: They are mostly Dutch people. As to accidents that is one of the best departments we have just now. The accident percentage is very slight there.

MR. BEAUDOIN: That is encouraging because as a rule in that department there are a great many accidents.

CHAIRMAN ALTMAN: Unless we do have a safety man in charge, this

is the department that will need special attention on account of the continuous turn-over and on account of not being able to reach them educationally, and for the reason that there are so many methods used in doing the work.

ADJOURNMENT.

#### THURSDAY MORNING SESSION

**CHAIRMAN ALTMAN:** I promised you a treat yesterday in the way of something which is to be very valuable and which will bring on, I know, a good, hearty and heavy discussion, and that is the result of the work that Mr. R. H. Guerrant, of the National Safety Council has done in the way of gathering data giving us comparative statistics on the frequency and severity rates in the Pulp and Paper Section of the National Safety Council. That isn't going to be the end of this work. As I explained in my report yesterday, we want to continue it for the coming year, and immediately following the reading of the paper we will be open for a discussion on ways and means of keeping the work up for the coming year so that we may have even more valuable data at the next Annual Congress.

#### PAPER MILL ACCIDENT RECORDS

R. H. GUERRANT, SAFETY ENGINEER, NATIONAL SAFETY COUNCIL, CHICAGO,

The officers of your Section, prompted no doubt by an article which appeared in the June issue of the NATIONAL SAFETY NEWS on the accident records reported from seventeen members of the Paper and Pulp Section, requested me to prepare a paper on the subject for this Congress. I undertook the preparation of such a paper mainly because there is quite a difference in the methods now followed by the members of the Paper and Pulp Section in keeping their accident records, and because it is very apparent that if the various mills will standardize one method it will be a distinct advantage to all.

The general method of collecting the data and keeping the accident records in your industry need differ but little from that used in any other industry. In fact the only difference is in the classification of accidents by causes and departments. While I have had but little experience in the Paper and Pulp industry and hardly feel competent to recommend a standard classification for paper mill accidents, I nevertheless have had several years' experience in this work in the steel industry, being for six years employed in the accident prevention department of a large steel corporation, four years of which I was assistant manager of the department. In that position I was responsible for the tabulation of from four to six thousand accidents each year and helped standardize the methods now in use by that company. I also had charge of the safety work and accident records for the United States Government arsenal at Rock Island, Ill., for about a year during the war, at which plant there

were between thirty and fifty accidents per day. My experience then has been enough to indicate that the general principles in all accident record work are the same.

#### PURPOSE FOR KEEPING ACCIDENT RECORDS

##### *Why are accident records kept?*

You no doubt have been in many plants where practically no record has been kept of the accidents to employees. I believe most of you will agree that in times gone by the principal reason for keeping accident records was to disprove and combat any fraudulent claims for damages on account of injuries to employees, and much to the discredit of a few employers, efforts were sometimes made to fight justifiable claims.

More recently however, and especially since the passage of compensation laws in the various states, the State Industrial Boards have required that records of all accidents be kept and reported. Many companies, even before the passage of compensation laws, kept complete records of accidents because these records helped to determine the causes of accidents in their plants and enabled them to concentrate their efforts toward remedying these conditions responsible for accidents.

Safety work has taught that another very good reason, if not the best reason, for keeping accident records is to impress upon the workmen and management the needless loss of time and money resulting every month from personal injuries. It will be found that the workmen themselves are as much interested in the effect of accidents on their pay envelopes, as is the management in the effect on the cost of production.

Accident records therefore should be kept and tabulated so that they may be used for showing the operating executives the need for continued activities toward accident elimination, and also for showing the workmen how much accidents mean to them, as well as for stimulating rivalry between the various departments or mills.

#### HOW TO KEEP ACCIDENT DATA

##### *Have you a satisfactory method for keeping accident records?*

About a year ago I prepared for the National Safety Council a Safe Practices pamphlet on "Accident Records—How to Compile them and how to use them" in which was outlined a uniform method for keeping accident records. That plan I believe, with possibly a few minor alterations here and there, can be used in any industry. Most of you are no doubt familiar with the plan outlined in that pamphlet; others doubtless have already established a satisfactory system for keeping your accident reports so that I need not dwell upon this further than simply to point out the five essentials which I consider necessary for any satisfactory method.

##### *1 See that injured men report promptly.*

Workmen should always be educated and encouraged to report at once whenever injured. If encouragement will not do then they should be compelled by their foreman to report.

**2 *Make a record of every man reporting for treatment.***

A daily record sheet of all men reporting for treatment is always advisable, even though as in the case of minor injuries, no further record of the accident is made. Such a daily record sheet may be kept in each plant hospital or first-aid station, or if there are two or more of those first-aid stations one record sheet should be maintained at each station. At the end of the week, or month, these record sheets should be collected and permanently filed. The record sheet used by the American Steel Foundries at each of their plants includes the check number and name of the injured man, the department in which injured, date injured, date reported, cause of injury, nature of injury, treatment given, and disposition (whether or not he returned to work or was sent home or to hospital). This sheet is kept as a permanent record and is of value should a workman appear at a later date with an infection and claim it was the result of a former injury. It is a simple matter to refer to the daily record chart and trace all injuries which were reported, as well as the treatment given. When men are given subsequent treatments, either at a first aid station, a hospital, or doctor's office, a record should always be kept showing the date, and nature of treatments. A day-book will serve the purpose in first-aid rooms.

**3 *Notify the proper departments.***

Whenever an injured man who will lose time reports for treatment, the medical department or first-aid station should at once make out a notice of injury slip, one copy of which should be sent to the Safety Department, one to the shop foreman, and one to the Employment Department. This will notify the several departments of the accident so that an investigation may be made, and the employment records properly kept.

**4 *Get all information for the accident report.***

The accident report for all accidents causing lost time is of much importance and should be made up with particular care. Many companies use the state form for this report. The employment record of all employees should be such that any information relative to the workman's past employment, his age, nationality, date of employment, and other such information is available.

**5 *Notify departments when man is able to resume work.***

Whenever a workman is able to resume work the Medical Department or plant dispensary should make out a "return to work" notice and copies should be sent to the foreman, employment department, and the safety department. Suggested forms for these several reports are shown in the National Safety Council's Safe Practices pamphlet No. 21.

**USE OF ACCIDENT DATA**

***What use should be made of the information on accident reports?***

Accurate accident experience data is of great value in preventing accidents. Simple effective charts will show at a glance the progress in safety work, the departments in which accidents occur, their cost as it relates to production, cost, etc. Such charts are useful for securing the co-operation of the executives, foremen, and men in safety work.

The forms suggested above if made out and carefully kept will contain all the information necessary for any kind of tabulated charts. Personally I do not believe it necessary or advisable to prepare many charts. Some companies go to the extreme in this particular. I have seen tabulations of plant accidents by age, nationality, color, length of service, hour of day, day of week, month of year, description of injury, etc., many of which were of questionable value. Some of this information of course may be interesting and have some value, such as a chart showing the hour of day at which accidents occur.

I recall that while with the American Steel Foundries I tabulated some five or six thousand "lost time" accidents extending over a period of four years, showing the hour of day, and day of week, on which all accidents occurred. Many other companies have prepared similar charts and they are of some value, such as for determining the effect of fatigue on employees, the value of good lighting, etc. So much data is already available in the National Safety Council's Library on many such questions that it seems needless for any company to go to the trouble at this time to prepare many tabulated records. Two or three charts will be found sufficient to answer most purposes. The most important are the classification by accident causes, and the classification by extent of disability.

#### CAUSES OF ACCIDENTS

It is highly important that all lost time accident be tabulated or classified by causes, for in this way only is it possible to determine what are the real causes of accidents in your plant. The Safe Practices pamphlet No. 21 gives a classification of accident causes which may be referred to for a general outline. This classification is, of course, not suitable for use in a Paper and Pulp mill as it stands, nevertheless any classification used should follow that general arrangement. I would suggest to this Section that a committee be appointed to prepare a standard classification of accident causes in the Paper and Pulp industry which all members and, in fact, all paper and pulp mills should be encouraged to use. There are many advantages to be derived from having such a standard classification. Many of the larger mills already have their own classification list. I have no doubt, however, that any and all companies will be glad to use whatever this Section adopts as standard. In the files of the National Safety Council are the reports of several companies in which classification lists are used; no two, however, are alike. This material is available for the use of your committee.

#### EXTENT OF DISABILITY

It is essential also to classify accidents according to the extent of the disability, for from such a table it is possible to determine the relative importance of accidents in various departments, and to know exactly what accidents cost in time and money. The standard method for classifying accidents by extent of disability is shown in table No. 3, Safe Practice pamphlet No. 21.

## THE FREQUENCY AND SEVERITY RATES

The frequency with which accidents occur, and their severity, is an exact measure of the accident hazard in any mill or industry. In order to compare the accident hazard of various mills and industries it is highly important that a standard method for computing these rates be used. The U. S. Bureau of Labor Statistics and the Association of Industrial Accident Boards and Commissions have decided upon a standard method for computing the frequency and severity rates of accidents in any and all industries. Formerly these rates were expressed in terms of a unit of measure, the "300 day worker", sometimes called the "full-time worker". Because of the variation in the number of hours worked per day and days worked per year in the various industries and localities it has been decided by the committee to abandon the "three-hundred day worker" as the unit.

In some plants it has been customary, and is still the practice especially in the mining industry, to express the severity of accidents on the basis of the number of days lost per 100 or 1000 shifts worked. The error which is unavoidable in such a system is that in one locality the shifts may be eight hours each whereas in another locality they may be ten, eleven, or twelve hours each. It is easily seen then that rates computed by this method are not properly comparable. For instance 1000 shifts of eight hours each present but two-thirds the number of hours worked in 1000 shifts of 12 hours each. As long as a man is working in the plant, mine, or mill, he is exposed to injury; the more hours worked, the longer is his exposure to injury. Therefore, the only logical and correct method is to base all accident rates on the actual number of hours exposure.

The adoption of 1000 hours exposure has been decided upon as a proper unit which is convenient in size and remains unaffected by changes in the length of the working day or variations in the working year. This unit of measure (1000 hours exposure) is a stable, scientific, and mathematical unit of measure which is what is needed for the measurement of accident rates. It has the additional advantage that rates measured by any other unit exposure may be readily expressed in terms of 1000 hour units and vice versa. For instance, all accident rates computed in units of the "300 day worker" may be converted into the rates of the 1000 hour exposure by dividing by three.

In order to determine the frequency and severity rates on the new basis of 1000 hours exposure it is of course essential that the total hours exposure be known. Where the "time" or "person" department keeps the total hours worked by each employee it is a comparatively simple matter to get the total hours worked by all men per week or per month. Where these figures are not available the approximate total hours exposure may be determined by taking the average number of hours worked (per week or month) by each employee and multiplying this number by the average number of employees for the period. Where there are two shifts, working a different number of hours, each shift must be figured separately and the total gives the desired time exposure. The frequency rate then is the number of lost time accidents which occur for

each, one million hours worked, and the severity rate is the number of days lost per 1000 hours worked.

This system of reasoning can be easily demonstrated by the following: Suppose that 150 automobiles pass a given point every two hours; then the frequency rate would be 75 per hour. Now suppose that these automobiles were loaded with five tons each; the severity rate (meaning by severity the weight of the load) would be  $(5 \times 75)$  375 tons per hour. In computing accident frequency and severity rates, however, a larger unit of measure is necessary and the unit best suited is 1,000,000 hours for frequency rates, and 1000 hours for severity rates. These different arbitrary units were established because by their use the frequency and severity rates are given in numbers of convenient size, ordinarily ranging from 1 to 100.

It is very essential that all plants should use this standard method for computing their accident frequency and severity rates. These rates represent the true accident hazard of the industry. Whenever used, the accident hazard of one industry is easily and correctly comparable with that of any other industry.

#### DAYS LOST BY INJURED EMPLOYEES

In computing the days lost on account of temporary disabilities the actual number of days lost during any month should be credited against that month. Where the injured employee does not return to work before the end of the month, all days lost in the following month should be charged to the month in which they are lost. This is advisable because at the time of an accident, it is difficult, if not impossible, to estimate the number of days which will be lost by the injured man. In order to keep a record of the days lost on account of accidents the form shown below is suggested. If at the end of a year it is desired to know the number of days lost on account of accidents occurring in each month, this may be easily determined from the several forms covering that year. This form has been successfully used by the American Steel Foundries for a number of years.

#### LOST TIME ACCIDENTS

| Month of.....19.....                                |                               |                               |                                   |                                      |
|-----------------------------------------------------|-------------------------------|-------------------------------|-----------------------------------|--------------------------------------|
| Report Number of<br>Accidents<br>of Prior<br>Months | Accidents<br>of This<br>Month | Date<br>Lost<br>Time<br>Began | Date<br>Able to<br>Resume<br>Work | Number<br>of Working<br>Days<br>Lost |

#### WEIGHTING OF PERMANENT INJURIES AND FATALITIES

One feature of computing accident severity rates sometimes not fully appreciated is that of expressing all fatalities and permanent injuries in terms of "days lost". This is necessary if permanent injuries and fatalities are to be considered as affecting the severity rate of a plant. The severity rate represents the true accident hazard of an industry. That industry having a large number of fatalities and permanent injuries each

year is, you will agree, much more hazardous than an industry in which serious accidents are of rare occurrence. There should be some way then to indicate the hazard of the industry by its severity rate. The only logical way is to reduce permanent injuries and deaths to a common basis, in other words to represent the serious injuries by arbitrary equivalents in days lost; the same equivalents being used in all industries. The U. S. Bureau of Standards and the Association of Industrial Accident Boards and Commissions have decided upon a standard table of equivalent days lost for all such injuries. (The table can be furnished by the National Safety Council.)

When given a little thought this method of computing the severity rates is as it should be. When your company makes an inventory of its equipment and stock, this inventory is expressed on the balance sheet in terms of dollars. It is of course necessary in making the inventory that all separate items be taken into account, but they are all converted into their dollar equivalents for statistical purposes. In a like manner, while it is necessary that a complete record of all permanent injuries and deaths be kept, for purposes of comparison these must be converted into terms of days lost in order to express the severity rates accurately.

The ratings of 45 mills who submitted their accident reports for the period January to June, 1920, inclusive, were printed in the September 27 issue of the NATIONAL SAFETY NEWS.

CHAIRMAN ALTMAN: This getting together on a standardized method of accident reporting and frequencies and severities has been one of my hobbies for the past year and while it is still in its infancy I think we could really get some good results by keeping this thing up.

To some of you perhaps Mr. Guerrant's methods were not plain. He is here now to answer any questions that may come up in regard to the work of the coming year. I recommend strongly that this be kept up next year. I hope that in this discussion we can get something that will be valuable for the industry as a whole.

#### DISCUSSION

MR. W. A. GLEASON (Hammermill Paper Co., Erie, Pa.): I would like to ask how you figure permanent injuries. On our list we had a man who was injured by having a thumb and one finger amputated. We figured the number of days lost and the number of days disability, but according to the permanent scale of injury I presume more is added on. I wonder if we should include the days of permanent injury lost in this report.

MR. GUERRANT: If you will kindly turn to page 11 of the NATIONAL SAFETY NEWS for September 27, we will be better able to discuss this matter. (Copies of this issue were distributed.)

Now in answer to your question, Mr. Gleason, no. In the case of permanent injury you only credit against that accident the number of days shown in the table. Do not add the number of days lost because one man may lose two months and another may lose six on the same kind of an

injury. In other words it is not fair to make it comparable with other industries by using any one number of days.

MR. BEAUDOIN: I would like to ask what he does in cases where the commission makes a special award in an accident. Often a man is awarded a third of a hand, another is sometimes given a part of a permanent disfigurement.

MR. GUERRANT: In case the commission makes a partial award, say a man has a broken leg but it remains stiff and the commission permits him two-fifths for the loss of a leg. For a leg say you have three thousand days. Put against that accident two-fifths of three thousand days. In case of any permanent disability of that nature, where the commission has given an award, always state the amount of the total that the commission granted.

MR. J. N. STEPHENSON (Gardenvale, Quebec): The Pulp and Paper Magazine, although it does not deal directly with accident work, is very much interested in it. Having followed out what Mr. Guerrant said, it occurred to me to remark that his table of accidents appears a bit incomplete. It appears that if a man loses time it is important to the mill to know how much time that man has lost, how long he has been absent from the work, and consequently how much wages he has lost on that account.

This is particularly important it seems to me, in connection with permanent injuries where the award by the commission would entitle him to a greater remuneration than his loss of time would represent.

If a man loses a finger on the fifteenth of September and he is out of work a month, his record would show that he began to lose time on the fifteenth of September and that he resumed work on the fifteenth of October. He didn't get any wages during that time in his normal way. He is entitled to certain compensation because of that, to the equivalent of a lost finger. Now if you want to have that record accurate you have to show how much he got from the accident because of his compensation, but your record has also got to show the fact that during a part of that time credited to his loss through accident, he is getting some wages because he has resumed work. It would seem then, that you should put in your records, the days lost in the current month due to all accidents whether coming in that month or carried over, and also the total days lost which would represent either the total days lost between the beginning of the accident and the results of the work, or the total days lost as calculated on the basis of equivalent hours because of permanent injury, and, in case there is a permanent injury, to show what that injury was. That then would give you your full information regarding that particular accident.

Another thing I would remark on is that three thousand hours divided by three hundred days does not give you a thousand-hour basis unless operating on a ten-hour shift. If you are operating on an eight-hour shift it doesn't come out right. You simply have to make a factor for each length of shift. It would also seem advisable that in connection with your accident work you have some means of keeping a record of time

lost due to sickness and in some cases, in some industries that sickness may be traceable to industrial conditions. But in order to keep a proper record of the men, what they are doing, and what their earning power is, it would seem advisable to have that record kept.

MR. GUERRANT: Of course I didn't touch on lost time in regard to sickness but I think it is highly important that one should keep such a record. I didn't include that in my paper because I was dealing only with accidents.

In reference to the first part of your remark, I believe that had reference to the form for the table I suggested. In regard to keeping the days actually lost by men permanently injured, the only way to tell the amount of money the man has lost is to keep the number of days he actually loses and use it in the plant accident record work. It is always advisable to keep the number of days actually lost by the workmen and use that record in computing the amount of money the accident costs the workman.

The method that I discussed principally had to do with the preparation of accident record charts for our industry as comparable with other plants and industries and the only way to make it comparable is to use the number of days lost for permanent injury.

For impressing upon the management what accidents are costing them it is better to use the amount of money it is costing the management, which is arrived at by the amount of compensation.

MR. T. F. SPEAR (Rumford, Me.): If a man were injured on September 15 and died from his injuries later, how much do they charge against the department for the year, how many lost days?

MR. GUERRANT: Of course when it is not known at the time of injury whether it is a fatality or not the only way to arrive at your monthly standard is to credit the number of days against your department, but at the end of the year the correction should be made and you should credit the plant with six thousand days attributed to death.

MR. C. K. BOYER (Wisconsin Rapids, Wis.): I would like to ask Mr. Guerrant as to the methods the various firms used in reporting lost-time accidents in Michigan. In Wisconsin, of course you know that there is a waiting period of seven days before you have to make a report of an accident to the Industrial Commission. But in making these reports to the National Safety Council I would like to ask on what basis the different firms represented in this table, are making their reports and what they consider, in making their reports, a lost time accident. There seems to be a confusion as to just what kind of an accident the different companies represented are reporting to the National Safety Council.

CHAIRMAN ALTMAN: That very question made us take this matter up so as to standardize the reporting method, and if Mr. Guerrant has anything in regard to it, we will be glad to hear it.

MR. GUERRANT: We ask for all accidents which necessitate the loss of time beyond the shift on which the man is working. I don't know how it was reported. I inferred that they sent it to the Commission. Some might have reported only those which they reported to the Industrial

Board and they of course lost every accident which we required as lost time accidents, that is we didn't get any of their accidents on which less than a week's time was lost.

The form the Council sent out asked plainly that all accidents should be reported together with the number of lost days. That is the only way to get accurate figures. If you do not report these you may have twenty men in a month who lost five days each totaling one hundred days lost on account of those five men, and you may have only one man who loses over seven days; that would show only one accident with a loss of ten days whereas as a matter of fact you have lost one hundred and ten days and have had twenty-one accidents.

CHAIRMAN ALTMAN: I have always been of the opinion that a man who was hurt on the shift, whether at the beginning or the end of the shift, should not have that time counted against the accident. The man in all probability has gone to the doctor if he had no doctor in the plant where he was employed, and so will not come back to work that day, and it wouldn't be worth while to have him come back. I think that even if he loses seven hours out of the eight none of those seven hours should be counted against the accident. In other words, the shift on which he was hurt is not to be counted as time lost on the accident. If he doesn't come back the next day on his regular shift then the time begins to count, but if he does come back the next day it would mean a no-lost-time accident, in my opinion, and I think in the opinion of the majority of those with whom I have been dealing.

MR. GUERRANT: I would like to say that that is the standard method adopted by the Council. A number of the States, however, require that the day in which the man was injured be counted as the first day. I would like to ask if there is any other industry in which they pay them for the full shift. If a man is injured at 7:15 in the morning, do you pay him for the full shift? We make a practice of paying the man for the balance of the day.

CHAIRMAN ALTMAN: We do the same thing. If a man is hurt at 5 o'clock in the morning we pay him for the balance of the day.

MR. STEPHENSON: I think that those interested in the production end will agree that the first day of the accident is the most serious day as it affects the production of the mill. It completely upsets the routine of the department in which the accident occurs and means a temporary and often hasty rearrangement of work in order to carry on that department at all. Setting aside for the moment the matter of compensation, as far as the mill is concerned the records should show the time lost on the day the accident occurs.

CHAIRMAN ALTMAN: We are figuring really on the comparative method and we have to standardize certain points in order that all may keep the same kind of records. If various mills pay and others do not, if some begin to count their time lost from the minute the man is hurt and others begin with the next shift, we would never get to a standardized method of doing this, and for that reason we have to adopt some standardized form to base our comparisons on.

**REPORT OF NOMINATING COMMITTEE**

The Nominating Committee has brought before us the name of Mr. F. S. Shattuck as Chairman for next year, Mr. F. P. Young as Vice Chairman, and Miss Mary Baker as Secretary. Mr. Shattuck, as you know, is with the Kimberly-Clark Company and so is Miss Baker, and Mr. Young is with the Interlake Pulp and Paper Company of Appleton, Wisconsin.

(The nominees were duly elected.)

CHAIRMAN ALTMAN: Our next paper is on "What is Being Done in the Pulp and Paper Industry to Bring Education within the Reach of Every Employee." We were very fortunate in being able to procure to discuss this question, Mr. J. N. Stephenson, the Editor of "Pulp and Paper Magazine of Canada," of Gardenvale, Quebec.

**WHAT THE PULP AND PAPER INDUSTRY IS DOING IN  
EDUCATIONAL WORK**

J. N. STEPHENSON, EDITOR, "PULP AND PAPER MAGAZINE OF CANADA,"  
GARDENVALE, QUEBEC

The need of some opportunity for young men to learn more about the business of paper making was impressed upon me about sixteen years ago when the frequent answer to my numerous questions asked of our Scotch machine tender was "Well now, Sliver, if I told you all I know you would know as much as I do."

Since that time a great deal has been learned about paper making, many improvements have been made in machinery and processes and many new inventions have made the work easier and more efficient. These machines and processes have been described more or less clearly in patent office records and occasionally a process or machine is the subject of an address at some meeting or a contribution to a trade periodical. Information on the equipment of the industry is therefore fragmentary and scattered and, although several very good books have been written, a comprehensive discussion and explanation of the fundamentals underlying the construction of machines and operation of processes is practically non-existent in convenient form in English. A movement instituted jointly by the technical men of the industry in Canada and the United States and financed by the manufacturers is now in progress which should go a long way toward the remedy of this condition.

**UNIVERSITY TRAINING**

In February, 1913, the first course in Pulp and Paper Making on this continent was conceived by Dr. R. H. McKee and offered by the University of Maine. This was given by Prof. A. G. Durgin, now with the Spanish River Pulp and Paper Mills, on the Manufacture of Pulp. In the fall of that year the speaker joined the staff, courses were organized in Paper Making and the University shortly had built up a department giving instruction in ten pulp and paper courses, four of which involved practical work in the laboratories which were equipped with pulp and paper making and testing apparatus.

The University of Michigan some time later began post-graduate work in pulp and paper. The University of Wisconsin is, of course, close by the Forest Products Laboratories, but we are not aware that under-graduate instruction has been given in pulp and paper subjects. The same situation is true with regard to McGill University and the Forest Products Laboratories of Canada, at Montreal. Several colleges include a few lectures on these subjects in the course in Industrial Chemistry. This fall the College of Forestry of New York State is offering for the first time, a consecutive course in Pulp and Paper Manufacture. This is based naturally on wood as raw material. Both the University of Maine and the New York State College of Forestry have attempted short courses especially for the man in the mill. They have not been entirely successful.

It will thus be seen, however, that the man who has the time, means, and ambition to prepare himself for the technical or engineering departments of the pulp and paper mill has fair opportunities for university training. The lack of schools devoted strictly to pulp and paper making is partly corrected by such means as prevail in Canada, where the Technical Section of the Pulp and Paper Association in co-operating with the universities so that students in Chemistry, Engineering, and Forestry are given opportunities to engage in the summer months in practical work with pulp and paper companies.

#### VOCATIONAL EDUCATION

The more difficult and the more interesting phase of the situation, however, relates to providing educational opportunities for the man in the mill or the young man in the schools who has a leaning toward this industry as a career. There are several distinct lines along which instruction may be given, some of which have already been followed up to some extent. At least there have been several night schools in operation and there is included in the International Correspondence Schools courses a few pages devoted to this enormous industry. Besides the night school and correspondence instruction there is the opportunity for part time instruction as advocated by the Federal Board for Vocational Education and there is also the lecture series. It seems that all of these methods can and should be made use of according to local conditions. The problem is largely a local one, and cannot be satisfactorily solved without the earnest attention and a good deal of energy from the men on the spot who have the knowledge of the industry.

As far as I am aware and certainly as far as Canada is concerned, the first distinct attempt to provide for the instruction of employees of the industry was the night school organized at Thorold, Ontario, by the co-operation of the local school authorities and the pulp and paper companies in Thorold, Merritton, and St. Catharines. Classes were organized in Chemistry, Electricity, and Mechanical Drawing. There was a very good attendance and great interest was shown by the students.

A similar school was organized at Hawkesbury, Ont., by the Technical Department of the Riordon Company. Here, again, the elementary subjects were taught and attendance and progress were reported as very

satisfactory. At Sault Ste. Marie, Ontario, classes were carried on by the Y. M. C. A. with the co-operation of the Spanish River Pulp and Paper Mills and the Algoma Steel Corporation. Here, too, the principal subjects were Arithmetic and Elementary Science. At the Spanish River Mills at Espanola classes were held for teaching English to the foreign population. This, I understand was directly in connection with the company's prominent activity in the cause of Safety First, it being realized that an essential factor in the success of the movement is the ability of the employee to understand the common language of the mill.

At Iroquois Falls, Ontario, which is the location of the Abitibi Power and Paper Company, and at Grand Mere, Quebec, where the Laurentide Company is situated, courses have been given consisting of a series of what might be called popular lectures on the principal departments of the pulp and paper mill. This is being extended this year by the Abitibi Company through the preparation of a special series of papers dealing with the fundamental processes. The papers have been appearing from week to week in the *Broke Hustler*, the paper on mill news and town topics published by the company. It should be mentioned also that the *Spanish River News*, the weekly paper published by the Spanish River Pulp and Paper Mills has also contained a series on the story of newsprint manufacture. It will be noticed that all of these places are centers of newsprint production although the vicinity of Thorold, that is, the Niagara Peninsula, produces perhaps as great a variety of papers as could be found anywhere in the same area.

A number of mills in the United States have undertaken somewhat similar work. The American Writing Paper Company went so far as to set aside one division of their organization for instruction purposes. This phase of the work of that company has not yet, however, been entirely organized. The Kimberly-Clark Company, has also, through its technical department, given instruction in certain phases of the work to groups of employees. The Champion Fibre Company at Canton, N. Car., are organizing their educational work for the coming winter and are planning a series of courses to be given by heads of departments in order to acquaint the men in each department, as far as his preliminary education will permit, in the fundamental principles underlying the processes and in the description of the various machines and their functions. There is much to be said in favor of carrying out the work as planned by this company. In the first place the men are listening to men they know and to men who are able to talk in their own language.

This type of instruction is likely to meet with some hitches because of the inexperience of the leaders in planning classroom work and in presenting their knowledge and their ideas to the student. This, however, is not by any means an insurmountable difficulty and with a little persistence, courage and patience and plenty of enthusiasm on the part of those who conduct these classes, there is bound to be a great deal of progress made both by the teacher and by the class.

You will have noted, perhaps, that, with rather few exceptions the emphasis in the educational work has been on preliminary instruction,

that is, the teaching of mathematics and elementary science. There are two reasons for this. In the first place many of the more ambitious men in the mill are the ones who have not had many educational opportunities and who find themselves handicapped in comparison with their fellows who have been through high school or even only through the eighth grade. The grown men who are now in the industry were not required to attend school to the age which is now fortunately becoming a respectable minimum for going out to work in the world. In the second place there cannot be satisfactory progress made in the study of the machinery and processes used in pulp and paper manufacture unless the student understands quite thoroughly the fundamental principles of mathematics and of science so that he may get a clear conception of the discussion of a process or the description of a machine.

#### TEXT-BOOKS IN PREPARATION

The Technical Section of the Canadian Pulp and Paper Association and the Technical Association of the Pulp and Paper Industry, formerly the Technical Section of the American Paper and Pulp Association have since their organization, which was almost simultaneous, each had a committee on education. Realizing the need for a text-book, a meeting was held at which all but one member of these two committees were present and a joint committee to proceed with the preparation of a suitable text-book was formed.

The material for Volume I is prepared and a large part of it is in type though not yet printed. This volume will include Elementary Arithmetic, Applied Arithmetic, Elementary Physics, How to Read Drawings, Mechanics and Hydraulics, Elementary Electricity, and Elementary Chemistry. The material is so prepared that it will be appropriate for either class room or correspondence instruction or for reference purposes. The provision for correspondence instruction is, of course, a feature of the whole work and is expected to be of particular benefit where a man cannot conveniently attend a class or would be embarrassed in younger company.

Volume II includes a very brief chapter on Logging; the Principal Properties of Pulpwoods; the Preparation of Wood; Mechanical Pulp; Sulphite Pulp; Soda Pulp; Sulphate Pulp; Treatment of Pulp; Bleaching Pulp; Analysis and Testing of Pulp and Raw Materials.

Volume III takes up the Manufacture of Paper and begins with a very brief discussion of the materials used and the history of paper making and a concise outline of the process. The following sections are then included: Preparation of Rag and Other Fibres; Treatment of Waste Papers; Beating and Mixing; Loading; Sizing; Coloring; Handmade Papers, and the Paper Machine.

In Volume IV the Manufacture of Paper is continued and includes: Tub-sized Papers, Finishing Operations, Special Papers and Boards, Paper Testing, General Mill Equipment and an Appendix including various tables and other miscellaneous but useful material relating to paper.

It is anticipated that this work, when completed, will form the basis

for many study groups and for much individual study as well as being a valuable work of reference. In order to facilitate the arrangement of what might be called a curriculum for the various classes of mills it is intended to publish the work both as bound volumes and in pamphlet form. The pamphlets are susceptible of arrangement by grouping so that, for instance, a man working in a sulphite mill, who would naturally not be directly interested in either groundwood or soda pulp, can study the pamphlets relating to Properties of Wood, Preparation of Wood, Manufacture of Sulphite Pulp, Treatment of Pulp and Bleaching.

#### ACCOMMODATION OF THREE SHIFTS A PROBLEM

One of the difficulties in connection with organizing night classes or outside classes of any kind for paper makers, is that the majority of the men in the mill work on three shifts so that it is not possible to have a time for the class which meets the convenience of all the men in the mill. This could be overcome by having an afternoon class early in the afternoon, for those who go to work at 3 or 4 o'clock, and another session in the evening.

One of the great advantages to be derived from this study of the industry by the men employed in it will be a greater knowledge of machinery and processes and consequently a decrease in accidents due to the lack of this knowledge.

CHAIRMAN ALTMAN: Now we can have a few minutes for discussion on any points that Mr. Stephenson made. Are there any questions?

#### DISCUSSION

MR. STEPHENSON: It might be made a bit of experience for some others, if those who have done, are doing, or are planning to do safety work, would briefly state what progress they have made, or what their plans are.

CHAIRMAN ALTMAN: I noticed that in your paper you mentioned the Champion people of Canton, North Carolina. Mr. Phillips is here and I was wondering if he had anything to add to that.

G. W. PHILLIPS: I will be better able to make a report on our venture later. We are just beginning the work. With the first week of October, and continuing for a period of six months, two lessons each week are given. We have a comprehensive program on vocational education. There are eleven classes including, if I can name them all, steam plant operation, applied electricity, chemistry, pulp making, tannic acid manufacture, carpentry, bricklaying, and so forth.

In outlining our program we decided it would be better to have practical men rather than technical men to teach these courses. We feel that the man who is able to do the work himself can perhaps teach others better than a technically trained man, so we have selected superintendents and general foremen to teach these courses.

Of course we realize that it is a big undertaking because each teacher has to outline his particular course of study, but we are hoping, and we believe also, that we are going to accomplish some good results. Just what those results will be we are unable to tell at this time.

CHAIRMAN ALTMAN: Is there any one else?

A. P. COSTIGANE (Toronto, Ont.): I would like to ask in what form those books will come out.

MR. STEPHENSON: The committee intends that the books shall be available in two forms. For study they will be available by groups of pamphlets relating to the department in which the man is working. At the same time they will be available in a complete set of four volumes which will cover the entire industry. The pamphlets will be better for correspondence instructions, so as not to discourage a man by handing him too big a mouthful at once.

MR. SPEAR: We started an experiment last year, and I really shouldn't report on it but I think it is different. We are taking the boys in the local high school who are interested in pulp and paper making. We started with last year's freshman class and they spent three afternoons a week in the mill under the instruction of a man who has had a college training and is also connected with the mill work, and this year those who desire will continue the work, and so on up until their senior year, so that they will get a four-year course in paper and pulp making. We are going to try to expand that educational work this year to include some of the employees in the mill, along the lines you speak of.

CHAIRMAN ALTMAN: Mr. Spear, do you find any trouble in going up against any State laws, or are the boys in the freshman year above sixteen years?

MR. SPEAR: We are working in conjunction with the State and Federal authorities.

#### U. S. BUREAU OF VOCATIONAL EDUCATION

MR. STEPHENSON: I might suggest here that the Bureau of Vocational Education in Washington, D. C., is very anxious indeed to co-operate to the fullest extent with any one that is interested in educational work. They have a good deal of data and considerable material which is immediately available and some experience that they can put at the service of those who want to make the most of this great opportunity for helping the young people of our country.

They are also anxious that the country make some use of the considerable fund that is being provided and it can be so worked that a company can get a good deal of contribution from the Federal and State governments by understanding just how to go about it. This Federal Bureau will be glad to assist them in getting all the outside contributions they can turn their way.

#### SOME ECONOMIC ASPECTS OF WELFARE WORK

H. P. CARRUTH, GENERAL MANAGER, MEAD PAPER AND PULP COMPANY,  
CHILLICOTHE, OHIO

Welfare work has been somewhat criticized of late as smacking too much of paternalism in these days of rampant democracy. It associates itself with "scientific management", "efficiency" and other words and

phrases that have been overused or misused until one hardly dares use them at all for fear of creating an unfavorable effect upon our audience.

To clear the air, therefore, let me say at once that I believe in welfare work, not as it has been practiced very frequently as a sort of general specific for all the industrial ills, but as part of a general industrial policy which is in line with the trend of the times and in sympathy with the modern idea that workmen are regular human beings, thinking and reacting like the normal man in any walk of life.

Under proper conditions efforts to improve the living and working conditions of men and women employed in industrial plants are a proper activity for manufacturing plants to consider because they can show a profit on the years' operations which is the legitimate field of industry.

You will notice that I said "under proper conditions". The importance of this cannot be over emphasized. All of the welfare work conceivable will be a most dismal failure if the general conditions of the plant are not sound before such work is begun. The employer who uses welfare work as a substitute for proper wages or working conditions is inviting trouble.

Assuming that conditions are sound—which means good wages (not only in the sight of the employee, but so admitted by the organization as a whole), a clean and well-kept plant, foremen who are fair and straightforward in dealing with their men, a sound business policy, and efficient management which protects its men against unemployment to the maximum degree, and a generous dash of the Golden Rule—we have then the foundation upon which profitable welfare work can be built.

It is almost inconceivable that a plant which conforms to the above specification could be doing no welfare work, but frequently it is quite unorganized, and when unorganized it is likely to be unfair and unjust. To illustrate; two men become incapacitated by serious illness. The first man has lived up to his income, the second is more thrifty and has laid by a bit against the rainy day. Our first man and his family soon become in abject need and sooner or later help is forthcoming, either from his fellow workmen or as a loan or gift from the company. The second man is known to be able to stand the strain for a while so no help is given. In other words, the man who has been thrifty is given less consideration than his less valuable fellow workman, assuming that thrifty workmen are better and more valuable in our mills than the shiftless. This is not a square deal.

My illustration might be given to show that unorganized benevolence to employees tends to create the exact opposite of the spirit which is desired, and of necessity it must be of the most paternal character except perhaps in very small organizations.

On the other hand organized benevolence in industry is likely to be a cold-blooded matter of fact thing which has no advantage to the company and very little to the employee.

The proper basis seems to me to be to put all such efforts squarely before the men as co-operative methods which repay the man and the company mutually, although perhaps, not in the same coin. The average

workman is suspicious of his employer and if you do not show him what gain you expect to make he will be likely to suspect a sinister reason.

To sell safety ideas to workmen you must convince them that care is a sound investment which they should make for themselves and their families and also show the advantages to the company. Don't try to force rules and regulations down their throats by means of signs and threats of discharge or punishment. Such means are no longer effective if, in fact, they ever were really of value.

To sell recreation to workmen it should be frankly stated that good health is an asset not only to the man himself, but to his employer because a healthy man is a better and more efficient member of the organization.

To sell insurance, whether it be wholly or partly paid for by the company, should be shown to be worth while to the company because it helps the men to stop worrying and so adds to their effectiveness on the job.

The same ideas hold in regard to all types of welfare work, such as free medical and dental attention, visiting nurses, restaurants, etc. You cannot fool your men on these matters and you know you wouldn't do it if it didn't pay. At least you wouldn't do it except as individuals rather than as a company policy.

Now let us see just how these various types of welfare work do pay the employer. Like any other investment it is quite easy to put in more money than can be taken out. Unfortunately, when dealing with the human machine, it is very difficult to place exact figures on the improvements which result from any policy and again these values are constantly varying with location, with time, and with general conditions. They are very different in different industries and change with the seasons. Nevertheless, every employer has a distinct idea what such factors as labor turnover, good morale, health, quick learning, care, etc., have in his own business and can best interpret values for his especial conditions.

Sport organized by industry is perhaps the most widely-used type of welfare work. This may be handled in many different ways, but has its chief value to the employer in its effect on morale and secondarily on health. In most plants the health factor is of small importance as relatively a small per cent of employees take active part in such activities, the effect on morale is much greater but varies much in degree. Some companies strive to get results by producing a winning team at all costs, even to the hiring of professionals, while others bring into play the idea of true sportsmanship. The first idea is dangerous because in any league there can be but one winner and the losing teams may have a bad effect on the organizations from which they are chosen. On the whole, in my opinion, sport is one of the least profitable forms of welfare work.

Safety probably comes next in general use. The effect on profits of safety work is fairly clear. First, we have the direct losses when men are hurt which must be paid in insurance premiums which such work eliminates to a greater or less extent. Second, we find that safety work is frequently one of the best contact points between management and men out of which grow various benefits to the bank account. Then again, it has its effect on labor turnover and general morale.

Insurance in various kinds, whether life, accident, or health, is valuable in its effect on turnover and helps to secure good men to fill vacancies. Its appeal is quite as much to the wife at home as to the man on the job. It also keeps the force as a whole in a proper mental condition by minimizing worry, and is especially valuable when a man returns from a siege of illness or incapacity due to injury.

Vacations are very highly regarded by the men, perhaps more highly than any other one thing. We all like to sit by the fire and plan our little outings for the coming summer and the workman is no exception to the rule. Idleness is a goal which always attracts in prospect, although seldom justifying itself in the present. For these reasons vacations are a very powerful stimulus to hold men to their work if used as a special reward for continuous service. The value lies in their effect on turnover which is considerable, especially with employees of long service, and on general morale, they also have an undoubted effect on health, although this is more mental than physical.

Outings are of little value in developing morale, although frequently used for that purpose. When morale is already good they may be a stimulus, however, but it is doubtful if they are worth the cost which they frequently run into unless engineered by the employees themselves.

Free medical and dental service has a very definite effect on morale, turnover, and production. Its value is naturally greater in those industries particularly liable to occupational disease, but is considerable in all cases. Many men will consult a company doctor, who makes no charge, long before they would spend the money to see their regular physician. This means the checking of contagion and in extreme cases might save a shut down.

House organs are almost a necessity in a well run plant as a means of selling the ideas of the management and increasing morale and loyalty. They form a connecting link between the plant and the homes of the men which is of the greatest value. They should, however, be something more than collections of trite phrases or collected sermons to make them a profitable investment.

Co-operative purchasing is frequently a worth-while addition to the best of welfare activities, but should only be undertaken after due consideration as there are many pitfalls for the unwary.

Housing is more often a necessary adjustment to operation than a real welfare effort. When necessary to consider, it should, however, be placed upon such a basis that it is something more than an expedient.

The above are only a few of the great number of activities possible to the welfare department. All are good, all are potentially profitable but only as conditions warrant. The field for such efforts will vary with your own conditions as stated earlier. Look over your own problems, talk to your men and the profitable series of activity will not be hard to find.

In closing let me add one word which, although not on welfare or safety work, still lies at the root of all such work.

It is my firm conviction that a workman reacts to the same influence

as any other human being. This "psychology of the workman" of which we hear is a myth except as it is the psychology of human nature. Most of our mistakes in the past have been due to a tendency to think of workmen as a class or species differing from ourselves in important respects. This I believe to be an error which has been very costly to industry and to civilization.

Assuming that your employees are just normal human beings and that you yourself are normal, then it becomes very easy to predict what reaction will result from any labor policy for by projecting yourself into the position of the workman your own reaction to the surrounding conditions may be expected to be the same as that of the great majority of your employees. There will be differences in degree, but not in kind. In brief, the Golden Rule is a practical and workable business policy.

CHAIRMAN ALTMAN: In the two-day program I am positive we all received a lot of good, especially so on this last paper, where Mr. Carruth covered a number of questions that have always come up before me and, I suppose, before quite a number of you. This question of paternalism: I have wondered how far we could go and have always been rather skittish when doing work that may be placed under that head. He has answered my question and I am sure he will be more than glad to answer any questions any one of you may ask.

Perhaps if I state the question that was settled so far as I am concerned, that may lead on to the discussion.

We have a group policy covering the sickness, health, and death of our employees, which is entirely paid for by the management and on two or three occasions when I mentioned the fact, I was covered with a wet blanket by people who told me that it is paternalistic. They say if we want to do that, to form our Mutual Benefit Association where the men will partly or wholly pay for the insurance which they get. I would like to hear any statement that some of you may make relative to this question of what is and what is not paternalistic.

#### DISCUSSION

MR. CARRUTH: We do exactly the same as you say you do. We do not have, at the present time, any life benefits directly, we take care of that through a stock-purchasing scheme, but we do have health and non-occupation accident group insurance.

At the time we first began thinking about putting into effect some such insurance, we started with the idea of having it a mutual plan, but upon investigating I found that it was going to cost, on the basis which we had first discussed, which was fifty per cent paid by the employees and fifty per cent by the company with the clerical work done in our plant, which isn't so very large—it was going to cost, as I said before, practically as much to pay half of the benefits and clerical fees, as it would to pay outright for the whole policy and have it taken care of by the insurance company, as they were willing to do. Therefore it seemed that it would be a waste of money to handle it in such a way that it took, for instance, a dollar and a quarter to do a dollar's worth of good.

In our plant I think we are especially fortunate in our working conditions and in the type of employees we have. This place we have is absolutely one hundred per cent an American organization and that is in itself a big point. We can get across ideas with our men that I know would be difficult, perhaps impossible in a great many other plants, some plants with which I have previously been more or less associated. We can tell our men the facts just as I have given them to you and that this is simply a co-operative effort, and the men will accept that.

On other things, our restaurant, for instance, is entirely paid for by the men. It is conducted in such a way that it even shows a little profit. It started out and ran into debt a bit and the company assumed the burden of the debt. Then we made an adjustment of the prices and the debt is gradually being eliminated and is now down to a very small figure.

We have a Mill Council and that has taken it upon itself to attend to the restaurant. They are organizing it and are going to enlarge its activities and have a meeting room feature, and whatever they say in matters of that kind is usually done, because we find that the men when seriously looking after a matter of management through the Mill Council, without exception have been willing to look at the thing in a fair, square, honest way, and no suggestion has as yet been made by that Mill Council that has not been of a nature that the management wasn't glad to adopt. You can get the democratic idea across, at the same time doing some things which perhaps would smack of paternalism in some other plants, but the conditions in the individual plant vary so widely that you have got to consider them carefully in determining what you can and cannot do.

CHAIRMAN ALTMAN: Yet your claim that it is one hundred per cent American seems to me just the point that is always the stumbling block, because if there is going to be a complaint it will come from the American side of it. I have seldom, in my experience, found any of the foreigners complaining of paternalism when the company is trying to do something for them. You have the extreme from which you could get the complaints and yet, as you say, no such complaints are forthcoming, so that in many cases, "paternalism" is nothing but a bugbear.

MR. CARRUTH: I think I can answer that in a couple of words. It is all in the way it is done. If you say to the men, "Here is your little present," and tell them if they will be good they will be happy, you will get that reaction every time, surely. But if you take the attitude which we try to have, and which I think we have, that we are all working together, we are all one family, that the management and the employee individually and collectively are friends, and get everybody working on that basis, then you don't have any trouble with that at all. You can discuss any matter at all, bring it up in any way you want to, and talk as freely with a lot of employees as with the directors of the company and get the ideas over in exactly the same way. In other words it refers back to my last paragraph, that the psychology of workmen is the psychology of everybody else and if you approach them in a matter-of-fact way you don't have any difficulty, but if you talk down to them and set yourself up above them, you are going to have a bad reaction.

Mr. W. E. HOWARD (Rumford, Me.): We insure every employee from the general manager, down, who has worked for the company six months continuously. The company pays the entire cost of this insurance. At first it was turned over to see what there was underneath, and this continued until first one and then another began to reap the benefits of the thing. Now I think it has been accepted whole-heartedly by the men.

Another thing I want to say is that this insurance increases fifty dollars. We have two classes of insurance, A and B. When a man works six months he is entitled to the full benefit of the insurance in his class. That increases fifty dollars each year.

This insurance automatically ceases when a man has severed his connection with the company, unless he wants to pay the premium on it himself.

About a year ago we issued a health certificate for each man and that is effective whenever he becomes diseased or incapacitated. This is also taken care of by the company.

Of course it was all looked at very carefully by the workmen. But, when a few of them got the benefits from it they accepted it in the spirit in which it was given and it has been beneficial in many ways, particularly in reducing the turnover of our organization.

CHAIRMAN ALTMAN: Before we go on with any further discussion of this topic we have the great honor of having with us for a few minutes one who has done a great deal toward getting at the origin and striking at the safety head in the way of educational work. He is going to talk to us for a few minutes and try to convince you that it is up to you to do something. Dr. E. George Payne, of St. Louis.

(Dr. E. George Payne, Principal Teachers' College, St. Louis, explained the method adopted in St. Louis for teaching accident prevention to children. Statistics and charts were shown to illustrate the remarkable results accomplished in reduction of accidents to children while in school, on the streets, or in the homes. For full report of Dr. Payne's address, see Education Section, page 200, and also Public Safety Section, page 377.)

CHAIRMAN ALTMAN: Is there anything that any of you have to bring up in regard to any of the papers read? If not we are ready to close our session and I want to thank you all very much for the part you have played in making these sessions successful.

I think that as a section we ought to give a rising vote of thanks to the Kimberly-Clark Company for the splendid program they gave us yesterday, and to Mr. Guerrant, Mr. Stephenson, and Mr. Carruth who gave us a splendid series of talks today.

ADJOURNMENT.

## Public Utilities Section

September 28 and 29, 1920

**WILLS MACLACHLAN**, Chairman  
Electrical Engineer, Toronto, Ontario, Can.

**CHARLES E. MORRISON**, Vice-Chairman  
Utilities Mutual Insurance Company, New York City

**H. B. HARMER**, Secretary  
Philadelphia Electric Company, Philadelphia, Pa.

### TUESDAY MORNING SESSION

**T**HE meeting convened at 9:45 a. m., Chairman Wills MacLachlan presiding.

**CHAIRMAN MACLACHLAN:** I notice that the first item on the program is the report of the Chairman, but I think that that can be easily included in the report of the Secretary. I will ask Mr. H. B. Harmer, our Secretary, to make his report.

#### REPORT OF SECRETARY

Several meetings of your committee were held in New York City and one in Chicago during the past year.

The National Safety Council delegated Mr. F. M. Rosseland, Safety Engineer, of the Council headquarters staff, to attend these meetings, so that more intimate relationship could be maintained between your section and national headquarters.

It was deemed advisable that the number of bulletins relative to Public Utilities be increased if possible so that at least one bulletin be issued weekly covering sectional problems.

National headquarters was requested to prepare various Safe Practices pamphlets for use of the member companies, selected subjects being transmitted to the headquarters staff.

The value of holding membership in the National Safety Council, was a subject of much importance and with the view of increasing the section membership, the National Electric Light Association, American Gas Institute, and similar organizations were asked to address a letter to their members pointing out the advantages of such affiliations. National headquarters were requested to supply a list of available speakers to cover the subject of the advantages of "section membership" particularly.

The total membership of the section at present is 223 member companies. There were 26 new members and 15 cancellations during the current year.

As much interest is evidenced in various phases of industrial relations work, and it being an important factor, it was planned to compile a digest of available information for the benefit of members of the section. An attempt was made to gather information on the following subjects: Insurance, service, employment, training, annuities, profit sharing plans, employees' benefit associations, employees' representation.

The information desired concerned only the public utility companies, no attempt being made to cover the entire field.

We also wish to express our appreciation to Mr. C. W. Price, General Manager, Mr. Rosseland, Safety Engineer, and the staff at national headquarters for their co-operation.

CHAIRMAN MACLACHLAN: Mr. Niesz will present a report for the membership committee and tell us something that was done in getting new members for the section.

MR. H. E. NIESZ (Commonwealth Edison Company, Chicago): The membership committee has no formal report to make. We have been reasonably successful in retaining the memberships and securing a slight increase, although it did not seem opportune to make an extensive campaign for new members. We believed that a conservative growth was better during the times of stress for public utilities than the launching of an extensive membership campaign.

CHAIRMAN MACLACHLAN: I will now call upon Mr. Lueck to present his paper on "Accident Hazards in Laying Conduit Underground."

### ACCIDENT HAZARDS IN LAYING CONDUIT UNDERGROUND

H. W. LUECK, COMMONWEALTH EDISON COMPANY, CHICAGO

The laying of conduit underground if not properly supervised has almost as many hazards in connection therewith as any other mechanical work. In reality conduit laid underground can properly be compared with wires strung overhead. The conduit line represents the line wires; manholes, the poles, where transformers are installed and taps for service taken off.

Employees have suffered injuries caused by unforeseen hazards and a few public accidents have been noted, where curiosity more than any other reason was the cause. Before proceeding further into the reason for accidents, let us know definitely what conduit is and how it is laid.

There are several different types of conduit used by Public Service Companies, such as fibre, tile, and concrete. As the kind of conduit used does not have any material bearing upon this discussion, we will select that made of concrete. Concrete conduit is a cylindrical pipe, having an inside diameter of three and one-half inches and from three and one-half to six feet in length. This tube is made of a fine grade of concrete and molded to shape. Where the ends butt together a small sheet-iron collar

is placed to hold the alignment and prevent cement from getting on the inside of the tube. When one layer of conduit has been laid, fine crushed limestone and cement called "grout" is placed between each line. Special care is taken that the entire group of conduit is properly "grouted in" to make it a solid homogeneous mass, this to prevent the line from sagging and the communication of electric trouble from one cable to another in adjoining ducts. The conduit line is laid with a gradual drop toward the manhole for drainage purposes, and is never run through manholes, where the cables are encased in cement for protection from external and internal causes.

#### HAZARDS IN BREAKING CONCRETE

Hazards are present at all times during the laying of underground conduit, both to the employees and to the public. Most of the streets in cities are paved with asphalt, brick, or macadam. In any case a six or eight-inch foundation is necessary to support this road surface. As most conduit is laid in the street, it is necessary to break out this concrete which forms the greatest hazard to the employee and the public. The most important protection to the man doing any concrete breaking is the eye shield or goggle. Goggles should be worn by all men when breaking concrete. Secondly, properly designed bull point chisels, asphalt cutters and handles should be provided. A bull point chisel is a tool which is used for breaking concrete and must be held by one man while two or three others strike it with sledges. A properly designed bull point will penetrate and break concrete and throw few chips, while a poorly designed one will create a real hazard in this respect.

The asphalt cutter is a tool with a cutting edge of about six inches, a large head and a long handle and is used in the same manner as a bull point with the exception that it is used to cut asphalt. Bull points and asphalt cutters may be a hazard to the workman by the head becoming "mushroomed" from continual striking of a sledge. The burrs or chips which break off these tools have caused many painful and serious injuries. Properly designed handles for these tools are necessary to prevent workman being hit on the hands or head with the sledge. At this point it may be well to state that only by close supervision on the part of the foreman can such accidents be prevented. There should be frequent and regular inspection of all tools and those found defective should be sent to the shop for repairs. The Commonwealth Edison Company employs a blacksmith whose sole duty is to keep these tools in the pink of condition.

#### DANGEROUS TOOLS

After the hard concrete has been broken out, it is often necessary to use picks to break up the earth beneath the concrete. This tool also offers many hazards to workman, if allowed to become defective. Picks should never be allowed to become round on the end, as this retards progress and also causes accidents by slipping off and striking the man on the foot or shins. If pick is allowed to become short, and consequently unbalanced, it is hard for the workman to exert enough pressure to break

out a chunk of earth or concrete. Picks should be wedge shaped on the end. When men are working with them, the men should not be closer than six feet from each other. Men should at all times be warned when working near conduit lines containing power or telephone cables, water and gas mains on account of the danger of driving the pick into them.

As the digging of the trench progresses the excavated dirt must be thrown on the sides. This should be so piled that wooden or chain barriers can be planted thereon, to prevent children and others from accidentally falling into this trench. At night these trenches should be indicated by red lights, at regular intervals, so as not to confuse drivers of automobiles and other vehicles. A watchman should be at hand to keep lights burning and also direct traffic when necessary.

Sometimes large excavations are made at crossings for manholes. Many times these manholes are from eight to ten feet deep. Special precaution should be taken to place barriers around them, also have a watchman at hand while work is going on to warn children and others of the danger. Large excavations should be covered, barricaded or fenced at night. If the hole is of exceptional depth, a platform should be built in them to assist the men in throwing the dirt to the surface and the uppermost platform can be boarded up at night, which will materially decrease the depth of the hole during the period that the men are not working. Manholes at line intersections are usually located so as to avoid city water, telephone, and other mains which are usually laid underground. This is necessary as many times transformer installations and disconnecting devices must be installed in manholes and these must be operated from time to time. The elimination of other conductors and pipes is desirable so as to make the operation safe.

#### CONDUIT MUST BE PILED SAFELY

When the conduit arrives it should be placed on the ground nearest the point it is to be laid. It can be piled pyramidically, not over four feet high. By no means should conduit be leaned against convenient fences, sheds, or buildings. This is the cause of accidents when falling over, also damaging the conduit. Picks, shovels, bull points, and other tools should be placed in the tool wagon when not in use. They must not be thrown about at any time, as they cause stumbling hazards as well as make an unsightly appearance.

The actual laying of the conduit does not involve many hazards, as by the time this is done, most of the hazardous work has been completed. Just previous to the laying of the conduit the tubes are placed along the trench, so all that is necessary is to hand the length down to the brick layer who lays them in place. The laying of heavy tile nine conductor telephone ducts does not necessarily create any more hazards than the single conductor cement tube. The former is lowered into the trench by means of pick handles stuck in upper tube at either end and which make an excellent and safe method for lowering this large multiple conductor conduit into the trench.

The Commonwealth Edison Company in recent years has laid consider-

able conduit in parkways. This is the space between the curb and the sidewalk. When this can be done it is not necessary to break through concrete and other hard substances. This has reduced the number of accidents to both workman and public. When excavating in parkways the excavated dirt itself forms a barrier to prevent people from falling into trench and it can be seen that vehicle accidents are entirely eliminated.

#### PROTECTING THE HEALTH OF WORKERS

The mixing of concrete which always has been hard and back-straining work has found its solution by the use of a gasoline motor-operated portable concrete mixer. This can be moved from place to place as necessity requires. It does away with hand mixing, expedites the work, and thereby saves considerable hard labor and long hauls by wheelbarrow. Water sometimes seeps into trenches and manholes, which hinder the progress of the work. Gasoline motor-driven centrifugal pumps are used to remove the water, doing away with cumbersome hand operating diaphragm pumps. I mention these various tools because I feel that they materially reduced the number of accidents as well as doing many of the unpleasant and back-breaking tasks, heretofore done by the workman.

All men working in wet trenches and manholes should be supplied with rubber boots and coats to guard their health. The tool cart should be equipped with a first-aid box containing sufficient supplies to take care of any first-aid emergency.

In summarizing the accidents which occur in the laying of conduit underground, this work has contributed a small per cent of the total accidents occurring in the entire Commonwealth Edison Company. There are few public accidents which can be attributed to the laying of the conduit. This remarkable record no doubt was attained through the ceaseless efforts of the foreman by observing all safety rules, exercising constant supervision and keeping all tools in first-class condition, as well as making proper use of all safety guards and appliances.

The subject of this paper has been treated literally. Following the laying of conduit comes the pulling of cable and hazards in connection with such subsequent work have not been touched upon. The hazards in connection with the pulling of cables provides a special subject which has not been here considered.

CHAIRMAN MACLACHLAN: I will ask Mr. Rosseland to open the discussion on this paper. I want a very free discussion on the different papers—don't let us waste any time.

MR. F. M. ROSSELAND (National Safety Council, Chicago): I want to call attention, first, to the fact that the Commonwealth Edison Company has long been engaged in safety work and has its safety organization in a more nearly perfect stage, at least the educational work, than have other public utility companies.

That is not said to the discouragement of others, but simply because they haven't been carrying on their work as long. The result is that the low accident records you have heard do not reflect truly the accident hazard.

In using some of the machines that Mr. Lueck speaks of, that have contributed so much to reducing the hazards, some of our good friends have installed them in industrial plants with the result that some of the heavier parts of the machine have come down and injured workers.

Some of them haven't thought so much about the accident hazard to the public, with the result that they have left piles of dirt in conduit work, in some places, brick, where they are building the manholes, and other material of that kind, in such a way that they form a very tempting place for children to play, and even though the watchmen chase the children away before they are injured, they may disturb the condition of the pile so that someone else is injured later. I don't recall any serious accidents in that connection, but I do have a distinct recollection that in the operation of some companies, accidents have not been as few as Mr. Lueck reports.

MR. W. H. MULLIGAN (Hydro-Electric Power Company of Toronto): I think Mr. Lueck's paper is instructive, but I imagine that in certain sections of the country they must run into rock. What process is used to protect the public and the employees in the blasting of rock in the thickly populated sections of the country?

Another thing—a man would no doubt run into a certain amount of gas, and what course is taken at a time such as that?

I would also like to know if, when the men are holding the drills in breaking concrete, they use holding tongs.

MR. LUECK: We don't blast rock. We contract for that work and we have very little of it. I can recall only two instances where blasting was done.

In regard to gas, our trenches are not of such depth that we encounter gas. We force fresh air into the manholes, if that will answer your question. We force the air in rather than suck the gas out. We find that by forcing the air in, we back up the gas.

In the matter of tongs, we use handles which are permanently attached to the cutter, with ring handles, and these ring handles must be loose so that the jar is not on the man's hand.

MR. H. A. MOTT (Chicago Telephone Company, Chicago): In regard to blasting, I might answer that question. In small towns such as New York and Chicago, where it happens to occur, it is usually done with a canvas placed over it, no matter how small the blasting job may be.

CHAIRMAN MACLACHLAN: I will call now on Mr. Reid to present Mr. Fisher's paper on "Hazards in Line Construction—Handling Poles, Erecting Poles, and Reconstruction of Old and Antiquated Lines".

### HAZARDS IN LINE CONSTRUCTION, HANDLING POLES, ERECTING POLES, AND RECONSTRUCTION OF OLD AND ANTIQUATED LINES

FREDERICK W. FISHER, EMPLOYMENT AND SAFETY MANAGER, THE ROCHESTER  
GAS AND ELECTRIC CORPORATION, ROCHESTER, NEW YORK

Experience has proven that many accidents ordinarily occurring in line work can be prevented. This result is accomplished through an intelli-

gent conception of the risks involved, the employment of physically and mentally high grade men, and the use of first class equipment, safe methods, and the right amount and kind of accident prevention education.

Line gangs as a rule are made up of a superior type of workmen. They are physically hardy, accustomed to danger, have positive convictions and are especially keen to detect and resent insincerity, inexperience, and canoufrage. To a greater extent than in any other occupation linemen respect their foremen and seniors. Line foremen in general are of large mental calibre, are poised and deliberate, and secure discipline, efficiency, and safety through character and by example. Line gangs in general understand very thoroughly the risks of their occupation, and, consequently, since the great majority of accidents are due to the personal equation, an analysis of the accident problem relative to them should be exceedingly practical.

Linemen must be trained in the school of experience, and regardless of professed previous training, experience, or other qualifications, must be tried out in the subordinate positions of helper and groundman under the eyes of the foreman, before being allowed to work on poles or live apparatus.

Linemen are subject to two major risks, i. e., falls and electric shocks. Their work, however, has many serious incidental risks which in some degree are shared by workmen in other fields. Accidents due to the use of tools and materials are numerically the largest, but the electric current and falls constitute a very much greater hazard from the monetary and humanitarian point of view. The latter accidents, although comparatively infrequent, are generally very serious. Under various subheadings the hazards will now be considered.

#### TRUCKING HAZARDS

Trucks should be of adequate capacity and kept in first class condition. Accidents are caused by overloading and improper loading, by defective truck mechanism due to design, age, or wear, by defective pavements resulting in broken springs, steering gears, knuckle joints, etc., and by fast and careless driving. Automobile driving is daily becoming more dangerous, requiring chauffeurs who are experienced men and who drive carefully and slowly, so as to avoid the accidents named, and avoid jolting the linemen from the truck or causing accidents to pedestrians and other vehicles. It is essential that drivers be furnished with copies of the State and local traffic laws and ordinances, and strict compliance with the same must be enforced. Accidents will be avoided by the observance of the ordinary courtesies of the road which have not as yet been formulated into law or ordinance, drivers being instructed not to stand on their legal rights but to watch out for careless driving on the part of others. The loading of trucks should be orderly, all tools being kept in proper places, and all line material properly piled or lashed in place. Serious accidents have been caused by material being

jolted from trucks due to improper loading or to rapid driving over poor pavements.

Ladders projecting forward may cause accidents by tripping the chauffeur when leaving the driver's seat and a danger flag or red lantern is required on ladders projecting in the rear. Ladders hung on the side of the truck should be placed in substantial brackets at a height easily reached and with the spur end in front out of the way. The truck equipment includes gloves, shields, rubber boots, rubber coats, climbers, insulated hand tools and a first aid kit.

The ordinary first aid kits on the market have not proved satisfactory for the work of the Rochester Gas and Electric Corporation. A special kit has been developed consisting of a substantial hard wood box, the interior of which is divided up into compartments of suitable size to contain bandages, adhesive tape, tubes of burn ointment, etc. Bottles containing liquids such as iodine, boric acid, etc., are held in spring clips inside the cover of the box. The box cover is fastened to the body of the automobile. The box opens down and being held in a horizontal position by a chain forms a working shelf.

#### HANDLING POLES

In unloading and piling wooden poles either in the yard or on the job, hazards are created by piling the poles too high and through the improper use of blocking. Unexpected rolling must be carefully prevented. Poles must not be piled against fences or back stops of light construction. Bruises and broken bones may result when moving poles with cant hooks, as crooked poles are unwieldy and roll in unexpected ways. Poles left on the job require guards unless rolled well beyond the street line, as pedestrians and trucks are apt to run into them. New poles are subject to dry rot and should always be tested before erection.

When trailers are used for trucking long poles, great care is necessary in turning corners, and linemen must not be permitted to ride on the pole or trailer.

In unloading poles from cars they must be taken in logical order to avoid rolling or dropping other poles than the one being removed from the car. Sometimes due to shifting in transit poles are wedged and require extra care in handling.

Many companies now make their own concrete poles and many manufacturing risks are involved, among which are those due to the machinery used, such as concrete mixers, cranes, and hand tools. Proper machinery guards are necessary in all cases, and manufacturing methods should be employed which will reduce as much as possible abrasions and bruises from handling forms, reinforcing metal and stay wires. Care must be exercised that the design is sound and that the concrete is well mixed. Green poles must not be used.

#### ERECTING POLES

In erecting poles it is necessary to have good team-work in the gang so that the men will reinforce each other and prevent hernia and strain

due to excessive lifting. Serious accidents have occurred through the pole jennys or dead-men being pushed beyond the center of gravity of the pole, causing the top to tip to the ground when the pikes were removed for a fresh hold. Derricks, wagons, gin poles, pike poles, etc., must be in good condition and carefully used.

Pole gangs should be of adequate size. While it is possible for four men to erect wooden poles in emergency, a larger force adds a very necessary element of safety in the work, especially when poles are erected through wires or branches of trees, in fence corners, near building, or under any other restricted working conditions.

In erecting concrete poles a minimum force of 8 men is necessary and great care is required in piking the poles that the pike does not slip off the surface of the pole. To prevent side tipping the pole hole should be dug with an entering trench about the width of the pole and two feet deep, through which the pole slides into the hole easily. Substantial and easy running rollers assist materially in handling poles near the holes, reduce the risk of bruises, and the danger of hernia from heavy lifting.

Removing poles is considerably more dangerous than erecting poles, as the ground offers a resistance difficult to anticipate. Danger occurs through the grounding of pikes while stones are dislodged in the hole, as a sudden shift of the pole renders it impossible to release the pike. Jacks are used to raise the pole from the hole and bruises are caused by the jack or chain slipping, and by careless manipulation of the jack lever.

A bad tripping hazard is created by the careless dropping of tools on the ground during work on poles. It is of course not practical to keep all tools, ropes, etc., out of the way as their use is intermittent. It is possible, however, to use some system in this work and to return tools to the line truck as soon as the men have definitely finished with their use.

#### DIGGING POLE HOLES

In digging holes all stones over which workmen could stumble should be removed before work is begun, and the stones taken from the hole thrown well out on one side. Dynamite should not be exploded by the use of dry batteries when digging holes in rock. There is danger when dry batteries are used of carrying batteries, caps, and dynamite together and short circuiting the batteries through the cap wires. A magneto machine, while somewhat more costly, is very much safer.

#### ERECTING CROSS ARMS AND WIRES

In putting up cross arms and wiring the use of first-class equipment is absolutely essential, especially ladders, belts, and climbers. Material and tools should be raised and lowered by suitable hand lines and bags. Ladders must be kept in good condition, be equipped with spurs and carefully placed. In pulling up lines, care should be taken that the ladder has sufficient top support to compensate for the side pull. This is especially necessary in making house service connections where the

ladder leans against the house. Belts should be worn while working on poles and while trimming trees. Great care is necessary that tree branches do not fall on other lines or fellow workmen. Slack transmission and guy wires sag and create both a Company and a public hazard.

#### ERECTING TRANSFORMERS

Transformers of large size are often erected on pole platforms and special care is required in passing up the lumber for the platform, and in all other work done. Platforms must be substantial and have suitable guard rails. All the tackle and rigging used must be of adequate strength and kept in first-class condition. Transformers fastened to cross arms must be carefully bolted in place.

#### WORK ON LIVE LINES

Work on live lines is necessary at times, and special care must be exercised in the use of gloves. Gloves require testing in the laboratory periodically, and before use in each case by rolling up from the wrist toward the finger tips. The confined air is thus put under pressure and will in escaping show up holes. A medium weight rubber glove inside a buckskin glove is the safest and most satisfactory combination, the buckskin glove protecting the rubber glove from abrasion. Insulation must never be trusted even when new, and all live wires in the immediate vicinity of the linemen at work must be carefully covered with shields to avoid accidental contact. In the eastern states it is considered dangerous to work on circuits of more than 2200 volts alive, except changes which do not involve splices.

The erection of new circuits adjacent to live lines has a bad accidental contact hazard, and in putting up the new line the men should wear rubber gloves whenever there is a possibility of the new line becoming alive by accidental contact. This is especially true where a new line is dragged across a cross arm supporting a live circuit.

The safe rule is of course not to work on live circuits, except when it is absolutely necessary to do so, and in such cases to use every precaution which has been developed. Many companies by the use of special rods and other appliances do change insulators and do other work on very high-tension lines with comparative safety. Men must be carefully coached for this work and thoroughly supervised. The equipment must be of the highest grade and kept in absolutely first-class condition.

The use of a grounding chain on high-tension circuits which are being worked dead is absolutely necessary, and this should be made up of round links of either brass or copper, as iron chains rust and make poor electrical contact. This chain should be grounded in all cases.

#### OLD LINES

In the re-construction of old and antiquated lines, special attention must be given to testing poles for rotten butts and poles of doubtful strength must be securely guyed before the supporting wires are cut.

Safety belts must never be fastened to cross arms and braces, but around the pole itself. The lag screws supporting cross arms and braces are apt to pull out of old poles. The use of belts on concrete poles shortens their life due to abrasion, and they require more frequent inspection and repairs. It is especially necessary when working on old lines to avoid contact with guy wires, cross arms, braces and other metal, as serious burns and fatal accidents have resulted from leaking current.

✓ Poles with rotten butts, poor ground support or few supporting wires should be steadied by three pike poles placed against the pole at an angle of about 45° and forced to a good bearing in the ground. The linemen can do their work quicker and easier and an additional factor of safety to prevent the pole falling is secured.

With concrete poles special attention is necessary that the pole is fully set, as the removal of supporting earth due to grading will not be as obvious as with a wooden pole. Concrete poles should have a prominent ground line mark cast in them when made.

In changing over lines, either on new poles, cross arms or insulators the wires must be carefully moved so that they will not swing into contact between the poles and short circuit the line.

#### DESIGN ELEMENTS

Many elements of design minimize risk, especially adequate clearance between wires. In some cases it is almost impossible for the linemen to go up through a series of circuits on a pole containing buckarms without coming in contact with some of the wires. Ground and fire alarm wires and cables should be covered; cables, transformers, switches, etc. should all be either on the front or back of the pole as a standard practice. Phases should be labelled especially at cut-outs. Telephone boxes on high-tension lines must be well insulated and an insulated platform on which a man must stand when telephoning must be provided, to avoid shock from grounds, static, or lightning.

In many cases poles are used jointly by power, telegraph, and telephone companies, and standards for the work of each must be agreed upon in advance and carefully lived up to. The question of responsibility for repairs should not be side-stepped.

#### RESPONSIBILITY OF STATION OPERATORS

The responsibility of station operators in preventing line accidents is very great and an adequate system for reporting trouble, killing circuits and making circuits alive must be lived up to. When a line is killed both the switchboard and the jack switches should be pulled.

#### STEEL TOWER LINES

The erection of steel tower lines is essentially an iron worker's job, and has the customary iron worker's hazards such as falls, bruises, strains, etc. The erecting equipment must be carefully inspected for

wear, and must be adequate for the work required. This work involves particularly stumbling and lifting hazards, and increases trucking hazards due to the inaccessibility of many of the tower sites. In the erection of large towers constructed of heavy members, the use of steel cable rather than rope on the erecting equipment is advisable.

#### SAFE PRACTICES

All wires whether insulated or not are to be treated as alive. Insulation exposed to the weather soon loses its insulating properties and becomes valueless.

In pulling disconnecting switches, especially the expulsion type fuse boxes, and in fusing as a test for burned-out transformers, goggles and gloves are necessary to protect the eyes and hands from flashes or contact.

Grounds are a common cause of accident both on grounded and ungrounded systems, and are especially to be avoided. In case of burned out transformers on a non-grounded system, there is great danger of full primary voltage on the neutral.

Accidents increase through fatigue and hence foot strain which may result in flat foot must be avoided by the use of shoes with a heavy in-step. Men often become unreasonably tired through standing on climbers. Fatigue also results in lessening of attention, and a failure to use safe methods which require extra effort. The spurs of climbers must be kept sharp and of proper length. Sharpening should be done by filing on the inside of the spur point. When points are worn down it is better to buy new climbers than to fit in new spur points.

Work in stormy winter weather adds other hazards as broken wires usually are alive, many times at high tension. This applies to telephone and telegraph wires as well as power wires. Patrol work also has its dangers, particularly in time of storm. Two men should constitute a patrol gang on windy nights, as one man is required to hold a heavy extension ladder in the wind. It is more difficult to work in heavy clothing and when one is cold, consequently frost bite and colds due to exposure are more common in cold weather, and the danger of falling due to numbness of the body greater.

Cable reel lagging when removed from the reel almost always contains nails which are dangerous for linemen, pedestrians or others who may be near the reel. When reels are stored they should be securely blocked so they cannot be rolled around by mischievous boys.

Pole steps create falling and other hazards. If the steps are placed low enough to the ground to be reached without a ladder, inquisitive boys are encouraged to climb the poles. When placed sufficiently high to be out of the reach of boys, the linemen must necessarily get up on the pole either by ladder or by the use of climbers. Many men have been injured by using a fence or box to reach the lower step. Steps sometimes break and hence this possibility must be kept in mind when climbing poles equipped with steps.

Some transmission line work is especially heavy and done in the vicinity of railroad crossings, harbors, and improved highways. This introduces additional public hazards caused by dropped tools, loose wires and wires sagging between poles. Special attention must be given these causes of accident to prevent children or other interested by-standers from becoming injured.

#### GENERAL CONCLUSIONS

In all line work there is naturally a right and wrong way to do everything. Simple illustrations of the wrong way are pulling a cant hook in such a manner that if the pole suddenly rolls the workman will be thrown to the ground, walking backward when paying out wire and increasing the stumbling hazard, melting solder and doing other work directly beneath other workmen on the pole where a dropping tool or part would fall, wearing climbers when traveling from job to job, etc. These unsafe practices must be discountenanced upon every occasion. The regular inspection of belts, gloves, climbers, and other equipment is one of the essential safe practices which must be rightly observed.

As in other lines of work it is the unexpected that happens. We know in a general way the major causes of accidents to linemen, but each accident case is usually a little different from any other case in the contributing causes or combination of circumstances. The solution seems to be a more thorough spread of the Safety spirit which stimulates workmen to anticipate trouble and possible sources of accident or injury. This spirit can be cultivated only by a policy of absolute frankness and by a willingness on the part of any management to spend money for good tools, equipment, and the necessary safeguards. One of the best methods of keeping up interest in safety is through a frank discussion with the linemen of a paper similar to this one.

The newest method of stimulating interest in accident prevention in the Rochester Gas and Electric Corporation is through a statistical analysis of accident costs, whereby departments are rated on the same basis. In brief the accident as taken from the insurance reserves is equalized for size of department, character of work done, and type of workmen involved by dividing by the departmental payroll. This furnishes a pure premium which is equalized for risk by dividing by the insurance rate. The resulting figure provides a standard of comparison indicating to some extent where concentrated safety work is necessary. Costs based upon production units are scrutinized with much interest by many of the members of the various departments for which such figures can be given. The cumulative rating of the Electric Distribution Department of this Corporation for the period January 1, to August 1, 1920 is 2.43 in comparison to a perfect score of 0 achieved by several of the power houses and the worst score of 45.84 for the office employees having outside work.

Nearly all of the hazards enumerated, together with their remedies have been well understood for years. Many closely related subjects have

not been considered as they already have been adequately treated by others and may be referred to in the published records of the National Safety Council, the National Electric Light Association, and elsewhere. Among these are standard methods of testing rubber gloves, resuscitation, the recognized machinery for accident prevention education, statistical data, etc.

Acknowledgement is here due to other writers and especially to the Line Department of the Rochester Gas and Electric Corporation, the members of which have freely criticized the original paper and furnished many supplementary suggestions of great value.

CHAIRMAN MACLACHLAN: When we appointed Mr. Fisher to write this paper, we knew exactly the type we would get, and I think we are perfectly satisfied with the results.

I will ask Mr. Foster of the Philadelphia Electric Company to open the discussion on this paper.

#### DISCUSSION

MR. WILLIAM FOSTER (Philadelphia Electric Company, Philadelphia): There is one question that has not been touched upon—the question of men being hurt on the wagons because of riding on the tailboard and being shaken off, or by sitting on protruding ladders and being shaken off. I find also that men have been hurt in unloading wagons, where the wagons were stopped on a sliding grade with small blocks, with the result that when they took off some ropes or something else, the reels rolled off. The question of transformers, particularly in wagons, is a very serious one. They are very heavy and hard to handle. We have tried to solve the problem, and I think with a great deal of success, by the installation of a traveling crane, which permits us to put the transformers up on the wagons and instead of the men skinning their knuckles and upsetting these heavy objects on their feet, etc., they merely take a small chain, raise the transformers up, and shoot them on to the wagons.

In the question of raising and lowering the tools, it has been the habit for years, as you all probably know, to tie the tools on the hand lines with a half-hitch and slip insulators in, and all that sort of thing, and if the fellow hadn't hitched them right, they came crashing down. That has been solved by the use of canvas bag which is used for its insulating features. I have seen some use metal containers for raising tools, but I don't think that is very safe.

The question of the first aid kit is one that I do not believe we have given enough attention. We feel satisfied in having equipped our wagons with the kits, but the thought arises in my mind as to what we have done in instructing men in the proper application of the various things in the first aid kits, the bandaging of wounds, etc. These are important topics.

In connection with the unloading of poles on highways, in order to prevent them from rolling over from curbs and hitting pedestrians, that is somewhat overcome by the use of a couple of blocks which will prevent them from rolling too far. At night a red lantern should be placed on each

end of the pole rather than in the center. In the transportation of poles on trucks, we have found it to be a good thing to place a red flag on the back end.

#### OTHER SAFE PRACTICES IN LINE CONSTRUCTION

In erecting concrete poles, we found it to be a good thing to place boards one inch thick, securely fastened to the side of the poles, so that our pike does not slip off the surface of the pole. Thus, we can erect concrete poles with about the same facilities as are used for wooden poles.

We use a butting board in all our holes where it should be used. That prevents the cutting out of the side with the butt, or the enlargement of the butt on rock, if you are in rock ground.

The question of using dynamite is an important one. It is always important that the storage of dynamite be designated at night time. We store dynamite by digging another hole in the ground about three or four feet deep, placing our dynamite in that hole, taking a chance on whether it gets wet or not.

In trimming trees, we have our tree gang in the trees and send two linemen along with them. The linemen are stationed at adjoining poles for the purpose of cutting the wires if they find the wire is becoming entangled, or if there is danger of the wires breaking.

In the question of rubber gloves, I believe that in addition to rubber gloves we should supply the men with talcum. I know that a great many men hesitate about putting on rubber gloves on a hot day, when their hands are warm and the gloves are hard to get off. I think if you will let the man have talcum it will be more of an incentive for him to put on his rubber gloves, because it is easier for him to get them off.

In stripping old poles, it should be mandatory to place pikes against the old poles. Those pikes should not be the smallest pike we can get on the highest pole. Judgment should be used there.

The question of supporting poles can be solved to a great extent by the use of extension arms rather than the buck arm. Extension arms can be made just as strong and are a great deal safer.

The question of dropping tools is one that is being experimented with now and the inverted tent is being tried out. This is a piece of canvas tied around the pole, the four ends of it being shot out at an angle of 45 degrees and supported by pikes.

It is a good idea to let your men know how much it is costing for accidents. It is just as good an idea, I think, to divide your crews up into classes and hold out a prize for a certain class; give your men a record of the class they are in and acquaint them with the conditions and statistics each month and pit one against the other.

MR. CHARLES B. SCOTT (Bureau of Safety, Chicago): I feel such an interest in this subject that I want to take up your time for a few minutes' discussion.

To my mind there are two points with reference to the safety of line work that need to be emphasized. I think one of them is stated in the paper that was read, contrary to my own opinion of the subject. As I remember it, Mr. Fisher says that in the line department there is a

greater appreciation of supervision and discipline than is usually found in other departments. I take issue with Mr. Fisher on that—my observation has been that there is a greater laxity of supervision and less enforcement of rules in the line department than in any other department of this business.

I believe that a great many of us are having a large number of line accidents which are nearly always serious, and which constitute a very large part of our accident costs, because we have no fixed, definite, written, enforced, and obeyed rules in the line department, and if any of you want my idea as to how you can best bring results about in your line department, I recommend that you have fixed, definite rules, and I also recommend that you see to it that those rules are enforced and obeyed. Until you do that, until you get within your line organization a proper appreciation of what correct supervision, what close supervision is, and what the enforcement of rules of the company means, you cannot do much in carrying out the splendid details that are suggested by Mr. Fisher.

One more point: The first is rules; the second is safety appliances. I believe that 90 per cent of the accidents in the line department are due to the failure to use the safety appliances provided. I was glad that Mr. Foster said that it was not sufficient to give a man a pair of gloves—it isn't sufficient to give a man a pair of gloves and to write in the rule book that that man must wear the gloves. You have only done your full duty and protected yourselves when you know that you have a foreman who sees to it that the man does wear his gloves. I believe that if there are any two things more than anything else that will reduce the fatalities, the accident costs, and solve the accident problems of the power and distribution companies, they are embodied in these two suggestions: First, that you have real rules, that you have your supervisory force enforce them, and that you have your men obey them; second, that you not only provide safety appliances, but see to it that they are used.

MR. E. C. CARPENTER (Northern Ohio Traction & Light Company, Akron, Ohio): The suggestions offered in Mr. Fisher's paper, and those offered by Mr. Scott, are quite practical, but there is one very vital proposition that to my mind has not been suggested, and that is how to get the employee to do the things that you want him to do. We formulate rules, we make requirements, and we tell the foreman to do so and so, but will the employees do it?

Just as an illustration: Within the week I have had sitting across from my desk a man who has had more than fifteen years' experience as a lineman, and who was considered a reasonably safe employee. He has been up poles, has helped to take down men apparently dead from electric shock and has helped to resuscitate them; and yet, later on this man, himself, failed to do the thing that he has told others to do, and that he has been told to do, and he gets grounded with a 2300-volt circuit with the result that he now has hooked hands and fingers that are practically useless.

How will you get instructions to the men so that they will obey them? That, to my mind, is a very important proposition, and one to which we should give attention. Rules are all right, but if they are not enforced,

we are going to have these hooked fingers and hooked hands and dead men to take care of.

MR. C. H. STEWART (Laclede Gas Light Co., St. Louis, Mo.): The same question has arisen in my mind. We have had two fatal cases within the last year and a half, both with men who failed to wear their gloves. In one case, the men were changing cross arms on the corner pole, a heavy pole, carrying an enormous lot of wires—not only the wires of our company but of other companies, telephone wires, and city wires. They were changing the 5000-volt line. Double cross pole men working in pairs untied the line, hooked it up on a block of cable, insulated, and it ran in front of this man. A dead alley circuit that was grounded—it did not belong to us—was there, and this man, within five or six seconds after untying this line, took his gloves off and was dead. All we knew was that he was badly burned on both hands, and it happened so quickly that nobody on the pole with him could give an accurate description of just what occurred.

In this particular case the men used metal blocks to raise up the line on account of being in close quarters. I would like to hear some discussion on the question of all metal blocks as compared with the combination of wood and metal blocks.

I have talked to our superintendent of construction and he advocated metal blocks in this particular location on account of the confined space the men had to work in, and because in snubbing up, they could snub closer.

We felt that the man who was killed was absolutely negligent in taking off his gloves and that if he hadn't taken them off he would have been alive today. This man had had ten or twelve years' experience, like the employee referred to by the previous speaker.

In the other case, a man handling a 2400-volt line took his position on the pole with his climber almost piercing a ground line carried down to the ground with a cable. This man had no gloves on at all. He had gone several pole lengths away from the wagon (they were stringing up a new line, taking down an old line, and putting a new cross arm up on this pole) when they heard the sizzle and flash and looked up to see the man hanging from the wires, practically dead. We found this man's gloves in his tool kit in the truck.

We felt that both of these cases were cases of negligence, but I would like to hear the experience of others on this question of enforcing rules. You can make rules until you are black in the face and you may have foremen who try to enforce these rules, but the foremen can not be standing with every man all of the time.

MR. HERMANN SPOEHRER (Union Electric Light & Power Company, St. Louis, Missouri): I want to say, in answer to Mr. Scott regarding the enforcement of rules, that we found on analysis of some of our accidents that invariably the foreman was busily engaged in writing a report of some kind and wasn't supervising the gang. We have now relieved the foreman of some of that clerical work and amended our bonus scheme so that each gang is affected financially by such an accident in that gang.

Among themselves, the men will not tolerate an infringement or infraction on those rules.

MR. J. C. MARTIN (Western Editor, Electrical World, Chicago): There is one thing that I believe the men do not pay enough attention to, and that is the design of transformer mountings on your poles. At best, clearances are small and too often it is left to the lineman to say how it should be done, and usually you find that he messes it up and doesn't give it near the study that can be given it.

I know from experience, that on transformer poles at least twice the space that is usually found can be given if the design is properly studied.

MR. W. C. BERRY (Commonwealth Edison Company, Chicago): There is one point that has not been brought out and that is the hazard to the public. We have a number of places where circuits are grounded and boys have ascertained that there is a leak there, possibly only 60 volts, and have attached wires to it and horses passing through the alleys have been killed. A clay foundation seems to form a slight insulation around the ground rod and this makes a permanent hazard to the public.

MR. CHARLES B. SCOTT: There are companies that have enforcement and obedience of rules; there are many companies that believe it is impossible to have enforcement and obedience of rules. The companies that have rules enforced and obeyed are the companies whose executives make safety a matter of co-operation. They are the companies where the manager gives the superintendents and foremen to understand that these rules must be obeyed, and where the foremen and superintendents know that if they are not enforced they lose their positions. The men who obey those rules are the men who come in contact with superintendents and foremen that make safety a part of their supervision, who really and truly are safety men and good superintendents and foremen, and who fire the men who do not obey the rules. The whole question of the enforcement of rules resolves itself into the spirit of the organization, and it begins with the man who has the biggest title on the problem.

CHAIRMAN MACLACHLAN: I am sorry to have to stop this discussion.

One matter that I haven't taken up yet is the appointment of a nominating committee. I am going to appoint a personal friend of mine as chairman of that committee—not because he is a friend of mine but because I think he knows the situation a little bit better than any other man in this section does—and I am going to ask Mr. Charles B. Scott of Chicago to act as chairman, and name with him Mr. Mitchell, representing the gas interests, and Mr. Mott, representing the telephone interests, so that we may have the power, gas, and telephone interests represented on our nominating committee, and our officers for the ensuing year fully represent the public utilities.

There is one question that has not been placed on the program, and that is the question of resuscitation from electric shock, gas poisoning, and drowning. I am going to take up a few minutes of your time for consideration of this question and I shall be pleased if Mr. Reid will open the discussion.

## THE PRONE PRESSURE METHOD OF RESUSCITATION

S. H. REID, BUREAU OF SAFETY, CHICAGO

The question of resuscitation has been presented to this body a number of times. I think it has been demonstrated at some of the meetings.

You will recall that the National Electric Light Association, through a resuscitation commission, studied this subject very thoroughly, and no doubt most of you have read the final report of that commission. Those who have read it will recall that the commission recommended what we now call it "prone pressure" method of resuscitation, and recommended that any mechanical devices which may be on the market either be sent to the scrap heap or confined to the use that they might be put to, in hospitals, or in the hands of trained operators. And if I understand the spirit of that report and the recommendation that was made, it means this—that no electric light company should have in its possession, around its power houses or anywhere on its property, any mechanical device for the purpose of resuscitating men who have received an electric shock. Now, there are many reasons for that, and I shall mention two or three.

In the first place, if the mechanical device does everything that is claimed for it, it has the disadvantage of being away off somewhere else at the time when it is needed when the emergency arises. That is one very serious objection to it.

Another is that if the mechanical device is in sight the men do not practice the manual method, but they depend upon the mechanical device, and, therefore, they are not equipped to meet an emergency which may arise because of an electric shock.

I know of one case which happened a short time ago, where a man received an electric shock and inside of less than a minute the linemen had that man down on the ground. They knew their business and immediately went to work, but before they got very far somebody came along with a mechanical device, and they lost about ten minutes in getting that thing adjusted. Part of the apparatus was out of order and it would not work. I shall always believe that that life was lost because they stopped for ten or twelve minutes and tried to resuscitate him with a mechanical device.

### MECHANICAL DEVICES FREQUENTLY OUT OF ORDER

That is another good reason why we should not depend upon a mechanical device. It is stored away somewhere and nobody is put in charge of it or takes care of it to see that it is kept in proper shape to meet the emergency when it arises, with the result that when the emergency does arise, the device is brought out and a piece of hose is gone or something else is wrong with it and another life is lost.

Now, the only thing for the people in this business to do is to see to it that every employee is versed in the manual method of resuscitation. Employees should not only be well equipped to handle such emergencies, but they should also be taught not to get out of the way and give up their time for any mechanical device somebody will bring along.

Sometimes those mechanical devices are kept in the fire departments

and they rush up, and then the fellow who is not a doctor but a lineman is pretty apt to give way to the fellow who knows less about it than he does. That is another thing that should be taught to the lineman—that he is not to give way for anybody.

I know of a case where a man went to work—he was alone—on a man who had had an electric shock. In about five minutes two doctors came along, and unfortunately (not casting any reflection on the medical fraternity) they did not know what this man was doing, but all they could see was the froth coming out of the patient's mouth and they said, "Get off of that fellow, or you'll kill him," but the man kept right on working. Then one of the doctors reached down and again told him to get off or the fellow would be killed. The lineman stopped just long enough to take off his coat, used some language that I do not want to repeat in the presence of ladies, and said, "I have charge of this patient and when I get through with him, you can have him." The company physician, however, saw that the lineman was doing everything he could, and inside of thirty minutes the patient was breathing, and when I saw him he was none the worse for the experience.

I know of another case where men depended upon a mechanical device and the thing was out of order. These are two cases I positively know of where the mechanical device was out of order. So, the only thing to do is to train your employees in manual resuscitation.

It's a big job to train four or five thousand men, as the Commonwealth Edison Company does, but for the most companies it means the training of from fifteen to fifty men, and that is not too big a job if you want to save the lives of the men who come in contact with the wires.

There is just one remedy that I would prescribe and that is to train all of your men so that they will be competent to deal with the emergency when it arises.

#### DISCUSSION

CHAIRMAN MACLACHLAN: You have heard the side presented by Mr. Reid of the advantage of the manual method. I would like to hear somebody speak of the advantages of the mechanical method.

(No response.)

CHAIRMAN MACLACHLAN: That is about the answer I expected.

I was told, when I presented this matter to the Executive Committee that it was a personal opinion. I knew the feeling of the public utility men of the United States and Canada and I think that our position ought to be placed before the Executive Committee this afternoon in the form of a resolution, so that they can be aware of what they are doing. I don't think they are aware of it at the present time.

MR. CHARLES B. SCOTT: I offer the following resolution:

"RESOLVED, That the Public Utilities Section of the National Safety Council in session assembled, express as their undivided opinion that the prone pressure method of resuscitation is the most effective method of resuscitation in electric shock, gas poisoning, and drowning;

"That the use of mechanical devices should not only be discouraged but should be prohibited;

"That all companies having the electric, gas, or drowning hazards should train their employees in the prone pressure method."

(This resolution was seconded and adopted unanimously.)

MR. J. J. O'CONNOR (Peoples Gas Light & Coke Co., Chicago): I might say at the present time that the managers of public utilities have an excellent opportunity to take advantage of the training that their young men who have now returned from the Service received in the army. All those young men (and about 50 per cent of your employees, at least, have been in the army) have had hammered into them, two or three times a week, first aid training and resuscitation. If you take advantage of the opportunity to use those young men as a nucleus in your training, I think the lessons that Uncle Sam has taught them will be of benefit to the public utility business.

CHAIRMAN MACLACHLAN: The next paper we have is by R. S. Carter of the Malden and Melrose Gas Light Company, on "Accident Hazards in Laying Gas Mains."

#### ACCIDENT HAZARDS WHEN LAYING GAS MAINS

R. S. CARTER, SUPERINTENDENT, MALDEN AND MELROSE GAS LIGHT COMPANY, MALDEN, MASS.

Accidents when laying gas mains may result in injury to employees, or to members of the public. These accidents can be largely prevented by consistent and systematic instruction and education on the subject of accident prevention.

Carelessness, the cause of many accidents, seems to be an inborn trait in all men engaged in hazardous occupations, and many times it reaches a point where familiarity with the risk causes a sort of scorn and contempt that many times results disastrously. Probably you have in mind a case where an employee has witnessed a serious accident to another, and maybe he has gone through the pain and inconvenience of one brought about by his own carelessness, but has not profited by the experience.

It has been estimated that from 30 to 50 per cent of industrial accidents can be prevented. The greatest preventive is *carefulness*. It brings its own reward in a marked decrease in the number, and in a reduction of the seriousness of the accidents not altogether to be avoided.

Certain industries include operations from which danger can never be entirely eliminated, and I think the work of laying gas mains comes in this class.

#### DANGER OF GAS POISONING

One of the greatest hazards when men are laying gas mains is the possibility of gas poisoning; and while the percentage of accidents from this cause is small, it is always before us, and must be carefully guarded against. Accidents of this nature occur when connecting new work to existing live gas mains.

To guard against gas poisoning, we use respirators that can be worn with comfort when men are obliged to work in the presence of gas. It has been our experience that equipment of this sort must be carefully

investigated before it is turned over to workmen for use. If a man has no confidence in the respirator or mask he is told to use when going into a gas filled trench, it is next to impossible to impress upon him the necessity for wearing the safeguard, and it is not unusual to find him "taking a chance", with the odds against him when working in a most hazardous place.

ILLUSTRATING THE USE OF THE RESPIRATOR  
THE EMPLOYEE IS ABOUT TO REMOVE A GAS MAIN STOPPER SECURELY WEDGED  
IN A 10-INCH PIPE

Also if an employee is exposed to a danger of this sort, a life belt and rope should be buckled around his waist with a man holding the rope so that in the event of an emergency, it would be possible to pull him out of the trench.

In all cases of accidents, the suffering, inconvenience, and interference with a man's regular line of work is so great that when an analysis is made of the cause, many could be avoided by following instructions and precautions. The results furnish a strong argument in favor of practicing care and caution in the performance of our daily work.

Preventive measures when furnished should be used. They make first-aid treatment unnecessary.

#### USING THE GAS MAIN STOPPER

In the illustration above I referred to a gas main "stopper". This piece of equipment is used to stop temporarily the flow of gas while con-

nections are being made. When working on small size mains, a rubber bag is used to stop the flow of gas, and as an extra precaution, when laying large mains, say from 10 inches to 30 inches in diameter, a canvas-covered bag is used together with a stopper. Cloth or canvas-covered bags retard the solvent action of oily water found in some mains which is very detrimental to rubber.

It can be readily appreciated if a bag or stopper should collapse from any cause when the main is open, a most serious and dangerous situation would immediately develop.

Handling this part of gas main construction work is particularly hazardous, and invariably we find men who believe they are immune from gas poisoning, and expose themselves unnecessarily to the action of the fumes.

When service pipes are installed, it is necessary to tap the main pipe preparatory to inserting the screwed fitting from which the service pipe will run. Many times the threads on service fittings and pipe are defective, and do not readily "make up". The gas will escape during the time the man is trying to screw the service fitting into the main pipe. If he remains too long at this task with the gas leaking around the fitting, he is running a great risk of being overcome. All threaded fittings should be examined before they are used, to determine the condition of the threads.

#### WHAT TO DO IN CASE OF GAS POISONING

When an employee is overcome by gas, it is important that his foreman and fellow employees on the job should know what to do, and how to handle the victim. To this end, frequent instruction in the prone pressure method of resuscitation should be given. Mechanical apparatus designed to assist respiration has its place, and when used by parties familiar with its operation, will do effective work. It is our belief, however, if all our employees are familiar with the prone pressure method of resuscitation, they are always prepared to meet an emergency, and render first-aid until medical assistance can be called.

Other accident hazards that exist when laying gas mains may be enumerated as—caving in of trench, defective tools, pouring hot lead in pipe joints, blasting, flying particles of iron when cutting pipe, tripping over loose material lying around, lack of, or poorly constructed barricades for enclosing street openings, and the absence of danger signs and lanterns.

The caving in of trenches occurs frequently in sandy and wet soil. This hazard can be overcome by close-sheathing both sides of the trench and firmly bracing it with strong timbers running lengthwise and crosswise of the cut.

It is better to close-sheath an excavation than risk the possibility of a cave-in.

Both sides of the trench are close-sheathed with boards braced with heavy timbers. The possibility of an accident from a cave-in is reduced to a minimum in this case.

Defective tools contribute liberally to painful and serious accidents.

A cold-iron chisel used when cutting cast-iron pipe if badly mushroomed on the striking head is a most dangerous hazard, not only to the parties using the chisel, but to persons near-by. The possibility of the handle breaking, permitting the chisel to fly and do injury is made even worse by the presence of the mushroomed head. It is from tools of this kind that pieces of steel break off, causing serious eye injuries. When men are cutting pipe by means of striking hammers and cold-iron chisels we provide goggles, and this simple, inexpensive preventive against eye injuries has worked wonders.

Explosions of hot lead when poured into pipe joints, particularly if

A 36-INCH PIPE LAID IN SHIFTING SOIL

they are wet, must be guarded against; and the danger of flying pieces of stone when blasting ledge must be carefully watched.

The tripping hazard is always present in all classes of work where loose material is left lying around. Its remedy is obvious and simple.

Frequently it becomes necessary to dig down to gas mains during the winter months when there may be from three to four feet of frost in the ground. When digging out frozen ground, great care should be taken not to strike sparks where gas is leaking; also when "barring" for gas leaks along the line of main, the "barring holes" should never under any circumstances be lighted off. Leaking gas is a serious hazard at best; it becomes a greater hazard when men attempt to find the leak with a lighted match.

The seriousness of searching for gas leaks with open flames is well expressed in a recent bulletin issued by the National Safety Council, which reads as follows:

**GAS MEN**

Looking for gas leaks with a match, lighted candle or other open flame is an old stunt, but—it's still being done.

**USE A FLASHLIGHT TO LIGHT THE WAY AND YOUR NOSE TO FIND THE LEAK.**

If the open end of a live gas main should take fire from any cause, it is practically useless to try to extinguish it with water. The flame must be smothered, and this can be done with wet blankets, sand, or dirt. Pouring water into an open end gas main on fire, might cause trouble in other parts of the system by stopping or "sealing off" the supply. If this occurs, a greater hazard than the fire itself will be present.

The fire hazard is also introduced by the curious non-thinking person who may be smoking in the vicinity of escaping gas. This danger is usually controlled by a watchman stationed on the job to keep a check on conditions of this kind.

**PROTECTION FOR THE PUBLIC**

Protecting the public from injury when laying gas mains is essential. This is accomplished by providing substantial bridges with adequate handrails over trenches at crosswalks. All openings in the streets must, of course, be properly guarded with danger flags and barricades so that pedestrians and vehicles will keep away. Distinctive colors, visible a long distance away, are used when painting the cross-bars of the barricades. Black and white bands arranged diagonally across the bar have been extensively used.

Summarizing, it has been said "Accident Prevention Saves Misery and Money." Until recent years, this two-fold saving has not been much appreciated, and in striving to put through work at low costs, the avoidance of accidents has been overlooked as one of the big factors in reducing the cost. This applies to laying gas mains just the same as it does when manufacturing staple articles.

Accidents to employees in all departments are costly to the employer. The injured man's services are lost and they must be replaced, temporarily at least, with a man lacking in experience and qualifications that made the injured man valuable.

It must be the constant endeavor on the part of all employees and executives in industry to keep the subject of accident prevention always in the front. It is our practice to set aside accident prevention and first-aid days at which time all employees of the company are brought together for the purpose of receiving instructions of how to avoid accidents, and how to render effective first-aid when they occur.

CHAIRMAN MACLACHLAN: I will ask Mr. Moroney to open the discussion.

## DISCUSSION

MR. W. L. MORONEY (Peoples' Gas Light & Coke Company, Chicago): What kind of a life belt does Mr. Carter use? We have had considerable experience with life belts. We had one some years ago that we thought was a dandy and I put it on myself to see how it would act and after a little while it was choking me. After that test, I got to thinking that we did not want a life belt that would slip and almost strangle a man. We immediately got together and now we have one that goes beyond the knee and is harnessed, which prevents its slipping. The ordinary belt we find is no good.

I would also like to ask Mr. Carter if he has any method of protecting the public. We have what we call a "chip screen," that is, a canvas mounted on a frame, used for large and small jobs. We find that chips broken away with a large point are liable to knock a person's eye out or go through a plate glass window.

I would also like to ask Mr. Carter what is the best method of bagging off. We find that by first inserting our stops in the main that if the stops should happen to slip, our vent will take care of the ventilation and gas without dislocating the vein.

MR. J. B. DOUGLAS (United Gas & Improvement Company, Philadelphia, Pa.): I heard only part of Mr. Carter's paper, but in his reference to hunting for leaks, there was mention made of using the flash light and the nose. I want to say that we have been quite successful in using soap and water on pipes—the result being that the escaping gas simply blows a little bubble.

I would like to say that one of the most experienced gas engineers of my acquaintance, Mr. Frank Schower, of the Philadelphia Company, Pittsburgh, is with us this morning. I am sure he can give us valuable information on this subject.

MR. FRANK SCHOWER (Philadelphia Company, Pittsburgh, Pa.): Use a rubber expansion plug or a wooden plug when you have your ends open. In bagging off a main it is very good practice to use a bag with a vent pipe between, but if you carry a rubber expansion plug or wooden plug, the main is protected if your stopper slips out.

In pouring hot lead, of course a man should always wear his goggles.

My experience within the last twelve or fifteen years has been principally with natural gas, which has very little odor, so in looking for leaks we use a safety lantern with a cup on it. We put a half inch pipe into the bare hole and put a safety lantern on it and if it puts the light out right away, there is gas there; if it takes a long time to put it out, there is very little gas there. After a while, the men become quite proficient in detecting gas.

ADJOURNMENT.

WEDNESDAY MORNING SESSION

**T**HE meeting convened at 9:45 a. m., Chairman Wills MacLachlan presiding.

CHAIRMAN, MACLACHLAN: Yesterday morning when the last paper was about to be given, competition was set up by the band outside, and we had to stop. I will ask Mr. Mulligan to present his paper now and after the discussion we will have the other papers.

HAZARDS IN BUILDING ADDITIONS TO POWER PLANTS  
—PROTECTING OPERATORS AND EQUIPMENT

W. H. MULLIGAN, HYDRO-ELECTRIC POWER COMMISSION OF ONTARIO,  
TORONTO, ONT.

The report of the Investigating Committee reads:

"The accident was preventable and was caused by man failure".

Yes, this is true but who was the man who failed—the poor unfortunate victim of the accident or some one higher up? We may blame the foreman for not having properly instructed the workman, or for not having seen that precautions were taken. But is he the man wholly to blame? Look over the situation. Try to place yourself in the workman's position. He has done the best he could with the conditions under which he was working. Too often the cause has been poor design. There may have been lack of foresight in the original design of the station or power house; or good safe design has been sacrificed to cost, but how often are we not met with the problem of trying to have work constructed in a station, the capacity of which has been doubled and the equipment crowded into the original space and then too, at a much higher voltage? Such conditions have even sometimes existed whereby it not only requires extreme care but considerable ingenuity to fit the apparatus into place.

The new Engineering Section of the Council has a great field ahead of it and efforts should be made by that Section toward the education of designing engineers, and placing the hazards clearly before them. Show them the necessity for ample working space around all apparatus and especially around circuit conductors and disconnecting switches; also teach them to consider maintenance men and construction men who have to do work in stations which are in operation, and the importance of providing space for them to work in safety.

In all construction work, accidents, which are common to all industries and classified under: handling tools, handling material, slipping, tripping and falling, stepping on nails, eye injuries, etc., and will not be dealt with here in detail.

LIGHTING

Good lighting is essential. This can usually be provided as in the case of reconstruction or an extension electricity is available. The wiring must not be makeshift but good material used and installed under proper supervision. In damp places, nothing but the best reinforced portable

cords and weatherproof sockets used. It should be the specific duty of some one person to see that all electrical equipment is in first-class condition.

#### LADDERS

On all building construction, ladders are in constant use and as a rule all types may be found. Every workman on the job feels that he has the inviolate right to take two pieces of wood, nail some cross pieces on them and use the results of his labor as a ladder. This must not be countenanced and only ladders properly constructed by a competent workman allowed. No ladder reinforced longitudinally with metal should be allowed on the premises. I cannot impress this too strongly: No ladder no matter to whom it belongs, that is reinforced longitudinally with metal has any place on any works which at some time will be used for electrical operation.

Ladders should be equipped with some form of non-slip footing. For outside use a spiked type has proven the most satisfactory and for inside use any type that will not damage the floor or allow the ladder to slip on a smooth floor on which there is oil.

#### SCAFFOLDS

The standards for scaffolds as given in Safe Practice pamphlet No. 12 should be adhered to as consistently as possible; that is, all scaffolds should be equipped with a railing 42 inches high and a toeboard. Particular attention must be paid to toeboards especially where a scaffold passes over equipment that may be alive.

On construction work too little attention is, as a rule, paid to scaffolds. They are only for temporary use and as they will be shortly removed, whatever material is handy is used. The scaffolds must be designed for the loads they have to carry.

Scaffolds which are substantially constructed are often entirely lacking in safeguards—no railings, no toeboards, and the platform obstructed. It is conditions such as this, we must try to guard against. The foreman must be held strictly accountable for the condition of all scaffolds and ladders on the works.

#### VENTILATION

Pure air must be supplied to the workman and fans if necessary should be installed. Care must be taken, especially when acetylene welding apparatus is used.

If salamanders are used in winter for drying purposes, the air consumed and the gases given off, must be considered.

#### GENERAL

Drills and hammer heads must be kept dressed, and when holding drills, tongs used and goggles worn. Care must be taken that the jaws of wrenches are in first-class condition; no defective tools should be used as a failure or a slip will result in, not only the ordinary hazard which would arise, but an extra hazard exists if live equipment is present.

If work is located below a cliff, scaling operations must be carefully and continually carried out.

Cranes, hoists, elevators, permanent stairways and ladders should be constructed as soon as possible.

If it is necessary to operate a railway, a proper set of operating rules and signals should be placed in effect and all men who operate the trains should receive the standard eye and ear tests.

In hydraulic work, when a diver is working, a telephone has been found to have been of valuable assistance, as by its means the operator is not wholly dependent on signals.

As on a large construction job, every hazard from the operation of a railroad to the digging of a ditch is included, I will not go into any details, but will confine myself particularly to the electrical hazards which construction men meet when enlarging existing layouts or installing new equipment in plants already in operation.

All work in a power house or substation that is in operation must be under the direct control of a man who has a definite set of construction rules for his guide. The operator in charge of the station should have the necessary authority to hold up any work which he feels is going to endanger life or apparatus and must work in close conjunction with the man in charge of the construction work.

#### DANGER SIGNS

For the protection of the workman and his guidance, danger signs should be installed. A proper sign must display the universal danger emblem accompanied by such wording, that the nature and location of the danger is apparent. On construction work there is the foreign element. To meet this requirement, we use a sign bearing the danger emblem with "Whenever you see the above sign it means danger—keep away!" in four languages. This sign is placed in all bunk houses and at tool wickets. For general use we have two signs both bearing the danger emblem: one reads "Dangerous electrical apparatus here—Admission by authority only—Keep out"; the other reads "Danger—High Voltage" and is made up both in enameled steel and cardboard, and placed on apparatus which is alive.

During construction, in order that operation may not be unnecessarily interrupted, certain pieces of apparatus are alive one day and dead the next. To reduce the possibility of a mistake, we use a sign bearing the danger emblem with "Danger—High Voltage—Safe Working Distance — Feet. H. E. P. C. Construction Department." The foreman assumes the responsibility for this tag and locates it on the apparatus which has just been turned over to the Operating Department, either for temporary or permanent use; he marks the voltage and safe working distance.

When we were adopting the universal danger emblem we used, with it the skull and cross bones with the word "Danger". The standard signs, such as are used at elevators, emery wheels, cranes, explosive storehouses and railway crossings, should all be used depending on the nature of the work in hand.

All equipment not yet turned over to the Operating Department, or which has been released by the Operating Department, should be tagged with a special tag for construction purposes; and when apparatus or equipment is so tagged, it must be wholly under the control of the construction foreman.

#### SAFE WORKING DISTANCES

The safe working distances as laid down by the Hydro-Electric Power Commission of Ontario, for their various operating voltages are as below:

|                                     |       |
|-------------------------------------|-------|
| 110,000 volt line or apparatus..... | 5 ft. |
| 46,000 volt line or apparatus.....  | 4 ft. |
| 26,000 volt line or apparatus.....  | 3 ft. |
| 13,000 volt line or apparatus.....  | 2 ft. |
| 6,600 volt line or apparatus.....   | 2 ft. |
| 2,200 volt line or apparatus.....   | 2 ft. |

These distances are truly only a minimum and should always be considered as such, and as much clearance as possible should be obtained.

If general work is being carried on in the vicinity of live apparatus it must be screened in such a way that it will be impossible to make accidental contact. There are times when it may be necessary to work within the foregoing minimum distances. No workman should be allowed to use his own judgment in this matter, but special permission must be obtained for each individual case and then only granted when it is impracticable to carry on the work in any other manner. At such a time, two men must always be present.

If work must be performed above live equipment, a scaffold must be built over the live section in such a manner that it will be impossible for tools or material in falling to cause an arc.

In all work of this nature, the operating man must not be forgotten when work has been finished for the day. Aisles must be left reasonably free from obstruction, any gallery rails that have been removed, replaced or the opening protected, and if any extra hazardous condition exists, which might interfere with operation, it must be pointed out to the operator.

#### FIRE

Care must be taken to leave no excelsior or packing around the switch rooms as such material is an added fire risk in the case of an oil explosion. Gasoline must be stored in minimum quantities and stored in safety cans.

Fire equipment must not be removed nor access to it blocked; and adequate supply of extinguishers distributed over the work—in the camps, storehouses, and offices.

#### RESUSCITATION

I would not be a true Public Utility Accident Preventionist if I did not say a few words re resuscitation. It will be impossible to get every man in a large construction camp to practice resuscitation, but a certain few men in each group should be trained and in your electrical construction gang every man must know and must practice resuscitation.

CHAIRMAN MACLACHLAN: I have had the opportunity of reading this paper before it was presented, and I know the experience that Mr. Mulligan has had covering a very large system, extending over some four or five hundred miles in length, and operating two or three hundred substations and a number of power houses. Some of them are under construction at the present time. These details are brought out from the standpoint of accidents that have happened and the methods to prevent them from happening again. Some of the details that were discussed in connection with scaling apparatus and the handling of chips pertain to the development that is now being made on Niagara Falls, where a power plant of 300,000 K. V. A. is being built.

#### DISCUSSION.

MR. HERMAN SPOEHRER: It is a fact that our construction organizations haven't become educated up to the same standpoint as our operating forces, and that applies as well to outside construction work.

The contractors have made an effort recently to interest the various contracting concerns and they are finally taking hold. Too frequently one shift of a construction gang will put a very light tackle up to hoist some material for immediate needs and use a light lashing, and they tackle it with a light rigging. The next crew comes along and without investigating the strength of it, tries to handle larger things than the tackle was intended for.

MR. H. A. MOTT: I should say that any crew which comes along and uses a sling put up by another crew without ascertaining anything about it is a pretty poor gang.

MR. J. C. MARTIN: Mr. Spoehrer has spoken of the lack of safety education among construction crews. I think you will find that the construction crews are usually more or less temporary. The men are up for a job and when there happens to be no work, the larger portion of the men are let go.

In making rules for safety work, or for any other work, that is the factor that has to be given very careful consideration, and special care should be taken to train new crews. I think that is really the reason why construction crews are not as well educated as the operating crew. The operating crews are on the job year after year.

MR. WILLIAM FOSTER: We invariably spend years planning construction and at the eleventh hour we get the order to go ahead with the work and try to complete it in the twelfth hour. That seems to be the great difficulty in construction work. I feel that if we devoted the same amount of time and care to designing safety plans that we do in designing construction plans, we could eliminate this danger to a great extent.

G. R. RINK (Utilities Mutual Insurance Company): I wish to call particular attention to the painters. They are hired for only a short space of time, usually, and experience has shown that apparently they do not realize the danger in working back of the switchboard or on other electrical equipment.

MR. C. B. HARDIN (United Railways Company of St. Louis): Who is

the man we are to charge with the direct responsibility of seeing that the men are properly instructed? In other words, when the accident happens, shall we charge it to the foreman, or shall we go to the man who is in charge of the job, or to the contractor, or shall we go to someone else? To whom shall we go for either the failure to have the necessary safeguards, the necessary safety apparatus there, or the failure to properly instruct the men of the presence of danger?

**MR. HERMAN SPOEHRER:** I think I answered that question yesterday in the case of our own organization. In our permanent organization we have written safety into all of our various bonus schemes so that if a man is lax in the enforcement of safety rules, his own gang suffers and the men won't tolerate any negligence because it affects their income. In the case of an outside contractor, I think that is a matter that should be written into the specifications.

**MR. J. C. MARTIN:** To get back to what was said yesterday about the executives, you have to charge your executives with the responsibility for seeing that the men under them are properly impressed with their duty. If your executives are not on the job and encouraging the men under them to carry out these measures, they will never be enforced.

**CHAIRMAN MACLACHLAN:** Mr. Mulligan, will you close the discussion?

**MR. W. H. MULLIGAN:** In reply to Mr. Hardin, I would say that with the Commission in Ontario it is my unfortunate duty to hold official investigations into every serious or fatal accident to any of our employees. This investigation is taken by a stenographer and I question everybody from the superintendent down to any workingmen on the job who know anything regarding the causes leading up to the accident or regarding the accident itself.

From this investigation I make up my report and I find that in every case within the last year and a half, the accident has been wholly up to the man himself. I have yet to find a case where the responsibility should be placed on the foreman. The foremen are there to instruct them—we have those rules—but the foremen cannot be everywhere on a large job at one time.

But from these investigations we very often find things which we did not know existed before, and we are able to make recommendations to the chief engineer, and through him to the Commission, whereby we can prevent the same accident happening the next time without a direct disobedience of the rules.

**CHAIRMAN MACLACHLAN:** I understand the nominating committee is prepared to make its report. In the absence of the chairman, Mr. H. A. Mott will make the report.

**MR. H. A. MOTT:** Your committee reports the following nominees:

Charles E. Morrison, Chairman  
 J. F. Naylor, Vice Chairman  
 J. J. O'Connor, Secretary  
 H. Spoehrer, Membership Committee Chairman  
 William Foster, Bulletin Committee Chairman  
 E. Vinet, Program Committee Chairman

(On motion duly made and seconded, the gentlemen named were elected.)

CHAIRMAN MACLACHLAN: I will call on Dr. C. H. Lemon to present his paper on "Medical Service in Public Utilities".

### MEDICAL SERVICE IN PUBLIC UTILITIES

DR. C. H. LEMON, CHIEF SURGEON, THE MILWAUKEE ELECTRIC LIGHT AND RAILWAY COMPANY, MILWAUKEE, WIS.

While public utilities in a general way do not differ from other large corporations in their internal relations, they do have a personal contact with people and things outside of themselves that many of the larger corporations do not get. As public utilities they are dealing with the public itself and this relation is reflected in the character of the employees, and in most instances the character of the utility itself may be judged by the character of the men who are employed in it. Perhaps it is easier for a public utility to have a medical service than an ordinary industry, for the reason, that as a rule a public utility has a medical department, or at least a medical officer, who responds to calls for services where the public in one manner or another suffers personal injury through the operation of the utility itself. All public utilities in their operation are more or less hazardous and accidents to employees are not uncommon, as well as accidents to the public; either on the streets or in houses or manufacturing plants, where these utilities are to be found.

Unless a public utility has an organized medical department and utilizes the skill of its medical men for the benefit of its employees, a medical service in the full sense is an impossibility. It is necessary to employ medical men of known skill and these are usually on a salary basis; and usually are found willing and anxious to do something in a definite way for the employees with whom they are necessarily brought in close contact.

As an illustration of the extent to which this personal relation may be extended, I would point out that perhaps the best known industrial surgeon today, is one who is the physician to a large mail-order house, where it is almost impossible to visualize an accident or a disease, arising out of the industry; and yet, because of the personal interest of the doctor employed, he has made the most of his opportunities and has practically built up a national reputation based upon a minimum of real opportunity, as compared with other large industries. What he might have accomplished in an industry such as I represent it is difficult to imagine.

It is this personal service by men who are enthusiastic in their specialty, that will count in the long run and produce results for the betterment of the employee, whether it is a mail-order house in an office building in a large city, or, whether it is a large manufacturing plant

spaced over many acres, or a public utility of the first order having its great shops and its larger contact with the general public.

#### ONLY HIGH GRADE MEDICAL SERVICE WILL SUCCEED

It is important for those desirous of instituting a service of this kind in their own industry, to recognize the fact, that without the presence of a surgeon of repute as the head of the organization, under pay by the corporation itself, and not by an employees' mutual benefit association, that nothing can be accomplished. Joint mutual benefit associations, particularly in the iron and steel industry, are by no means a recent development. For thirty or more years these mutual benefit associations have been in existence and the reason they have not developed beyond very restricted lines, is that their medical service was selected either by competitive bids from the doctors themselves, or none but men of mediocre ability could be persuaded to interest themselves in this work, because of the low salary or fees that it was possible to pay out of the funds of the organization.

A half-hearted medical service is in my opinion worse than no medical service at all. Those who are engaged in labor, do not always employ mediocre physicians or surgeons. Among laborers there are discriminating thinking minds, and those who are capable of thinking for themselves are just as apt to differentiate between medical men as are their employers. In fact, it has been my experience that many employers of labor show less discrimination as between the skilled and the unskilled in the medical profession, when seeking medical counsel for themselves, than do those whom they employ.

What I would seek to bring home to you, is the thought at the beginning, that if there is to be a medical service in a public utility, that the public utilities themselves must be ready to spend a liberal sum of money each year, in order that men of the first ability, men of standing in the locality in which the utility is operating, may be interested to give their time and services for the benefit of the employees and their families.

The day has long since gone by when you can treat medically the employee and lose sight of his family. The two are so intertwined and dependent the one on the other, that either they must be treated as a unit or not treated at all. The health and happiness of the bread winner who is the public utility employee, is dependent to a large extent upon the welfare of those who are dependent upon him; and his efficiency at all times is increased or diminished by worry, incident to sickness or chronic ill health of his dependents, unrelieved by medical or surgical treatment, which in the past many of these employees have not been able to provide.

#### INCREASES EFFICIENCY OF EMPLOYEE

The employee himself who has free access, at convenient places and times, to medical service will be more efficient than another who is denied this service. This is not an arbitrary statement but is based

upon statistics, which the company I have the honor to represent, has for the past eight years reported annually. It has been the good fortune of The Milwaukee Electric Railway and Light Company, during the past twenty-five years to have as its presidents and general managers, or both, men of broad vision, who so far as I am able to learn have been and still are pioneers and progressive thinkers along these lines.

To those who have not experienced the personal contact that arises out of a well directed employees mutual benefit association, in which employer and employee are so amalgamated that the thought of differentiating the two never occurs to one, it is impossible to convey an intelligent idea of what that relationship is. You must know it and feel it and live it in the most intimate personal contact, in order to, in any measure, appreciate what it is.

The medical service is the first intimate contact between the employing agency and the employee. The man seeking employment is examined before he is employed. Only desirable risks are admitted to the close relationship. The commonwealth by its workmen's compensation laws and regulations has provided for the employee injured on duty. The medical service on the other hand takes care of the employee injured off duty or taken sick, either on or off duty and reaches out its beneficent work to include in the benefits the dependents of the employee under eighteen years of age.

The man who steps into the employment in which this service is provided, whether it is a public utility or a private corporation, is certainly receiving something that the vast number of employees in our industries in general know nothing about.

As the physicians and surgeons employed by a utility must for economic reasons be on a salary basis, the so-called "free choice of physician" which has been the stumbling block in all organized movements of this kind, is obviously an impossibility. It is a fair presumption that a large corporation would employ none but men of known ability and good standing in their community. No one who may receive these medical benefits, is obliged to avail himself of them. They are his for the asking. Should he prefer to exercise his "free choice of physician" he may do so, but he must pay for the special service himself. It is our experience after eight or nine years, that seldom do we find a mind so prejudiced that it desires to exclude the regularly appointed medical man of the association and substitute one or more of his own choice.

It is of course highly desirable for the economic administration of this work, that the membership as a whole should be satisfied with the service offered. A consultation is always possible between the particular man whose duty it is to respond to a call and the Chief Surgeon or one of his associates. This service is included free of charge, as are the laboratory facilities of the Company.

In case of accident under the workmen's compensation law there is no free choice, the regularly appointed surgeon of the Company takes care of the man under the compensation laws; and in Wisconsin the

Commission by its regulation, provides that the employing company shall provide medical service.

I merely cite this fact because in the inception of these mutual benefit associations, there is apt to be more or less organized opposition on the part of physicians in the community, to the formation of these mutual benefit associations, because of a fear that they may infringe upon their personal rights, as they construe them.

#### SERVICE SHOULD BE COMPREHENSIVE

I have suggested, that the service should be as comprehensive as possible, for the reason that when an employee comes for medical advice he should find a surgeon who is competent to take care of him. He may be a new man in the employ and a stranger in the community and when he seeks advice as a member of the association, it may be a question of life or death with him; therefore the service that is offered him should be so comprehensive, that if an emergency exists that service will protect him and see him through until he has recovered.

Of what possible value to a new man on the job and a stranger in the City is a diagnosis only, made in the company's offices of acute appendicitis, when the service that is to be rendered must stop there? Under many forms of medical relief this is all a man gets. He is advised to consult a surgeon and without knowing who is competent to treat him and with an acute abdominal pain, he goes home and calls in some local doctor who may be without the slightest experience, but who is willing to tackle the job at the expense of the man's life.

The only medical service worth taking up or worth considering for a moment is the medical service which makes the diagnosis of an acute appendicitis, immediately places the man in an ambulance, sends him to a hospital, follows him up, operates upon him, relieves him of his dangerous symptoms and within two hours at the most, places him safely on the road to recovery.

This is an extreme example, I know, but illustrates the point. I have no patience whatever with this semi-annual examination of employees by experts or others, which we are told will unearth latent diseases of which the man is not conscious. We know that beyond forty years of age, most men have some defects and many of them show these defects much earlier.

In a large organization the ordinary daily medical service afforded these men freely, will bring to light these conditions and they should be treated by the men who make the diagnosis, and these medical men should be regularly employed, either by the corporation or through a mutual benefit association, back of which stands the corporation as its financial backer. In no other way can you ever build up a successful medical organization. The relation between the employee and the doctor representing the employees' association, should be as intimate, as confidential, as personal and as thorough as the relation that should exist between any patient and any reputable doctor, whom he may consult.

## MEDICAL SERVICE OF A LARGE PUBLIC UTILITY

I have been asked many times just what this medical service is that The Milwaukee Electric Railway and Light Company and its Employees' Mutual Benefit Association furnishes. We furnish to the employee, his wife and his dependents under eighteen years of age, everything that he needs in a medical way, excepting the services of specialists in medicine, such as skin specialists, eye and ear specialists, etc. We confine his wife and we take care of the baby. If she needs a surgical operation, we remove her to the hospital and operate on her. The only charge to be met is the hospital service, which the employee must pay for himself.

We do not furnish medicines to the wives or dependents under eighteen years of age. We do furnish medicines to the employee who is a member of the Employees' Mutual Benefit Association. We furnish the medicines to the employee because we are anxious to keep him on the job and because we know that where preventive measures are taken in a beginning illness, that in a large percentage of the cases the illness or disease will be promptly arrested.

In order that these services shall be rendered to the fullest extent and with the least possible loss of working time to the members, we place a doctor at some convenient hour in each one of our car stations, our car shops, and our central office building, where they may be freely consulted. At the Chief Surgeon's office in the central office building, we have laboratories, X-ray and chemical, where examinations of special character can be made. The doctors forming our personnel have been selected because of special training along definite lines and to them are referred cases in which their training makes them experts. All doubtful cases that can do so, are sent to the central office building for consultation.

The City of Milwaukee is divided into districts and each district has its own medical man. We do not permit the calling of a physician in a district other than the one in which the patient resides, except for special reasons. Outside the City of Milwaukee where the Company has large activities, we again adopt the district system, and in remote places the member selects his own physician, pays his bill, presents it to the Mutual Benefit Association and he is reimbursed for the expenditure. We do not pay hospital fees. Experience has shown that working people frequently are extravagant in the selection of accommodations in hospitals and the hospitals only too frequently encourage them in this extravagance. The only way that a corporation could offer hospital service to its employees is for the corporation to run the hospital and assign to the employee quarters which in the opinion of the attending surgeon are ample and proper for the service to be performed. Many of the large railroads have such hospitals.

## MEMBERS OF EMPLOYEES' FAMILIES TREATED GRATIS

The medical and surgical service rendered is so comprehensive that nothing which would endanger life is omitted from that service. Acute

as well as chronic ailments are treated to the fullest extent, whether medical or surgical. For this service no charge whatever is made and so far as the surgical service is concerned, it is not furnished by the Mutual Benefit Association, but is furnished by the Company itself.

The wife of the employee, who may have suffered injury at the time of her confinement, is restored to health by appropriate surgery. The baby that is born is cared for by our visiting nurses and everything pertaining to its welfare is taught to the young mother. If need be it is circumcised; later on its tonsils and adenoids are removed and the many and perplexing diseases of childhood are cared for by our medical service. When the child becomes eighteen years of age, we render no further services.

The many accidents that befall children and require surgical attention are cared for by our medical service up to the age of eighteen. Our X-ray laboratories and our surgical service are available at all times. We have visiting nurses who are graduates of reputable hospitals, who go from house to house as they are invited. We have a trained surgical nurse in our central office building where we have a well equipped operating room, which is available for the treatment of minor surgical emergencies.

#### BENEFITS TO EMPLOYEES

The employee injured off duty is likewise covered by all these facilities, for which no charge whatever is made to the employee or his dependents. We do not go into the homes of our members unless we are invited. We propose and offer to them nothing but the best medical and surgical service we are able to procure in our community and if a study were made of our annual report, it would be seen that practically every known operation is performed in the course of a year on this large clientele, which at the present writing, including the members and its dependents, numbers 12,000 souls.

The medical service thus rendered is not only curative in its nature, but in the higher sense preventive, and many ills that befall those who cannot avail themselves of such a service and that incapacitate them for service, are in a large measure prevented in our own groups by this intensive service. The man is kept on the job. Our statistics show a consistent reduction year by year of the average disability of nine days per man per year lost time, to a little over four days per man per year, notwithstanding various epidemics that in recent years have resulted in such great morbidity.

By improving the general health through this medical service, we keep the man contented with his work: his family life is very greatly improved; his average expense for medical service is reduced to the minimum and his efficiency is so greatly improved that he may be in his daily work compared with the well-trained soldier, whose hygienic life and welfare from the moment of his enlistment, is equally safeguarded, by the well-trained medical service provided by his Government.

**CHAIRMAN MACLACHLAN:** This section is to be congratulated upon having such a paper presented to it. Many of us have investigated various medical services, but I have yet to hear of one that will compare to that under Dr. Lemon's charge. This is a subject that I think the Public Utilities Section has not investigated as thoroughly as it should, and for that reason we haven't reaped the benefits of medical service in public utilities.

**DISCUSSION**

**MR. C. B. HARDIN:** I should like to ask Dr. Lemon a question. Are you as chief surgeon and all of your assistants paid by the company or by the mutual benefit association?

**DR. C. H. LEMON:** The chief surgeon and two of his assistants are paid by the company; all of the other payments are made by the mutual benefit association.

**MR. C. B. HARDIN:** Do you render assistance to those employees of your company who are not members of the mutual benefit association?

Do you allow the members of your association to call the division doctor direct, or do they have to communicate with their superintendents before the doctor is sent to their houses?

Is there any objection on the part of your employees to your sending nurses into their homes?

**MR. WILLIAM FOSTER:** I understood the doctor to say that the service has taken care of 12,000 people. I would like to know the number of physicians carried and I would also like to know if the doctor has any record of labor turnover since the introduction of this medical service department.

**MR. J. F. NAYLON** (New York Telephone Co., Newark, N. J.): The doctor spoke of his disbelief in the semi-annual examination of his employees. That is a subject that I think might well be discussed for the reason that our company has greatly improved the physical being of the employees with the semi-annual examination and have found a great many diseases that probably would not have been found in any other way.

Where does the money come from to keep up this splendid, comprehensive service that they give? It must cost a tremendous amount of money and I wonder where it comes from. A public utility usually doesn't have much money.

**MR. J. C. MARTIN:** In the construction camp work, particularly where camp conditions are likely to be bad at times, my experience is that if the physician does nothing more than maintain proper sanitary conditions in the camp, he is worthy of his cost. I have known cases where, without proper camp sanitation, the construction gang has gone to pieces.

**CHAIRMAN MACLACHLAN:** Dr. Lemon, will you close the discussion?

**DR. C. H. LEMON:** In answer to the question about services being rendered to employees who are not members of the association, that suggestion is a little bit of a joke. With us the Employees' Mutual Benefit Association is the employment agency of the company. We have a closed

shop from the inside out. The Employees' Mutual Benefit Association does not hire anybody who isn't going to be a member and, therefore, we have no non-members of the association.

In answering the question, "Do we allow the members to call the doctor or must the order come through the superintendent?" the order is that it must come through the superintendent, but we do allow them to call the doctor direct in cases of emergency. The employees learn to know the doctors pretty well, and if we would allow them to call the doctor direct, such calls would become the doctor's private practice. The rule is that the call must come through the superintendent.

Another reason for the rule is that I anticipated that some of the members of the association who paid fifty cents a month might feel that they had the doctor under their thumb, and no matter what time of the night they were sick, they would feel at liberty to call him out of bed. So we established the rule that all calls made before noon must be made before nine o'clock in the morning and that all calls made in the evening must be in before five o'clock in the evening, and no calls would be made after seven o'clock except in cases of emergency.

Do we find objection to nurses being sent to the home? No, because we don't send them into the homes, nor do we send the doctor, unless they are invited.

How many employees have we and what is the labor turnover? Four thousand employees; with their dependents, 12,000. The labor turnover has been as low, or lower here than almost any other place in the country.

This mutual benefit association has other things besides medical service. It has the building and loan association and many other activities.

As to the semi-annual examinations, I put that in my paper because I knew somebody would say something about it. There are a lot of places where they cannot afford to have a doctor all the year around and, perhaps, in such plants the semi-annual examination is desirable. But, if a doctor is on the job, and the man is coming month after month, I don't think it will be very long before the doctor gets a line on him. We find that these hidden diseases are unearthed months before they would be by this semi-annual examination. If you can't have the weekly or even monthly examination, then the semi-annual plan is a good thing, but the man who keeps coming and does not feel just right will be steered up against that X-ray machine, or one of these experts we have in our organization, and we are able to tell the man promptly what the trouble is and suggest the remedy.

To illustrate that, one of the heads of a department, a most valuable man, had not been feeling well for some time, and one evening he dropped in along about five o'clock and said, "Doctor, you know I have to sit in my office for half an hour after the business is over to pull myself together so that I can get strength enough to go home." I looked at him and I saw that this man's eyes were very bloodshot and sitting out of his head somewhat and he certainly looked the part he described.

"Good deal out of order?" "Yes!" "Sweet taste in the mouth?" "Yes!"

"Don't sleep well nights?" "No!" And I examined his urine and found that it contained 6 per cent sugar.

Supposing this man had to wait six months for that expert to come around? Where would he be? I laid down the plan that he was to follow, and from that day to this—six months—we have examined him frequently and he has never had one particle of sugar in his urine.

It's simply the persistent medical service with the man who is willing to co-operate with you that brings results. Now, if this man had not had that service and if he had waited for the semi-annual examination, he would have disclosed a badly developed case.

CHAIRMAN MACLACHLAN: I want to thank you very much for giving this paper. I think it's a thing we should study and I know it will be of great value to the Public Utilities Section.

I will now call on Dr. E. George Payne to give his paper on "Utility Accidents to the Public Prevented Through School Safety Education".

#### UTILITY ACCIDENTS TO THE PUBLIC PREVENTED THROUGH SCHOOL SAFETY INSTRUCTION

DR. E. GEORGE PAYNE, PRINCIPAL, HARRIS TEACHERS' COLLEGE, ST LOUIS.

The newness of the plan for the reduction of accidents through school instruction requires a careful study of its methods and results in order to make a case for or against the plan. There is no better way to do this than to submit to careful scrutiny the methods and results in so far as public utility accidents are concerned.

The problem of utility accidents is subordinate to that of public accidents and therefore submits to the same kind of treatment. Both problems appear upon examination comparatively simple.

There are only a limited number of situations in which accidents happen to the public, perhaps thirty in all. The situations in which accidents are possible from public utilities are much more limited.

Of the one hundred thirty-seven children, five to sixteen years, of elementary school age in St. Louis in the years 1917, 1918, and 1919, that were killed in public accidents, forty of the deaths were caused by public utilities; that is, railroads, street cars, and electric lighting and power companies. The remarkable thing about these forty deaths and perhaps a thousand accidents from the same causes not resulting fatally during this period is that there are only four situations in which they occurred as follows: first, from stealing rides on street cars; second, from running into the streets while playing and being struck by street cars; third, from contact with live wires, generally from grasping dangling wires; fourth, from playing on railroad tracks. The accidents not resulting fatally were due to the same causes.

Note now, the conditions under which these accidents occurred. In the case of every accident, more than one thousand in all, including the forty which resulted in death, the children were out of the direct control of all those who are accustomed to exercise authority over them

in the city; that is, teachers, parents, and policemen. Furthermore, these accidents occurred under conditions when it would have been impossible for control to have been exercised directly. The accidents occurred while children were running errands, going to or from school, or playing in the streets in congested districts where play space is not available.

#### AN EDUCATIONAL PROBLEM

From this foregoing presentation, it is evident that the problem is an educational one and very simple. It is educational because the controls of the behavior of children must be exercised by forces within themselves, and the development of these is always a matter of education. Stated specifically, it is the development of habits, knowledge, and attitudes toward four specific situations, so that children will possess as a result of this education controls within themselves that will protect them against the dangers to which they are exposed. The significant point of the whole matter is that the control has to be developed within the child and that is an educational problem, whether the education is carried on by the teacher, parent, policemen, or other children. It is really a matter of self control, and self control is a matter of education in the final analysis.

The problem of interest to every one concerned with public accidents, and this particular group with utility accidents, is to determine how controls in children may be developed with reference to these situations. I am leaving out of account at this point the accidents that happened to adults, because that is a totally different problem that time will not permit me to discuss here, except to say that thorough knowledge, adequate points of view, and specific habits in children with reference to the situations in question are conveyed economically and effectively to the parents in the home. There is no more successful way of getting parents to observe safety rules than to arouse the interest and enthusiasm of children in safety. But our point here is how we may develop controls in children themselves, for if the children are taken care of at the present, it is only a matter of a short time until the whole population will be educated, for the children themselves are becoming very rapidly the adults of society.

#### SCHOOLS SHOULD INSTRUCT CHILDREN IN SAFETY

The development of controls, moreover, is primarily the function of school education. To be sure, it has been the practice in the past for parents to give the instruction to children concerning safety, but the machinery of present-day society has become so complex that the average parent does not know what is necessary for safety. Every person who has looked into the matter of street accidents, for instance, is perfectly aware of the danger of crossing in the middle of the streets or at other places than at designated crossings. Every person who has studied the problem of accident prevention knows how necessary it is to look in both directions in crossing the street, but one needs only to present these points of view to the average citizen to see how completely ignorant he

is of the danger of doing these very things which are recognized by the tutored as so seriously dangerous. The average citizen will tell you that it is nonsense to walk one hundred yards to cross at a designated point when you can go directly across the street and save time.

With this attitude of mind on the part of parents, it is obvious that they would not be effective teachers of children in the observance of safety methods. Furthermore, every one is quite aware of the inability of policemen to patrol the streets in any adequate fashion or to teach children to cross at crossings. It is, therefore, necessary for the teacher and school to perform this very important work if it is to be done.

Then the question we have before us is how the teacher may develop in children the controls necessary for their safety, virtually with reference to the four situations mentioned above. In answer to this question, we need but to look at the controls exercised in society to get our answer. When you come to analyze the behavior of individuals, you see how their conduct is shaped at every turn by social forces which lie outside of themselves, or rather by the individual's attitude toward his fellows and toward the community of which he is a part. It is the community opinion and one's sensitiveness to it that counts in the development of controls in the individual. This is just as true among school children as it is in an adult community.

Having in mind the method of social control, the problem of educating children against these four dangerous situations in which utility accidents occur is exceedingly simple. First, the children themselves must become conscious of the dangerous situations and ways of avoiding them, and second, there must be developed a community spirit with reference to accidents themselves. The method by which these results are achieved are exactly the methods used constantly in schoolroom instruction, and I do not need to dwell here upon this point.

#### HOW TO TEACH CHILDREN SAFETY

However, it would be well to recall just what the process is. First, it is a matter of direct instruction. This is done most effectively in connection with the regular subjects rather than as a specific task in addition to the curriculum. Second, dramatization. There is no field that lends itself more effectively to dramatization than that of accident prevention. There is scarcely an accident situation that does not give opportunity for dramatization and that does not make a direct appeal to the instinctive tendencies and acquired experiences of the child. The fundamental point is that accidents are directly connected with a group of instincts which tend toward the preservation of the life of the individual, and when you touch these instincts, you come in contact with the most fundamental nature of the child. Therefore, there is never a question of intense interest, there is never difficulty in securing motive, and there is no possibility of unreality. In the second place, accident situations are within the experiences of the child.

The most serious difficulty in school instruction is to find material that comes within the child's experiences. It really requires an artist as a

teacher to bring the subject matter of the curriculum to the child in such a way that it will touch his experiences so that the material of instruction will be comprehensible. Accident situations afford invaluable help in this respect because the accidents occur upon the streets and in the home, and the child is familiar with them. This is particularly true of utility accidents. In addition to this, the literature dealing with accidents is genuinely real. It consists of vivid posters, drawings, and newspaper and magazine descriptions. This material is not only within reach of the child, but it is the most real and vital to him because it is the kind of reading matter with which he has come into contact since his earliest childhood. Therefore, dramatization may not only be used and used effectively, but it serves to give reality and point to instruction in the various subjects of the curriculum, a matter that cannot be over emphasized from the school point of view. Fortunately, the interest of the school and the teacher in this respect coincides with the interests of business men and the community generally.

The third respect in which the children may become conscious of accident situations and of their relationship to the problem of accident prevention is through the school organization. This is a means that we have long neglected in our school keeping.

#### CHILDREN'S SAFETY COMMITTEES

For the past two and one-half years, I have been meeting each week with the executive committee of the Mississippi Valley Division of the National Safety Council, and for nearly that time, I have been meeting monthly with the public division of this committee. There are perhaps twenty other persons who have been as faithful as I have in sticking to this one problem during the period. These meetings have all been in the interest of the conservation of human life. This fact is not unusual and may be duplicated in almost any community with numerous social groups.

It does not, however, seem to have occurred to school people that children might be more or less permanently interested in the same type of problems to which these adults have given so much time and attention, at great sacrifice and expense. It is a fact, nevertheless, that they are interested, and when children once organize under school direction to deal with the problems of accidents, they are approaching a very natural social group and the functions of this social group are not unlike those with which adults deal. It is no wonder then that children will meet from week to week, plan ways of preventing accidents in the schools and in the community environment and then go out and rigidly carry out the decisions agreed upon in these meetings. Furthermore, it is not surprising that the children, like adults, enter enthusiastically and wholeheartedly into the work of making their school and community safe from accidents.

I have in mind an incident that illustrates vividly what I have just said. In one of the schools composed almost entirely of foreigners, the principals and teachers formed, last year, a school safety organization. The

children organized themselves to carry on the work of accident prevention in their community. They determined what was necessary to secure the safety of the school population, assigned members to perform the various duties in connection with its safety, and then each member fulfilled the office to which he was assigned.

As the children were guarding the streets when the school was dismissed, a young Greek child of eight years crossed in the middle of the street at a dangerous point. The pupil in charge apprehended him and tried to explain why he should not cross in the middle of the street. The little Greek boy, not able to understand, fought the pupil for interfering. The safety boy, not deterred from his purpose, led the other back to his teacher only to find that the Greek boy understood English very little. The teacher sent for a larger boy who spoke Greek. He explained to the youngster the purpose of the organization, and the Greek boy asked to be put upon the safety committee and became one of the best boosters, not only in the school, but throughout the community among the adult and child population. Why? Simply because children, as well as adults, are interested in the conservation of human life, and when they are once faced with the problem of accident prevention, they are perfectly capable of organizing and carrying out the work effectively.

From the educational point of view, an important value of this function must not be overlooked and that is the value that comes to children from becoming interested and participating in such an important activity as the saving of human life. Furthermore, it is true that the interest of children is also one of the most effective means of converting adults, fathers and mothers of the children, to the ideals of safety. I could not pass over this part of the discussion without noting the practical outcome of this instruction so far as it has gone in St. Louis.

#### RESULTS ACCOMPLISHED IN ST. LOUIS

There has been in St. Louis about an average of fifty deaths among school children between five and sixteen years each year for some time, with a constantly increasing number from year to year. The work of safety was begun in St. Louis schools the latter part of 1919. In the first eight months of the year 1920, we had sixteen deaths among children between five and sixteen years as opposed to thirty-five for the corresponding period of last year. This result was achieved in spite of the fact that the conditions for accidents have increased and become more complex. Of these sixteen deaths, our Superintendent stated a few days ago that if no other result had been achieved during these eight months of school than to save nineteen lives, the effort would have been worth the cost of carrying on the schools for the year.

It is interesting in this connection to note that we have had only one death from a public utility, a street railway accident, in the first eight months of 1920 as opposed to twelve for the whole year of 1919, and nine for the first eight months of that year. This, moreover, is the first decline in utility accidents to children over a number of years.

I have sketched the problem, method, and results of accident preven-

tion through the schools, but it is equally significant to note here the preliminary work that is necessary in any city to the successful reduction of utility accidents through school instruction. The preliminary work necessary is an adequate analysis of accident statistics. This analysis has been made of all the accidents occurring to school children from the time they leave home in the morning until they reach home again in the afternoon. Time will not permit a presentation of the complete data. A few conclusions are however pertinent. First, the accidents tend to center in certain districts, reaching as high as one per cent of the school population in one school community, with forty-eight of the school districts with no accident in them. Second, there is no relation between the accident opportunity—that is, dangers to be avoided—and the accident frequency. The fact is the largest number of accidents occurred in the high school most favorably situated and with fewest dangers. Third, while no fatalities to children occurred during the school day, the fatalities to children outside of school center themselves just as do non-fatal accidents. Fourth, the cause of accidents is an unfavorable attitude of mind, that is carelessness. Fifth, this attitude of mind is common to the community, as well as to the school children, for the high per cent of accident in the school corresponds to that outside of school. Sixth, the cure for carelessness is education, for that is the only means of changing mental attitudes. What school education can do has already been pointed out in statistics presented.

CHAIRMAN MACLACHLAN: You have heard this admirable paper of Dr. Payne's. We have all heard him before and look forward to the time when we may hear him again, particularly with relation to public utility accidents. We have very little time to give to the discussion of this important question but I think Dr. Payne possibly has answered most of the questions in presenting his paper. It is a subject we are all interested in, and we always look forward to hearing the doctor at these various national congresses.

#### DISCUSSION

Mr. J. B. DOUGLAS: Knowing something of the success of accident prevention weeks, I would suggest that the Public Utilities Section conduct such a drive among its members and other public utilities annually in the month of May.

CHAIRMAN MACLACHLAN: I would say that the suggestion can be carried out by our Section advantageously to all public utilities, and I shall be glad to refer the matter to the incoming administration of our Section.

I will now call on Mr. Foster of the Philadelphia Electric Company to present his paper on "Fixing the Responsibility and Penalizing Those Responsible for Accidents and Awarding Those Showing Meritorious Action in Time of Accident". You will remember that this paper was prepared particularly for this section, due to the instructions of a resolution passed last year to have a paper prepared and presented on the subject, so you could discuss it.

**FIXING THE RESPONSIBILITY AND PENALIZING THOSE  
RESPONSIBLE FOR ACCIDENTS AND REWARDING  
THOSE SHOWING ACTIVITY IN TIME OF  
ACCIDENTS**

**WILLIAM FOSTER, PHILADELPHIA ELECTRIC COMPANY, PHILADELPHIA, PA.**

In investigating the causes of accidents and fixing the responsibility therefor, many problems of a complex nature present themselves to the investigator, and it is his duty to weigh each factor separately and impartially and amalgamate them in a decision which will be based solely on the facts.

That accidents do occur, and with too great frequency, none will deny, and that some one is responsible for them there can be no question. It may be the individual who performs the work, or it may be the foreman who has immediate charge of the individual, or it may be the management who has charge of the foreman. Some one is responsible, and that responsibility should be definite.

In these days of scientific and efficient management, accidents should be on the decrease. But are they? Statistics compiled by the various state authorities indicate that they are not decreasing as rapidly as they should when one considers the effort spent by organizations of this type and the amount of money spent in accident prevention and welfare work throughout the country.

It is true that our industrial progress is marked by the increasing substitution of mechanical for manual labor, and it is well that progress continues along this line. This will not result as some have shortsightedly concluded in the elimination of man as the most important factor in industry, for that can never be, the mission of the machine is rather the multiplication of man's productive powers and the elimination only of the drudgery in work, and the more men that are required in connection with machines, the greater is the necessity for securing their full effort.

**SPECIALIZING IN MEN**

You can buy a man's perfunctory service, but his full-hearted co-operation in your business you must win. You must make him feel that his best welfare is your genuine concern. You must, in short, specialize in men as well as in products if you would achieve success in the management of men and business. It is this specializing in men to which we want to devote our attention for a moment. In these days when safety first is so firmly established, none will gainsay that consideration of human welfare requires that working conditions be as safe and healthful as possible. Yet, until the advent of compensatory legislation and country-wide agitation in behalf of organized safety work, accidents were quite generally regarded as a necessary part of industry, and the risk chiefly of the employed.

Now that the burden has been placed where it rightly belongs, on the industry itself, the interesting discovery has been made: That not only

are most accidents preventable, but that systematic prevention work is highly profitable; in fact is proving to be the handmaid of efficiency and the accident record is becoming a good index of managerial ability.

After a management has expended large sums of money for safety education and appliances, it has a right to demand from its employees a full and hearty co-operation in accident prevention. The adoption of a policy fixing the responsibility for accidents and penalizing those responsible, and rewarding those performing meritorious safety work is of primary importance in securing this co-operation.

The simplest and most practical application of human effort is a military organization. The units are selected on a basis of physical and mental characteristics and are taught, to a high degree, co-ordination of effort. The army that co-ordinates the largest number of units is invariably the most successful because the most efficient. The question of authority, and obviously responsibility, is however definitely determined by the very nature of its organization and admits of no question among those invested with it.

#### PURPOSE OF DISCIPLINE

Modern industrial organizations are probably more complex than military organizations. Manufactories devoted to a single line of products exhibit the best efficiency and are the least difficult to operate, those manufacturing diversified lines presenting problems peculiar to themselves; but the necessity of perfection of organization is ever present and as every one knows the basis of all military organizations is discipline, so discipline should enter very largely into our commercial and industrial life.

"Discipline," said Miss Ida Tarbell in one of her addresses, "is nothing else but training yourself and others to do in the best possible way the thing you have to do, to learn what that thing is and *then to hold yourself to that*" or as another well known writer has defined it: "A complete elimination of personal preferences, prejudices, and opinions and a complete co-operation with authority."

Americans do not like discipline. The laborer doesn't like it. The manager doesn't like it. The proprietor doesn't like it. They think it interferes with individuality. I personally believe we are beginning to realize that we pay too great a price for the individuality which we prize so highly and which is not true individuality after all.

In a commercial organization discipline arises from the fact that every man unconsciously feels there is an eye on him, not necessarily an unfriendly, unkindly eye, but just an attentive look in his direction. It may contain a smile, it may contain a reproof, a glare, but it must be an eye, an all-seeing eye, that is felt in all parts.

The part that discipline plays in an efficiently conducted business is educative. It educates the employee to do the work safely and without waste. It develops power from strength as the trained athlete is made from a clod-hopper. It makes clear thinking from muddy dreaming. Good discipline does not rest on any frail foundation of lip service, but depends

on two things which managers of men must gain and foster and which no subordinate can give unless he has them: viz., enthusiasm for the cause and confidence in those in authority.

#### TWO KINDS OF DISCIPLINE

As I know it there are two classes of discipline adaptable to our commercial and productive business life:

First. Discipline by indirection.

Second. Discipline by deflection.

Discipline by indirection is illustrated by placing a man in an atmosphere where he can do his work only in the right way because it will be the easiest way to do it. It is like placing a recruit in the middle of a veteran company in close formation. If he does not keep step, the man behind him is going to walk on his heels, the man along-side will jostle him and he will walk on the heels of the man in front. Necessarily he will keep in step.

Discipline by deflection is best shown by the following example, where every effort had been made to reduce accidents to a negligible quantity:

Instructions had been issued, discipline by indirection had been tried and yet to no avail, and finally the group of men were divided into teams of 5 men each. A large blackboard was put up at the end of a room where all could plainly see it, on which appeared the names of the men comprising the crews and each morning an inspector listed the score each crew had made the day before. At the end of 3 or 4 weeks, promotions were awarded and increases of pay given to those who showed satisfactory improvement. In a short time over 40 per cent of the accidents had been cut out.

Suppose the discipline by deflection fails because the person deliberately decided to take a by path: an "I'll do as I please path," knowing all the while it was against the rules, wishes, and even good of the organization. Place before that man the error to which his road is leading him: show him what others are getting by taking the right path, and what he will get by going the path he is pursuing. This will require that you have in facts and figures what the results are. Place before him for comparison what he accomplishes and what those who are following the better road are accomplishing, and if necessary, show him the inevitable end of the pursuit of his policy—separation of himself from the position he occupies. Self-interest will invariably bring him into the right road.

In too many organizations good results are taken as a matter of course, only inferior service is given special attention. Both should receive attention and the meritorious service should be conspicuously enlarged upon so that every one may know of it.

#### PROPER DISCIPLINE BUILDS INITIATIVE

We have learned that it is far more productive of good results to call men up than to call them down. It is more profitable to prevent accidents than to correct them.

It is being realized more and more every day that there is a duty of the superior to instruct the inferior as well as a duty of suggestion to the superior by the inferior. In accident prevention work it is realized that this duty of the superior to the inferior is very much larger, both in scope and quality, tension and social value, than the duty of the inferior to the superior. It is certainly vastly easier to instill loyalty to the cause of Safety First when we indicate to the inferior that the rules of discipline laid down for him are for his benefit and this benefit appears as soon as the spiritual, physical, and mental powers are increased.

Discipline, however, that drives out the desire to make good and reduces the employee to an automatic machine warns us that ignorance is in the saddle. Such discipline is productive of much harm and should have no place in the body economic. There are four factors which prevent the development of discipline in a force or an individuality:

1. Failure to set an example of observance of the rules of Safety.
2. Failure to make it physically easy to do the work expected.
3. Failure to see the end from the beginning of the rules you make.
4. Failure to capitalize the enthusiasm which you arouse in your organization.

A wise philosopher once said: "Under any given condition, that thing is right for the individual to do which would be right if everybody did it." That is a good thought and has a right place in safety work.

If you cannot tell a man what to do and how to do it, tell him how he can find out. If you can't tell him how he can find out, ask somebody inside or outside the organization, who can give you the information.

The disciplined mind says: "Do it, no condition will thwart me." And such a mind naturally proceeds to find out because it never occurs to disciplined intelligence to consider a thing hopeless unless it knows it to be.

Discipline is the heart and soul of efficiency. If a man would be free in his work to do the best thing that can be done, he must have a sense of responsibility. He must be responsible for the amount of work produced, the character of work, and for the safety of those under his jurisdiction. He must have the sense of co-operation for no man can do effective safety work alone.

#### FOUR TYPES OF ACCIDENTS

In safety work, as in every other line of human endeavor, the frailties of human nature are ever present and these frailties, together with the taking of unnecessary chances, are responsible for a very large number of avoidable accidents. The accidents occurring in a Public Utility Company, such as the writer is connected with, can be classified under four general headings:

- Accidents to Employees
- Accidents to Non-Employees
- Accidents to Company's Property
- Accidents to Public Property

All accidents are reported in full at the time or immediately after occurring and are fully investigated, statements being obtained from all witnesses present, or those having any knowledge of the details. Responsibility can then be placed where it belongs.

The investigating of an accident to an employee is made by the head of the department or division to which he belongs, assisted by the safety engineer or his representative, and consists, as mentioned above, of obtaining statements of fellow employees and from the injured person, together with the report of the foreman in charge.

The investigation of an accident to a non-employee is along the same general lines as above indicated, except that all statements made by the injured party are obtained by the Claim Department and copies forwarded to the division head for comparison with statements obtained by him.

The investigation of accidents to company property, as well as public property, takes the form of a full report by the foreman, personal statements of all witnesses, their names and addresses obtained and forwarded to the Claim Department.

All modern safety guards should be submitted to the foreman responsible for their use and those approved should be furnished to employees and the foremen held responsible for their being kept in good condition and being used when necessary.

There is a decided tendency on the part of some employees, either through a desire to show off to their fellow-workmen or lack of interest in safety work in general, to avoid the use of safety appliances and this is where the foreman should step in and either insist on the appliance being used or penalize the man refusing to use it. Foolhardiness on the part of workmen should not be tolerated.

For instance, there have been cases where men working on live wires refused to use rubber gloves because they made their hands perspire in warm weather or made their fingers cold in cold weather and took chances using a pair of cheap cotton gloves without any insulating value. Such foolish chance-taking workers are in every industry and the chance taken not only jeopardizes the worker's own life but the lives of others. The day is fast approaching when there will be no room for such indifference for safety in our industrial life, as science has reached a point where things can be determined with such exactness that chance-taking with men's lives and limbs is absolutely unnecessary.

#### SELECTING SAFE EMPLOYEES

At the present time when a man is employed, his word is usually taken as to his ability. If he appears to be competent, he usually secures work, but to place a man properly the following factors should be considered:

First. What has been the Environment of the applicant

Second. What has been the Training of the applicant

Third. What are the applicant's ideals, ambitions, and expectations

The first, in order to obtain some information of his early life and associates together with his method of spending his spare time.

Second, in order to determine his fitness for the occupation he seeks;

his aptitude for the work, his dexterity in the handling of tools required in the position to which he aspires.

Third, this is a factor which will determine very largely his future when employed and will indicate the lines along which he should be encouraged.

The task of getting the right man for the right place is the most important employment problem confronting us today and it can only be solved by close application to the task. It is failure of this very important function that constitutes one of the causes of so many accidents today and it is an endeavor to correct it that has prompted the necessity for using not only corrective but punitive measures in accident prevention.

Should a man who has been provided with proper safeguards and neglected to use them be permitted to continue in an organization that is striving for safety perfection, or should such a man be punished or dismissed for his neglect that it may stand out as a warning to others and through this warning tend to prevent similar accidents by other employees? The writer believes that the time has arrived, or is rapidly approaching, when a man's productive record will read "Safe Productive Record" and he will be valued by this record as much if not more than by the productive record only.

If accidents are a tax on production and all scientific management is based on economy of production, we should give as much consideration to the tax as we do to the production.

Man is more or less a creature of environment and requires discipline of some form whether it be by moral, social, or religious laws.

#### NO SAFETY PERFECTION WITHOUT DISCIPLINE

In industry we require discipline, be it in the form of prevention, correction or punitive action, and we cannot hope to obtain safety perfection without such discipline.

Rules should be fair, clear, and well meaning and enforced. Too often we see boards thrown around store yard with nails protruding upward, articles placed on stairways that should be kept clear, ladders being used when they should be in the repair shop and many other accident producers and yet when an accident occurs and an investigation is made, no one can be found who is directly responsible for such infraction of safety rules.

Such conditions indicate a lack of discipline, for had discipline been well enforced, no man would lay a board down with the nails protruding upward or would have placed articles on a stairway for his fellow workmen to trip over for fear of the disciplinary measures his act would bring forth.

Temporizing with conditions of this kind will bring its harvest of indifference toward safety work on the part of workmen and this we cannot and should not tolerate.

"Accidents can be prevented and will be prevented" is a slogan adopted by one of our men (although not officially approved) who proceeded to

give one of his fellow employees a severe thrashing for violating one of our safety rules.

In fixing the responsibility for accidents and penalizing those responsible, we have been forced from time to time to resort to measures that have resulted in demotions, sometimes for periods extending for a year or more with the understanding that if during the period of demotion the man produces a clear record, he would be restored to his former position when a vacancy occurred and in all cases the result has justified the action.

Where an Employees' Beneficial Association is maintained to take care of accidents, an effective method of penalizing an employee who has become indifferent to safety is to notify him that he is too great a risk for the Association and that his membership has been cancelled and that he cannot be reinstated until he shows active interest in safety promotion.

#### PENALTIES FOR NEGLIGENCE

In some cases we have been obliged to punish foremen when their negligence was very evident by obliging them to lose a period of time equal to the time the injured person was under compensation.

It is true we have lost to our employ a few men through punishment of this kind, but the news of what happened has had a salutary effect on those remaining and it was immediately disseminated among new men.

We are quite well aware that there are those who will not agree with us that a policy of penalizing is justifiable, but this method exists in all military and naval services and those who are responsible for accidents and failure to perform duty know well that they must appear before a Court of Inquiry when the fixing of blame and the penalizing of the person responsible under the rules of the service is effected. Penalties vary with the degree of carelessness and the damage wrought and it extends from a mild form of reprimand to dishonorable discharge from the service.

Why should there be any difference in the administering of the safe operation policies of industry when the same life and property losses are involved?

In rewarding men showing special activity in time of accident, in every case a personal letter of commendation is forwarded to the man and a copy forwarded each crew foreman who is instructed to read it to the men comprising his crew when they assemble at starting time or assemble for lunch. It is also good practice, in addition to the personal letter referred to, to recognize with some material token such employees as have rendered special service in rescue work. This token or reward should be of value in proportion to the importance of the service rendered. Recognition of this character serves as an incentive for men to familiarize themselves thoroughly with safety methods and to be constantly on the alert and become generally interested in the subject of accident prevention.

This method can be elaborated upon by giving a wide circulation to the

facts through a company organ if they have one or by posting a notice in a conspicuous place in the building.

#### REWARDS FOR MERITORIOUS ACTION

Right or wrong, men work for and appreciate rewards. That reward may lie in the honor of being called the best man in the organization. It may be in the satisfaction of an inner ideal, when a man knows he is listed as a hero. It may be for the purpose of obtaining a well filled purse or the hope of promotion to a higher position, but the hope of reward is generally there. I do not mean to infer that men will not rise to great occasions unless the hope of reward is dangled before their eyes like the proverbial "handful of hay before the nose of the donkey", but I do believe that the hope of reward is a great incentive toward heroic action in time of accident and if the hope does not arise beforehand, there is always a certain expectancy of it afterward. In these days of compensation awards and beneficial association payments, both of which are admirable and should be highly appreciated by all; yet in order to win the advantage they hold out, one must become a victim of circumstances. Whereas the efficient careful worker who is not a drain on the resources of a business but distinctly an asset, receives nothing but his wages as his reward.

Of course no man injures himself intentionally, but a great many do so needlessly and it is these we are most anxious to correct. Just as every industry has its own problem of management so it has its own problem of fixing the responsibility and rewarding those showing activity in time of accidents, and no doubt they can work out their own methods in their own way better than a person who is not familiar with the many complex questions extending into the matter. So we come to the conclusion that any system which hopes to keep a man at his top efficiency either in production or safety must be prepared to see that the reward which should come to him shall be commensurate with the acts performed.

In life, as it is, loyalty must be rewarded with loyalty and sympathy and co-operation. Punctuality and continuous service in all modern organizations are rewarded with body comforts and ease when the body has lost its vigor, and so should special safety acts be rewarded as best befits the effort put forth to promote the habit, correct the evil, or alleviate the suffering of the injured.

Ideas, methods, and suggestions for safety should be rewarded by opportunities for educational or other advantages.

No organization can afford to be less careful of the reward for the safe worker than it is of the reward for its own efforts, for taking and not giving is a doctrine of the past. Taking and not giving has put a world in arms and has brought abysmal woe to the Nations of the Earth. Taking and not giving shortens the lives of the drones in every hive, for nature demands her price—a compensation for everything—and it is the veriest truism to say that she will be paid.

**CHAIRMAN MACLACHLAN:** You have heard a paper that comes into the work of everyone here. You know, as well as I do, when you talk to a foreman or superintendent regarding a man who is careless and tell him to reprimand that man, you get the answer, "He's a good man and we have got to keep him". We know the result of keeping some of these good men that are careless, and I would like to hear a very thorough discussion on this paper.

**DISCUSSION**

**MR. J. B. DOUGLAS:** Having heard the subject brought up and discussed along rather unusual lines last year, at which time there arose quite some difference in opinion in the question of disciplining employees, I didn't know just what turn Mr. Foster's paper would take, and I was certainly very much pleased to find that it was most reasonable in every respect.

A number of employes have, of course, been discharged. During the last two or three years the habit has been to retain certain men that otherwise would not have been retained, due to labor conditions, but one or two concerns with which I am acquainted have claimed that they would discharge a man instantly if he were guilty of neglect of duty, and I have often wondered just how they did it and maintained their organizations intact. I thought that it might be interesting to get the viewpoint of two department heads in our work at Philadelphia, and with that end in view I brought comments with me from our engineer of manufacturing and our engineer of distribution, the engineer of distribution having to do with all the work on the street, and with your permission I will read first the comment contributed by Mr. P. T. Dashiell.

**PHILADELPHIA GAS WORKS**

September 13, 1920

**DISCIPLINE AND ACCIDENT PREVENTION**

In the Manufacturing Department of the Philadelphia Gas Works in case of a serious accident, great care has always been taken to find out the cause of the accident; and if the accident was shown to have been caused by neglect of some employee or employees, great care has always been taken definitely to locate the responsible parties.

If, in cases of this kind, it can be fully shown that the accident was due to wilful negligence—sleeping on duty, for instance—or to complete disregard of the Company's interests on the part of the employee, the employee has been discharged forthwith. At the same time a complete exposé is made of the whole matter to other employees who might be brought in contact with a similar situation, so that they may profit by the experience, and so that they may also know what might happen to them in a similar case. It has been extremely rare, however, that any of the accidents that have occurred could be traceable to direct wilful carelessness.

In nearly every case, the accidents have been caused either by lack of foresight, slowness on the part of some employee to realize what was going on about him, or to the lack of judgment on the part of some employee. In such a case, where the desire of the employee has been to do

the right thing and to work to the Company's interests, we have always felt that a serious talk with the employee, by some one in authority, preferably his immediate superior, but in some cases by some one very much higher up than his immediate superior, was better for the Company's interests than the dismissal or disciplining of the employee.

In very many cases after an accident in which the Company has been the loser, but which came about rather from lack of judgment or oversight than from carelessness, the employee has usually shown that he felt the damage more than the Company, but, of course, in "a different place." We have always felt that, after an accident of this kind, the employee was a better man for the experience, provided he thoroughly realized what he had done and what the results of his action or inaction had been. A careful talk over the happenings which led up to the accident and a clear understanding of the results of the accident by him will make him more careful the next time, will add to his experience and will make a better all-around man, unless the accident has been of such a serious and horrible nature as to destroy his nerve control, in which case we believe that the man should not be discharged, but given other work and an attempt made at least to resuscitate his nerve strength.

In my own experience, there have been very, very few occasions where it was necessary to discipline an employee for an accident, and I have seen many men benefited very much by the experience of having been through an accident. In the case of chronic bad judgment, however, or wilful carelessness, lack of appreciation of his relation to the Company's interests, I believe that the employee should be let go promptly and not given a second chance to bring about a financial loss to the company which he serves.

P. T. DASHIELL

Assistant Engineer of Works

#### PHILADELPHIA GAS WORKS

#### ACCIDENT CASES FROM THE STANDPOINT OF THE EMPLOYEE RESPONSIBLE FOR THE ACCIDENT

In the Distribution Department of the Philadelphia Gas Works, we have always tried to proceed upon the theory that our employees mean to do the right thing. Therefore, when an accident occurs and the circumstances indicate that it may have been due to the carelessness of an employee, we attempt to keep an open mind in the matter until all the facts are known and it has been definitely shown where the blame lies. If there is no doubt that the employee was to blame for the accident, and if, in addition, the accident belongs to a class about which cautions have been previously issued, we are brought face to face with the fact whether or not the employee should be disciplined. Assuming it is not believed that the punishment need be as extreme as permanent dismissal, then the justification for any punishment at all lies in such punishment being deemed necessary either to prevent a repetition of the accident on the

part of the employee concerned or on the part of any other employee. We believe that a case of this kind should, wherever possible, be handled by the department head, and if he is wise, he will not make any decision until after he has had a heart-to-heart talk with the employee himself. Of course, his action should also be influenced by the previous record of the employee.

We recently had a case where the company paid over \$5,000 in damages to three persons injured by a motor truck. There is no doubt that the driver was careless, and yet after a thorough consideration of the case and a talk with the driver, it was decided that he had already learned his lesson and that no good would result to him from any punishment. Therefore, as he had always been a trustworthy and efficient employee, he was not disciplined. To prevent his case being used as a precedent later on, a suitable notice was posted on all the bulletin boards, calling attention to the case and the fact that its disposition would not serve as a precedent for similar accidents in the future.

In the above, we have tried to make clear that when treating accidents in which employees are concerned, we follow our general rule of emphasizing the personal element and of treating all our employees as individuals rather than as a mass.

WALTON FORSTALL,  
Engineer of Distribution.

**Mr. E. C. CARPENTER:** In questions involving discipline, who passes upon the discipline and who administers it?

**Mr. C. B. HARDIN:** Is there any reward given to the workman for the prevention of accidents?

I think we have been a little lenient on account of labor conditions in the past. We think a man has to be a very objectionable character before we would penalize him to the extent of discharging him. We have, however, two very pointed cases of accident where one of the men was found to be absolutely careless, and in that case we discharged him and that was all there was to it. In ordinary carelessness, we reprimand the men and draw their attention to the matter but we don't discharge a man for those little things.

I don't believe we can get the just results by offering a reward. I think it is better to teach the man that he has to do these things because they are right and until we succeed in getting the men to take that point of view, we are not really going to get the best results.

**Mr. W. A. NESSER:** I was interested in a plan for penalizing workmen for infraction of the rules of a large railway company in the East. I asked the superintendent for the ideas of his company along those lines. He said that they held the employees accountable for a knowledge of the safety rules as well as the operating rules, and they penalized them in this way: Rather than discharge a man for a first or second offense, if he broke any of the rules, they gave him a suspended sentence of ten days and then within the course of a year, if he did not break that or any other rule, the slate was wiped clean; but if, in the course of the year, he did break the rule, then he was given the double sentence. I believe

the suspended sentence is a mighty good thing. This superintendent told me that his company found it worked very well and that they have very few repeaters.

**MR. HERMAN SPOEHRER:** I have referred once or twice to a bonus system which we have. We have a research department that goes into the cost of operation, the cost of installation of meters, etc., and when unit costs are established, if a particular crew obtains better results than another accomplished in the installation of meters, for instance, and does the work at a lower cost, those crews are given a bonus. In that way the reward always comes to the crew that has the best record for lack of accidents or loss of disability hours, and that automatically takes care of the penalty and reward.

**CHAIRMAN MACLACHLAN:** I will ask Mr. Foster to close the discussion.

**MR. WILLIAM FOSTER:** We seldom have occasion to enforce the rule regarding discharges. We do discharge men but we have been obliged within the last four years to discharge only two men. That has been so effective that it was unnecessary to discharge others. We teach our men the safety rules and expect them to live up to them, precisely in the same manner as we teach them construction rules and expect them to live up to them.

As I said in my paper, "Temporizing with conditions of this kind will bring its harvest of indifference toward safety work on the part of workmen and this we cannot and should not tolerate." I believe that we should not temporize with this situation any more than a business manager should temporize with a commercial man who is unable to give him his support.

**CHAIRMAN MACLACHLAN:** I want to thank Mr. Foster for his excellent paper.

Mr. George Opp, of the Detroit Edison Company, Detroit, will now present his paper on "Accidents to Meter Readers and Other Employees on Equipment Outside of the Company's Premises."

### ACCIDENTS TO METER READERS AND OTHER EMPLOYEES ON EQUIPMENT OUTSIDE OF THE COMPANY'S PREMISES

GEORGE OPP, SAFETY ENGINEER, THE DETROIT EDISON COMPANY,  
DETROIT, MICH.

In the consideration of the electrical phase of this subject, we may consider:

First, the hazards that are potentially and actually causing the accidents in the varying degrees;

Second, the manner and method of avoiding the occurrence, and surely by all means, the recurrence of all such accidents.

By way of introduction, let us remember that accidents are ALWAYS to be regretted. They serve no beneficial purpose and their effect generally is to upset schedules, delay useful operations and inflict pain and injury

often causing rush trips to the hospitals and sometimes regrettably premature flower-bedecked caravans to the so-called "marble orchards" on the hill.

The only iota of good than can possibly be extracted from an accident lies in the study of its causes—and generally accidents ARE caused, though sometimes we feel that they just happen with a wicked perversity—and in the determination of the possibility of its happening again, and the taking of adequate and effective action to ward off any recurrence.

We shall attempt to get a close glimpse of the regular routine of, and to enumerate briefly the various accidents that may befall an electric meter-reader, and then also take a glimpse into the lines of their closely associated workers, the meter testers, meter repairmen and meter inspectors, and, finally, to complete the subject as it has been assigned, we shall take up the other departments of an electric utility that sometimes work on equipment off the company premises.

#### METER READERS

When we consider that within our own company there are 31 meter readers, walking upwards of five hundred miles in the aggregate daily, climbing up on elevations and hurrying down stairs to read on the average of from eight hundred to one thousand meters per day, and when we consider that each step taken is potential of casualty, whether on icy pavements or in dark and littered basements; whether up or down stairs that are in all conditions of upkeep and lack of upkeep—sometimes so full of eatables that the iceman would growlingly refuse to go another step, yet our faithful readers politely essay the hurdles or the inclines and risk their necks in accidentally stumbling; when we stop to think of how often the readers need to cross the streets, frequently so congested as to require a serpentine course to dodge all the vehicles, or streets so beset by the monster trucks or the dashing imps of "speeders" as to sometimes require more than the usual sense of sight and sound and the quality of agility to make the crossing safely; when we think of these men (and due to war-imposed conditions, women as well, because we have had women meter readers in our service) having to adjust their eyes from the glaring sunlight on the shiny pavements and sidewalks, or the glare of winter snows, to the darkness of back stairways pierced by the feeble attempts of the pocket flashlight, and just as readily to meet the physical reaction of extremities of temperature in going in and out of buildings in rapid succession, especially in the winter season; when we stop to consider all of these various possibilities in passing, is it any wonder that there are some accidents occurring these days to the "Knights of the Tin Books and Lead Pencils"?

We wonder, especially when we realize that the existence and removal of the hazards that are encountered are beyond the scope of the meter readers themselves, and in most cases beyond power of action by the company, that the number of accidents is not multiplied several times over.

It is often a game of politeness to eradicate those points of hazard to the meter readers, and the thing has to be handled, I tell you, in mighty

diplomatic fashion, especially at a time like this, when we are somewhat up against it on the proposition of furnishing all the service that is demanded, to win the co-operation necessary in repairing stairways or cleaning up debris in basements, providing clear passageways to meters, furnishing guards on pits and offsets, removing hazards, etc.

#### HAZARDS FREQUENTLY ENCOUNTERED

A list of the definite conditions that may be set down as most hazardous to life, health, and limb, and most frequently met in the regular routine of the meter readers, would show such items as:

1. Steps missing in the stairways.
2. Loose treads on stairs.
3. Obstacles on stairs such as foodstuffs, cans, mops, baskets of clothespins being dumped into or stepped into by the men coming in from the outdoor light and being unable to discern the objects in time.
4. Poorly constructed platforms.
5. Unguarded pits and off-sets.
6. Unsanitary and treacherously slippery floors in basements left perhaps by some folks who very nicely scatter a lot of water over the high spots to wash all of the debris into the low spots and leave it go at that, generally happening shortly before the meter reader comes in.
7. Dark and unkempt storage in basements, including rubbish, broken glass, rusty nails, ensnarling bits of wire, and the like, which create stumbling and tripping hazards. (If we might enlist the Boy Scouts in this new field of activity in a campaign to get into people's basements and back stairs to clean them up, I venture to say that gathered there would be more than again as many tin cans, by far than that mass which was mentioned in yesterday's discussion in the Public Safety Committee meeting.)
8. Ofttimes the meters are located, against all requests to the contrary and contrariwise to all reason and logic, apparently, in such almost inaccessible places as over ice-boxes, in close contact with the ceiling over stoves and ovens that are invariably hot when the reader appears to give the dials the "once over"; and sometimes in cubby-holes that require the agility of a house cat, the slenderness of a Venus, and the native training of a mouse to reach.

It is funny how the attempt is made, in many cases, to "hide" the little pulsating box.

These unfavorable conditions of meter location, of course, lead in turn to climbing and straining that often involve physical peril by reason of the lack of a suitable ladder or safe substitute; and certainly we cannot expect our meter readers to always carry their own ladders!

#### LOCATING THE METER

Surely these conditions compel the undesired, yet sometimes necessary, use of such expedients as boxes and tables and chairs or stoves to build

up a mount to the zone of vision of the dials of the pulsating meter, which the contractor or owner seems to think of such minor concern when he allots the space for its presence, and which sometimes—happily infrequently, however—he later considers so seriously when he orders the “miscreant racer” out of his premises by reason of “the ridiculously high bill this time.”

We attempt to discourage the thoughtless practice of placing the meter “just anywhere”, but we find that it is being done in some cases. There is where we need, once in a while, to exercise a little bit of diplomacy in securing the change which oftentimes can be made, and generally is made, quite readily, when called to the attention of the proper persons.

Sometimes, of course, due to foresight on the part of the architect, builder, owner, or due to the provisions of building code and ordinances, the meters are quite properly located, but the customer unthinkingly and quite unintentionally blocks the passageway to the meters by articles of storage, ranging from small boxes and pails in the basement or discarded hoopskirts in the attic at home, to automobiles in the garage, or huge store-boxes that resemble elephants in repose, down at the business places. These conditions lead to possibilities of accidents.

#### DODGING THE WATCH DOG

Man's most faithful animal friend, the dog, presents for the apparent stranger reader a considerable bit of worry, torment, and even menace. Some dogs show much faithfulness—faithfulness to devilry—as they come rushing upon the unsuspecting meter man from an obscure hiding place and attack an unguarded flank. Yes, dog bites contribute quite a goodly share to our meter man's accidents, although by reason of prompt attention bestowed upon such injuries, and by reason of the special police surveillance placed upon the vicious and playful dogs that figure in these accidents, our records for the past few years show no time loss due to accidents of this cause. Some time ago we made a special effort and secured the co-operation of the police department in Detroit (and in the municipalities outside of Detroit) to the extent of having every dog-bite accident thoroughly investigated and the dog retained in pound for at least two weeks for close observation. Now we also have the assurance of the possibility of legal action against parties who might permit vicious dogs on their premises without displaying adequate signs near the doors or gates leading to their premises. So, we are going to have a real effective way of eliminating, to a large degree, that bothersome, if not really serious, source of accident.

Then, too, there is the moral hazard that is often encountered by men who have the occasion and the privilege of entering all manner of homes, hovels, stores, and hostelrys; but very fortunately, and proudly too, we can say that for some time our company has not received a complaint of even a pin having been stolen, nor has there been experienced any of the salacious circumstances that you gentlemen may know are occasionally encountered.

Sometimes, too, a meter reader has been the unfortunate passerby or by-

stander at an altercation, arriving at the scene of a domestic quarrel probably just in time to receive a shoe, a broom, or a flatiron—we have had instances of that kind—the meter man having been mistaken for the returning husband in the case.

#### METER INSTALLERS

We may next consider the accident experiences of the members of the Meter Installation Department, who logically precede the meter readers in the rotation of work but who, as a class, slide considerably behind them in the results of hazards encountered.

In addition to nearly all of the aforementioned risks that fall to the lot of the readers, the installers have a few that are peculiar to themselves. Their work takes them into partially completed structures where overhead clearances are reduced by carpenters' scaffolds and horses, or when, as yet, mayhap, no housewife's broom or porter's shovel has cleaned up the debris of construction work, and in this situation frequently are found nail-punctures, skinned knees, scraped shins, bruised bodies and bumped heads. Of course we infer that we have such competent men engaged in this class of work—and justified we are to make such assumption when borne out by an almost clear record of accidents of this nature—that such things as smashed fingers, pinched and battered thumbs and badly scratched hands are almost unknown and surely very infrequent happenings among our meter installers. Nearly all the conditions of hazard which they meet are, as in the instance of the meter readers, quite generally beyond their own or even the company's legal powers to correct physically. The meter readers have only one rule of safety—we always try to simplify these days when the "world is growing tired of codes and rules" as Mr. Berresford so aptly remarked yesterday. That rule reads "Use the utmost care in moving around on customer's premises and report at once any unsafe condition in getting to a meter."

#### METER TESTERS

Closely associated with the meter readers and installers are the meter testers. They may be grouped into two classes:

First, shop and laboratory men, who are subjected to the shop hazards of pinched and scratched fingers and hands (I pass by the electrical hazard because in the case of meter testers in our shops that source of harm has been obviated by reason of the improved cables and contact clips, flush receptacles eliminating exposed contact surfaces and loose wires).

Second, outside testers. These men periodically test substation meters, meters on 500 volt direct current railway service, and meters measuring service supplied to Primary (4600 volt) customers. Electrical hazards are ever present but are largely under the control of the testers. Special cables with convenient and positive connectors are furnished. Tools are carefully selected and inspected to remove all possibilities of harm due

to mechanical defects. Some of the tools are given additional insulating qualities. Insulated stools, rubber gloves, goggles, etc., all play parts in reducing the possibility of accident to the very minimum.

In going off company premises, the meter inspector sometimes meets such other peculiar risks as faulty grounds of meter cases, electrically charged metal doors or door knobs and key holes of primary service houses or industrial substations.

In the typical service meter installation the primary service is well removed from the meter wiring, the testing is done on the low-voltage side of the instrument transformers, and a special connection box and special wiring and apparatus are used to safeguard the testing work. The accident hazard in working on or about live circuits must be thoroughly appreciated and these men are trained to think and act safety.

Meter men are instructed to report immediately any unsafe condition. Their department's Safety Rule No. 1 emphasizes this by saying: "If the apparatus to be worked on is in a dangerous condition, or if it is located in a dangerous place, do not work on it, but make a complete report to your foreman." The testers are fully instructed in the right way of testing all installations, and the serious results of the wrong way are also pointed out.

#### BACK FEED HAZARDS

I want to take just a few minutes right here to recite the circumstances of a condition which had strong accident possibilities—one that is apt to be encountered in some of your own companies.

Recently our Inspector Sievers was sent to a primary meter installation, at the State fair grounds to replace a number plate on the meter connecting box. As the customer was through with this service, the high tension disconnect switches had been opened. While at work on the meter connection box, Sievers discovered evidence of current at the terminal and upon a further investigation it was found that this installation was being energized due to a back feed from another meter installation on the ground. This created an extremely dangerous condition about the primary house, reversing the current through 250 K. V. A. transformers, and stepping up the potential to 4600 volts.

This was the existing condition on some of the lines about the fair grounds, but was not known to any of the electricians who were about to take down some transformers from these lines. Sievers immediately disconnected the circuit which created this condition and advised the construction foreman of his finding.

The condition was quickly corrected and the man who called this condition to our attention was given a money reward as a token of appreciation. I might further state that in our practice every safety suggestion received is promptly acknowledged and acted upon, and where adopted, a check is given to the man who suggested it.

We recently had one of our boys take a backward flying trip across a customer's premises when he touched a key to the lock of a transformer house at an industrial plant. It appears that the wiring in the lighting

was obliged to stand in a puddle of water while opening the door and when he touched the lock he received a rather severe shock, the full benefit of 110 volts.

#### IS THE 110-VOLT CIRCUIT DANGEROUS?

It might be well at this point to say that 110-volt circuits demand respect. Let me read from the National Electric Light Association Bulletin of July, 1920 (page 420) relative to low tension current:

"Too many men have a feeling of confidence in their immunity against injury by shock from circuits with potentials of 110 to 250 volts, and some have far too little respect for railway currents at 600 volts. It should be remembered that while 110 volts does not ordinarily produce a very unpleasant sensation of shock and to some persons 250 volts is only mildly unpleasant, yet it is a matter of record that numerous men have been killed by 110 volts alternating current, and others by 250 volts direct. If men can be killed on 250 volts direct current, attendants in railway substations should remember that the output is decidedly dangerous, and is capable under some conditions of producing death by shock."

And from "Power" (Vol. 51, page 341) we have the following excerpt which I believe is pertinent and justifies reading in this connection:

"A report made by G. S. Ram, Electrical Inspector of Factories in England, contains some very interesting data on fatal accidents on low voltage circuits. Out of 99 fatal electrical accidents occurring in England during the period from 1915 to 1918, inclusive, 20 were on circuits of 1,000 volts and over, while the other 79 were on circuits of 550 volts and less; 59 of these were on circuits having voltages between 550 and 346, and the remaining 20 happened on circuits of 240 down to as low as 105. Of the 69 accidents occurring on circuits of 440 volts and less, it is doubtful if any of the fatalities were due to pressure greater than 250 volts, since the voltage to earth on any of these circuits was not above the latter value. Ninety-five of the total number occurred on alternating-current circuits. This is probably due to the wide use of alternating current for industrial purposes.

"Since the probable voltage of the shock in 66 of the foregoing cases was between 250 and 200 volts, it would seem that these voltages are as dangerous as 550 volts. One of the greatest dangers of accidents from electric circuits is the disregard that a large majority of workmen have for low voltage circuits, which develops from knowing that under ordinary conditions a serious shock will not be received from these circuits. However, if a low-resistance circuit to ground is made and the individual cannot readily get clear of the circuit there is danger of as low as 110 volts or even less causing fatal accidents; therefore such circuits should always be treated hazardous.

Similar cases of serious and fatal accidents have been discussed recently in other publications and electrical periodicals: i. e., The California Safety News, The 1920 Report of the National Electric Light Association Committee on Accident Prevention, and Electrical Review of May 22, 1920.

## INDUSTRIAL POWER EQUIPMENT HAZARDS

Another source of danger in the industrial power class lies in the growing complexity of dual or multiple source of potential, use of dynamotor sets, gas engine set-ups and steam turbines in stand-by or part-time industrial power plants. All contribute to the possibility of back feed from other connections to lines which may be presumed to be dead for tests and repairs.

There is, of course, the proposition of some of the industries (because they feel they cannot always depend upon the central power stations, as they have in the past) setting up their own industrial power plants and generating equipment feeding to common busses, permitting change over for power requirement. In forgetting to handle their switches properly, or on account of inadequacy of control permitting potential at unsuspected places and intervals, there is a serious hazard to our meter readers and testers which would have become a prolific source of accidents if action were not taken along definite lines of switching control in charge of the company's system operator and providing adequate locking and safeguarding of disconnect switches and busses.

## UTILIZATION DEPARTMENT

Then there is the utilization department, another group of employees who operate on "foreign soil." I speak of the inspection and service division which has to contend with such conditions as:

1. Electric hazards in changing fuses
2. Stair hazards
3. Street hazards—driving automobiles, temptation to speed for "Service First" when it is thought that "Safety First" is not appreciated by the irate and momentarily anxiously waiting customer, who may have tried to patch up his old lamp cord or lamp socket and after an intense flash, finds himself in darkness that gives him thoughts only of Hades before he finally stumbles to the telephone to summon the "Minute Men Light Restorers".

## SALES ENGINEERS

Our sales engineers are deserving of a comment under the broad and very liberal topic which I have been assigned. In their behalf I might say that they often get into rather unpleasant places in the performance of their scouting duty for the advance of the company. I might refer here to such a predicament as standing under a leaking steam pipe in a run down privately owned plant that the owner is trying to show to the sales engineer with perfect equanimity, saying, "You see, I don't need your service as bad as you might surmise. Oh, excuse me, Sir, you better step out this way. Oh, look out for that pump there; it isn't guarded. Look out for that hot pipe; it isn't insulated. Look out, there goes a part of the rim of that god-darned flywheel!" Yes, these are cited from actual happenings which sales engineers of central stations have had to face in their quest of selling service.

## OTHER GROUPS

Of course we might refer also to the experiences of linemen, both overhead and underground, who handle equipment and lines outside of the company's premises, strictly speaking; of garage and truck men who are handling equipment outside of the bounds of the company's property, furnishing repairs and service to vehicles totalling over 600 automobiles and trucks; and of inspection and test operations performed by the purchasing department and construction engineering bureau on equipment before acceptance and arrival on company premises, or of the many peculiar plights which our customers' accounts department and claims division of legal department get into regarding such bits of illegally-used equipment as jumpers and meter off-setting devices—(all off Company's premises)—but these various phases have either portions of time assigned them in the splendid program of this section, or else are so fruitful of interesting accounts and anecdotes as to require passing over at this time.

You will note an almost complete absence of mention of electrical hazard in these various phases of work—not because it is not there, for just last week I read of the case of a man who was shocked to death in the simple operation of handling a defective extension cord on a wet basement floor—but because, I believe, our men are constantly warned to be on the alert and their familiarity with the "silent juice" has bred respect and not the oft-mentioned contempt that is cultivated with familiarity.

The following is a tabulation of the accidents during one year to employees considered in this paper:

## ACCIDENTS REPORTED IN ONE YEAR (1919)

| No. of<br>Cases                  | Dept.                                                      | Total<br>Time<br>Lost<br>Hours | Percentage of<br>Time Lost to<br>Total Available<br>Man-Hours<br>Per Cent |

In the departments which we have here discussed, I believe we have struck the real keynote of the success of safety work anywhere—we make the proposition of safety a personal obligation of the man himself. We stand ready, yes, eager, to co-operate with him in any way that he may designate. The special educational training of the meter man, especially, is considered to be of importance. The training and coaching bestowed upon the man before he is assigned to a place of responsibility inculcates in him the alertness and regard for accident prevention that grows to be a matter of personal pride.

We try to get our employees to see what the practice of safety means to them. We try to make safety a *personal matter* in their own individual cases and to get them to respond by making suggestions and working for the elimination of every possible hazard.

CHAIRMAN MACLACHLAN: I will now call upon Mr. L. D. MacLarty, of the Denver Gas and Electric Light Company, to present Mr. Tewksbury's paper on the same subject as related to gas companies.

#### ACCIDENTS TO METER READERS AND OTHER EMPLOYEES ON EQUIPMENT OUTSIDE THE COMPANY'S PREMISES

F. A. TEWKSBURY, CLAIM DEPARTMENT, DENVER GAS AND ELECTRIC LIGHT COMPANY, DENVER, COLO.

The first department to come in contact with the gas after it leaves the company's premises is the street or gas distribution department, which handles the installation of mains and services. The next departments, in order, are the fitting shop and meter reading departments, including the turn-on and shut-off men.

The first division of my subject includes the main gang, and the hazards most commonly met by these men are as follows:

The gas mains of the present day are either of cast iron or steel pipe,

\*Note: This classification includes one accident to girl in office tripping over a loose telephone cord, spraining ankle, causing loss of 801 hours. Exclusive of this very exceptional accident, the time loss is reduced one-half or to 776 hours, which in turn brings the percentage of time lost compared to total available man-hours, down to 0.73 per cent instead of 1.46 per cent shown above.

The writer is indebted to Mr. Geo. Wherle for excerpts from his book, "American Gas Practice".

the latter being the so-called wrought iron pipe in general use. Cast iron pipes are joined together by bell and spigot joints, with case lead, wool lead, or cement packing, or by a universal ground joint, with white lead or red lead packing. Steel pipes are either screwed, welded, flanged, or joined by use of a patent coupling. Several cases of injury have been cited where workmen have received injuries by being pinched or caught between the joints of pipe, or burns received while making connections or couplings. I believe that most accidents of this nature could be avoided, if the pipe layer or man making connection would take ordinary precaution, while the laborers are engaged in putting pipe in position, by means of cross ropes from top of trench, to see that he keeps his hands and arms in the clear, while guiding the pipe, so joints will meet. Burns occur in most instances from the careless handling of the ladle as the hot metal is being poured around or in joint. Care should be taken to keep moisture, such as snow, water, etc., from the hot metal. The pipe layer should be supplied with proper, fitting goggles. Discretion should be used in choosing the type of glove that he wears, but under no circumstances should the pipe layer be allowed to wear a glove with a gauntlet attached.

#### DANGERS OF CAVE-INS

Many injuries in this class of work have resulted from trench cave-ins, in sandy and filled ground; precautions must always be taken to guard against cave-ins, and possible injury to workmen. In such soils the weight of the earth thrown out should be kept back at least two feet from the edge of trench, and sufficient cribbing or bracing used to insure safety. Tight cribbing is usually unnecessary unless the trench is more than six feet in depth, or the soil very treacherous in nature. Generally, either one or two sets of stringers between each bulk-head, held parallel with trench walls by use of screw braces, will suffice. The foreman should, however, use his discretion and avoid taking any chances.

After the trench has been completed for a sufficient distance the work of pipe laying can commence. For sizes up to twelve inches, the use of a derrick is unnecessary, the length of pipe being rolled to the edge of the trench, and let in by use of ropes. In this operation two ropes are necessary, one at either end of the pipe, and a knot tied in one end of ropes that are laid at right angles to the trench beneath pipe. The men standing upon the stationary end of ropes push the pipe over the edge of trench and pay out the other end of ropes, over the top of pipe to allow it to roll slowly into the trench. The men handling these ropes should wear gloves to protect their hands from rope burns and splinters. For pipes over twelve inches in size, the use of a portable derrick is recommended. In this case the pipe should be skidded over the trench opening in as near the position it is to occupy as is possible. The weight of the pipe being lifted with the derrick, the skids should be removed and the pipe lowered.

#### COLLAPSIBLE BAGS AND EXPANSION STOPPERS

Where the main is of small size, or when it is desired to supply new consumers, before the completion of the entire job, the connection to

existing mains may be the first thing to be done, and gas carried along as the pipe is laid. This policy is not to be recommended if it can be avoided, as there are hazards in every length of pipe laid in the possible failure of the bags and stoppers. In bagging off, or stopping of the mains temporarily, there are two methods in use: collapsible rubber bags that are inflated with air after being inserted in pipe, and expansion stoppers. Experience teaches that each one has its particular advantages and disadvantages, while a combination of the two make an ideal arrangement. The gas bag is liable to burst or become dislodged by excessive pressure, but is usually a gas tight arrangement, while the stopper when properly set will not become dislodged, although it is not as a general rule, gas tight. It is recommended that on all mains six inches or over both the bag and stopper be used. By this arrangement the advantage of one offsets the disadvantage of the other. Another precautionary measure taken by the company that I represent is that all pipe layers or workmen connecting or tapping the main where workmen are liable to be overcome with gas shall wear some type of breathing device. At first we had the two hour, heavy type of self contained oxygen breathing device, but in our work the men complained they were too heavy to work in and were greatly hampered in getting in and out of the trench. In most instances the men refused to wear them, stating they would sooner take the chance of being "gassed." After this discovery was made, we adopted the lighter one-half hour type. We also have a nose arrangement equipped with a positive face mask. Since the time of the adoption of the lighter devices, we have experienced no trouble with the men, and all wear them while making gas connections.

Falling or tripping, another hazard to be met in the laying of gas mains, is largely due, I believe, to the carelessness of the injured or their fellow workers. All tools, such as bars, picks, shovels, etc., should, when workmen are through with them be returned to the tool box, and should at no time be left carelessly lying around the trench, where someone is liable to stumble over them, or knock them into the ditch. Another hazard in this class of work is the danger of falling pipe. The lengths should, if possible, be placed a safe distance away from the trench opening, or if this is not possible, wedges should be placed under the lengths to prevent rolling. At the time of lowering a pipe to its place at the bottom of the trench, no one should be permitted in the trench until the pipe has been completely lowered, and then it is time for the pipe layer, assisted by men on top, to place the pipe in position for coupling. The foreman should at all times assign plenty of men to carry out this work to prevent workmen receiving strains from excessive lifting.

After the main has been connected up and before the gas is turned on in the consumer's premises or turned into the existing main systems, the air contained in the pipes must be thoroughly expelled. In small mains this can be safely and thoroughly done by removing the plug at the extreme end of the new system. In a large installation this is of vital importance and is extremely hazardous. In purging large main installations, a stand pipe should be arranged in the holes to be used for "gassing" long enough to discharge over the heads of pedestrians. A control-

ling valve should be conveniently arranged in the stand pipes, and a fine mesh gauze inserted near the top of the stand pipe. All lights and flames should be kept away, and in no case should an attempt be made to light or burn the escaping mixture.

#### TAPPING SERVICE MAINS

When a consumer makes application for gas service, in either a new or old building, on a street where the gas main has been laid for some time, the company sends out several crews consisting of three to ten men. In many cases the men are ignorant and of foreign birth, and consequently they are more liable to accidents. The foreman must constantly be on the job reminding and talking safety to the men. In tapping service mains the same precaution should be taken to protect the worker as in similar work on new construction. Curb valves are required by city fire ordinance on all services larger than two inches. We use the gate type valve, which varies in weight from seven to forty pounds, according to the size of service on which it is to be installed. Care must be exercised at all times to prevent dropping these valves and striking the workmen in the trench below; the same precaution should also be taken when installing to prevent worker from being "gassed."

While drilling through cellar or basement walls, the worker should be furnished with proper, fitting goggles, and care should be taken to see that hand tools are in proper condition, that drills have no mushroomed heads, and hammers no cracked or broken handles.

The second division of my subject, while involving several departments of the company, has to deal with the interior of the consumer's premises.

Meters and governors are installed by the gas fitting department, after the service has been installed by the distribution department.

While our company does no piping of buildings for light, and feels that its liability ceases at the meter, we believe that the consumers should profit by our experience, and therefore we insist on two inspections on all work done by outside plumbers or fitters. One inspection is made before the piping is concealed, and the final inspection is made after the pipes have been plastered over. The former is to ascertain if the piping has been laid in accordance with the rules and regulations of the Company, and the latter is to ascertain if the job is tight. At each inspection the piping should be subject to air pressure.

Upon setting meters or appliances, the fitters should take precaution to see that all tools are in good condition. Particular stress should be laid on the subject of proper objects on which to stand while working on meters or appliances. A number of injuries have been caused either from a wrench slipping or breaking, due to defective jaws or handles, or the object on which the workman was standing giving way and allowing him to fall.

#### GIVING THE CONSUMER SAFETY INSTRUCTIONS

The fitter should instruct the consumer in the use of appliances installed on his premises. For instance, the consumer should be instructed

always to open both doors of the gas range oven before lighting, and to be positive that gas is burning before closing them. Attention has been given this fact in late years by the manufacturers, so that on most modern ranges an oven explosion seldom occurs, but an impression of carefulness without creating fear is a thing to be desired.

All water heaters should be equipped with a flue or vent pipe, connected direct to chimney, or some other suitable place whereby the fumes will be carried off and expelled into the air outside the building. No water heater should ever be installed in a room of less than 1500 cubic feet air capacity, unless such room is equipped with a permanently open ventilator not smaller than 13x14 inches. In no case should a gas water heater be installed in a bathroom or bedroom.

The permanent abolishment of the use of rubber tubing or metallic tubing with rubber ends, or in fact, the abolishment of all rubber connections for gas appliances is a thing very much to be desired. There is no reason why all hot plates or other small appliances cannot be rigidly connected with pipe and fittings, while the movable or temporarily connected appliance, such as room heaters, etc., should be connected with metallic tubing fitted with a ground joint union at either end. I believe more life and property has been jeopardized by rubber gas connections than perhaps any one thing pertaining to the gas industry.

Tubing pulls apart, or becomes leaky, or the ends split or become so large that they fall off the hose nipple or cock, or someone stumbles over the tubing or steps on it, with the result that gas escapes and a dangerous condition is created.

While the work of a fitter is not particularly hazardous, it may become dangerously so at times. He is working with a gas which under favorable conditions is not dangerous, but which may as a result of accident or incompetent handling become a deadly menace.

#### OPEN LIGHTS PROHIBITED

All workmen should be forbidden to use open flames in searching for leaks. A number of accidents which occur each year from naked flames being employed in the search of leaks, demonstrates the necessity for absolute prohibition.

If there is a strong odor of gas about the premises reporting a leak, the first thing to be done is to open doors and windows to ventilate the rooms where the odor is detected. Then examine all fixtures and apparatus in the rooms and all exposed piping. Make examinations either by smelling along fixtures and pipe, or by rubbing fingers over them and smelling fingers, or by listening for the sizzling noise made by escaping gas. Where these methods fail to locate the leaks, apply a solution of soap and water by means of a soft brush to all exposed piping and fixtures, particularly to each joint filling or cock, and along pipe seams. Watch closely for the bubble that will appear where a leak of any magnitude exists.

Meter reading, turn-on, and shut-off of meters is handled by the meter reading department. The largest number of accidents occurring to mem-

bers of this department is due to causes outside the company's premises, over which we have no control, such as dog bites, power vehicles and collisions. Meter readers should be furnished with an electric pocket flash light, and the practice of using matches while reading meters should be forbidden. One of the greatest sources of evil we have to contend with from the meter reader is his effort to locate a gas leak around meter when told of a leak by the consumer. This is a very dangerous practice, because in most cases the man is ignorant of the gas business, or the dangers from fire and explosions. All men upon entering any dark hall or cellar way should first make certain that the passageway to the meter is unobstructed, and that there are no broken risers or treads on stairs, or boxes or other material lying on the floor. Falls cause many injuries.

As a further precaution to our meter readers, at any house where there is a vicious dog, dangerous stairway, or dark or dangerous basement, we have this information printed on the meter book, so when a new man goes there he knows what the danger is before he enters. This costs but very little time and expense, and prevents many accidents of this nature.

#### DEPARTMENTAL SAFETY COMPETITION

As an incentive to keep the foreman of the various departments interested in safety, we have installed a plan of safety competition, based on lost time accidents. Each competition extends over a period of six months. The standings of the various departments are posted on all safety bulletin boards throughout the various plants on the first of each month. When this competition was first started, about two years ago, the departments were grouped in two classes, each having its handicap, based on the frequency and severity rate of the departments for the two years past. To the winning department the company presented a silver trophy cup, which when won three times in succession, would remain permanently in the department. A cash bonus of \$100 was paid to the foreman of the winning department. While this plan worked well, it was decided that a higher degree of efficiency could be obtained if the various departments could be grouped under two classes according to their employment hazard. We now award \$50 to the foreman of the department having the highest standing in each of the above groups at the end of the six months' competition. Also a trophy cup is presented to each department, which, if won three consecutive times, remains permanently in that department. Some time ago we organized a question and suggestion department, composed of the heads of the different departments. Meetings are held once a month. We have installed in convenient places throughout the various plants and shops suggestion boxes, and all the workmen are encouraged to offer suggestions regarding their work, whereby greater safety and efficiency may be obtained. These suggestions are collected a few days before our meeting and are carefully looked over, numbered, and then brought before the meeting for discussion. We also have a committee of four, who afterward go over the suggestions and award three capital prizes, first prize, \$5, second \$3, and third \$2. Each man also receives one dollar for each suggestion submitted by him.

## THE RECORD FOR 1919

In conclusion it might be well to mention a few statistics of the work carried on by this company for the year 1919, together with the number and nature of accidents occurring throughout the various operations in the several departments described in the foregoing.

In the gas distribution department a total of 20,992 feet of new main was laid, making at the end of the year a total of 2,108,556 feet of main (all sizes) in use in the city. This department also connected or put in gas services on 835 new installations, making a total of 42,858 services or gas connections in use in the city. We had only two accidents, both from gas poisoning, with the loss of only three days' time. These two accidents were caused by the failure of the men to use safety devices with which they were provided.

In the gas fitting department, a total of 2,561 meters were connected, while 290 were disconnected, leaving a balance of 49,763 meters in service (not including the changes of meters due to leaks and other causes, which were also handled by this department). Two thousand six hundred and seven appliances were set and 24 disconnected, making a total of 86,468 appliances in service throughout the city. We feel that this department had an unusual record, inasmuch as it did not have during the entire year a single accident which resulted in the loss of time to a workman, a record which the men so far this year seem likely to maintain.

The meter reading department with 49,763 meters in service at the end of the year, and employing an average of twenty-five men per month, had 32 accidents with a loss of 79 days. Most of these accidents were due to animals or power vehicles, over which we have no control.

CHAIRMAN MACLACHLAN: You have heard two admirable papers on this subject. I would like a short discussion on the question.

## DISCUSSION

MR. J. F. CONNER (United Gas Improvement Company): It is essential in the hose type respirator that we take care in taking it off not to get that in a contaminated atmosphere, otherwise the person who is wearing the mask is apt to become asphyxiated. An accident along that line occurred in a demonstration in Chicago.

In regard to the self-contained respirator, instead of using the three-hour type, we use the thirty-minute type which is very satisfactory. In opening the mains we use the safety tapping machine and it does not expose the workman to any escape of gas.

MR. L. D. MACLARTY: I notice that downstairs they are exhibiting the army type of mask, smoke mask. I think this should be discouraged for use in gas companies because it will not protect the wearer from carbon monoxide which we have to contend with. I have noticed these masks around fire departments where they are used through ignorance more than anything else.

Speaking of that safety tapping device, we use it but in many cases it

leaks a little bit, so we always take the precaution of seeing that the man is equipped for the emergency if it does break down or leak.

MR. I. GORDON (Bureau of Safety, Chicago): The speaker I believe said that they gave a dollar for each suggestion. Is that given to each suggestion that is adopted or to all those contributed by the men?

MR. MORONEY: In the elimination of accidents to meter readers, it seems to me that we can make quite a campaign with the public. It's the public we have to reach by sending out a flyer attached to the gas bill. In that way we could reach the consumers and possibly educate them, although it may be hard to educate them and make things clear for us.

MEMBER: Do you ever use the wire jumper in making gas connections?

MR. B. S. BEAUMONT (People's Gas Light & Coke Co., Chicago): What satisfaction do you get in case of dog bites? We have about from five to seven a month, and where they do have signs of warning up, the owners of the dogs do not use any care—in fact, they seem anxious, sometimes, to have the meter reader get bit.

MR. GEORGE OPP: In the question of dog bites we have the assurance of legal action. In the case where a dog is known to be vicious and is kept at the home or on the premises of a customer without adequate signs, we have the chance for legal action which not only involves the proper disposition of such dog but also recompense by way of damage to the man who suffers from the dog. I think that will most certainly solve the proposition.

MR. L. D. MACLARTY: To answer the question whether or not we pay the men for all suggestions or merely for the suggestions adopted—we pay for all in order not to discourage the men and let them think that we ridicule their suggestions in any way.

In changing meters on old hose pipings, if a leak is discovered and cannot be remedied by the meter changer, he refuses to set the meter and refers the customer to a plumber to correct the leak, and when that has been done the customer notifies us. Then the meter changer goes back again and sets the meter.

The use of wire jumpers for gas connections is an engineering feature with which we have had no experience.

CHAIRMAN MACLACHLAN: I would recommend to the incoming officers, that the only way of holding these sessions is to have the papers printed beforehand, distributed to the members, and then read here in abstract, in order to give us time for discussion.

I wish to thank the speakers for presenting these papers. I also wish to thank the Executive Committee and the chairmen of the various committees who have made this meeting such a success.

ADJOURNMENT.

## **Rubber Section**

**September 29, 30, and October 1, 1920**

---

**SIDNEY M. SCHOTT, Chairman**  
Morgan and Wright, Detroit, Mich.

**E. H. FITZGERALD, Vice-Chairman**  
Federal Rubber Company, Cudahy, Wis.

**R. N. WATSON, Secretary**  
Goodyear Tire and Rubber Company, Akron, Ohio

---

### **WEDNESDAY MORNING SESSION**

**T**HE meeting was called to order at 9:45 A. M., by the Chairman, Mr. Sidney M. Schott.

**CHAIRMAN SCHOTT:** We will start the meeting with the reports of the various committees. This is the first year that the Rubber Section has done any work as a formal section and most of the work done for the past year has been to get things standardized and on such a basis that the various members of the rubber industry will be on common footing for comparisons and interchange of ideas.

Report of the Bulletins Committee, Mr. W. N. Fitch of the B. F. Goodrich Company, chairman.

#### **REPORT OF BULLETINS COMMITTEE**

**MR. W. N. FITCH:** During the year—up to September 15—there were eighteen bulletins of the Rubber Section published; sixteen will have been distributed by the National Safety Council at the time of this meeting. Permit me to add that we have had splendid co-operation from a great many of the rubber companies. It is to be expected that photographs and subjects for bulletins will be sent in which are not applicable in all of the rubber plants. The importance of this point was brought to my attention upon the receipt from one of the rubber companies of a suggestion for a bulletin which operation I knew was not carried on in the Goodrich mill. It occurred to me that such might be the case in other rubber plants. Would the bulletin be of any value? Therefore, I communicated with nearly twenty rubber companies, stating the situation and asking

them to advise whether it existed or if they had had any accidents and whether a bulletin would be of any value on the subject. I received thirteen answers and in only one of them did the condition actually exist.

Bulletins to be of any value must cover the situation in which accidents have occurred. The right and wrong way should be demonstrated in the photograph or sketch on the bulletin, each one being emphasized by a very plain and short description.

The subject of the bulletin must be short and to the point. It is important that in showing the right way that you do not leave in the same photograph an opening in which an accident might occur. Bulletins of this type have been sent in and have even been published. Where an employee notes such a discrepancy, the value of the bulletin is then destroyed and it has a moral effect on all future bulletins.

Too much importance should not be placed upon bulletins of severe accidents as being the only ones of value. There are thousands of minor accidents occurring continually in rubber industries of which bulletins can be made and the thought conveyed to help eliminate future accidents.

Gruesome bulletins are considered by many of no value. However, an occasional one leaves a very lasting impression upon the mind of many employees.

Comical bulletins have their value and should be run occasionally to put a little spice and merriment into life, yet there are many comical bulletins which are very constructive.

Mr. Rosseland, who has charge of the preparation of safety bulletins for the Council, has requested me to turn over any material that I may have on hand for future bulletins. I am very sorry to find that we have none on hand.

Please permit me to thank you, other members of the committee, and the various rubber companies for their splendid co-operation.

CHAIRMAN SCHOTT: Report of the chairman of the committee on Accident Standardization and Statistics, Mr. R. N. Watson of the Goodyear Tire and Rubber Co.

#### REPORT OF COMMITTEE ON ACCIDENT STANDARDIZATION AND STATISTICS

MR. R. N. WATSON: I suggest that you all get copies of the National Safety Council's "Safe Practices Bulletin No. 21," which is on accident records—how to compile and use them—and then change the charts which are shown in this Safe Practices pamphlet to correspond with the sheets we have prepared, and use the explanation given in the pamphlet.

One change that some of us want to make is to add a column showing the cost in cents per hundred dollars of payroll. That corresponds to the rating which an insurance company gives you. They say, for instance, our rating in Ohio was 80 cents per hundred dollars of payroll with the Industrial Commission, and we would like to know what it is actually costing per \$100 of payroll. At the present time our cost at the Goodyear is running 30 cents per hundred dollars of payroll against the commission rating of 80 cents, and I think Schott at his plant has a rate which is

around 27 or 28 cents. So that shows you that the Industrial Commission rating on the rubber industry is entirely too high, and it is my opinion that if we get a lot of figures together showing that we can actually run our compensation section for 30 or 35 cents per hundred dollars of payroll, we will get a reduction in our rate as charged by the insurance companies.

We put in a plant in California and they wanted to charge us \$1.35 a hundred dollars, and we refused to pay it. We went out there and took up the matter with them and showed them our statistics, and right off the bat they gave us a reduction of 70 cents per hundred dollars of payroll. It certainly paid us to have the figures available. The rest of you can profit to a similar extent.

Here is one other sheet—the schedule which is used on the severity rating. That is, if a man loses a finger or a hand, and you want to rate it on your severity and extent of disability chart you have to know how many days we assigned to that particular entry, and I have some figures here which are made up and adopted by the National Safety Council and which have also been adopted by the United States Department of Labor as being standard figures. These are available to all of you.

Please check this proposed method up with your own work and see how it compares with the charts that you have at present. I wish you would correspond with me on any suggestions or changes that you have on the charts, and I hope that by the time of the meeting next year we can get figures from each company. I don't propose to come up here and say that the Goodrich and the Goodyear, etc., had such and such rates, but I think we ought to assign numbers. We will say Plant No. 1 had a rate of 10 accidents per thousand men employed and Plant No. 2 had a rate of so much, etc., and you will know what your own number is and you can pick out your place on the chart and see how your score compares with everybody else's. The same thing on the rate per hundred dollars of payroll. I think that way we will be able to get something out of our accident statistics.

CHAIRMAN SCHOTT: Undoubtedly some discussion is required as to the best manner of compiling these statistics, but the fundamental idea as expressed by the National Safety Council in all its researches and investigations and working with the U. S. Bureau of Labor Statistics has been that it is possible to standardize statistics for any given industry.

CHAIRMAN SCHOTT: Report of the chairman of the Program Committee, Mr. H. T. Martin of the Fisk Rubber Company.

MR. H. T. MARTIN: I think the program reports for itself. We have been fortunate in having no refusals and it stands about as originally adopted.

CHAIRMAN SCHOTT: The work of the Rubber Section is largely inspirational and for that reason the first and third programs of the section were designed to be inspirational and the second session on actual mechanical safeguards.

Report of the Engineering Committee, Mr. C. B. Mitchella, Engineer of Design and Construction, The B. F. Goodrich Rubber Company, chairman.

## REPORT OF THE ENGINEERING COMMITTEE

Mr. C. B. Mitchell: This Committee has been requested by the Executive Committee to submit a report on the best type of floor in Mill Rooms and in front of mills.

There are several kinds of floors and floor coverings being used in mill rooms. Among them wood and cement are most common. Wood flooring is not suitable for a mill room, as the boards will invariably shrink and produce wide crevices. The edges of the boards will be broken off by truck wheels because they do not lie tightly against the adjacent boards, and gradually the whole surface may be broken down. The crevices hold dirt and germs and in time a wood mill room floor becomes very insanitary.

A wood block floor will stand up under all the abuses which may be expected in a mill room, but it cannot be kept as clean as desirable because dust and pigments will lodge in the spaces between the blocks. It is very doubtful if any mill room floor receives sufficient abuse to warrant the greater expense of a wood block floor.

A cement floor is best, as it will withstand indefinitely the most severe usage and is clean and most sanitary. However, a cement floor may become polished and slippery from soapstone and other pigments if proper provisions are not made. New floors can be laid so as to be smooth and hard, but not slippery, as follows:

Proceed as in a neat cement floor finish to the point where the area has first been wood floated to a level surface and finished smooth with steel floats, then sprinkle the finished area with a dry mixture composed of one part 12-30 carborundum grit and parts of Portland cement. Wood float to a smooth surface and finish with steel float. Sprinkle the area a second time, wood float to a smooth surface and again finish with a steel float. In the two sprinklings use one and one-third pounds of carborundum grit to each square yard of surface. Cover and keep wet seven days, or longer, same as would be done for neat cement finish.

The above method will make a floor surface which is considerably harder than the ordinary cement finish. This method can also be used in combination with the metallic floor hardeners.

However, many mill rooms are in operation with old cement floors, laid improperly and insufficiently hard, which are breaking down under heavy trucking loads and various abuses. Wherever possible, portions of these old floors ought to be replaced as required with a cement finish as specified above, but where this is not possible the old surface should, at least, be hardened by a liquid floor hardener. If the old floor is smooth and slippery there does not seem to be any satisfactory way to make it non-slip. Frequent scrubbing will help, but this cannot always be recommended.

In front of the mills a slippery cement floor may be overcome by covering with a rubber mat, preferably perforated. In several instances such a cement floor has been roughened by a steel pick with good results so far as the slipperiness is concerned, but not best from the standpoint of cleanliness. Metal floor plates have also been placed in front of mills,

but these will wear smooth and slippery unless a non-slip material is instituted within the metal. The latter is a rough surface and cannot be most thoroughly cleaned. The life of any floor will be prolonged considerably if all truck wheels are covered with rubber tires.

Floor surfaces ought to be level throughout so that workmen will not be compelled to step down into pits or up on platforms.

CHAIRMAN SCHOTT: The Engineering Committee has been formed for the purpose of rendering service to any members of the Rubber Section. Engineering problems in the rubber industry should be sent in to the chairman of the Rubber Section who will transmit them to the Engineering Committee for action.

Report of the Committee for the Standardization of Safety Rules in the various rubber plants—Mr. Harold Keating of the Morgan & Wright Plant, Detroit, Chairman.

#### REPORT OF COMMITTEE ON STANDARDIZATION OF SAFETY RULES

MR. H. F. KEATING: I wish to present a report of the *Committee on Standardization of Safety Rules*. These rules apply particularly to the Morgan & Wright factory. It is realized that the rules of one factory cannot wholly apply to all others. Time has been limited preparing these rules, so as to be of more general application to all of the factories in the rubber industry.

These rules are compiled from the safety rule books of several of the largest rubber companies that have given splendid co-operation along this line.

The rules may be either printed in a book, for the whole factory, or may be printed separately for each department. The general rules on the first page should be printed in every case with each of the departmental rules.

There is a set of rules which apply to Foremen only, and should be furnished to them for their instructions and guidance.

Complete sets of these Safety Rules will be furnished upon request.

CHAIRMAN SCHOTT: We realize that these rules will not apply 100 per cent to any factory, but they are the result of comparing the rules of five or six of the largest rubber factories and incorporating in these rules all the rules which were common to those factories. We present them to you for whatever use you wish to make of them. It is hoped that these rules will be given out to the managements of the various plants throughout the country, to the foremen and in many cases to the men in the shops themselves.

Report of the Membership Committee—Mr. E. H. Fitzgerald of the Federal Rubber Co. is chairman.

#### REPORT OF MEMBERSHIP COMMITTEE

MR. R. N. WATSON: Last year at the time the Section was formed we had 43 members. During the year we gained 11 members, making a total

of 54. However, there were two companies that were dropped from the list, which makes a final total of 52. We have, I think, assurance that those two companies are going to come back in again.

CHAIRMAN SCHOTT: The next order of business is the appointment of a Nominating Committee, and I would like to appoint Mr. Harold Martin, Mr. W. H. Larkin and Mr. C. B. Mitchell as members of this committee to report at the beginning of the third session on Friday morning.

## PRESENT AND FUTURE OF SAFETY IN THE RUBBER INDUSTRY

S. M. SCHOTT, MORGAN AND WRIGHT, DETROIT, MICH.

The formation of the Rubber Section of the National Safety Council one year ago was the result of a definite need for the services which could be rendered for the betterment of conditions relating to safety, health and sanitation in the rubber industry. The desired results can only be obtained through co-operation and concerted efforts among members of the rubber industry. The purpose and intention of this Section is to benefit all persons engaged in the manufacture and handling of rubber goods.

The larger firms and manufacturers, as a rule, have very good and elaborate organizations for the improvement of conditions governing safety and health conditions, and have a staff of men who devote their entire time and thought to these subjects. The smaller firms, however, are not as highly developed, and need guidance and assistance which can be given by co-operative efforts. The interchanging of ideas and experiences will be of great benefit to them. This service will gladly be given, and it is hoped that they will take advantage of the discussion and solutions of problems which are the result of the intensive thought and effort which could only be obtained by dealing with large groups of men, and handling materials and machinery on a big scale.

The general feeling of friendship and fellowship among competitors is being fostered. The saving of life and limb, and the betterment of working conditions is of common interest to all, and future results will grow in proportion to the interest manifested. It is expected that this feeling to a large extent, already developed, will grow as time goes on.

The executives of all companies are realizing more and more that it pays to have safe plants. This lies not only along lines of physical equipment, but in the training of safe and careful workmen. All efforts should be made to have workmen realize that they should be more considerate of their fellow workmen, and more alert to avoid and prevent accidents. The only real organization for safety and health starts at the top, and not only the President should be "sold," but the works manager, superintendent, foremen, inspectors, and men,—down to the humblest worker—should realize that *Safety pays*,—not only in dollars and cents, but in the feeling that "I am my brother's keeper."

The installation and revision of manufacturing processes have in the

past been carried out with comparatively small thought as regards to safety and health, but, the successful executive of today, and the future, has constantly in mind that all processes and equipment *must* be made as safe as possible in all respects.

It is no longer the common practice to install machinery and put guards on "at some future time." Guards *must* be installed at the time the machinery is set up. In fact one of the largest manufacturers of rubber goods has printed at the top of its stationery the following:

"In selecting equipment we give special consideration to the character and completeness of safeguards provided by the manufacturer."

There has been an idea in the past that it was more dangerous, and that it was harder on the health to work in a rubber shop, than a great many other industries. This idea is now largely eliminated, and statistics will show that conditions are vastly improved, and that accidents due to machinery, and the handling of materials have very much lessened.

The work of the Rubber Section has been carried on with an idea of attacking those problems which are of the most pressing importance. Among these are the following:

#### PROBLEMS OF PRESSING IMPORTANCE

1. *Standardization of Accident Statistics:* This can be accomplished to a large extent, and will then be of great benefit to the members of the industries in promoting a spirit of friendly rivalry. It will then become a contest among the firms as to which one will have the best record of improvements.

2. *Education of the Workmen through Bulletins:* A series of these have been furnished for distribution, and these will be distributed at cost by those who wish them. In the past it was found that only about 5 per cent of the bulletins issued could be used in rubber shops. Bulletins relating to accidents common to the Rubber Industry are now being printed and distributed. Most of the lost time accidents are due to handling of heavy materials—such as cores, molds, etc.—or to carelessness—such as knife accidents, shears, picks, riding on trucks, etc.—and the bulletins are intended to call the workers' attention to these types of accidents.

3. *Standard Safety Rules:* Rules for such departments as Mill and Calender Rooms, Tire Building Rooms, Cement Shop, etc., are now being formulated, and will be presented for discussion and approval. No set of rules can apply to *every* plant exactly the same, but they are being presented as the results of experience, and can be applied where needed.

4. *Engineering Standards:* There are many problems in which members of the Rubber Section desire aid and guidance. The Engineering Committee stands ready and willing to work on any problems presented by the members. At the present time they have presented a report on best types of floors for Mill and Calender Rooms, and they are working upon standards for making Mills and Calenders safe.

5. *The Inspirational Work afforded by a Good Program:* Meetings of the Rubber Section which may be called from time to time are of great

value, and all persons are urged to hand in their ideas relating to the subjects for discussion.

The present lends much room for encouragement. May the future bear out the hopes afforded by the present.

CHAIRMAN SCHOTT: One suggestion which has been made is the appointment of a committee next year on Publicity. The work of the Rubber Section has not been advertised enough. Possibly there wasn't enough to advertise, but during the coming year we want to let all the members and the general public know what work is being carried out in the rubber industry.

Address by Mr. James Newton Gunn, Vice-president of the U. S. Rubber Company, New York City.

### SAFETY AND THE MAN

J. N. GUNN, VICE-PRESIDENT, UNITED STATES RUBBER COMPANY,  
NEW YORK CITY

I have been asked by your chairman to give an inspirational talk, though after some acquaintance with the extent of your program and of the work in safety that has been done through all of the participants in the National Safety Council, I think that I can safely agree to do just that, but we will divide the task. You will get the talk and I know I shall get the inspiration; for the secret of your work is that you must and you will continually get your inspiration from your work, and from the magnificent opportunities which that work presents.

You are members of the rubber industry which stands in importance in the employment of capital and men and the influence on the lives of the world, and the people of the United States particularly, very high among basic industries. I wonder if we all visualize the extent of that, and the importance of the rubber industry and some of its peculiarities.

I am going to digress for a moment to give just this picture. The rubber industry is peculiar in that it is concerned with two principal raw materials—rubber and cotton—which are the only two vegetable products that are consumed wholly away from the land where they are raised. In the instance of rubber, the Englishman is the farmer and the American is the manufacturer. In the case of cotton, we are the farmers and he is the manufacturer. That is true to a substantial extent, for, as you know, the British have many more spindles than we and they are dominant manufacturers in cotton.

The rubber industry is peculiarly bound up with the recent development of industry of the world. Of course, I understand that recently the rubber industry has been going through a little experience that I firmly believe is just what we might call "having growing pains"; nothing more serious than that. But irrespective of immediate difficulties in the industry, it is so well founded, and its opportunities are so great, and because it is new and attractive, it has brought to its service the minds of some of the best men in the country.

## SAFETY MAKES BETTER MEN

It is rather necessary for us to know why we are interested in safety work. It is not sufficient reason that we are preventing accidents, that we are effecting great savings against employers' liability, that we are protecting plant and men and product, nor is it a sufficient reason that we are protecting the property of the shareholders. Those things to my mind are really incidental. They are second in importance. As a result of your work you are building better men—better physically, better mentally, and better morally.

You build men with more peace of mind if your work is well done. To show how important a factor that is, insurance men will tell you that annuitants enjoy a much longer life than other members of their class. As soon as a man or woman has an annuity his stress of mind is relieved. Now, if you can relieve the workers in your factories of stress of mind you are going to add to their efficiency and add to their lives.

I think it is also interesting to note that much of your work in safety is very closely akin to the work of instruction of a child to walk or of a boy to swim or to motor. You are teaching him the elementary things, but if you are going to teach him to walk well and to swim well and to motor well in time of danger or stress, he must be taught through intensive and accurate training. The initial training is simple, but it is only the intensive training that will count.

We have all had this experience. I have driven a motor car for many years. In the last two or three years I have driven comparatively little, but seldom do I ride in a car when an object that must be avoided comes into view, or a possible danger presents itself, but that unconsciously my left foot presses the clutch and my right goes for the brake. It is automatic.

## TRAINING MAKES MEN DO THE RIGHT THING INSTINCTIVELY

It is the general use of your scheme of education to free the individual of taking SPECIFIC thought so that he may in time of danger do the right thing automatically. The rigidity of military training has little other reason than to insure the individual in time of battle performing all the multiplicity of ordinary acts that have become the subject of his intensive training so that the mind may be free to plan and execute the required unusual act.

Training men to do the right thing is so vital, not merely for the immediate ends of safety, but to insure the morale of the men, that it is the thing that should be accentuated above all of the provision of mechanical devices and all of the supplementary things to which perhaps too much attention has been paid in your scheme of publicity. Right acting cannot be extemporized. Instinct alone will not save a man. Trained instinct and intensively trained instinct is the thing that must guide him. To make the right play in the game, to do the right thing instinctively in an emergency or crisis is the result of exact training. To meet the unavoidable accident in the best way involves possibly months and even years of precedent training.

**BIG BUSINESS HAS HEART AND BRAIN**

There is another thing about this safety work that I think is noteworthy, and especially at this time when there is such an amount of ignorant criticism from many persons against large aggregations of capital. Safety work is peculiarly the development of and the product of big business. It has been made possible by big business. It has been made possible by big business because big business has a heart and a brain, but the heart and brain of big business is an aggregation of all of the hearts and all of the brains that big business has brought into its service and to which it has given big opportunity. It would be useful, therefore, to have our men understand that and realize that big business has given great opportunity to them.

I have been very deeply impressed in the last few days in realizing the extent to which the life of one big business man has influenced the lives of thousands and hundreds of thousands of people. Within the week in New York passed on a great American, a great banker, a great Jew, a great man—Jacob Schiff. The genius of this man's life seemed to be his ability at all times to keep in touch and to feel the throb of the life of men in every line of activity and every plane of thought. His example is truly worthy of the emulation of every worker, big or little.

It is particularly noteworthy that the new attitude toward our industrial problems is peculiarly the product of the last few decades; during the revolutionary period of the last half century. I don't know how to make this clearer than to call attention to this fact that the Pharaoh of the oppression—I don't remember how many years ago it was that he lived; we don't know exactly, three or four thousand years ago—had exactly the same facilities of transportation and communication that Napoleon Bonaparte had, just as good. He had roads and he had horses and he had vehicles and he had labor. Napoleon Bonaparte had nothing more. The entire world history has been changed since the time of Napoleon by the development of transportation and communication, and you in the rubber industry have contributed and are contributing to the further solving of that problem.

**THE HIGHER FUNCTION OF SAFETY WORK**

There is another reason why it is necessary for us to get very clearly the picture of our problem. In one of the Jewish books of wisdom is this picture of industry. "How shall he become wise that holdeth the plow, that driveth oxen and is occupied in their labors? Without these shall not a city be inhabited. But they shall not be sought for in the councils of the people and in the assembly they shall not mount high. But they will maintain the fabric of the world."

It is your privilege and your duty and the privilege of all of those who are directing the activities of these large aggregations of capital so to train these men that while they are "maintaining the fabric of the world" they will also have a chance to think about other things than immediately about their work; to give them the intensive training that shall protect them and make better men of them. That is the kind of a picture that I

want to give you today of the vitally important thing, the important end of all of this safety work.

It seems to me it would be extremely important if we in the rubber industry and in others could bring about the better selling of safety; not the selling of safety for safety's sake but the selling of safety for the sake of training men. We must bring about a close correlation between our other industrial activities, our Americanization work, our general educational work, and our work in safety. If we could elicit the interest and co-operation of some of our large universities and technical schools, it would be useful. It is quite within the range of possibility that the rubber industry can take the initiative and create that needed interest. You will then have men coming out of these schools with an intelligent knowledge of what this safety work is all about, and make the impression at a time in their lives so that later when they get into positions of responsibility, executive and engineering positions, they will help in the up-building of public sentiment to a very much greater extent than you will ever be able to accomplish in other ways.

It is not only important to relate the Americanization and education of our workers to safety work to build up their self-respect, their esteem of sanitation and health, their pride in their organization. Build safety work into the whole scheme of good organization and administration. Sell safety to the salesmen, to the sales department, not because the salesmen are greatly exposed—they are not—but you need their help in your propaganda. I have studied many reports of safety work and they seem to deal too much with the mechanical details and often as though they were written by insurance men endeavoring to show how good a record they have made in saving their company from something. That isn't the real end. That is only an incidental thing. It is much more important to train men and to build men, and so cure the evil at its source.

#### SAFETY'S STRONGEST APPEAL

Safety is so closely associated in the minds of employers with insurance and with protection against loss that you have to wipe all of that out if you are going to build up a dynamic interest and accomplish the thing you are working for.

It is emblazoned on the outside of your program that "Safety must be incorporated into the civic and school life and organized as a community activity." You are not going to get that until you give them something else than the saving of much money and possibly the saving of a few lives. We are so accustomed to hearing of accidents and deaths that our sensibilities seem dead, but if you can sell the idea of building better men and building new men, it will galvanize our hearts and minds to action.

A number of years ago two children were playing with one of these dissected maps of the United States. After having the map partly fitted together, they suddenly brushed it aside and commenced to turn the pieces over. Their father chided them for their impatience and for not finishing their task. One of the two daughters, who were at work with

the puzzle, said: "Oh, father, when we get very, very tired trying to fit these old rivers and towns and things together, we turn on the other side and work on the Man." The father then saw the opposite side of this dissected map had a large picture of an American Indian. The picture was large and broad, and when they had worked that out, which they could do very readily and easily, they turned it over on the other side and had the other completed map of America.

That is your problem. After you have worked very hard over your mechanical devices and all of the petty things, for after all they are petty things no matter how interesting they are, just turn on the other side and work on the Man.

CHAIRMAN SCHOTT: Address: "Health Hazards in the Rubber Industry," by Mr. C. F. Horan of the Hood Rubber Company, Watertown, Mass.

### HEALTH HAZARDS IN THE RUBBER INDUSTRY

CHARLES F. HORAN, HOOD RUBBER COMPANY, WATERTOWN, MASS.

In order to consider the occupational disease phase of industry from the standpoint of safety engineers it is necessary that we understand something of the chemistry and physics of life and the physiology of the human animal. From a strictly physiological standpoint there is but one type of natural death. When an individual lives to a ripe old age and his body is filled with the end-products of natural metabolism—when his body is actually worn out—he alone can be said to have died a natural death. If this same individual had died when thirty years of age from benzol poisoning, typhoid fever, or an industrial accident, his death would have been an accidental one, as the bacteria of typhoid or the vapor of benzol would have been foreign substances to his animal body. Accepting this fact, we have accidental and natural deaths and accidental diseases. There are no natural diseases to the human body.

The problems of a safety engineer in industry would seem to be:

1. The prolonging of the individual's natural life.
2. The prevention of accidental deaths, whether due to traumatic or other causes.
3. The prevention of accidental diseases with their resulting poverty, misery, and economic loss.

It would seem, therefore, that one of the duties of a safety engineer is the preventing of occupational diseases and deaths. But in order to prevent diseases one must know what the diseases are, how they are caused, and how they may be prevented.

The occupational diseases may be defined as the unusual physical conditions due to specific poisons, mechanical irritation, physical and mental strain or faulty environment, resulting from the specific conditions of labor. They may be either acute or chronic; may be the cause of instant death, more or less prolonged invalidism, and incapacity for further work; and may lay the foundation for other diseases of equal or greater hazard. They arise from a variety of poisons, irritant substances and exposure to

unusual physical conditions. They are for the most part the outcome of conditions of modern life, whereby new combinations of substances are being constantly employed in industry. In some cases diseases arise from the general environment of the worker. In addition to the diseases derived from the hazardous occupations there are others, notably tuberculosis and pneumonia, which readily assail those whose physical resistance has been undermined by exposure to toxic substances or faulty environment.

Broadly speaking, occupational diseases may be due to one of three causes:

1. Poisonous or irritant materials which enter the body.
2. Conditions associated with methods of work.
3. General unhygienic conditions surrounding the workman.

In a general survey of the subject of health hazards, there are three factors to be considered; namely, the industry, the worker, and the worker's home.

The industry includes the special hazardous substances employed, the conditions of cleanliness, ventilation, temperature, light, hours of labor, monotony of work, and average weekly wage as against the number of living dependents.

The worker presents the problems of sex, age, individual physique, and natural or acquired immunity.

The worker's home may be so poor, ill-kept, and ill-ventilated and his food so insufficient that some disease may arise from the home environment rather than the actual conditions in industry. This is a fact that many of the investigators have neglected to consider in charging industry with producing more than its share of accidental diseases.

There are only three ways by which an industrial poison can be absorbed:

1. As a gas or vapor
2. As a liquid
3. As a solid substance or dust

And there are only three channels through which an industrial poison can enter the system.

1. By the lungs in breathing, either as a vapor or dust
2. By the digestive tract in swallowing
3. Through the skin itself by actual contact

Several other points naturally need to be kept in mind in considering occupational diseases; such for example as to how soluble the material is in water and how far it is able to dissolve fat. The rubber industry is very fortunate in having, because of its very nature, very few industrial poisons which are soluble in water. If rubber shoe and tire stocks were mixed with soluble compounds, we should lose our automobile tires and our rubber shoes the first time they were exposed to a heavy rain. For this reason most of the compounds in the rubber industry are usually very insoluble in water. On the other hand most of the solvents used in the industry are capable of dissolving fats. This tendency to dissolve fats is what makes benzol extremely dangerous to use.

In order to illustrate the seriousness of the occupational disease problem it is of interest that the 1915 Mortality Report of the Federal Bureau of Census shows the number of deaths from chronic poisons increased from 258 as an average from 1901 to 1913, to 636 in 1915. This is an increase of 150 per cent.

In Massachusetts during 1917 there were 73,320 days lost by the employees of industry on account of occupational diseases. The rubber industry with its 2.1 per cent of all the persons in Massachusetts industry, reported all of the cases of benzol poisoning and 8½ per cent of all the lead poisoning cases. One and two-tenths per cent of all the injuries reported to the Industrial Accident Board were due to occupational diseases. Of the fourteen fatal accidents reported in Massachusetts by the rubber industry since 1916, 67 per cent were due to occupational poisons.

#### OCCUPATIONAL DISEASES

In the rubber industry the occupational disease hazards begin with the washing of the crude rubber. The work in most of the wash rooms is fairly heavy and wet. The high relative humidity interferes with the elimination of moisture from the body; and there is danger from the constant wetting of the body. At the present time it can be said that there are no recognized diseases which are transmitted by the rubber itself, although there does seem to be an unusually large number of boils and carbuncles among the employees who handle the raw rubber. A bacteriological examination of raw rubber usually shows a number of spore-forming bacteria; but before raw rubber can properly be charged with producing infections, additional laboratory research work should be done. It may be that the infections are due to the fact that the employees who handle raw rubber also are exposed to much insoluble dust and the dust may be the cause of irritating the skin, and thus opening entrances for bacteria through the skin. However, in the light of our present knowledge we are compelled to say that we do not know whether or not any disease condition is caused by the rubber itself.

The mixing and compounding rooms usually present the seat of greatest hazard from the standpoint of an industrial hygienist. Here we find the hazards of lead, antimony, zinc, anilin, tar, mica, and various organic accelerators.

Of the lead compounds used in the compounding and mixing of rubber the most dangerous is probably white lead, the basic carbonate. White lead is more soluble than litharge and pound for pound is more poisonous, but it is not so light and fluffy and therefore—from a practical standpoint—is probably less dangerous. Litharge is of much more importance because it is used much more frequently and in larger quantities than white lead.

Lack of proper ventilating and washing facilities, personal uncleanness, and ignorance of the dangers from lead seem to be the major faults in most mixing and compounding departments. It is always of interest to see the excellent ventilating systems installed in the lampblack rooms and compare them with the lack of ventilation for the employees han-

dling dangerous lead compounds. In the rubber industry the lead salts are handled with a carelessness that is alarming. They are taken from open barrels, run through open casks, dumped and shoveled with as little care as if they were chalk or coal.

So long as the coal miners wear red tubes and the motorists insist on red tubes we shall always have the danger of antimony. I believe it has been conclusively shown that much of the chronic poisoning among typesetters is not due to lead or to antimony. The physical symptoms of poisoning from antimony are not unlike those due to the lead salts; and further that the miner or compositor is equally exposed to both lead and antimony. It is not improbable that some of the cases of lead poisoning are in reality due to antimony, or it might be that the employee is suffering with the results of a combination of the two metals rather than either metal by itself. In a case of industrial poisoning where the symptoms seem to indicate a condition due to lead and where it is impossible to recover lead from the excretions, the history of exposure to antimony should be carefully noted.

There has been much discussion as to the toxic effect of zinc, but it seems that those conditions which have been attributed to this metal have been due principally to other metals which have been associated with it.

#### DANGER FROM ANILIN OIL AND ITS COMPOUNDS

Probably the most dangerous materials which are handled in the rubber industry are anilin oil and its compounds. Anilin oil is produced by the action of hydrochloric acid and iron filings on pure nitrobenzol and carries with it many of the dangers of nitrobenzol. It is not improbable that the rubber industry has had a number of deaths from anilin or its derivatives but because of the difficulty in diagnosing the diseases, the deaths have probably been reported as due to heart disease. It is of importance to remember that the exposure to anilin need not be for a long time for serious symptoms to arise. There have been two cases reported in Jena which came on after an exposure of only two hours.

The records of the State Board of Labor and Industries of Massachusetts show that in three years, five employees in the rubber industry died of benzol poisoning. Many of the rubber factories continue to use this material as a solvent and its continued use is a real danger. Proper ventilation, which means an air change of at least forty times an hour, or the substitution of naphtha, or xylol compound for the benzol, are the only safe methods of dealing with this material. The English rubber concerns are substituting xylol compound for benzol. So far as I know none of the American industries are making use of xylol compound. I am not acquainted with the chemistry of this compound as it is said to have been discovered by the English Ministry of War and is produced only by English concerns. Many of the experienced rubber men object to the use of naphtha because of the fact that it is almost impossible to evaporate all of the naphtha from the cement. Benzol or xylol compound do not present this difficulty.

Because of its toxic hazards and its liability to oxidation, carbon-di-

sulphide should give way to carbon tetrachloride and even when the latter is used adequate ventilating systems should be installed.

Recently the addition to the rubber stock of hexamethylene tetramine has produced among the employees a typical formaldehyde rash. There seems to be a direct connection between the acidity of the employee's sweat and the susceptibility to this rash. Several of the rubber factories have tried to neutralize the acids in the sweat by the use of alkaline washes but this has not worked out as satisfactorily as might be expected. Substitution for this compound by some other accelerator would seem to be the safest method that could be adopted.

Owing to the increase in use of certain organic accelerators in the vulcanizing of rubber; and the fact that many of these compounds are sold under trade names which do not indicate their true hazard, it is suggested that the various rubber factories take steps to ascertain the true nature of their accelerators. The Committee on Organic Accelerators of the Rubber Section, American Chemical Society, has done some interesting work along these lines. The short report of the committee was published in the October, 1918, issue of the Journal of Industrial and Engineering Chemistry.

#### SUGGESTS COMMITTEE ON HEALTH HAZARDS

Considering the fact that 67 per cent of the fatal cases in the rubber industry in one state have been due to occupational diseases, the necessity for the appointment of a Committee on Health Hazards within the Rubber Section would seem to be needed. I shall leave this suggestion with you and hope that before the sessions of the Section are over that some action will be taken for joint co-operation among the various rubber companies for a reduction of occupational diseases peculiar to this industry.

#### DISCUSSION

MR. HORAN: I recommend that we have a Committee on Occupational Hazards in the Rubber Industry, and that it be one of the duties of that committee to get in touch with manufacturers of organic accelerators under trade names and either get information from them or otherwise and advise the members of the section of the dangers from each individual organic accelerator.

CHAIRMAN SCHOTT: I think that suggestion will be well taken and presented to the chairman for the following year for his consideration. Undoubtedly an important step forward can be taken by following out Mr. Horan's suggestion.

MR. HORAN: Both industrial physicians and the family physicians are soon going to be able to make better diagnoses on occupational conditions. There is constant agitation for health insurance and the people who want health insurance want all the information that they can get.

We must act by first of all finding out what our hazards are in the particular plants, and working with the industrial physicians and the family physicians in getting correct diagnoses. We have had three or four lead

poisoning cases reported by the family physician in cases where the employee was a boot stripper. The only lead he is exposed to is the lead in the boot. We went to the Board of Labor in Industry and they said: "Sure, your men have lead poisoning." And we said: "How can they get it from a vulcanized product?" "We don't know how they get it, but they have got it." So we went to Harvard Medical School and Johns Hopkins, etc., and asked that they give us the approximate chemical constituents in human sweat, and we made up three or four hundred samples of synthetic human sweat and we tried to dissolve lead out of a vulcanized product with human sweat, and it can't be done, and if your industrial physician or family physician tells you that a boot stripper who handles a finished product gets lead poisoning, you tell him it absolutely can't be done.

MR. OLMSTEAD (DuPont Fabrikoid Co., Newburgh): In regard to benzol poisoning, is there a way to build up men after they have been slightly affected?

MR. HORAN: In order to answer that you have to first of all look into the chemical and physical effect of benzol on the human body. This is apparently what happens. The benzol either is taken in through the skin or breathed in through the lungs and is taken up by the blood supply. It dissolves quite a lot of fat. The temperature on the inside of the body is hotter than the temperature on the outside of the body, and as a result the blood in the heart or around the inside of the body can hold more benzol per cubic centimeter than cold blood can. The blood comes to the surface and is cool, and just as soon as the temperature drops some of the fat drops out and you have a supersaturated solution of fat. Some of the fat drops out and blocks up your blood supply.

We had five cases of benzol poisoning, all acute cases. All of them died. That is the disadvantage of benzol—you don't know that you have a case of it until somebody is sick, and then there is practically nothing to do but let them die.

MR. OLMSTEAD: We have used benzol for a great many years and never had trouble until this year.

MR. HORAN: We use benzol but it is all under cover. We make a tire with a double vulcanization. We put the fabric on the core and then take the core to a stand. A man puts the chafing strip on, wets the cloth with benzol and holds it on the tire and turns the tire, wetting it with benzol. Then he puts a little white shiny cloth on the tire so that when he puts on the first vulcanization the chafing strip won't become dirty. I think benzol poisoning could have been prevented there by merely having them turn the tire the other way. It is well to remember that most of the solvents used in the rubber industry are heavier than air and if you use benzol or naphthol or sulphur chloride and you want to ventilate you must exhaust at the floor. Take benzol vapor—if benzol vapor was poured on that table it would run off just like water does; because you don't see it run off, however, you think it doesn't. So when you are going to ventilate in the rubber industry, first of all find out whether your material is heavier or lighter than air, and then you will know what to do.

MR. IRVING: Where you object to the use of aniline as an accelerator in tire factories, the people in charge usually tell you that they use it only for a short while, and therefore they don't have any constant danger. Two weeks ago I read of two fatal cases of anilin poisoning where the employees were exposed less than two and one-quarters hours. When they tell you that they don't have any anilin hazard, call attention to the fact that there were two fatal cases reported where the employees were exposed less than two and one-quarter hours.

MR. R. N. WATSON: Another point in connection with these fumes and gases that I run into, and that is when I go to the Engineering Department with a proposition it is a question to them of when do the gases reach a point which is dangerous. That means fire danger as well as the health hazard, and as safety men we are interested in that too. I have been working for the past year on an apparatus which would show the percentage of gases in the air. I had written all over the United States and several other countries trying to find if there was such an apparatus made. We couldn't find anything that was satisfactory so we had our experimental laboratory work on the proposition and they have developed an apparatus which will show the percentage of gases in the air. The apparatus has an explosion chamber. The gases are sucked into that chamber and there a heating element explodes or ignites them. It works on the principle based on the percentage of gas exhausting at a rising temperature. The higher your percentage the greater will be the temperature rise in your explosion chamber.

We can't say that the thing is down to a fine point yet, but we are now having some of them made up for use in our cement mixing departments, spreader rooms, drying rooms, and such places where we know the gas vapors do become dangerous. If we can get an apparatus it will have to work on a continuous recorder system, and we are working this thing out so that as the gas percentage rises if it gets within a certain pre-determined amount, within a certain pre-determined distance of the danger point, it will sound a signal and you can stop your operations then or proceed to get more ventilation. I don't know whether the medical profession is ready to say just what percentage of gas is injurious to the man, but I am ready to say what percentage of gas is explosive, and that is one of the things that enters into it. I thought some of you might be interested in knowing that we are working on an apparatus of that kind.

MR. OLMSTEAD: Would the variation of humidity make a big difference?

MR. WATSON: Yes, we are taking that into consideration. All of our spreader rooms and cement houses have humidifying systems in them. That makes some difference in spreading cements on fabric, etc., in connection with your static propositions, and we have already provided those, except that in our bead drying rooms we haven't such devices. This apparatus should show you when it is necessary to humidify your room or raise your humidity figure.

CHAIRMAN SCHOTT: One of the problems which confronts us is the problem of ventilation, and in some of our factories the complaint has been made that the rooms become excessively cold in winter if you in-

stall a large number of fans in the rooms to take away the gases. It is simply a question of proper ventilation. In our plant in the millroom the incoming air is brought in through ducts and it is warmed before entering the room. In other factories it may be a case that the fresh air is simply drawn in through openings in the windows and in the walls, etc., and a considerable amount of attention ought to be paid to the manner of supplying the fresh air to the room. As many men will tell you, it is almost impossible to properly ventilate a mill room or calender room because the room becomes so excessively cold in winter.

MR. E. A. HOENER (Firestone Tire & Rubber Co., Akron): The only ventilation system we have had or ever attempted to install is the type that you mention of warming the air previous to putting it into the room. That is, in the winter time. We have found it impractical to do anything else. The great difficulty we have in addition is that the men, no matter what we do, insist upon opening windows, and especially in operations in the tube department where there is a series of acids and that sort of stuff. We have a great deal of trouble through the men opening the windows, which spoils your ventilation system. It is hard to convince a man that we are supplying him with washed fresh air. He seems to think if he is working next to a window that if he opens it he gets better results. That is one condition we have always had to fight against both summer and winter. We have never had any great trouble in our mill and calender rooms because we have always heated the air before putting it into the department.

MR. HORAN: We haven't paid much attention to ventilating the calender room. Our mixing room is entirely separate from the calender room, and we do exhaust air above the mixing mills. There is a formula that I found in the Harvard Library for determining the velocity needed to remove a given dust. The formula is that the velocity equals seven hundred times the square root of the weight of a cubic foot of the dust. You weigh the cubic foot of dust and find it to be 144 pounds; your velocity would be 700 times 12. That ought to be valuable in designing ventilating systems, especially where you are trying to handle dust removal.

MR. W. H. LARKIN (U. S. Rubber Co.): One of our plants in the vicinity of Boston ventilated a mill room with 54 mills in it by putting in the usual type of hoods over the mills. We found that not only did we take the air from the room and remedy the condition of dust, but we made it so cold we could not keep the men warm enough, and we had another room next year which was added to it and that made the condition so bad that we shut the plant down. The only remedy we had suggested was by the Sturtevant people who tried to sell us their air washer, and I think it is quite possible that the air washer might be a solution.

For these two rooms the dust and air were exhausted through a 48-inch pipe. The result was that we removed the dangerous dust and the poisonous pigments possibly from the mill rooms and simply deposited them in a new place, and to overcome that we finally moved them to the penstock, and the landscape was pretty white in that vicinity, even at that.

Ventilation in the mills presents several problems which need additional study.

MR. HORAN: When you exhaust the dust when you are mixing in compounding rooms you can run most of the dust through a cyclone separator and recover about all of the heavy dust. Some dust wouldn't be recovered there. You can then take and run it through an air washer. If you do that you won't get much talc back. If you put some liquid soap in the air washer the soap bubbles do take off some of the talc dust or you can use an electrical system. My idea is to use a cyclone separator and an air washer with soapy water in the air washer. I think that will be probably developed within the next year or so.

MR. E. A. HOENER: We have a system of drying crude rubber, and if that air from drying the crude rubber were put through an air washer, would in your opinion there be any harm if we exhaust that, for instance, into the mill room as a heating unit or system in heating the mill room? Our mill room is very large. It is one great big room and we do experience some trouble especially in the morning when we start out, before the mills give any radiation at all.

MR. HORAN: You could undoubtedly do it. I wouldn't even wash it. You have got a highly volatile odor and we haven't been able to take out any of that odor with an air washer. I think it would take something a little stronger than an air washer to take some of that odor out, but if you can get it by your employees' noses, I would say it would probably be safe to do it.

MR. C. E. MURPHY (Ajax Rubber Co.): In Mr. Horan's paper he passed over lightly boils and carbuncles. In the past year we have had a lot of trouble. He said that in the compounding room few cases occur. Most of them have happened in the finishing tube room rather than in the compound room. I would like to hear the experience of some of the other members on that.

MR. HORAN: The question of boils and carbuncles might be caused from many conditions besides those in the rubber industry. We know that certain nationalities—take the negro, for instance—are very much more susceptible to pulmonary tuberculosis than others. The Armenian is very susceptible to some infections and the Syrians and the Italians are subject to other infections that apparently don't seem to touch other types of people. I think we have got to be very careful before we say that either raw rubber or a finished product is causing boils. It is perfectly possible for a very sharp dust—take dust from an emery wheel, if it was rubbed into the skin it might produce lesion that might be easily infected. The dust from talc or soapstone, on the other hand, because of the fact that the dust is rounded probably wouldn't produce that, and if he is getting it in the finishing room and it is due to the finishing room and not to nationality or poor housing conditions or other exposure to infections, I would say that it was probably due to the sharp particles of dust rubbed into the skin. I have never known of cases where that happened, but if it is due to the industry it would probably be due to that particular cause.

MR. LARKIN: Is the rubber mill a place where the slightest scratch results in blood poisoning and infection? I have never fully believed it.

MR. HORAN: To answer a question like that properly one should have some statistics on a number of cases. I am trying to get that this year. Infections might be due to rubber. I don't know whether they are or not. They are probably not. In the rubber industry, as I said before, we use insoluble compounds that aren't soluble in water and are quite difficult to wash out of the hands, and I can see a possibility of a man cutting his finger and getting some insoluble compound into it, and in another industry he might get salt or chocolate or sugar or something else in it that would dissolve in water and wash out. It might be that because of the fact that the compounds are insoluble they don't dissolve and they keep the incision open, and keep it open for a longer time than they do in chocolate industries or some other industry, and for that reason the employee is exposed to infection. It might be that in a chocolate plant a wound might heal up in two days, and it might be that in the rubber plant, because of the amount of dust and the fact that the dust is insoluble, the wound would not get a chance to heal up for a week, and that means that the employee is exposed to infection for seven days whereas in the other case he is only exposed two days. Or it might be due to the fact that he is getting it from the rubber, or it might be that there isn't anything to it. I don't know.

The only way to find out would be to take the number of treatments on account of boils in your hospital by departments and by sets—perhaps by nationality—and add a couple of factors of safety and make up your mind. But up to the present time I don't know of anybody that has done it. I am trying to do it.

MR. MURPHY: In answer to Mr. Horan,—I investigated in all our departments on boils. We only employ foreigners in our curing room. We have very few boils in the curing room. I contend that if it is rubber we must have boils then in the mill room. In the mill room we never had a boil. Practically everything we have had is up in the tube room, and also in the finishing room, and they are about 80 per cent Americans, and 90 per cent of them at that time were under 33 years of age, so they are all strong, healthy, young blood.

MR. HORAN: A bacteriological examination of the pus in these boil cases might tell one thing or another. That is, you may find that one man's boils were due to one particular organism and another fellow's were due to something entirely different. Unless you find the same type of organism all through all your cases of boils, you could rule out any one particular kind. If you find that one was a scrofula and another something else, you know that they are not due to the same cause. If the infection is different they couldn't be due to the same organism and couldn't be due to industry. It is merely a coincidence that everybody happened to have them in that department.

MR. H. F. KEATING: Is there any figure showing the ages of the employees afflicted with boils and carbuncles? As I understand it the youth is more subject to boils than men of a riper age.

Mr. HORAN: Young people have more boils than older people. Young people have more whooping-cough and young people have more measles and scarlet fever than older people have. The first reason is that with whooping-cough or scarlet fever or measles after you have once had them your blood, your white corpuscles, are educated as to how to deal with these micro-organisms. Now the youngsters get boils, and they get an immunity to the particular organism that causes the boil, and the older people don't get so many because they have already had them. Everybody doesn't become immune, but some people do get a fairly good immunity to a particular micro-organism.

As to whether or not they are beneficial—a boil is mainly a lot of pus and I would assume it is beneficial to get the pus out of the system, to get rid of the toxins and the old dead micro-organisms and dead blood cells. That is, if you have a boil it is a good thing to get rid of, and if you don't have one I wouldn't say that it is a good thing to get.

The work in the rubber industry does not result in boils except in the fact that the dust might keep your entry for micro-organisms open. I don't want anybody to think that I came in and said that the rubber industry—everybody in the rubber industry—was going to die of poisonous carbuncles, because I don't believe it.

ADJOURNMENT.

#### THURSDAY MORNING SESSION

THE meeting was called to order at 9:45 A. M., by the Chairman, Mr. Sidney M. Schott.

CHAIRMAN SCHOTT: "Safe Methods of Handling Products and Material," by Mr. P. B. Martens of the Firestone Rubber Company.

#### HANDLING OF MATERIAL

P. B. MARTENS, MANAGER LABOR MAINTENANCE BUREAU, FIRESTONE TIRE AND RUBBER COMPANY, AKRON, OHIO.

This subject covers a great many items and it is impossible to touch upon all of them in the time allotted. However, we find that a great many lost time accidents occur while material is being handled. In a great many cases mechanical guards cannot be placed, and we therefore have to resort to other means of safeguarding, namely, by educational methods.

This requires the support of the foreman and his assistants, and we feel that the foreman should be held responsible for all accidents in his department, if he has not rigidly followed and enforced the following method:

1. Instruct each new workman carefully as to his duties, especially call his attention to the danger pertaining to same, and point out to him the unsafe methods.

2. He should make clear to workmen how to use the safety devices, and insist that his instructions be carried out.

3. He should make follow-up inspections and see that his men are using the safety appliances. He must not relax his vigilance in the use of safety methods.

4. He should not hesitate to reprimand or if necessary dismiss men who continually disregard safety instructions.

The foreman who follows the foregoing rules will soon eliminate the careless and shiftless workman, and accidents will be cut down to the minimum. Co-operation of this kind must be given by the foreman before we can hope to obtain the desired result in educating the workmen to use safe methods. We must convince the workers that they themselves are the greatest losers when injured. Statistics show that 80 per cent of all accidents are due to carelessness, and could have been prevented. Therefore, the management, foremen and workmen should all assume responsibility for accidents.

#### CAUSES OF ACCIDENTS

We may put causes for accidents in two classes:

1. Carelessness, indifference, recklessness, poor judgment, lack of forethought and inexperience.

2. Lack of proper safeguards, defective tools, and defective machinery.

The causes of Class No. 1 can be overcome by consistent efforts of the foreman and his assistants, while the causes in Class No. 2 are more easily controlled, for every progressive concern wants to have its equipment guarded, and it is only a matter of inspection and installation of the required safeguards to machinery and the replacing of unsafe tools.

In the tire industry, about 60 per cent of the lost time accidents are caused by drums and cores falling upon employees' limbs and feet. In a great many cases these injuries result in partial disability. Investigation of these cases show that men frequently disobey the rules and attempt to carry tires alone, or run while carrying tires. Workmen should not be permitted to carry alone any tire over 30 inches by 3 inches clincher type, and when they carry any tire alone they should be shown how to carry them in a safe manner. We have found workmen carrying tires looped over their heads leaving the tire hang on their necks and shoulders. The workman who carries a tire in this manner has no chance when he slips or stumbles. Therefore, the method of carrying tires while on the core must be looked after very carefully. Sizes above the 3½-inch type should be carried and handled by two men up to 5 inches. Above the 5-inch sizes they should be handled by mechanical devices, either chain block or air hoist.

The foregoing also applies to solid motor tires. Workmen should not carry sizes above 4 inches alone, and when carrying this small size alone they should be carried so as to permit the top of the tire to rest against the body. Tires should not be carried with the entire weight upon forearm, as this is liable to cause strain or perhaps rupture.

Dropping of tires either pneumatic or solid will cause damage to the tire as well as injury to the workman. When a solid tire is dropped the

result will be a flat space in the rim, and this will cause trouble when applying the tire. The result of dropping a pneumatic tire while on the core is a cut in the fabric. Therefore, great care is necessary when handling tires.

When rolling tires or cores, workmen should only handle the same diameter at a time, never try to roll two or more diameters at the same time, because the larger sizes will travel ahead of the smaller and the usual result is a smashed foot. New workmen should not be permitted to roll more than one tire or core. Experience will determine the number of pieces which each workman can handle, and the condition of the floor should also be considered.

#### TRUCK HAZARDS

When trucking solid tires, we recommend that they be placed on the truck standing against solid support on one end at an angle of 80 degrees, and the last tire should be on an angle of 60 degrees, or just low enough so that the top of the last tire will fit under the inside of the second last tire. This will form a lock and prevent the tires from falling over, even if the truck should strike a depression on the floor.

When piling solid tires they should be laid flat on the floor, and the flanges of the rim base must be straight on top of the lower tire. This will give you a rigid stack of tires, but if they are not piled straight a jolt against the stack is liable to topple it over.

All aisles should be kept clear and wherever possible we recommend that a permanent clearance line be painted on the floor. This should be done at all elevators at each floor, and all trucks should be kept on the outside of this line. This will prevent loss of time while elevator unloads, and it also eliminates the danger of trucks striking against the elevator gates or being caught between the floor and elevator. Height of loads on trucks should be at least six inches below the elevator gates, and the practice of the elevator operator assisting truckers to move trucks on or off the elevator should not be permitted. The operator should be at his control levers at all times. Operators should also be instructed regarding the safe carrying capacity of their elevators, and if in doubt as to the weight of loads to be taken on, they should not hesitate to get the exact weight from the supervisor in charge.

The unloading and storing of crude rubber is the cause of injury very frequently. Workmen while breaking the boxes or while removing the covering from the bales receive cuts and lacerations, which in their judgment appear to be minor, and the usual neglected infection is the result, because the workman did not go to the hospital to have the injury properly taken care of.

Great care should be used in piling crude rubber, especially the bales, and if not properly bound by cross pieces, the pile will be very likely to fall over, as rubber will settle, especially in hot weather.

We recommend the use of a three-wheeled truck for trucking single rolls of fabric. This will enable the workmen to use one hand to steady the roll on the truck to keep it from falling when he strikes a bump or

depression in the floor. This truck should be a warehouse truck with a swivel wheel attached, which will take the weight of the load and permit the trucker to use one hand to steady the roll.

#### INJURIES FROM IMPRINT TINS

The tin used to imprint the serial number on tires has been the cause of many injuries. The tin is very sharp and when workmen remove it from the tire they cut their fingers. In some cases the tin will be covered by the stock and leave only a corner of the tin projecting, and when the workmen handle the tires, there is great danger of cutting their fingers. The elimination of this evil should be given consideration by this section. There is need of a substitute for this method.

Workmen cut and puncture their fingers while handling stock books, caused by loose nails or wires. This can be eliminated and inspection should be made to see that nails are all properly cleated, and when cleaning the books, the inspector must remove the wires or cleats which have been left in the books.

At the present time conveyors are being installed and large quantities of material formerly handled on trucks, is now moved by conveyors. This will eliminate many hazards, but the safe guarding of the conveyor must not be overlooked. The hooks which carry the material should be so constructed that material will not fall from them, and the runway should be so guarded that workmen will not be able to get their hands caught in the guide rail or under the wheels.

Accident prevention while handling material must be accomplished through educational channels, as a very small portion of this work can be mechanically guarded. Therefore, local conditions must be taken care of as they come up, and each case should be handled individually.

#### DISCUSSION

MR. W. H. LARKIN, JR. (U. S. Rubber Co.): In a mechanical mill a great many accidents are due to the fact that they take a bolt about ten feet in diameter and try to roll it along like a hoop. We have frequently had serious accidents from that cause.

MR. W. N. FITCH (B. F. Goodrich Company): In regard to the question of the men working in compound rooms eating their meals, I think that the best scheme is to provide wash rooms and, in addition, a lunch room. Whether you furnish a lunch or not, furnish the material so that they can eat there—tables and chairs, etc., and insist upon their going in there and washing. Even insist upon their lunches being left there.

MR. LARKIN: It also brings in the same old question that one of the crying needs of the safety game today is to enforce the rules and get the foremen interested.

MR. FITCH: Not only get the foremen interested, but you have to sell it to the men. You have to get those men to understand it, and you have to get up there yourself and explain that situation. If you build a lunchroom or a space set aside, a space for lunch where it is clean and

healthy and there is plenty of fresh air, and a table, and if you perhaps furnish them with hot coffee, or something to coax them across—and have them go through a washroom to get there, not allow them to go into the lunchroom until they have washed their hands—I think you could sell it to them and get them to see it. They will enjoy it after they have once gotten into it.

#### ELEVATOR GATES

MR. R. N. WATSON (Goodyear Tire & Rubber Co.): Regarding the problem of the elevator man helping a trucker push his truck on or off the elevator, I find that it is very hard to eliminate that practice, and the management doesn't seem willing in most cases to supply enough truckers to push trucks off elevators. If the load is heavy the elevator will sag a little under the cables, and it is sometimes hard to get the truck off. The elevator man will invariably give it a shove off, and the possibility of a truck being pushed on or off and striking the handle of the controlling lever has been quite a problem. We have finally put a little lock-bar on that which can be dropped down into position if the man wants to leave his elevator. It is also provided with a padlock to lock the elevator in case a man wants to leave the elevator for any reason, and I think that is a matter that might be looked into.

CHAIRMAN SCHOTT: The elevators we use at our plant are of two types. We have in our old buildings what is known as the Christianson gate, a gate which collapses vertically and when that gate is up you cannot move the elevator more than four inches above or below the floor level. The minute that the elevator gets above or below the four inches the power is automatically shut off and a brake is set. The reason that we allow the four inches leeway is for the sag in the cable when a heavy load is going on or coming off of the elevator. It is impossible to move that elevator unless the gate is down.

In our new buildings we have another type of gate which is furnished by the Houghton Elevator Company. There are two gates, one of them travels with the car and the other one is at the floor landing. When the elevator comes to the floor landing and we want to raise the gates there is an interlocking toggle device and both gates go up simultaneously and the car is then locked in position at the floor level, and when we want to move the car both gates must be lowered and the car is then ready to move either up or down. The gates are rather heavy and they require a counterweight and a good steel cable. That is the only thing I could see that would possibly even remotely be of a dangerous character, because if those gates ever fell it would be rather serious.

MR. HOENER: We have an Otis elevator of the microdrive type, which is an automatic floor leveling device. It is worked by means of a small worm drive in connection with a floor limit device. In other words, when the elevator gets within about 6 inches above or below the floor, the operator shuts off the power and automatically the elevator is brought to an exact floor level, and if a heavy load is put on the elevator it will automatically rise, at a very slow pace. It will rise so slowly

that no possible accident could ever happen to it. And then we use a Quincy elevator gate with the gate mechanism on top of the elevator, and it is handled by two chains, one on each side. It is a very heavy gate also, and the elevator cannot be moved when the gate is up even an inch off its proper location on the floor.

Mr. Scott: I have seen that work very satisfactorily, that Otis lever device, but I know of a case where they weigh about 450 to 500 pounds. It is in a large gas plant, and they have heavy coal cars. There is a possibility of them shoving these cars against the gates. They have very heavy steel gates with bumpers on them. A regular lifting device and a hydraulic is used and works very satisfactorily. You can't move the car until the gate is shut, and you can't open the gate until the car is at a full stop. They have been in service for a number of years.

#### FLOOR LOADS

Mr. LARKIN: We have a great many old buildings and many of these old buildings are used for storing material. All buildings used for manufacturing purposes or for storing material, where there are heavy weights on the floors or variable weights on the floors, should be posted with signs saying: "This floor will carry 150 pounds to the square foot," etc. In one building there was a heavy load on the third floor, and a great many people working on the first and second floors. The superintendent had on the third floor about 600 pounds to the square foot. The floor boarding was good for 600 pounds to the square foot; the joist was good for 500 pounds to the square foot; the girders were good for 300 pounds to the square foot; the columns were good for 150 pounds to the square foot; the column caps good for 75 pounds to the square foot, and how the building stood up I don't quite understand, but it was there. They often say a building stands up because it is used to standing.

That is something that more thought and attention should be given to.

Mr. A. KORINGEL (Mechanical Rubber Co., Chicago): We have an inspector who looks after that. They come around once a year and inspect the buildings, and if they find the floor card is gone they make you put up another one pretty quick. They have to approve all these cards after they are printed. They take the measurement and it is approved by the building commissioner.

Mr. LARKIN: Undoubtedly the building inspectors have charge of that, but nearly all the city departments are overworked and they come when you send for them and not otherwise.

#### PILING CRUDE RUBBER

CHAIRMAN SCHOTT: One subject of common interest to all the people in the rubber industry is the handling of crude rubber itself. Rubber comes in various forms, bales, biscuits and boxes. When the rubber comes into the plant from the freight car, the first problem is that of piling it. Our rubber storerooms are long buildings with an aisle down the center and we formerly stacked our rubber simply in large piles. We found

that in the case of boxes the wood was rather flimsy and broke, and if the piles were too high the boxes fell over. If there were bales they also fell, and biscuits, of course, just had to be piled in a mound. We therefore constructed bins in our crude rubber department. These bins are about 15 feet wide and 20 feet deep, and all our rubber is piled in these bins so that there is no danger of the rubber tipping over. This also aids in the sorting of the crude rubber.

Down the center aisle we have a portable electric elevator conveyor, so that when the rubber is piled up above the height of five feet, the men do not have to lift the bales at all but they simply throw them over on this electric elevator conveyor, and we can convey our rubber right to the back of the bin, and simply move the electric conveyor around to all parts of the bin and pile the rubber evenly, and there is no danger of the rubber tipping over.

This is a solution of a serious problem because so frequently men are injured by the piles of rubber tipping over.

MR. H. F. KEATING (Morgan & Wright): Our experience has taught us that more accidents occur in the unpiling of the biscuit than in the unpiling of the boxed rubber. We have put a rule in force that in piling biscuit rubber they have to be piled bonded. Between each layer of biscuits planks must be placed. Since we have put that rule in force we haven't had any accidents at all in that department due to this cause.

CHAIRMAN SCHOTT: "Safety and Sanitation for Rubber Mills and Calenders," by Mr. C. B. Mitchella.

## SAFETY AND SANITATION FOR RUBBER MILLS AND CALENDERS

C. B. MITCHELLA, THE B. F. GOODRICH COMPANY, AKRON, OHIO

Safety and Sanitation for Rubber Mills and Calenders covers many opportunities that if discussed fully would fill a large volume. Many schemes have been tried with varying success for accomplishing the same purpose, and it is the intention that this paper shall present only the most important precautions and the most successful installations.

### EDUCATION OF OPERATOR

Although the education of the operator is the most important of all precautions in preventing injuries on mills and calenders, this part of the subject will not be presented in detail; instead, the discussion will be confined to mechanical safeguards. However, a few pointed suggestions or rules, to develop mental alertness of the operators are submitted as follows:

#### General Rules

1. Follow instructions of your foreman and your inspectors only.
2. Wear no clothing which can be caught in the machines, such as long sleeves, loose neck ties, aprons, or unbuttoned jackets.

3. Keep your eye on the job all the time, and give your work your entire attention.
4. Keep your hands off moving rolls.
5. Never force the rubber into the bite of the rolls with your hands.
6. Never oil, clean, or repair your machine while it is in motion.
7. When cutting stock off roll, always cut below the center.
8. If you feel ill, or in such condition as to interfere with your work, report at once to your foreman.
9. Stop machine at once in case of emergency. Do not wait for instructions.

*Rules for Mills*

10. Never allow your hand to go past the top of the roll, and never reach over one roll to work on the other.
11. Watch your hands when the rubber folds over. Don't let them get caught in the folds. Be careful in doubling the ends of batches when "batching out."
12. Never cross arms when cutting or rolling stock from the mill. Learn to cut and roll with both hands. When cutting from left to right, cut with right hand and roll with left; when cutting from right to left, cut with left hand and roll with right.
13. Never take anything out of the rolls while the mill is in motion. Stop the machinery.
14. Never stand on the mill pan, compound boxes, platforms, or make-shifts.
15. Never work with one hand under the rolls while the other is above them.
16. Take care not to catch your fingers between the guide and roll.
17. The back roll of the mill runs faster than the front. Be careful.

*Rules for Calenders*

18. Never pick stock out of the bite of the rolls.
19. In starting end of liner in building up plies, keep your hands at least six inches from the rolls.
20. Never start calender unless properly signalled.

## SAFETY IN OPERATION OF MILLS

*Safeguards on Mill Parts*

**Safety Throwout to Stop the Mill:** A horizontal safety throw-out bar heavy enough to resist the struggling of an injured operator should be placed over each mill roll. These bars should be located six feet above the floor upon which the operator stands, and in plan be located eighteen to twenty-one inches to the front and rear of the bite of the rolls. (Fig. 1 illustrates this double type of throw-out.) The cross bars are made of one-inch steel rods rigidly attached to the double levers.

There are three predominating methods of cutting off the power from the mills: (1) Magnetic clutch brake mounted on motor shaft; (2) mechanical clutch on either the drive gear of mill, or on the motor shaft; (3) dynamic braking of the motor. From the experience the writer has

had on all the above types, recommendation is made to use either the magnetic clutch brake, or the dynamic brake, preferably the former, and the discussion is confined to those types of apparatus. If the magnetic clutch brake is used, it is best to place over one housing of each mill an electric cut-out switch. Many installations of mill lines have been made with only one switch for the whole line, the switch being operated by a cable running from one end of the line to the other, or operated by an equivalent rod. This method is not perfectly reliable because of the lost motion due to the variable tension in cable, or the torsional deflection and binding of rod, any of which will slow down the responsiveness of

FIG. 1. DOUBLE BAR SAFETY THROWOUT TO STOP THE MILLS

the switch. In order that the cut-out switch may be opened with the least travel of the safety throw-out bar, the switch spindle should be geared up to the throw-out lever shaft in a ratio of about five to one. Consequently, it is not necessary to move the safety bar a distance of more than three and one-half inches either up or down. The travel of the safety bar and lever is limited by an adjustable stop, which prevents damage to the electric switch by being thrown too far, and which makes the safety bar more rigid to resist the struggling of an injured operator. It should not require more than a five pound force on safety bar to throw the switch. The electric switch should be entirely enclosed so that dirt cannot gather on contacts. The wiring from the mill switches should be carried in conduits down the housing, and through the mill pits to the panel board and magnetic clutch. The brake on the magnetic clutch should be operat-

ed by a counter weight and be capable of bringing the mills to a complete stop in one second. While the mills are running this counter weight is held inoperative by a solenoid electrified by a circuit which connects the mill safety switches and the clutch (Fig. 2). This circuit is fed through circuit breakers which are held closed by a solenoid operated latch. After the clutch circuit is broken these circuit breakers cannot be closed except by operator's going to panel board and re-setting by hand. Therefore the clutch cannot be engaged if operator should first close the safety switch. It is probably useless to describe the well known construction of the magnetic clutch, but it may be mentioned briefly that this

FIG. 2. SOLENOID HOLDING COUNTERWEIGHT INOPERATIVE

clutch is of the disc type, the two discs being drawn together by electro magnets.

Dynamic braking is accomplished by cutting off the current which feeds the motor and at the same time places a low resistance short circuit across the brushes of the motor armature. The motor then acts as a generator requiring considerable driving power. Obviously this power comes from the rotating parts of the mills decreasing their momentum. As the speed decreases, the power generated by the motor decreases and brings the motor and mills to a smooth yet rapid stop.

There are numerous types of mechanical clutches which have been applied to mill drives, most of them without brake. Among these, the

spiral coil clutch and a disc clutch operated by compressed air are used, probably more than other types. No doubt a mechanical clutch can be designed for quickly cutting off the power, but a great many of these clutches now in use do not release readily. In no event should a mechanical clutch be installed without a powerful brake in connection therewith.

The foregoing methods have been applied principally to groups of mills driven by one motor, but the method is equally applicable to an individual mill with its motor drive. An individual clutch for each mill on a line of mills is not so advisable as one clutch controlling a number of mills, because the greater the number of mills, the greater is the resistance and the quicker is the stop.

It is possible that the best throw-out mechanism that might be devised may not operate when most needed, and therefore, it is very necessary that daily inspection and tests be made to determine the condition of these safety devices, and a record kept of the surface travel of the rolls. No day ought to start without this test and no mill ought to be operated until its safety throw-out is in perfect operating condition. Frequent tests with the mills loaded should be made to ascertain the surface travel of rolls.

The location of the mill pan has much to do with the safety of operator, particularly as to the distance which the operator is kept from the face of the rolls. One of the principal precautions in safety to mill operators is to prevent the operator from placing his hands beyond the top of the nearest roll. It has been found excellent practice to have the least distance from bite of rolls to edge of pan 3 feet 8 inches on 84 inch mills, and 3 feet 1 inch on 60 inch mills. If, for any reason, it is not practicable to locate edge of pan so far from rolls, then a bar or pipe guard ought to be placed at the equivalent location. The front and rear edges of pan should be smooth, preferably turned down or beaded, to prevent injury to workmen's legs.

The height of top of mill rolls above the floor upon which operator stands should not be less than 4 feet 2 inches. A height less than this gives the operator too great an opportunity to place his hands too far into mill. This height may be increased to as much as 4 feet 6 inches without making it difficult to feed stock into the mill.

The speed of mill rolls should not exceed twenty-five revolutions per minute. Higher speeds cause difficulty and danger in cutting and rolling of stock.

The roll adjusting screw which projects through front of housing should have threads of large lead, so that the mill rolls may be separated in the shortest possible time, thereby releasing an operator caught between the rolls, before he can be burned seriously. With threads of large lead, the adjusting screw will tend to back off, because of vibration, but this can be overcome by placing a quick operating clamp back of the head of the screw.

Between the roll adjusting screw and front roll bearing is usually placed a safety breaking cup. This cup often breaks into many small

pieces which frequently strike operator. A band or screen ought to be placed around the cup to confine these pieces.

#### GEARS

Gears ought to be guarded *most* thoroughly if it is probable that a workman may be compelled to be adjacent to them. It is advisable in any case to enclose the outside perimeter or face of gears with a sheet steel band to prevent oil or grease from depositing on the floor of pit. For most thorough guarding, a solid enclosure of steel plate should be

FIG. 3. GUARD AROUND PIT

provided over face of gears and down the sides beyond the depth of teeth, and the point of contact between gears covered completely. Projecting keys, and other projecting revolving parts, as well as spokes, ought to be covered with removable wire mesh, which will not prevent visual inspection of the gear parts. Proper door openings must be provided in various parts of the guards, to facilitate inspection of the gears, and the guard designed so that it may be most quickly removed when necessary to repair the mill. Guards should be attached neatly and rigidly to a machine to prevent rattling or sagging, or being knocked out of shape, for otherwise the guard may suddenly be removed by a self-appointed specialist, because of its being an aggravation and eyesore.

If there is no passageway between the ends of mills set in a group, then there is no necessity to guard the gears so thoroughly. Instead, a

pipe railing, at least 3 feet 6 inches high may be placed between the mills and be fastened to the mill housings. Pipe railing, with gate, should be set around motor panel boards and other electrical equipment, and these railings wrapped with friction tape, particularly where workmen may operate electric switch and be in contact with railing. Pipe railings around pits, such as for motor drives, are often covered with steel plate from floor to top of railing so that materials may be stored adjacently without falling into pit.

A mixing apron is desirable for continuously feeding rubber and pigments into the rolls. This apron reduces the number of manual operations which would otherwise be necessary to feed the mill entirely by hand, and therefore, it proportionately reduces the possibilities of injury to the operator. The apron should not be closer than five inches above the mill pan.

#### *Miscellaneous Safeguards Around Mills*

Many injuries have resulted to workmen who fell on slippery mill room floors, and various floor coverings such as rubber mats and non-slip metal have been provided for operator to stand upon. These are not entirely satisfactory except that light weight non-slip metal can be used to good advantage for cross overs between mills to cover pit and line shaft, and where it is necessary to remove floors for repairs to equipment. A non-slip cement floor can be made perfectly satisfactory and maintain a perfectly smooth surface. Several prominent firms have laid such floors for years by constructing the original floor finish with a carborundum treatment as follows:

Proceed as in a neat cement floor finish to the point where the area has first been wood floated to a level surface and finished smooth with steel floats, then sprinkle the finished area with a dry mixture composed of one part 12-30 carborundum grit and two parts of Portland cement. Wood float to a smooth surface and finish with steel float. Sprinkle the area a second time, wood float to a smooth surface and again finish with a steel float. In the two sprinklings use one and one-third pounds of carborundum grit to each square yard of surface. Cover and keep wet seven days, or longer, same as would be done for neat cement finish.

The above method will make a floor surface which is considerably harder than the ordinary cement finish. This method can also be used in combination with metallic floor hardeners.

#### **DANGERS OF GLARE AND EYE-STRAIN**

Several accidents have been attributed to improper lighting of mill rooms. Momentary blindness of workman caused by excessive glare of lamps may be the cause of a workman's making a wrong movement. A poor lighting system will produce fatigue due to continuous eye strain. A general lighting system of uniformly spaced units distributing light equally over the whole mill room, with an intensity of 5 foot-candles (as shown in Fig. 1) will make the mill room a safe and cheerful place to work. An inexpensive lighting unit may be used, the reflector being of

metal, dome type, porcelain enameled. This reflector used with a bowl enameled type C lamp of high wattage, will produce a diffused, high intensity, non-glaring illumination. However, where ventilating hoods are placed above mills it will be necessary to install a local lamp under the hood, in such a location that it will be up and out of the normal vision. This lamp should be covered with a heavy cage to protect it from breakage. The intensity of light on the mill rolls should be the same as provided in the general lighting system. This is important, for if the light on mill rolls were different from that outside the hood, eye strain would be produced with resulting discomforts and hazards.

*Safeguarding Health in Mill Room*

Ventilation and cleanliness are equally important with mechanical safeguards. It is possible that a workman can operate for a lifetime a machine having not a single safeguard, but not so, if he is compelled to work in a poorly ventilated, dirty room, for he may eventually become as much, if not more, a physical wreck, as if he had been injured on his machine. Bad ventilation and dry, dusty atmosphere dull the workman, and slow down his productiveness. In mill rooms the installation of a ventilating system is absolutely necessary. Oftentimes natural ventilation may accomplish fairly good results, especially in a small mill room having a high ceiling. However, it is impossible to handle a few pigments, such as lampblack, zincs, and leads, as well as soapstone, satisfactorily, without mechanical ventilation. The ideal ventilating system is one which will heat, ventilate, clean, and humidify the air; but local conditions and first cost often prevent a near approach to this ideal. Because the maintenance of air washers handling rubber pigments has been difficult, many systems have been installed without the washers, with success. A brief description of such a system is as follows:

Heat, dust and fumes arising over the mills are carried away by an exhaust system. Each mill is provided with a sheet iron hood covering the mill. The under side of this hood should not be less than 6 feet 6 inches above the floor upon which the workman stands. (Fig. 4 illustrates this hood and the air ducts.) The two sides of hood over the housings are enclosed with sheet iron, but the front and rear are open. However, conditions often demand that canvas curtains on spring rollers be mounted upon the front or rear of hood to prevent the operator actually throwing compounds across the rolls and out on other side of mill. The preferred type is the ordinary box style of hood with the air duct connected to the middle of the top through a flared connection. This style of hood insures that the air currents carrying dust and heat from workmen will go directly to the middle of the top of the hood, where the duct connection is made. An alternate type of hood has a so-called false ceiling which makes a small space through which the air passes near the outside edges of the hood. This small space creates a higher velocity near the edges of hood. There is also an opening in the top of this ceiling directly into the air duct. This alternate type does not carry all the dust-laden air directly from operator to the middle of the hood. It has the objection of carrying a great portion of the dust to the front or rear edge,

where there is a possibility of its rolling out from underneath the hoods, and it is necessary in order to overcome this last objection, to maintain a very high velocity of air which will actually carry away all of the dust.

In the preferred type a slower air velocity may be maintained, and it is found that near the center of the hood a considerable amount of the dust actually drops back onto the rolls and is mixed in with the rubber. This is one of the best features of this type of hood, for it does away with the necessity of an air washer, and the small amount of dust which is carried away through the ducts is easily collected. The hood should be

FIG. 4. EXHAUST HOOD OVER EACH MILL TO CARRY AWAY HEAT, DUST, AND FUMES

connected to the air ducts by a flexible connection so that the vibration created on the mill will not be carried to the ducts and cause leaky joints. The ducts are carried to a centrifugal multivane exhaust fan which discharges into, preferably, a vertical flue carried to the top of the building. In the case of a one-story building it is preferable to carry this exhaust flue at least forty feet above the ground level. At the base of this flue is a collecting chamber located below the entrance of the fan duct, into which nearly all the dust descends by gravity and may be removed through a cleaning door. For an 84 inch mill the volume of air for the preferred type of hood is thirty eight hundred cubic feet per minute, at a velocity of thirteen hundred feet per minute. The static pressure necessary to be maintained in the ducts varies according to the design of the

ducts and the length of runs. Such pressure will rarely exceed one and one-half inches of water.

In order to offset the large volume of air removed from the mill room through the hoods, it is necessary to feed in fresh air. In summer time this is most simply accomplished by opening the windows, but in winter it is necessary to force heated air into the room by fans. This air ought to be heated to about ninety degrees Fahrenheit, and distributed equally over the entire room. It is also possible, in order to save expense of heating the entire volume of air, to re-circulate a portion fed into the flue by exhaust fans, and also to draw air from other portions of the building, preferably from stair and elevator towers.

With the best type of ventilating system, as described, there is still an opportunity for dust to collect in various parts of the mill room. Perhaps the most frequent cause is from dusting batches of stock with bags of soapstone. This dust will accumulate on the floor and stock racks. To keep these parts of the building and floor in the cleanest condition a vacuum cleaner is advisable. With this system of cleaning there is no dust stirred up, as is the case with brooms or brushes, and the cleaning is more easily facilitated. With the vacuum cleaner system one man under ordinary circumstances, ought to clean thirty-five hundred square feet of floor per hour. This system is also very desirable to clean walls, ceilings, pipes, machinery and equipment, and motors.

Another aid to cleanliness is the running of curbs around all pits, so that rubbish, etc., may not be kicked into them.

#### SAFETY IN OPERATION OF CALENDERS

##### *Safeguards on Calender Parts*

The various methods of quickly stopping mills, previously described, are equally adaptable to calenders. The dynamic braking of motor is perhaps most simply applied and operated and requires no more floor space. A throwout bar is necessary in both front and rear of calender, and this bar should be of steel rod or pipe and be placed full width between calender housings.

Signal bells or their equal, should give warning each time the calender is to start or stop; one bell to be so connected that any workman may signal when he desires the calender started or stopped, and another bell directly connected with the motor controller or other starting and stopping device. The latter bell will automatically give warning to all workmen. If calenders are operated in trains, the safety appliances should be so arranged that operation of any one of the safety switches on the various calenders will instantly stop the entire train. The operation of a train of calenders should be as a unit, and under the control of one operator, the only person who can start the machines.

All switches and control boards should be of the enclosed type, making it impossible for the operator to be in contact with live parts. Control panels are best situated in a separate room open only to authorized electricians. Rubber floor mats are necessary in front and rear of all control boards.

## FEEDING STOCK INTO CALENDERS

Feeding stock into calenders has caused more accidents on these machines than any other operation. Nearly all of them resulted from feeding fabric or sheet rubber into the calender rolls, and into windup. Statistics show that comparatively few accidents have occurred from feeding batched gum, and there is no good reason why any should occur. A sheet metal table about twelve inches wide and the same length as the rolls, located about six inches below the bite of the rolls, will hold the gum while feeding. If it is necessary to feed small pieces of gum this may be done with the aid of a wooden paddle or pusher.

Feeding fabric or sheet gum is not so easily accomplished, and it is necessary for operator to place his hands close to the rolls, unless it is possible to use a guard which will also assist in starting the fabric into the rolls. Although numerous efforts have been made, it seems that no really efficient guards of this type have been devised, and experimental ones have generally met antagonism from the workmen as being a hindrance to rapid and successful work. Such a safeguard is most needed to feed sheet stock between closed rolls, but the space available is not sufficient to provide safety without impeding production by making it impossible for workman to place his sheet within a reasonable distance from the rolls.

## GUARDING THE ROLLS

If a calender does not require the two bottom rolls to be in contact with each other, and if the bottom roll is used only as an idler roll to return the stock to other side of calender, then the bottom roll should be lowered about three inches, a sufficient opening that a man's arm can pass between the rolls and not be pinched. Where the rolls cannot be separated to such an opening, it may be possible to separate them to such an extent that a guard can be used successfully. A guard used in several factories consists of two horizontal steel plates about 1½ inches apart, extending in between the rolls. The lower plate does not extend so far inwardly as the upper plate, and this allows workmen to place the stock onto the lower roll; and if the travel of the roll should carry his fingers forward they will strike the upper plate without harm. To be successful, this guard must be constructed very heavily, and be very rigidly attached to the machine. A scraper bar is attached to the lower section of the guard after the guard is in place, and so adjusted to the roll that there is only a very small clearance between the scraper and the roll. This scraper is for any stock which may get around the lower roll and which would have a tendency to roll up under the guard and bend it out of shape. It must be urged most forcefully that a man who is working on a calender with separated rolls shall never be transferred to another calender having its rolls in contact, for the knowledge of not being subjected to danger on the first type forms a habit of placing the hands between the rolls, and this habit will unconsciously be continued on the latter type and result in severe injury.

All wind-ups and let-offs should have a stationary handwheel for adjusting the tension in stock. This can be accomplished by mounting the handwheel on the wind-up bearing, the outside of the bearing having screw threads upon which the handwheel adjusts itself against the friction disc.

To hold the stock shell bar into the wind-up spindle, a smooth ring should slide on the spindle and cover the end of bar. This ring can be locked in position by a pin with a spring. No projecting set screws or pins should be placed on any revolving part of the windup.

All idler rolls ought to be placed as far as possible from calender rolls. Particularly is this true where the stock passes between the idler and the calender rolls, for serious accidents have occurred where the operator was caught by the stock and drawn between the rolls.

Gear guards and pipe railings as described under the subject of mills, are equally adaptable on calenders.

Non-slip floors are particularly necessary around calenders. A concrete floor with carborundum treatment, previously described, will not become slippery from soapstone because the grains of carborundum cut the pigment and prevent the latter polishing itself into the floor finish. Between the housings of the calender it is usually not practical to lay a concrete floor, and therefore, a metal floor predominates. This metal floor surface ought to be rough. Objections are often heard against this, and it is contended that a rough floor may damage the tail end of the stock which drags along the floor before being wound up. However, this objection is greatly overdrawn.

#### GOOD LIGHTING IS IMPORTANT

Illumination for calender work is important, not only to safeguard the workman, but particularly to produce work of highest quality. Too many calenders are being operated with local lights attached to the machine. The general lighting system described for mill rooms is recommended for calender rooms, except that the maximum amount of light should be given the calenders, and a lower intensity in the aisles. The intensity on the calenders ought to be 10 foot-candles uniform lighting, and about 5 to 6 foot-candles uniformly in the aisles. If glare is eliminated this difference in intensity will not produce eye strain.

The tendency in calender work has been toward increased width of stock and greater lengths, which has produced rolls of stock of great weight and unwieldy size, and consequent greater chance of injury to operator. Careful consideration of methods of handling heavy rolls of stock becomes very important. An electric or air hoist mounted on a trolley is perhaps the simplest and quickest means of lifting these rolls.

A calender may produce excessive heat or fumes, making it advisable to install a ventilating hood above, and connected to an exhaust fan. However, it is far better to have a high calender room, preferably one story, with saw tooth skylights to give good ventilation and light. If the room has a low ceiling then mechanical ventilation is necessary, especially during summer months and times of high humidity.

## VACUUM CLEANERS FOR FLOORS.

Where excessive soapstone or stock dusting accumulates on floor under calender wind-up and let-off, a suction system should be provided. This dust should fall onto and through a latticed or perforated floor into a chamber from which it is drawn into a duct and thence to a fan exhausting into a stack as described for mill room ventilation.

The vacuum cleaner principle has been applied to the cleaning of liners and this obviates most of the flying dust around calender let-offs and wind-ups. A vacuum cleaner is of even more importance in a calender room than in a mill room, for in addition to the benefit to workmen, there is an extreme necessity for cleanliness of calendered stock.

All pits and openings in floors should be free from rubbish and grease, and should have proper curbs around them.

The foregoing descriptions have covered mechanical safeguards which for a large part depend upon a little common sense on the part of workmen in providing personal care. Workmen should be educated to know thoroughly the dangers which a safeguard covers, that he may furnish the precautions which the safeguard cannot. It may be possible to safeguard a machine so thoroughly that it would be impossible for a workman to injure himself deliberately, but with the result that the workman would eventually dismiss from his mind any thought of danger. It would be folly to place such a man on another machine which cannot be so well guarded. Thorough education in safety is, after all, the most important requirement; and it not only provides protection in his mechanical duties, but it expands his mental capacity and alertness to provide protection for himself and his fellow men at all times, everywhere.

CHAIRMAN SCHOTT: Mr. Mitchella is chairman of the Engineering Committee of the Rubber Section. The greatest part of this has been worked out personally by him. This is one phase of the work which the Rubber Section is attempting to accomplish to render service to its members. We started on what we considered the most pressing needs common to all members of the rubber industry. Any other problems which come up will be welcomed and reports made on them.

## DISCUSSION

MR. G. B. WILLIAMS (Mishawaka Woolen Mfg. Co.): In regard to mill room equipment for footwear plants—that is, the safeguarding of power die machines—have you ever investigated those? We have more accidents in that line than we have in any other part of the mill room.

MR. MITCHELLA: I take it that it is a press machine, a type of punch press in which the stock is placed on a lower platen and dies the shape of the stock are placed on top of the stock, and the power comes on presses through perhaps a dozen different layers of stock. Our principal precautions on that have been to place an operating bar in front of the press—that is, two operating bars. A man must use both hands in turning on the power, and it cannot be turned on in any other manner, and those bars are far enough apart so that he can't accidentally get his

body on both at the same time. Therefore, his hands are removed from between the platens when he turns on the power.

MR. WILLIAMS: The power is not turned on. The men work in pairs. It is piece work and they are in a hurry. Sometimes there will be a little reaction and it will come down unawares. Have you anything to safeguard that?

MR. MITCHELLA: We formerly had a type of press formed by a trip clutch. We have done away with all of those so you cannot possibly turn on that power without an operator. We have one operator on each press, not two operators.

MR. WILLIAMS: Does your type of machine interfere with the efficiency of the workmen?

MR. MITCHELLA: I don't think so. We have feed rolls which feed the stock in.

MR. BRUMM (Industrial Commission of Wisconsin): I have in mind one press—I think there are three types in this particular factory—where they use a number of layers or sheets of this rubber placed on the plate. The form is set on a number of the sheets—I don't know just the number they use—and they trip this press and the die comes down. I have investigated three accidents in the past five months where the man has had the top of his fingers pinched and lacerated. A suggestion was made for a means of preventing these accidents and the man said he was going to dispense with the use of these presses and intended to use a machine that resembles a jack, where it has the swinging beam and one hand is required to swing it. I saw him about a month ago and he said that he was trying to get in touch with the men in the rubber industry to find out which would be the most practical machine in that particular line of work.

I suggested that in the meantime a little flange be attached to the form, extending probably a quarter of an inch over the side. That is, that a flange extend outward a quarter of an inch from the top of the side so that a man's hand would be underneath the die. I realize the number of forms required, but that would eliminate any chances of the man getting his finger over on top of the form. They are equipping the smaller dies now, or forms, with a handle, which of course eliminates any possibility of the man getting his hand underneath the die. They are a hazard especially where two men are working on this type of machine, and where it is piece work. The chances for accident are, of course, then increased.

MR. LARKIN: In the average rubber mill, especially in the footwear and mechanical goods, there is usually a long line of "beckers" as we call them, big machines, and a man comes along and takes a large slab of rubber, and he steps on the machine and that machine makes about 100 revolutions a minute. Every time it comes down it presses out perhaps five heels, or perhaps soles, or whatever it is. In other words, that man stands in front of the machine and works all day turning out heels or soles and a great many of them, and the press isn't quiet except when he is putting in a new slab. We have had a great deal of trouble and I imagine everybody has.

Here is what we have done to help matters. In the first place the treadle that the man puts his foot on to stop the machine has over it a long bar so that he can rest his foot on it when the machine isn't working, and that bar should be forward far enough so that when his foot slips off, as it frequently does, he won't start the machine.

In many of the mills the dies shaped like a sole or shaped like a heel were too short, and a great many people threw away equipments of dies that were perhaps only three inches high, because when a man held one would have to hold it in his hand in a certain way, and if his mind became distracted his finger would get over the top. Another trouble was that they were too long. When they are too long they tip over slightly without his knowing it, and then the thing will come down on the side and his thumb will be under it.

It was suggested that a beading or enlargement be made at the top of each die so that when a man's thumb approaches the danger point at the top of the die he knows it; unconsciously he withdraws it because it feels different from the rest of it. Another scheme was to put a little pin through so his hand couldn't get above the die. I think most accidents, however, are caused by the man carelessly getting his finger or thumb over the top of the die, brought about by the same old thing—mental lapse.

MR. HOLMES (U. S. Rubber Co.): We have had success with a traveling safety head on that type of press, and it is necessary for the operator to use both hands to move the head over the die. Should he trip the press in any way before that traveling safety head is in place, the press would operate but it would take up on this safety head and his hands would have three or four inches of space so he would not be in contact with the die in any way.

MR. E. T. FOOTE (Cutler-Hammer Mfg. Co.): In connection with the safety stop on rubber mills, some tests which we recently made I think possibly might be of interest to this section. The tests were made on a mill line consisting of two 22 by 60 inch mills driven by a 250 horse power 580 R. P. M. motor. This line was provided with a Cutler-Hammer clutch brake, the breaking torque being 4,850 foot-pounds, the torque of the motor being 2,300 foot-pounds. These figures to give the relation between the motor torque and the brake torque. We have been attempting to get a safety stop of four inches measured on the front roll. Mr. Mitchell speaks of ten inches. I don't know whether he had reference to the mills loaded or unloaded. He says it is an unloaded test.

These tests point out one thing which is very significant when studying the matter of safety stops on mill rolls. With the mills unloaded and the rolls being permitted to drift to rest there was a drift on the front roll of 240 inches. Disconnecting the motor and permitting the mills only to drift to rest, there was a drift of 103 inches. That is, there was approximately 137 inches of drift accounted for in the energy of the motor rotor. With the clutch brake—that is, disconnecting the motor rotor and applying the brake—there was obtained a stop of 8½ inches. That is keeping in mind that the mills were unloaded.

With one mill loaded, which was equivalent to about 130 H. P. on the motor, about half load, there was obtained a stop with the clutch brake of  $4\frac{1}{8}$  inches. That means if the operator were to be caught in the pinch of the rolls and immediately threw his tripping bar, he would probably not lose more than a hand. If he were to be caught in the rubber, which is frequently the case, before his hand got to the pinch of the rolls the chances are the rolls would stop and he would not be caught. Mr. Mitchella speaks of dynamic braking. I would like to ask him if he has attempted to apply this on mill lines where alternating current motors are used?

MR. MITCHELLA: We have not.

MR. FOOTE: Most mill lines are operated by alternating current motors. Of course, dynamic braking is possible with alternating current motors, but it is complicated. It is hardly a thing which can be considered in the rubber industry. It has been done to a limited extent on coal bridges and coal hoists, but it is not an entirely practical engineering problem when considering the matter of first cause. Dynamic braking caused on a direct current motor will give you a stop; you get a decreasing torque as the rotor of your motor slows down. That means that you do not get or cannot get as quick a stop as you can where you apply a constant torque, because your average torque throughout the stopping time will be less. In that method of stopping, of course, you still have to combat the high kinetic energy of your rotor, which is the element of highest kinetic energy in the line because it is the highest speed element of your mill line.

There is one other point upon which I would like to obtain some information, and that is the question of using—assuming that a clutch brake were used in a mill line—the safety stop to stop the line every time it was stopped. In these tests it was shown that there was in the brake approximately twice the torque that there was in the motor. That means that the braking effort is probably not a great deal higher than that obtained sometimes in starting, if started under conditions where one or two mills might be loaded on a long mill line. It is essential to get the men to do things instinctively. If you train them to stop mill lines by tripping the safety bars, the chances are that if a man is caught he is going to instinctively throw his arm over his cradle and get his safety stop. The objection that has been raised to this is that stopping by means of the clutch brake every time they stop the line imposes too severe a strain on your gearings and bearings. But it has been a question in our minds if this is the case. We feel that with the braking torque which is provided the strains are not so great but what your average mill line will stand it without excessive wear.

MR. MITCHELLA: We have used safety devices for service stops. I don't altogether approve of it myself. Now the same principle applies to the closing down of the mill line by a clutch brake. The clutch brake will close down the mill line very nicely, but the maintenance problem is the principal issue there.

I think this would impose overwork upon the brake. There will be a

wear on the brake and it will leave a tension. I am considering, notwithstanding, that the brake is operated by a counterweight which ought to drop and will compensate for a great deal of wear. It is simply a matter of judgment between maintenance and the point which you bring out in regard to getting a man trained to always stop his mill in one manner, which of course is a good point.

MR. HOENER: We have a system in our plant where the conditions make it practically necessary to use the clutch brake as a service stop for the simple reason that our mill motors are all at one end of the room, entirely enclosed away from the line, and we do not allow anybody but an authorized electrician to go into the mill motor room on account of the electrical hazard involved. So we insist that the inspector on the line when he is through with the line use a safety stop as the method of closing down the mill line.

We have considerable trouble sometimes on our mill lines due to the rubber tripping out the safety stop repeatedly on the line. We have had occasions just recently—perhaps with a new mill man who doesn't cut his stock properly—where the line tripped out six, seven, and eight times a shift, and on our large mill motors it causes delay and is rather expensive. I would be interested to know whether any of the other rubber companies have experienced similar difficulty. This constant stopping of a mill line antagonizes the operators towards the safety devices which we place on these mills, and we usually have quite a job to get them to keep them in shape and report any occasions where the safety doesn't work.

MR. G. A. MATER (General Electric Co.): It seems to me that on the calender dynamic braking has been satisfactory. You can set that dynamic braking for any figures you want. As far as I am able to determine, dynamic braking is perfectly satisfactory on the calender motors. Direct current motors are used almost universally on calender motors. There are very few cases where counter motors are used and they are not satisfactory.

The almost universal practice is to use a counter motor on mill lines, and there are three ways of stopping that. You can use a clutch with brake; you can plug the motor, or you can use a brake of some type, mechanical or airbrake.

Mr. Mitchella gave the time of stopping as one second. I think that should be verified by the various companies and some definite recommendation made as to the time of stopping the mills. If you should decide that a braking of some kind was sufficient, figure up the amount of torque required to stop that mill line in the time you determine upon. See what that would mean in mechanical strains along your machinery.

Another point should have consideration here. That is the manner of reversing and taking a man out from the rolls. Some companies recommend that they reverse the mills and pull a man out, and others loosen up the rolls and dig him out. We usually recommend in all of our equipments that a reversing switch be provided with the mill line equipment, but that is not for releasing a man unless they want to follow that practice.

On the calender motors again Mr. Mitchell made some recommendations as to the signal bell on there. Just how would you like to have that arranged, on the first step of the controller? Would you want that bell to ring all the time? Do you want that to ring every time you change the speed?

MR. MITCHELL: I think that would be preferable. I don't know whether it is necessary.

MR. MAIER: What do you think about putting on a warning light of some kind to show the direction of rotation—whether you are going forward or reversed?

MR. MITCHELL: I see no objection to it.

MR. R. N. WATSON: Goodyear uses that on all calenders, a red light when it is running reverse.

MR. MAIER: I should like to see the chairman here appoint a committee to make some definite recommendations on these various points, so we would have something definite to work on and use in our designs. It would be of material benefit to everybody, to electrical companies and other companies as well.

CHAIRMAN SCHOTT: What you have suggested will be put in our records and taken up during the course of the following year.

MR. HOLMES: Regarding the switches on the mills, we have had that trouble and we have also had the added trouble that the employees themselves would try to make adjustments, and would set up the adjusting screws on the bottom of the spindle so tight that I have tried with all my weight to pull the cradle bar down and I couldn't budge it. We overcome the trouble of the gum hitting the bars by placing a fitting on the end of the bars and raising the bars four inches which still gives a good operating distance, eliminating that trouble. The operators, unless they are watched, tie up those bars at times, so the safety man has to be on the job in the mill room.

MR. MITCHELL: I would like to clear up the records on this time for stopping mills. It was mentioned that I set the time as one second for the stopping of mills. I asserted that a maximum time should be no greater than one second. Nothing is desirable that breaks the machinery all to pieces. Our machinery will stand just as sudden stopping as any motor can be designed for.

CHAIRMAN SCHOTT: "Vulcanizing Apparatus," by Mr. Frank Scott, Superintendent of Inspections of Hamlin & Co., New York City.

## VULCANIZING APPARATUS

FRANK SCOTT, SUPERVISOR OF INSPECTIONS, SAFETY DEPARTMENT, HAMLIN AND COMPANY, NEW YORK CITY

Vulcanization is the act or process of treating rubber with some form of sulphur to affect certain changes in its properties, so as to render it insensible to atmospheric changes, to increase its durability, and to adapt it for various purposes. Since the process of vulcanization was patented by Charles Goodyear, in 1844, pure India rubber has been very rarely

used, the vulcanized rubber being far preferable for almost every use. In general, the process of vulcanization consists in mechanically mixing rubber at moderate heat with sulphur, which is the only essential ingredient necessary, although other materials are often added at the same time, such as silicate of magnesium, carbonate of lead, asphalt, and tar, each of which imparts a different quality to the product. After the sulphur and other ingredients are added, the curing takes place in sealed vulcanizers generally by heat from steam at 250 to 300 degrees Fahrenheit. The substance thus formed acquires extraordinary powers of resisting compression together with a great increase of strength and elasticity, and cannot be dissolved by ordinary solvents. By using a greater proportion of sulphur and a higher temperature, hard rubber, known as "vulcanite" or "ebonite" is produced.

#### VULCANIZING APPARATUS

Vulcanizing apparatus is made in numerable forms: long horizontal cylinders, vertical cylinders with hydraulic ram pressure plus steam pressure, pot heaters, special cast-iron castings of various forms for vulcanizing and repairing tires, platen presses of various sizes and shapes for belts, etc., but the types most generally used are the large horizontal cylindrical ones. Although in the tire industry, the vertical cylindrical presses, having a hydraulic ram, are used in great numbers, also. The horizontal cylindrical vulcanizers run in standard sizes from 12 inches to 84 inches in diameter, and are usually about 20 feet long. For some purposes, they are made considerably longer. The construction of these should consist of shell plates, but straps and heads of open hearth fire box steel or of open hearth flange steel having a tensile strength of not less than 55,000 pounds nor more than 65,000 pounds per square inch of cross section; the rivets to be of boiler rivet steel with a tensile strength of not less than 45,000 pounds nor more than 55,000 pounds per square inch of cross section. The flanges and doors should be of cast steel, conforming to all of the requirements of the Boiler Code of the American Society of Mechanical Engineers for Class "B" steel, castings soft grade. The doors should be hinged and provided with rollers, so as to support the weight of the doors when open. They are usually held shut by means of bolts, although there are a number of different types of quick opening and closing doors on the market, all of which are not approved by insurance companies. It is advisable when insurance of the vessels is to be considered that the approval of the Insurance Company be obtained before the equipment is purchased. On this type of vulcanizer the utmost care should be taken in setting up the equipment, in vessels longer than 5 feet, to have it supported on the tail end by a saddle, fitting the shell with plain surfaces at each end to bear on turning metal roller which would lay between the finished guides and a sub-base. All intermediate saddles on long vulcanizers should also be this way, so that a shell when contracting and expanding would roll longitudinally instead of the shell scraping and cutting itself, which is a very important factor on account of the great amount of contraction and expansion that takes place, due to the

rapid heating and cooling of the vessel. The vessels should also be so set as to drain to steam traps which are essential to remove condensation. It is very necessary to eliminate all possible water traps to prevent injury to the vessel by corrosion.

**TIGHTENING ALL BOLTS ON DOORS**

The utmost care should be taken on the part of the foreman to see that employees properly tighten up *all* bolts on doors, and in doing this, to use a wrench of suitable length to enable them to do the work properly without causing injury to threads on bolts, which is often done by the use of pipes on wrenches, thus weakening the bolts and causing serious trouble. Emphasis should be made on the fact that *all* bolts should be tightened, and it should be instilled in the minds of all those having any connection with the vulcanizing equipment that all vulcanizers are subject to an internal pressure by means of steam, a highly dangerous element unless handled properly. A high temperature of steam together with its terrific expansion, I believe to be second only to explosives. On account of its general use, the danger is ignored, and in the case of most operators, they are ignorant as to the possibilities of serious accidents which are liable to be caused by not manipulating the equipment as it should be. It is all important that the element of danger from improper handling be forcefully called to the attention of the foremen and workmen, and care taken to see that they perform their duties, in connection with the handling of this equipment, in a safe manner. They should be thoroughly instructed, particularly with reference to the question of bolting the doors, opening the vents (which should be at least 1 inch) when the steam gauge shows no pressure after the steam is shut off, and not attempting to open the doors until it is definitely known that the pressure has been relieved.

*Reading of the Gauge.* They should also be instructed not to depend on the reading of the gauge, as it is possible that it may not show a proper reading. Many cases are known where men have been injured by depending on the gauge which was incorrect, and releasing the fastenings in the door without first opening the vent, the door blowing open with serious results.

*Safety Chains.* Safety chains, to be kept in place until it is absolutely known that the pressure is entirely relieved, are sometimes used on doors.

*Drainage.* Another source of trouble in connection with the horizontal type of vulcanizer, from an accident point of view, is improper drainage. In a number of cases when the doors have been opened, men have had their feet scalded, or when the water is trapped in the vulcanizer, men have gone in and have been burned. This is a condition that should be watched carefully.

*Elimination of Steam.* In some cases, to eliminate the steam from the vulcanizing rooms, the vulcanizers are connected to a suction pipe and a valve on the back of the vulcanizer opened, and the suction in the suction pipe thus exhausts the steam. This can be condensed and water saved. The feature, however, is the elimination of steam from the work

rooms. This same method can be applied to the vertical type of vulcanizer.

*Safety Valves.* Every vulcanizer, regardless of the type of apparatus, should be provided with a safety valve on the vessel side of the steam connection. This would bring it between the reducing valve and the vulcanizer. The safety valve should be set at the minimum pressure permissible with which to accomplish the desired results in the equipment. All valves should be tested daily, and at least every six months by allowing the pressure to raise in the vulcanizer until the valve pops itself. Care, however, should be taken to see that the gauge used at the time is correct, and that the allowable working pressure is not exceeded on the vessel. It is always advisable to have the safety valve set for at least five pounds pressure under the allowable pressure. Of course, if a vessel is allowed 100 pounds pressure and only 60 pounds pressure is required to accomplish the results, the valve should be set as close to 60 pounds as is feasible. Safety valves should be in size equal in area to the size of the supply line to the equipment.

*Insuring Vulcanizers.* It is my opinion that vulcanizers should be insured, so as to receive the benefit of inspections by men specializing in this work. In connection with this question of insuring vulcanizers, it is advisable that before vessels are purchased, the approval of the Insurance Company be obtained, or that there be a stipulation in the contract that the vessel will meet the requirements of the steam boiler insurance companies. Some of these companies have very strict rules as regards requirements for vulcanizers, especially of this horizontal type and, of course, the Boiler Code of the American Society of Mechanical Engineers should be followed in construction.

*Numbering Vulcanizers.* All vulcanizers should be numbered, and when once given a number, it should be maintained during the life of the equipment, so that their records can be kept without any question, which is a very important matter.

*Inspections.* Regular inspections should be made by men properly qualified to judge conditions correctly, and a careful record kept of inspections. This record should be checked periodically to see that inspections are made and the recommendations complied with promptly.

#### VERTICAL SHELL VULCANIZERS

Vertical shell vulcanizers of the French press type used generally in the manufacture of automobile tires, are constructed along the same general lines as the horizontal vulcanizers, with the exception that they are heavier to withstand the hydraulic ram pressure plus the steam pressure. Care should be taken not to use a type of press of this kind which would permit the water pressure going into the cylinder. I understand that this type is practically obsolete at the present time.

#### TIRE VULCANIZERS

Tire vulcanizers for small repair shops are usually of cast-iron and are generally in the hands of persons inexperienced in the handling of

steam equipment. Consequently, the element of danger is not appreciated or known. Therefore, the utmost care should be taken to have those using equipment of this kind instructed as to the possibilities of serious trouble that may result from improper handling. The vessels in all cases should be equipped with safety valves set at the lowest minimum pressure necessary to perform the work. It has come to my personal attention that in small equipment of this kind in branch stores, the spring loaded safety valves have been so set that they were nothing more than plugs. In another case, I found an equipment in branch store where they had a lever safety valve loaded with extra weights so as to make it practically useless as a safety valve.

To generalize in connection with vulcanizers, there are a number of points that should be considered:

*First:* In many of the rubber plants of today, they continue to operate vulcanizers anywhere from 25 to 50 years of age, and not infrequently, they are equipped with all kinds of attachments and other items making internal inspection difficult, and with their entire exterior completely covered with insulating material, precluding any possibility of external inspection. For years, they have alternatively been heated and cooled, and why more of them do not explode under pressure due to metal fatigue is a question.

*Second:* A great many of these old vulcanizers were built by rule of thumb by handy-men (master mechanics of the old days). The doors, hinges, hinge pins, swing bolts and pins for the latter together with the lugs for holding the pins on these old vulcanizers are all items under stress, and in every case, should be given a most careful scrutiny by a man who knows what he is doing. Such items in a vulcanizer are very like the different items in a building structure where the floor is good for not more than 25 pounds live load per square foot, while the columns, or a combination of all members, lacking one, would be good for 200 or 300 pounds per square foot. The whole structure, whether building or vulcanizer is only as strong as the weakest member.

*Third:* Every vulcanizer in a rubber plant, after being inspected and figured, should have set against it with the usual factor of safety (at least five) the maximum working pressure. This figure to be determined and given to the owner without any regard as to what they may want. Where the examination proves that the vessel is not in a safe condition to be operated at the pressure required to do the work, it should be replaced by a vessel that is of safe construction. It would be advisable in all states to have a law, making it compulsory, where vessels are found unsafe, to have such conditions reported to the state authorities for the enforcement of the discontinuance of their use, where necessary.

*Fourth:* Vulcanizers are occasionally removed from one part of a plant to another, and two things are liable to happen. First, in skidding or lowering and raising them, more weight is handled than is known by the gang, and serious accidents are likely to occur by the failing of tackle or the carelessness of the men. The other point concerns the safety of the vulcanizer itself. In falling or even in moving it, the

plates, rivets, heads, or castings; long subjected to metal fatigue might easily be ruptured.

In summarizing safety features:

*First:* Cast-iron should not be used on large vulcanizers. Where castings are necessary, they should be of steel.

*Second:* Vulcanizers should be built according to the American Society of Mechanical Engineers' Boiler Code. This means of tested material. They should be subject to a hydraulic test of one and one-half times their safe working pressure before placed in service.

*Third:* All vulcanizers should be regularly inspected by specialists on boiler inspection.

*Fourth:* They should be properly set so as to allow contraction and expansion to eliminate undue wear or strain.

*Fifth:* All vulcanizers including belt presses and platen presses should have safety valves between the reducing valve and the connections, the size of the relief to be governed by the size of the steam inlet connection.

*Sixth:* Employees should be thoroughly instructed as to the proper use of the equipment and the hazards due to improper use.

*Seventh:* All vulcanizers should be properly drained so as to eliminate the possibility of injury due to burns. In this connection, it is advisable with vulcanizing equipment and other steam pipes to place pipe coverings where possible, so as to eliminate accidents caused by contact with the hot steam pipes.

*Eighth:* The men should be thoroughly instructed to fasten all bolts securely in vulcanizer doors, and not to open same until it is absolutely known that the pressure has been entirely relieved. Check on this as described above, when the gauge shows no pressure, open the vent pipe which would show the true condition.

*Ninth:* Wrenches should be of suitable length to fasten bolts on vulcanizers without using pipe on the wrenches which causes unnecessary strain on the bolts. This use of pipe is a common practice and should be avoided.

*Tenth:* Protection should be placed in the vulcanizers to prevent cars from striking the heads, as continual bumping is liable to cause injury to the vessels.

*Eleventh:* Special attention should be paid to the drainage of vulcanizers and efficient traps of ample size should be used.

*Twelfth:* Care should be taken properly to fasten leading tracks. The wheels of truck carriers should be checked, so that in loading the heater, the possibility of upsetting the load will be overcome.

*Thirteenth:* Where track bridges are used to run cars from the floor level to the heater, these should be counterweighted with weights under the floor. This would make the bridges secure when in use, and eliminate the tripping hazard when they are out of service.

*Fourteenth:* Where CO<sup>2</sup> vulcanizing apparatus is used, special attention should be given to the fact that this gas is very dangerous and the following precautions should be observed:

a. Do not let the CO<sup>2</sup> drums drop.

- b. Keep caps on tops of drums when not charging.
  - c. When charging CO<sup>2</sup> tank, see that the valves between CO<sup>2</sup> drums and tank are opened before valve on top of CO<sup>2</sup> drum is opened.
  - d. See that there are no leaks in CO<sup>2</sup> tank or piping.
  - e. Pump vulcanizer to zero pressure before opening its door.
  - f. When throwing away old CO<sup>2</sup>, see that it is discharged out of doors where it will not be injurious to the health of employees.
  - g. Test all safety valves daily or during each heat.
- The CO<sup>2</sup> drums stand a much higher pressure than any pipe, tank, or fitting which is used in connection with them, so it is absolutely necessary that the full drum pressure be prevented from extending to any connection or related apparatus. If a drum head breaks, the drum will fly around like a fire hose nozzle, and is liable to do serious damage, so great care must be taken in handling same.
- CO<sup>2</sup> gas should not be permitted to escape in a confined space where persons are present.

ADJOURNMENT.

#### FRIDAY MORNING SESSION

THE meeting was called to order at 9:50 A. M., by the Chairman, Mr. Sidney M. Schott.

CHAIRMAN SCHOTT: Report of the Nominating Committee, Mr. Harold T. Martin of the Fisk Rubber Company, chairman.

MR. H. T. MARTIN: Mr. Chairman, the Committee has selected for your approval as Chairman, Mr. E. H. Fitzgerald of the Federal Rubber Co., as Vice-Chairman, Mr. P. B. Martens of the Firestone Company, and as Secretary, Mr. W. N. Fitch of the Goodrich Rubber Co.

CHAIRMAN SCHOTT: If there are no other nominations I suggest a motion for the unanimous election of those named.

(A motion was made and seconded that the nominees be unanimously elected. The motion carried.)

Address on "Industrial Sanitation" by Mr. W. N. Fitch of the Department of Safety and Hygiene of the B. F. Goodrich Company, Akron, Ohio.

#### INDUSTRIAL SANITATION

W. N. FITCH, DEPARTMENT OF SAFETY AND HYGIENE, THE B. F. GOODRICH COMPANY, AKRON, OHIO

To many, sanitation may seem to be a new word but history carries the word "sanitation" back to the time of Moses, who along with many other honors was recorded as being the first sanitarian.

Agrippa in Caesar's time, in the year 27 B. C., built the Pantheon, called the All Holy Place, which was a wonderful structure of Roman art and contained the splendid baths in which the Romans took such high delight. One of the characteristics of the ancient sanctuaries of the old churches of Rome was the provision for bathing accommodations for the weary pilgrim. So down through the ages the various angles of sanita-

tion have progressed, but only within the last few years has industrial sanitation been given any consideration by the employer.

As a result of investigation by progressive employers, the safety first movement was inaugurated and this was the first step to improve the working conditions of the workmen. Then paralleling it came the sanitation movement.

Employers, recognizing the economic side of sanitation as applied to industry, have taken the lead and made great progress toward improving working conditions, not waiting for the representative boards of health, state factory inspectors, and commissioners of labor to secure legislation to force better sanitary conditions.

Those who have given sanitation consideration realize how much workmen are affected in their health, habits, personal appearance, and efficiency by the environments under which they work. In passing through our industrial centers we have only to gaze upon the manufacturing buildings of yesterday and those of today to appreciate the fact that industrial architects are giving important consideration to the two great problems confronting the working conditions of employees in industry—safety and sanitation.

#### GENERAL CLEANLINESS

There is probably no type of factory sanitation which is so much neglected as general cleanliness. Industrial managers are just beginning to understand the economic values resulting from proper cleansing of the floors, walls, ceilings, light fixtures, and machinery.

To maintain a pure air supply, both artificial and local ventilation are now being applied to units which produce large quantities of dust, thus eliminating the particles of dust flying and settling about the room and impairing the health of employees.

Two prime essentials in the different operation of any plant are sufficient light and pure air, clear of dust or poisonous vapors. Light and cleanliness are to some extent interdependent; for however good the first installation may be, if layers of dust are allowed to accumulate on fixtures and windows as well as walls and ceilings which act as reflectors, the lighting standard will be greatly lowered. Then, the dark shop while not necessarily dirty is usually so. Dark, uncleanly surroundings have a noticeably depressing effect on the cheerfulness and morale of the employee, a fact clearly recognized by physicians and hospital superintendents.

The broom and brush formerly used almost entirely as a medium of cleaning the floors and benches, are fast being relegated by progressive employers to the museums as relics of the past, while the up-to-the-minute manufacturer turns to new and improved methods.

The large and progressive ventilating and vacuum cleaning manufacturers, who have made it possible for the housewife to clean carpets, rooms, walls, and upholstered furniture with less physical effort and more efficient results by eliminating flying dust, realize the possibilities of cleaning industrial plants by a similar method.

### *Rubber Section*

It is true that vacuum cleaning has been used for a number of years on specialized processes but it is only within the last year or two that real efficient vacuum equipment has been introduced to the industries and today industries are having an opportunity of trying out portable machines of large units.

One of the foremost industrial plants has for several months had a machine on trial. The room in which the machine is located has been painted white and a complete test is being made both as to the efficiency and the economic value of vacuum cleaning of floors, walls, pipes, and machinery as against the old broom and brush method.

Observations taken so far show that the floors are not only being cleaned but the dust is being absorbed instead of stirred into the air. The dust is being sucked from the cracks. As a result, no dust is circulated into the air, therefore, the walls, ceilings, and pipes remain comparatively clean. Furthermore, it appears that the operation of the layout is much more economical than the broom and brush method.

Industry has only to be patient and co-operate with the vacuum cleaning manufacturers in their efforts to work out the problem and industry will soon be cleaned by the most economical and efficient method yet produced—vacuum cleaning.

Of great importance to general cleanliness is prompt and efficient removal of all rubbish, sweepings, etc. It is very good sanitary practice to furnish receptacles of fireproof material in which rubbish and sweepings can be deposited. Employees can be persuaded to use these sanitary receptacles for rubbish by means of education through the house organ and by bulletin boards.

### **DRINKING WATER**

Every industrial establishment should have an adequate supply of drinking water of a pleasing temperature as well as attractively clear and, by far the most important, it should be pure. Drinking water should be tested for impurities daily by a bacteriologist.

In some of the older plants there still exists the crude method of serving water to employees by the use of the Bristolware jars. Water of a proper quality but of varied temperature may be served reasonably safe in this manner if the jar is provided with a faucet and an individual cup of either metal or paper is used. However, extra care must be exercised to prevent the contamination from others using the same drinking vessel.

The filling of these jars safely depends largely upon the unit used. A tank mounted on wheels equipped with a pump has been found very efficient. This method prevents the possibility of an operator with dirty hands filling the jars from a pail and coming in contact with the water, also is less likely to catch any flying particles of dust that may be in the atmosphere.

Many industries where they have a good pure water supply either of their own or from the city, have installed individual cooling fountains at various points throughout their plants which are equipped with sanitary

drinking fount heads, the water being cooled by the medium of ice placed in the cooling tanks. This system works out fairly successfully.

The most satisfactory and effective method of distribution of water is by an automatically cooled circulating system with founts located at convenient places throughout the building for employees. There are several types of drinking fount heads on the market and if considering such a system, great care should be taken to give a thorough study to the drinking fount head as this is the point at which contamination can occur.

One of the heads which has given exceptional satisfaction and by many is believed to be the safest from contamination is one from which several streams of water flow from the inside of the ring toward the center. These streams unite in the center and form a larger stream of such pleasing quantity of water as to satisfy the employee.

It must be emphatically borne in mind that these founts as all other types of drinking units must be thoroughly cleansed daily to prevent contamination and to present a wholesome appearance.

A cuspidor is sometimes placed a short distance from the fount for the use of those who are in the habit of chewing tobacco. It is claimed by many to eliminate the possibility of employees expectorating into the bowl of the drinking fountain, which is very disgusting and insanitary.

Those desiring further information along the best lines of drinking equipment are referred to the United States Public Health Reports, Volume 32, issued May 11, 1917.

#### CUSPIDORS

Cuspidors are a most necessary nuisance both in offices and factories to prevent spitting on floors and other places. The proper cleansing of the cuspidor is a very serious problem. First, because the work is not desirable; and, second, there are very few really efficient methods. However, I have in mind one which has been used for several years and has given fair results. Cuspidor is made of galvanized metal about 9 inches in diameter with a removable top which is concaved with 2-inch opening.

#### COLLECTION AND DISTRIBUTION

The collection and distribution is done through the medium of a rectangular metal box equipped with a cover in four parts mounted on a four-wheel truck and demountable in order that the load, box included, may be promptly removed from the truck and a load of clean cuspidors started on its tour of distribution and collection.

Cuspidor is emptied into a digester composed of  $\frac{1}{4}$ -inch screen receptacle placed on a sewer, the opening of which is surrounded with a metal cylinder with foot operated cover. When the solid matter has filled the screen receptacle, it is removed from the cylindrical vessel and an empty screen replaces it, the full screen being emptied into a garbage can and covered ready for final disposition at the incinerator. Cuspidors after being emptied at the digester are passed to a bench provided with

racks properly equipped with pegs to set the bowl and covers of the cuspidor. These racks are placed in a machine having a capacity of four racks.

This machine is provided with warm water into which has been placed a washing solution. The water is pumped on to the contents through rapidly revolving sprays of considerable force. When the washing is done, which requires 1½ minutes, pump is stopped and the cuspidors are rinsed with a douche of steam and hot water. This thoroughly cleanses and disinfects also heats the metal of which the cuspidors are made and they dry rapidly after removing from machine. After removing from trays they are again placed in the metal box ready for distribution.

#### TOILETS

Perhaps in some industries no item is so neglected as toilet accommodations. Frequently you find them located outside of the factory, sometimes quite a distance, causing a loss of time and endangering the health of the employees. Toilets should be located within a factory building on an outside exposure for light and ventilation.

All industrial and sanitary codes demand separate toilet compartments for each sex in every factory where men and women are employed.

It is good practice to provide toilets on each floor with due consideration as to distance the employee has to travel. Frequently toilets are installed in a tower especially built for elevator, stairs, and toilet rooms located at the most practical point for the convenience of the occupation of the building and due consideration for future building construction. Much expense and trouble will be eliminated if the industrial engineers will select a standard of toilet equipment, considering the various points as applying to sanitation and efficiency. (See Safe Practices, No. 27, p. 14, "A Toilet Room to be Proud Of.")

The following points have been tried out and found practical to good, sanitary toilet equipment:

1. Location on outside walls for light and ventilation.
2. Solid porcelain closets with open front type of seats automatically flushed by seat action.
3. Each closet enclosed in a metal cabinet with doors.
4. Inside dimensions of cabinet 48-32 inches, door having a minimum height from the floor of 18 inches.
5. Each door provided with a spring which will close it up to a point of about 1½ inches.

(Where a compartment door is ajar, not locked, it gives the same privacy but eliminates possibilities of employees loafing, maneuvering with the equipment, or writing inscriptions on the walls.)

6. Metal for cabinets formed in such manner as to leave practically no opening for the accumulation of dirt.

(Fig. 1 shows lock on door which is not practical, use spring instead.)

7. Floors constructed of concrete pitched to floor drain.

Hose bibb supplied for attaching hose for flushing entire unit.

8. For convenience, one small porcelain or white enamel lavatory foot control, no stopper, spray head should be installed in every toilet room having five toilets or less with an additional lavatory for each multiple of five.
9. For the sake of cleanliness, closets should be washed every twenty-four hours with a solution saturated with a disinfectant. It is desirable that some standard painting scheme along practical lines be adopted, such as a 6 inch slate wainscoting, white enamel walls and ceilings and cabinets, and black around the handles of the doors.
10. Full-length solid porcelain urinals equipped with supply pipe for

FIG. 1. A GOOD TYPE. THE LOCK ON DOOR, HOWEVER, IS NOT CONSIDERED PRACTICAL

constant running water is good installation. If there is more than one urinal, they should be separated by a screen for privacy.

11. Urinals should be set on floor slab with concrete platform 6 inches at the outer edge and tapered to the lip, platform to be  $30 \times 30 \frac{1}{2}$  for a single unit.

A clearance of  $\frac{3}{4}$ -inch to be left on sides and filled with pyrex.

#### NECESSITIES AND COMFORTS

Until recent years little or no attention was paid to the comforts of employees in reference to where they should hang their coats, hats, or

dinner baskets; how or where they should wash their hands or take a complete bath. In most instances, the coat and hat were hung on a nail in the workroom, the dinner basket was set under the work bench and if complete change of clothing was made into a working uniform it was done in the open workroom. It can be readily understood that under the old type of sweeping and performing of work without ventilating units, the dust circulating in the air settled over the clothes and dinner basket.

Many plants have no washing facilities and lunch is eaten with hands soiled from work. Investigations and efforts upon the part of progressive industrial managers have worked many improvements. The locker has taken the place of the hook, washing facilities and showers, even tho in some instances crude, have come to stay. In most instances lockers and washing units are distributed on working floors. Investigations and systematic study develop that from an economic standpoint lockers, washing units and showers should be centralized under a caretaker at one or more entrances in the mill.

Almost invariably the individual locker system is being adopted as the cleanest, safest depository for outer garments. Some system of inspection, however, must be provided to prevent the housing of unnecessary articles in lockers and to bring about the proper care of the locker itself by the employees.

Lockers should be constructed of metal connected in units to the best advantage of space available. Sufficient depth should be allowed for the use of a coat hanger in order that the garments of the employee could be spread out, for on some occasions they will be damp as a result of rain and spreading them on a coat hanger they will dry more quickly and will have a more presentable appearance. The width of the lockers should be sufficient to allow the hanging up of the hat and other garments if the employee desire to make a complete change. The height should be sufficient to take care of the average length coat.

The top of the locker slanting toward the floor eliminates the catching of dust, the catch-all for various types of material which might fall off and injure employees, and presents a more orderly appearance. (See Safe Practices, No. 27, "Drinking Water, Wash and Locker Rooms, and Toilet Facilities, p. 10.)

For purpose of cleaning, locker should be set up sufficient height from the floor, at least 8 inches, also to make it possible to attach a ventilating system to the bottom of the locker.

The selection of the latch and lock have much to do with the life of the locker. The latch should be of a type that the handle may be operated by pulling upward and outward. Cabinet lock system is more apt to get out of order than a padlock system and combination padlocks have been found to be the most appreciated by the employee on account of there being no keys, to bother with or lose. Less garments have been stolen as a result of combinations being picked.

The following is a description of a locker unit used by one of the largest industries of the country after a most thorough investigation and

test made both by the Engineering Department and its Safety and Sanitary Organization:

Unit composed of 5 lockers setting upon a base of 4 legs, 8 inches from floor.

Height from the floor of the locker from the base to top is 5 feet.

Height back is 5 feet 6 inches.

Width of each locker 10 inches, and depth 18 inches with a shelf within same 54 inches from floor extending 9 inches from back.

A groove in the shelf upon which the coat hanger can be hung.

Two hooks on the opposite side from groove.

In the bottom 2 inches from the back end is a 2-inch hole.

Edges turned down for ventilating purposes.

Over this opening is a slanting hinge cover, back of which is 5 inches from the floor, louvred so as to allow passage of air.

This installation protects garments from covering up the ventilating floor of locker or any material falling into the hole.

Slanting roof, combination padlock insert from top of locker door.

In selecting lavatory equipment, economy of course is a most important factor. The type of unit as to construction, material, control, life and appearance is also important. Units of porcelain and white enamel iron are perhaps the most desirable.

In large washrooms where the control of water can be handled by a caretaker, very practical lavatories are those constructed 8 feet in length of white enamel iron with five goosenecks provided with spray heads about 2 inches in diameter located 20 inches from the bottom of the lavatories through which the water flows with some pressure. Liquid soap dispensers are located between each spray head. No stopper at the waste openings should be supplied thus allowing the dirty water to run away, the employee washing under clean running water from the spray heads. Individual linen or paper towels can be used. (See Safe Practices, No. 27, p. 8.)

Where lavatory units are not under the control of a caretaker, it has been found most desirable from a health standpoint to control the water by foot equipment. The box foot control valve is considered one of the economic types of individual controls, requiring less upkeep.

A most desirable individual porcelain unit is now on the market. It is simple in construction, having no stopper and water is supplied by a gooseneck with spray head and a foot control. The soap can be either furnished by individual tilting style of liquid soap container or from one container with individual control for each lavatory. (Fig. No. 2 illustrates this type.)

#### SHOWER BATHS

Every industrial plant whether they do or do not have centrally located locker rooms ought to have a few shower baths. Where you have centrally located locker and washrooms, it is most desirable and efficient to put in a neatly constructed shower bath equipment, taking into consideration the number of showers required for the type of occupation of

plant. If the work is dirty and grimy and poisons are used, men should shower before leaving for home especially if they change all their clothes upon entering and leaving the mills.

#### LUNCH ROOMS

The sanitation in industrial lunch rooms is most frequently a much neglected situation. The success of the lunch unit and the health of the employees depends largely upon the inspection and sanitation of the unit itself and the control of the foods. I shall not go into detail on this

FIG. 2. PRACTICAL TYPE OF LAVATORY WITH LIQUID SOAP DISPENSERS.

subject but I wish to warn all industrial managers that if their lunch units are not a success, they should make a thorough personal investigation and without doubt they will find that sanitation enters more than any other item into the unsuccessful result.

After all, we are all human and we have more or less pride not only in our dress and cleanly appearance but in the food we eat. The Bible tells us: "Cleanliness is next to Godliness."

The better dressed and cleaner an employee, the greater asset he is to your business.

It goes without question that in the future both men and women are going to be attracted to the industrial plants which have good, clean, healthful working conditions.

## DISCUSSION

MR. HOENER: One question that has often come up in various layouts for new plants is the question of whether or not washrooms should be located in toilet rooms, or whether they should be located adjacent.

MR. FITCH: The general washroom should not be in the toilet room. I think that in every toilet room there should be at least one lavatory. That is very important.

MR. J. T. BURKE (Chief Factory and Office Building Inspector, Province of Ontario, Toronto, Canada): Is it necessary to provide double lockers, one to take care of the shop clothes and the other for the street clothes?

MR. FITCH: It is a question in my mind whether we ought to have double lockers; at the present time we are using the single locker. In our compound rooms we have just built on new locker rooms and a very fine shower bath. We are studying the plan of what to do about the clothes. Every man who comes in, who works in our mill rooms where there is dust and in our compound rooms, comes into the locker room which is centralized, removes his street clothes and puts on a uniform which he himself pays for and is properly numbered. I am figuring with the vacuum cleaning people to see if we can't secure an arrangement whereby those suits, until they become so dirty that it is necessary to wash them, can be thrown into some type of vacuum cleaning apparatus so that we can clean them quickly. The caretaker can take care of the clothes. They are all marked, and my idea is to put a hook on the outside of the locker where the clothing will be hung for the caretaker.

In the new locker room I propose to go further and put in some sort of washing unit so that we can wash those clothes and dry them over night, or between shifts if necessary.

Each man should be given a washrag and towel, and either liquid soap or individual cake soap should be furnished. Those who are using lamp black are probably having a lot of trouble trying to find a soap that will quickly get rid of the lamp black. We are using a soap put out by the West Disinfecting Company. We have used all kinds of cake soap. We also have a colored fellow in there and he is put into a bathing suit and he washes the backs of the men. At the present time he is using a brush which he sticks in a solution between each act, but we propose to give them a washrag and they can wash themselves, and he will take this washrag and wash their backs.

MR. BURKE: How many showers have you determined for a certain number of employees, and how long does it usually take each employee to take a shower?

MR. FITCH: I don't think we have been able to work that out ourselves.

MR. BURKE: Do you find, as a matter of fact, that the men take the shower bath opportunities?

MR. FITCH: We don't have a bit of trouble. The first thing they do is look for the shower. Adjacent to that same room we have built a lunch-room. The men in the compound room go there to eat their meals, and they cannot get in there until they have washed. We have provided a

special washroom outside of the lunchroom so they have to go through that. We haven't put that lunchroom into action yet, but that is the scheme, and one of the foremen every day stands at the door and sees that the men are washed.

MR. SCOTT: In the white lead industry they have two locker rooms with a shower bathroom between. The men come in and leave their street clothes in one room, go through the shower room to get into their working clothes, and when they get through they take their working clothes off and have to go through the bath and shower room to take their shower before they can get their street clothes. A law in the State of New York provides for that. The National Lead Company uses that system and employs men to see that the men do take their showers.

The United States Steel Company has some statistics and figures on the number of showers required per unit. The New York State Safety School also has some information on that.

CHAIRMAN SCHOTT: Mr. Fitch, what is your opinion regarding the spraying of locker rooms, lockers and workrooms? Have you had any experience on that?

MR. FITCH: We haven't done any of that work at all. I have talked with our doctors and they laugh at it, so we haven't started it.

MR. R. N. WATSON: I may say that the employees sometimes request that you clean out their lockers. We have had that experience, men coming in from the factory and requesting that old lockers be cleaned out before being put into use, and we have had to use a disinfectant spray on those. I think our medical department claims the same as Mr. Fitch says—that the spraying actually doesn't do any good, that the best way to do is to take a scrubbing brush and water and wash the locker out thoroughly on the inside. We have made a practice of doing that in rooms used by compound men and lamp black departments, etc.

MR. HOENER: We have had considerable trouble in some of our shower bathrooms, especially where the men use soapstone, due to the men slipping on the floor, and we have found it necessary to put in wooden racks made out of slats about one inch wide spaced about a half-inch apart to prevent slipping.

MR. FITCH: We have used matting in our mill rooms.

MR. HOLMES: How long have you had the seat-operated valves in your factory? Have you had more or less trouble with them than with the hand-operated valves? Can you give me any comparison as to the upkeep and maintenance?

MR. FITCH: We have had the seat power valves for a good many years, and while there is some upkeep sometimes from the abuse of the employees, it isn't any greater than that of the other type. One of the reasons we changed is so that a man does not have to touch his hand to it. This is worth while from the standpoint of health and cleanliness, even though it costs a little more.

CHAIRMAN SCHOTT: Regarding lighting at night for purposes of cleaning the factory and other purposes, what is your opinion regarding the

Cooper-Hewitt light in factories? Has anyone had experience with those lights?

MR. HOENER: We had considerable experience, and we have had quite a discussion with the Cooper-Hewitt people recently. The United States Government at the time we were making balloons insisted on the Cooper-Hewitt lights in our assembly plant. That happens to be our present calender room and we have left those lights in. Our medical authorities took the stand that even though they didn't injure the eye they had something of a bad effect on the morale of the employees, and recommended that we change them.

MR. FITCH: I think the Cooper-Hewitt light leaves a sickly impression, and the workmen look up and see the effect and it kills the cheerfulness of the room.

MR. LARKIN: We went into the subject thoroughly at Chelsea and we put Cooper-Hewitt lights in the mill and calender room. After a week or so the employee gets used to it and he can't see that yellow color. A Cooper-Hewitt light is a peculiar affair in that respect. The first time you see it everything looks purplish. After you have worked in it for a week everything looks white. You love that effect absolutely. We had Cooper-Hewitt lights in the drafting room, for instance, and there were great objections—everything looked blue but after a short time everything looks the right color. After a month's use in this calender room the men preferred it to the old system. It gave far more light with less expense and less wattage. We call it a success.

CHAIRMAN SCHOTT: One of the objections to the Cooper-Hewitt light has been that the men could not distinguish the colors of the various stocks, but the Cooper-Hewitt people say that the Cheney Silk Mills use Cooper-Hewitt lights, so I guess rubber plants ought to be able to use them.

MR. C. W. KENNEDY (Wisconsin Industrial Commission): Recently the Advisory Committee in this state has been revising its orders on industrial sanitation, and we have reported on some of the points that have been taken up in Mr. Fitch's paper.

We have reported favorably on cleaning equipment in plants that have explosive dust, and we are recommending the use of the vacuum systems in all other plants for the purposes of cleaning. Taking up the matter of pure water, I find in going over the state that many plants do not consider cross connections as important; yet you will find your drinking water sometimes cross connected with process water which sometimes has many different kinds of industrial poisons in it. That is one thing that I think is important.

One thing that our committee on sanitation here is recommending throughout this state—the considering of the main points on new construction, and we have two conditions that face us—new construction and existing construction. In plants that are now operating it is well sometimes to consider, instead of fixing up and patching up the present department, the construction of new buildings to take care of those departments.

I want to commend that part of the paper which so well took up the matter of toilets. It seems to me that there is a very common sense way of putting it—the requirements which are necessary to make a plant as clean and efficient as it should be.

The matter of double lockers for street clothes and working clothes was taken up, and we almost concluded to report favorably on the asking for the use and furnishing of those lockers by the employer whenever the man was working in industrial poisons—when his clothes were covered with poisons and not merely dirty—but we did not come to a unanimous decision in regard to that. We did, however, come to a decision in regard to the cleaning of clothes, and we reported that some help should be given and some attention should be paid to the matter of cleaning the workmen's clothes when he is working in industrial poisons in such a way that his clothes become saturated with them.

MR. L. H. SHEA (Lycoming Rubber Co.): We have had considerable trouble with employees who would not take cement from their hands after making shoes. They would go direct to the cafeteria or eat their lunches that way, and those who would clean it off would use benzine or anything they could get a hold of, and the fumes would remain on their hands and probably a considerable amount of this material. The results of this were that quite a number of severe headaches were reported by employees who reported to the dispensary four or five hours after taking this into their system through the food. We have tried petrolatum, to be applied to the hands in a very small quantity before beginning work in the morning or after they have had their hands cleansed at noontime. It worked very well as far as taking the cement from the hands is concerned, but it left a yellow tinge, and also the employees claimed that it had a disagreeable odor.

I would like to know if any of the men here have a knowledge of anything which will not be disagreeable which can be used either to take the cement off the hands, or be put on the hands before they start work in the mornings?

MR. SCOTT: We have had cases where people using gasoline to wipe the cement off of their hands have burned themselves. They don't like to use kerosene. They don't want to use kerosene and then go to the lunch room. I would like to know if anybody knows anything that would take it off without being objectionable.

MR. FITCH: I won't attempt to answer that question as to what will take it off. To my mind it is a matter of control—you have to impress upon a number of employees the importance of good health, the importance of eating their meal with clean hands, and while you can't do that to the whole group you perhaps can bring some leaders into your medical department and convince them of the importance of that, and have the foremen with them. If you sell it to them it will gradually percolate through the department. You have to deal with the employee like a human being. You have to talk to him in a business way and convince him of the proposition. I don't think you will have much trouble then.

MR. SCOTT: Do other people have trouble in the shoe plant with burns on the hands? We have actually had cases where the men washed their hands with gasoline to get the cement off and in rubbing under certain atmospheric conditions a friction fire was started.

MR. BURKE: The first thing some workers do is smear their hands with heavy machine oil before they start to work in the morning. They don't attempt to remove that until noon, and then, of course, that brings up another question as to whether the hands are better washed in hot or cold water. Some medical authorities say lots of hot water. Other medical authorities say that lots of hot water opens the pores and allows the stuff to get into the pores and in that way the system is inoculated. The majority of our shoe workers say that is the best way—to smear the hands in the morning and wash them at noon. When they come back to their work they smear their hands again.

CHAIRMAN SCHOTT: "Selling Safety in the Factory," Mr. Harold T. Martin, Manager of the Health and Safety Department of the Fisk Rubber Company, Chicopee Falls, Mass.

### SELLING SAFETY IN THE FACTORY

H. T. MARTIN, MANAGER, HEALTH AND SAFETY DEPARTMENT, THE FISK RUBBER COMPANY, CHICOPEE FALLS, MASS.

The greatest results will be attained in accident prevention work in the factory when the safety habit has been sold to every employee.

The accident reduction problem is one of salesmanship and must be dealt with accordingly. There are always three things of vital importance in any selling campaign—the article for sale must have merit, the sales force must be organized to the highest point of efficiency, and the advertising connected with it must be the very best possible.

The article for sale in this instance is the safety habit and there can be no question about the merit of the goods.

#### THE SAFETY SALES MANAGER

Before we go far into the details of organization we must have a sales manager. The logical man for this job is the factory manager—let's look him over. If he is not qualified for the position it would be better not to fill it at all. He must make good or the whole plan will fail. He must be sincere, have plenty of back bone and pep and be willing to spend some of the company's money to make the plant mechanically safe. Assuming that he has these qualifications, he is made sales manager. This fact should be given considerable publicity. It pays to have every member of the factory organization familiar with the fact that the manager is heart and soul for safety.

In looking over the field for a sales force, we find the foremen particularly adapted because of their relationship with the people with whom we are going to do business. The workman judges the company by the foreman with whom he comes in daily contact and will listen to him

as to no one else. The foremen, therefore, have long lists of prospective customers. They are intelligent, and when they once realize their responsibilities in connection with this selling campaign, they will sell effectively and are, therefore, engaged. At a series of meetings called by our safety sales manager, these men are instructed about their new duties and advised of methods to be used in order to become efficient safety salesmen, which is essential if they expect to remain on the payroll. They should be put to work immediately in their respective departments.

It is not always possible for the foreman in a large department to get the desired personal contact with the worker, and of course ultimately it is the worker we must reach. In such cases, the work of selling the safety habit must be delegated to an assistant, the foreman becoming an assistant sales manager and his subordinate the salesman. These men should receive preliminary instructions similar to those given to the foremen from the sales manager, and frequent conferences of members of the sales force should be held for the exchange of ideas. There must be no lost force to the selling talk, even though it is transmitted two or three times. Such an organization cannot help being efficient if the boss insists that the men show results. Accident records will soon show where the weak spots are, and they should be strengthened at once even though the extreme measures of removal have to be resorted to. The movement is very contagious. Volunteer salesmen from within the ranks almost invariably join the forces and work with a will. This is highly desirable and should be encouraged in every possible way.

Up to the point of sending the salesmen into the field, the Safety Department has acted in an advisory and statistical capacity only; but when the sales force is organized and on the job, the Safety Department becomes also the Advertising Department and assumes responsibility for snappy safety advertising which will be of real assistance to the sales force, keeping the subject alive and reaching not only the foremen but the workmen as well.

#### THE SAFETY ADVERTISING MANAGER

The safety advertising manager must be a thoroughly human individual, capable of gaining the confidence of the several classes of men with whom he must mix. He will get co-operation if he knows how, and he must have it to succeed.

The Safety Department must keep the foremen posted on results they are securing, and give them every possible assistance by studying conditions and making known to them everything which has any bearing on their accident records.

Further work must be done by the Safety Advertising Department which will reach the worker direct. Safety Departments in various concerns as a general thing find it very difficult to put over a new idea. Generally some one else has used and discarded the same thing. The advertising must not be permitted to become stale, changes being made frequently in order that the subject may be of interest.

Some of the methods used to assist the foremen in their selling campaign are described in the following paragraphs:

Many concerns issue periodically pamphlets devoted to safety giving accounts of recent accidents within the plant, and material of a general nature. However, it has been found that a far more valuable method of driving home the gospel of safety is through the factory house organ. This paper contains many items of interest and is invariably taken home, so that in cases where a certain space is devoted to safety propaganda it is difficult to avoid those articles. The fact that other members of the family are made familiar with this reading matter means that more pressure is brought to bear upon the man we are trying so hard to impress, by some one to whom he may be more willing to listen.

We all appreciate the value of motion pictures in safety work. Many of the larger concerns have prepared films which are interesting as well as instructive and are taken seriously by many who pay no attention to other kinds of safety propaganda. In some cases it is not practicable to make films of this description, but where they can be used, they are always effective.

Safety meetings for the workmen may be held at infrequent intervals to great advantage. However, these meetings are made as short and snappy as possible and are planned to make the men feel that they have an actual part in the whole affair. They are sometimes held away from the plant on the men's time, and in that case arrangements are made to give them as good a time as possible. Safety meetings held at the plant on the company's time can best be confined to subjects interesting the particular department for which the meeting is held.

#### DEPARTMENTAL SAFETY RULE BOOK

Instead of the cumbersome rule book which is often given to the new employee in many concerns, a departmental safety rule book has been published which deals with the operations in a single department only. In that way the individual about to enter upon a new position can easily familiarize himself with the rules pertaining to the operation at which he will work. This subject is important, and gives the foreman the kind of backing he needs in the event that it becomes necessary for him to insist upon a strict adherence to some of the simple rules mapped out for the prevention of accidents which are common in his department. It is advisable always to have the foreman draw up these rules with the assistance of the Safety Department.

One of the best ways of reaching the man on the job is to designate some definite date as No-Accident Day, to advertise this day in every way possible, by special notices, special literature and bulletins, rallies or meetings, by erecting a large score board, tagging every man in the organization with a tag suitably inscribed and to see to it that all of the workers understand the meaning of the tag and the idea. It is advisable in events of this kind to count as an accident only those which result in the loss of time. To do otherwise may prove detrimental because the desire on the part of some not to mar the record may keep

them away from the hospital for some slight injury, the neglect of which might prove serious. This plan guarantees action and a real, honest-to-goodness drive for safety for the time specified at least, and the after effect is very beneficial. These days may be repeated with variations, such as following with a tagless day after a reasonable interval. After a date has been selected the foreman may be made responsible for the passing of information down the line without the assistance of tags.

#### THE SPIRIT OF CONTEST

Safety contests are sometimes used with success. The spirit of contest is in us all whether it be baseball, pie eating, or accident prevention. All that is needed is the necessary stimulation. Plants, departments, or units may be pitted against each other in contest for a specified time. In one instance, a contest was held between two departments with about the same degree of hazard existing, and the same number of employees, where there was at stake something in which both factions could participate, such as a theater party or picnic. Each employee made a small deposit, the money to be refunded to the winning department, and the money of the losers together with some of the company's money to be used in defraying the expenses connected with the event. This proved to be a big success arousing the personal interest of each individual, and has been worked out along similar lines several times since. Care should be taken to keep the deposit so low that no one will be hurt financially, and extremely close supervision should be exercised to guard against the neglect of minor injuries.

In some plants it is considered advisable to give the workmen an active part in the accident prevention program by placing them on inspection committees, serving for an interval usually of one month, at which time the committees change, retaining one member as chairman of the new committee. There is a variety of opinions as to the merit of such committees. It is a fact of course that by actually engaging in the work they may take more interest, while it is equally true that a great percentage of items reported by such committees are of trivial nature and refer to other than humanitarian errors which they seem to overlook.

A means of direct contact which should not be overlooked can well be carried on by the factory doctor, safety man, man paying compensation insurance, and the visiting nurse. These people coming in contact with the man who has received an injury find him in a most receptive mood, and it generally follows that he returns to work a 100 per cent safety salesman. After he has been through the mill, he can well describe to his fellow workers some of the trials and tribulations of a man who is forced to remain away from his work because of injury.

A court of inquiry on all serious accidents conducted by the factory manager has the effect of keeping all foremen and departmental heads on their toes, as no one is anxious to accept the responsibility of a serious injury to his fellow man.

"TELL IT TO THEM QUICK AND TELL IT TO THEM OFTEN"

A pretty good slogan for this advertising campaign would be, "Tell it to them quick, and tell it to them often." The workman can easily grasp one thing at a time, but in order to make a deep impression on him, an idea must be kept constantly before him.

The entire safety movement is still in its infancy. The efforts for preventing accidents are not confined to industry, but are being carried into every walk of life until every one realizing the enormous unnecessary loss of life and crippling of men and women, forms habits of safety which will reduce accidents to a minimum, and so we urge every thinking man and woman of America to join the ranks of salesmen who are trying to make this world a safer place in which to live.

CHAIRMAN SCHOTT: Mr. Martin has presented an aspect of the safety work which gives an entirely new light on the subject, and which if adopted by a great many safety men would make the work many times more enjoyable and effective than it is at the present time. I had occasion to visit one of the largest plants in Milwaukee yesterday, and although the plant has an international reputation, yet it is extremely dark and I don't know whether the windows have been cleaned since the plant was built or not. I wasn't quite sure. But we had occasion to ask some of the chief executives whether they had a safety man in the plant. Two of them said: "Well, we have some men that do some such sort of work." But it would be absolutely impossible to start any safety work in a plant of that type unless the plant were brightened up and shined up, and it was clearly shown that the management hadn't been sold on the work. There could be a proper "esprit de corps" among the workmen because the plant itself wasn't shined up.

#### DISCUSSION

MR. E. B. LEWIS (Gillette Rubber Co.): Regarding the movie situation, it seems to me that movies are an effective medium through which to get safety into the plants. We have not a movie projector in our own plant, but recently an insurance company put on a program in which they showed bulletins on the screen with lectures and a human interest picture. Every seat in the auditorium was filled. I think the movie has a great deal to do with this business of safety. My idea of selling safety to our men is through the bulletin. I think the bulletin board can be made effective and will bring out the points that you want to especially illustrate. There is a bulletin that will apply to almost every accident that might happen in your factory.

Relative to clean windows, aside from the fact that it brightens up your factory, it has a moral effect on the men of making them think that you are looking after their welfare. You expect to keep your windows clean at home, but keeping factory windows clean is something entirely new, and a man who sees his fellowman up cleaning the windows in the factory is affected, I think, in a way that is very lasting.

Every window should be cleaned at certain specified periods, and to my

mind that is one of the most effective ways of keeping the good will of your employees, through both good light and ventilation.

**CHAIRMAN SCHOTT:** Mr. Martin made a statement which the chairman disagreed with more or less, and that was to the effect that the safety rules should be made by the foreman. It is indeed true that if all foremen could be interested enough to take the time to get up a set of safety rules for their department, it would be immensely effective. However, the fact remains that a great many foremen do not take the time or the trouble or the interest to make safety rules, and in the smaller rubber shops where you may have simply one mill and calendar, or just a few mills and calendars, the amount of accumulated experience to get up safety rules is not great enough for them to do this with any amount of authority. For the benefit of those particular shops a suggested standard book of safety rules has been gotten up, and anyone is welcome to as many copies as they wish. These books are the compilation of safety rules from five or six of the largest rubber shops in the country.

One of the main reasons why there should be safety rules is ignorance of what to do. You can walk through many rubber shops and find a man sitting in the mill pan, for instance, at lunch time when the mill rolls are probably running, and you say to the man: "Please get out of the mill pan", or else you say: "Get out of the mill pan", and the man says, "What do you want me to do that for?" "Well, it isn't safe." "Well, nobody ever told me that before." And so it is all the way through the factory. No one ever told them that this practice was wrong.

The wearing of gloves in warming up rubber can be eliminated if you go after it right. There are ways of warming up rubber without the use of gloves by wearing long sleeves and carrying the rubber in the fold of your arm, for instance, and if you have certain rules by which you tell your plant management, your foremen, and your inspectors what is right and what is wrong, you are taking a long step in the right direction.

**MR. FITCH:** A suggestion system in a plant will bring out many things along safety lines. The Goodrich Company has carried on a suggestion system for a good many years. We started on this basis. A man makes a suggestion in which there is no change made in making the installation and which is approved by the committee, and we pay that man from \$2 to \$5, depending on the suggestion. If there has to be some remedy—if we have to help him out and he simply brings in an idea, we pay him \$2 for it if it is approved. And we follow this plan of asking that man to come into the office of the secretary of the Suggestion Committee after his working hours, and discuss the plan with him. We get in personal touch that way.

Those who had the opportunity of sitting in some of these public safety hearings, and the Local Council Committee yesterday, can't help but appreciate that one of the efforts to secure results is going to be through the public safety movement. If we are going to strike home with the man and the boy, we have got to go through the community and the home. All of us would do well to go home to our plants and get behind a good public safety movement in our city. Get to the man through his children in

school; the boy bringing in safety suggestions and ideas from the school will have more effect on the father in his work at the plant than almost anything that the plant can put over. You may be able to reach the foreman to a certain degree, but the man you are after is the man that performs the operation, the man that is being hurt, and you can hit him through the schools, and you can hit him through the community. The public safety movement is one of the biggest movements in this safety game. I have been in it for several years, and I know it to be a fact that if we can get into the public safety movement with a lot of spirit, it is going to aid the industrial managers that have been trying to put over safety and sanitation through the plant.

**MR. SCOTT:** It is not generally known that the National Fire Protection Association issues a book "Safety in the Home" which dwells both on fire and accidents, and it is written up so as to be interesting both to the child and the grown person, and I have noticed in their ad that they are sold in quantities at four cents a copy, and they are good.

**MR. FITCH:** The National Safety Council has lessons on safety for foremen. In a great many plants in cities where there are local councils they are using these to great advantage and accomplishing a great deal of result in lining up their foremen along safety lines. These lessons can be secured from the National Safety Council, and a copy should be given to each of your foremen.

**MR. LARKIN:** Mr. Martin, in his paper, touched upon the great importance of selling safety to the manager. It isn't so terribly hard to sell the idea to the foremen, and perhaps some of the men, but after six or seven months you wonder why it is they don't make progress, and after a long time it dawns on you that there is a brake in the movement in some stage of the game, and we realize after a while that this brake is in the management. The manager is there to save money. He has an overhead. If his overhead runs 15 per cent this year and 16 per cent next year, perhaps there will be a new manager. Now you are asking him to spend money out of the overhead. He is the brake on the whole matter, and if you don't sell the manager, your chances of success are very small, because he controls expenditure of money and he says what work shall be done and what work shall not be done. From a practical standpoint you must sell safety from the top down.

**MR. BURKE:** During the two safety weeks, did the production suffer?

**MR. MARTIN:** I don't know that I can answer that question accurately because I am not familiar with that so much. I do know that there is a very great element of danger in a "no-accident week" in the possibility that minor injuries may be neglected. It requires the very closest of supervision because we know that there are probably just as many small cuts and scratches during safety week as any other time, but invariably you will find a reduction of 50 or sometimes even greater per cent in your hospital visits for the small injuries. Now the 50 per cent who don't come may get away with it all right, and on the other hand if one or two of these men finally get infected because of that neglect, then you are better off if you never held a safety week. It is very, very seldom that I disagree with our chairman, but on the subject of safety rules I

can't let him have the last word. I don't think that safety rules are so very important when you come down to it because they are very seldom if ever enforced anywhere. They may be enforced for a few weeks. Our scheme is to go into a department and spend the time necessary with the foreman, draft rules from his past experience, and publish them in an illustrated booklet. The rules are not mandatory, simply suggestions to the man on how he may avoid some of the pitfalls that others have fallen into in the past. Yet the foreman is given the weapon to dismiss a man if he wants to. Perhaps the best thing that we have ever tried is the safety contest between departments.

The difficulty perhaps is the same as in "accident week"—watching very sharply for minor injuries, and the desire on the part of the contestants to have a big feed somewhere at the expense of the losers. The contests certainly do get a personal touch into safety work that I had never heard of in any other way.

**CHAIRMAN SCHOTT:** In formulating the program for the year the Executive committee of the Rubber Section realized the fact that this proposition of selling safety was of utmost importance. It was decided that we enlist the aid of the most prominent men in the rubber industry, and to our intense gratification we received immediate acceptance from two of the most prominent men in the industry—Mr. James Newton Gunn, Vice-President of the United States Rubber Company, whom we had the pleasure of hearing last Wednesday morning, and Mr. Arthur A. Frank, General Factory Manager of the Federal Rubber Company, Cudahy, Wis.

### A BROADER FIELD FOR SAFETY WORK

**A. A. FRANK, FACTORY MANAGER, THE FEDERAL RUBBER COMPANY,  
CUDAHY, WIS.**

The words "Safety First" and "National Safety Council" have stood for many broad principles in the prevention of accidents and sickness and since their coinage and adoption have done a wonderful work. When the campaign was first launched, all attention was turned to the guarding of hazardous machines and operations and it was felt that by thus properly guarding equipment accidents would be reduced, but this was just the beginning. Statistics quickly showed that the big majority of accidents were due to personal negligence and apart from machines where the mechanical guard could not be placed. What then, did this require? It required education and training in the art of self-defense against harm. This was much more difficult than the placing of mere guards.

Large industries at once undertook this difficult task of teaching and are meeting such success that the movement is making itself felt all over the world. The more this subject is studied and analyzed, the more one begins to realize that it is so closely allied with about everything we do that we can well carry it along in all our phases of livelihood. The fundamental of safety in industry lies in good industrial relations. A plant that has a good morale will generally be one with a low accident record. Safety should not mean merely safety from accident or

injury to the body—it should mean safety for the mind and soul. It should cover clean surroundings, fair wages, efficient work, proper home protection, recreation, and outside interests.

An industrial plant that interlocks the prevention of accidents with all of these will find it to be not only humanitarian but a paying investment as well.

The Organization Plan of industry is generally to divide a plant into a dozen or more units to facilitate proper control and I want to show that each unit can further the safety movement. The Industrial Commission of Wisconsin has said that safety is essential to efficiency. I believe that efficiency is essential to safety. Most executives in seeking maximum safety strike at the end instead of at the beginning of the chain of factors which jointly act to reduce accidents.

In my opinion the most important of these units is:

#### INDUSTRIAL RELATIONS

Where the feeling between the management and employees is that of the best, the putting over of a thorough accident prevention campaign is made considerably easier. It is difficult at best to train men in such subjects as being careful regarding health and accidents. However, if we have the proper co-operation behind it, it becomes a pleasure. The men must have confidence in the firm and the rest is comparatively simple. Confidence is a wonderful thing and is the basis of all sound business today, and will be forever. There are many ways that industrial relations are being promulgated and developed but the fundamental in all must be confidence. Some of our largest manufacturers have organized what is commonly known as Industrial Democracy, Shop Committees, and the like, which, so far as is generally known, are proving more or less successful, although the experiment on the whole is quite new. Industry is watching such concerns as the International Harvester Company, Goodyear Tire and Rubber Company, and others with great interest. Other companies have planned their relations on less radical lines and carry out many activities in a less organized form to promote this good feeling. But there must be confidence in back of it all. An employer must do whatever he does with earnest and whole-hearted endeavor. He must be sincere in all he does to create this confidence.

The rubber industry has fortunately been free from any serious labor disturbances in the last few critical years, which shows that good feeling must exist and I know that this industry ranks among the foremost in the safety movement. The two go hand in hand.

Next to good industrial relations, and just as important, comes the matter of a clean plant, not only to further a good product and a better morale, but it is the foundation-stone upon which a Safety First Campaign should be built. A plant, no matter how large or how small, how intricate or how simple its process of production, must first be put in good physical condition and must be so maintained to promote safety. Aisles littered up with material, dirty dark corners, and rubbish piles must be eliminated if accidents are to be reduced.

We have a department called PLANT INSPECTION the sole purpose of which it is to keep the plant clean, co-operating with the foremen to prevent congestion, which helps production; but also makes for safety.

Then there are the MECHANICAL ENGINEERING AND PLANT LAY-OUT DEPARTMENT which can do a great deal for the promotion of safety.

In so far as guards for machines are concerned, I need not go into detail because most all industrial plants have this well in hand. It comes almost as second nature in installing machines nowadays to plan a guard for them.

It is in the proper construction of buildings, the proper lay-outs of both buildings and machinery, ventilation and good water supply, that this department can best prove its worth not only for production purposes but directly to further the safety movement. At the present time factory buildings are designed to give the most light possible to further production. Possibly safety was not given a thought when these buildings were planned but just think what they have done toward the reduction of accidents. Then the location of departments for proper movement of materials and the location of machines in departments: A proper lay-out must mean a reduction in accidents notwithstanding that it naturally helps production. Shall plants generally allow foremen to lay out and plan their departments and locate their machinery? I believe it to be money well-spent to have a separate department or only an individual whose sole duty it is to plan lay-outs of the entire plant. When we consider the large investment of machinery and equipment of even a small plant, is it not worth while to spend at least the salary of a good plant lay-out engineer to place it most efficiently? Such a man has a mental picture of the operations of all departments, and considers a lay-out for the plant as a whole and plans production along the simplest labor-saving lines. This ease of flow of materials must necessarily mean safe practices for the human element.

#### STANDARDIZATION OF EQUIPMENT

The Plant Lay-out Department is one of the most efficient units we have in our organization today. It functions separately from our Engineering Department, reporting directly to the Factory Management. Lay-outs are given to the Mechanical Engineering Department for execution and standardization. We endeavor to standardize all equipment that is used in practically all of our departments. Equipment like motors, shafting, and hangers have long been standardized. Endeavoring to standardize tables, racks, benches, and trucks to satisfy the needs of various departments is, however, comparatively new. We have a standard table which was designed after taking into consideration every use that any table might be put to. Safety was the chief requisite, it being perfectly balanced and with every consideration to prevent injury. Then we have standardized such items as trucks for internal or departmental trucking.

Only a few years ago when a foreman wanted a truck he picked one out of the most convenient catalogue and it was ordered. In consequence, we had some 70 different species of equipment, much of which was in-

efficient and highly dangerous to our employees. No truck is ordered now unless the requisition passes through the hands of our Internal Transportation man; then the truck must be one of 22 standard pieces of equipment. The trucks have been so standardized as to insure the best methods of handling and in this instance also with the safety factor kept well in the foreground. We are still refining this and expect, within the near future, to have three distinct types of chassis to cover all requirements and that these chassis will accommodate any of a dozen or more types of superstructures. I could enumerate a good many items of equipment that we have standardized in the past five years but I believe it is needless for me to tell you that this method of standardization is not only helping from the angle of duplicating equipment but it has a big bearing on the reduction of accidents. The Engineering Department, outside of its routine safety work, can be made a very important factor in reducing accidents. They, of course, must have the full support of the management in bearing in mind the safety movement when laying out the plant and designing and locating equipment.

The standardizing of trucks was brought about largely by the development of an INTERNAL TRANSPORTATION DEPARTMENT. This is a unit that should be included in every organization no matter how small the concern. It saves money in itself—it cuts down one of the greatest causes of accidents today. Our experience during the last three years has proven this beyond a doubt. The reduction of accidents is not due alone to standardizing of trucks, but due to the fact that we have put all of our transportation in the plant under one man. A certain small group of men handle all of this work, whereas under our old system of every department having truckers, ten times the number of men handled trucks and the accidents were considerably higher.

Then we have a comparatively new department in industry:

#### INDUSTRIAL ENGINEERING

which was first installed to control the methods of remuneration for production, piece-work, bonus-methods, etc. More recently, however, it has branched out into a very valuable asset by having it control production standards. If properly supervised and with the proper support, this department can be made one of the most valuable adjuncts to safety that we can have in any industry. When time-study men are sent to study an operation it should be their first duty to analyze the work and suggest better methods of handling. They may even recommend the relocation and alteration of machines in order to facilitate the ease of operation. By ease of operation I mean reduction of labor effort or fatigue, which is a large factor in the reduction of accidents. The chief object of a time-study man, of course, is to submit what some may call 100 per cent time, which is the time it takes to produce an article under the best conditions in the best way, in the least possible time. Obviously in suggesting the best way under best conditions, the man unconsciously is recommending operations in the least hazardous way, as the simplest is generally the least dangerous. If the industrial engineer is instructed to watch operations from the safety angle, just think of the value he

must be when drawing up production standards. There may be some question about piece-work or bonus methods of payment being detrimental to safety but from personal experience I can assure you that our accidents to piece-workers have shown to be less than to day-workers. It is, of course, always highly recommended and desired when setting rates to have the earnings on the part of the men reasonably high so that men not quite so efficient as others can draw good wages. A fair and good rate will always tend to balance an operation and not develop into a mad race to make money and thereby possibly cause accidents.

#### EMPLOYMENT DEPARTMENT

The duties of this department are many, chief of which is the keeping of a perpetual inventory of the human machinery of a plant. The employment man should know the condition of all the employees. He must endeavor to keep them on the job and endeavor to keep down labor turnover. This is one of the most costly items of expense in industry today, not only because of breaking in men but it also means higher accident losses. Our accident chart shows that as labor turnover fluctuates, our accident frequency also goes up and down. Many men say that safety cuts down turnover. Here again I believe the cart to be before the horse—turnover cuts down accidents.

In the placing of men where they are best fitted to work, this department can do its best for safety in industry. This is most important, not only for the prevention of accidents but is a link in the chain that spells success or failure in building up a stable and efficient force. The Employment Department is generally given the responsibility of being the "go-between" between the management and the individual workers and acts in the capacity of a Personal Service Department. They are the first ones to express to the new man the policy of the management and can do so much in promoting good industrial relations that they possibly should head the list of departments that indirectly further safety.

Then there is the Production Department that controls about 75 per cent of the men of a plant. This is the department that must see that every individual worker carries out the rules and specifications laid down by the Factory Management, which covers every phase of industrial life. The foremen of the Producing Departments are the lieutenants of the management and upon their efficiency depends the success of the work planned and laid out by all of the other units that I have mentioned heretofore. Their chief function, of course, is to produce rubber goods according to specifications but they must manage their departments as real managers, taking into consideration every phase of activity that their men are supposed to engage in. Their influence counts for so much in any activity, whether it be safety or otherwise, that it pays to have good foremen and good department heads in the producing departments. It is the men from these departments that are generally chosen to act on safety committees and in this way tie in each individual worker of this department to the Central Safety Department and others that plan the campaigns that are to be followed and carried out through the entire institution.

In many instances, when selecting foremen, generally the most proficient workman is taken off the work-bench and given the opportunity to run a department. This may or may not be satisfactory, depending entirely upon the man himself. It is not so essential that the foreman be an efficient worker as it is that he be a good manager and a good handler of men—in other words, a good executive. In most industries in the country the method of making various products is all laid down by the Engineering and Specification Departments for the various producing departments to follow. Therefore, it is not the most essential qualification to be a good workman. I cannot express myself too strongly in selecting men to become foremen to see that they are properly equipped to handle men.

#### HEALTH AND SAFETY DEPARTMENT

I am bringing this department in last not because it necessarily belongs there but because I want to show that all of the departments of an organization play such an important part, that if they were not co-operating, the Safety Department would have great difficulty in making progress. The most difficult work this department has in launching a safety campaign is the training of men to be careful and to co-operate in the safety movement, but as I mentioned in the beginning of my talk, if the proper foundation of good feeling exists and the plant is in good physical condition, the equipment is right and the men are happy, it is a simple matter to make a showing on the part of the Safety Department. I do not mean to infer that this department must wait until the others have done their share. They can be very instrumental in pointing out to the various units of an industry, how they can assist the movement.

I trust I have shown that safety cannot be isolated to be successful. A Safety and Health Department does not mean a safe plant. Every unit of an organization must help directly and indirectly to further this great cause. I believe this spirit is fast developing in American industry and is making American industry rank foremost in the world today.

CHAIRMAN SCHOTT: I want to call upon Mr. E. H. Fitzgerald, the newly elected chairman of the Rubber Section, for a few remarks.

MR. E. H. FITZGERALD: A year ago when the Rubber Section was organized I little thought that we would get the expression from the different companies that we have at this session. The Rubber Section has really grown to something. Next year I promise you that we will be up in front and unless business conditions are entirely shot, our next convention or sectional meeting will mean more than this one has meant.

I wish to announce the chairmen of the different committees for the coming year. Mr. Schott will be chairman of the Program Committee for next year. Mr. Frank Scott of the Membership Committee, Harold Martin, the Building Committee, Ray Watson will still remain on the Standardization and Statistics Committee, and the Engineering Committee will again be in charge of Mr. Mitchella, of the Goodrich Company.

I want to thank you for the honor conferred on me, and I want to tell you that I will give my best endeavors to making this section one of the liveliest of the Council.

ADJOURNMENT.

F. J. Masen, Baltimore, Md.  
 E. H. Mattingley, Chicago Terminal, Chicago, Ill.  
 W. A. Mitchell, Safety Agent, Grafton, W. Va.  
 J. C. Morgan, Safety Agent, Baltimore, Md.

*Bessemer and Lake Erie—*

A. A. Stebbins, Superintendent of Safety.  
 S. G. Watkins, Superintendent of Safety, Boston, Mass.  
 T. C. Whiteman, General Attorney, Greenville, Pa.

*Belt Railway of Chicago—*

E. D. Swift, Chairman, General Safety Commission, Chicago, Ill.

*Buffalo, Rochester, and Pittsburgh—*

John S. Rockwell, General Agent, Rochester, N. Y.

*Central of Georgia—*

S. S. Morris, Chairman, General Safety Commission, Chicago, Ill.

*Chesapeake and Ohio—*

L. G. Bentley, General Safety Agent, Richmond, Va.

*Chicago and Alton—*

R. J. McDonald, General Safety Agent, Bloomington, Ill.

*Chicago, Burlington and Quincy—*

E. M. Switzer, Superintendent of Safety, Chicago, Ill.

*Chicago, Cleveland, Cincinnati and St. Louis—*

A. L. Mason, Safety Agent, Bellefontaine, Ohio.  
 T. R. McCampbell, Safety Agent, Indianapolis, Ind.

*Chicago and Eastern Illinois—*

J. F. Lord, Superintendent of Safety, Evansville, Ind.

*Chicago and Great Western—*

O. P. Larson, Assistant Chief Clerk, Oelwein, Ia.  
 G. O. Perkins, Superintendent of Telegraph and Signals, Chicago, Ill.  
 E. L. Waltz, Superintendent of Telegraph and Signals, St. Paul, Minn.

*Chicago, Milwaukee and St. Paul—*

W. Anderson, Superintendent, Milwaukee, Wis.  
 B. J. Bjorkholm, Assistant Master Mechanic, Milwaukee, Wis.  
 C. O. Bradshaw, Assistant General Manager, Chicago, Ill.  
 C. Busch, Assistant Superintendent, Milwaukee, Wis.  
 A. J. Cassette, Milwaukee, Wis.  
 W. H. Cobb, District Safety Inspector, Milwaukee, Wis.  
 L. T. Curtis, General Store Keeper, Milwaukee, Wis.  
 Tom Hamlin, Section Foreman, Milwaukee, Wis.  
 G. T. Gilliop, General Manager, Chicago, Ill.  
 W. E. Grant, Special Agent, Milwaukee, Wis.  
 M. F. Hogan, District Safety Inspector, Spokane, Wash.  
 J. T. Johnston, Superintendent, Superior District, Green Bay, Wis.  
 J. F. Kane, District Safety Inspector, Cedar Rapids, Ia.  
 D. Kelly, Superintendent, Portage, Wis.  
 H. F. Killilac, Solicitor, Milwaukee, Wis.  
 J. Macdonald, Superintendent, Madison, Wis.  
 Ben Ohara, Claim Agent, Milwaukee, Wis.  
 Harry Riley, Machinist, Milwaukee, Wis.

A. W. Smallen, General Supervisor of Safety and Fire Prevention,  
Chicago, Ill.  
Wm. Thiele, Superintendent, Milwaukee, Wis.  
N. P. Thurber, Superintendent, Milwaukee, Wis.  
C. L. Whiting, Superintendent, Milwaukee Terminal, Milwaukee, Wis.

*Chicago and North Western—*

F. G. Brown, Conductor, Fond du Lac, Wis.  
E. J. Finel, Signal Foreman, Lake Bluff, Ill.  
Wm. Gebel, Car Dept., Chicago, Ill.  
T. J. Holland, Machinist, Antigo, Wis.  
Charles Jehlik, Machinist, Chicago, Ill.  
J. W. Kilgour, Conductor, Chicago, Ill.  
P. J. McAndrews, Road Master, Sterling, Ill.  
P. E. Parish, Conductor, Baraboo, Wis.  
R. C. Richards, Chairman Central Safety Committee, Chicago, Ill.  
M. A. Schuster, Air Brake Foreman, Milwaukee, Wis.  
James Sullivan, Safety Inspector, Chicago, Ill.  
A. W. Tabert, Roadmaster, West Allis, Wis.  
C. L. Young, District Claim Agent, Milwaukee, Wis.  
W. W. Young, Chief Engineering Electrician, New Butler, Wis.

*Chicago, Rock Island, and Pacific—*

L. F. Shedd, Superintendent of Safety, Chicago, Ill.

*Delaware and Hudson—*

R. C. Helwig, Safety Agent, Albany, N. Y.  
J. E. Long, Superintendent of Safety, Albany, N. Y.

*Duluth and Iron Range—*

W. A. Clark, Chief Engineer, Duluth, Minn.  
E. T. Freeman, Machinist, Two Harbors, Minn.  
W. Johnson, Hoist Engineer, Two Harbors, Minn.  
H. A. Rowe, Secretary Central Safety Committee, New York City.  
J. C. Wingate, Two Harbors, Minn.

*Duluth, Missabe and Northern—*

Wm. Axford, Duluth, Minn.  
T. H. Bell, Chief Electrician, Proctor, Minn.  
J. Dormedy, Foreman, Duluth, Minn.  
G. Fremanus.  
B. H. Miller, Safety Inspector, Duluth, Minn.  
A. V. Rohweder, Superintendent of Safety, Duluth, Minn.  
M. Scanlon, Conductor, Proctor, Minn.  
J. Shea.

*Elgin, Joliet and Eastern—*

W. F. Congdon, Safety Inspector, Joliet, Ill.  
O. F. Gnadinger, Superintendent of Safety, Joliet, Ill.

*Florida East Coast—*

W. W. Scott, Safety Agent, St. Augustine, Fla.

*Great Northern—*

C. L. La Fountaine, General Safety Supervisor, St. Paul, Minn.

*Gulf, Colorado and Santa Fe—*

J. G. Fitzhugh, Safety Supervisor, Galveston, Texas.

A. E. Hutchinson, Safety Inspector, Galveston, Tex.

*Hocking Valley—*

E. R. Cott, Safety Agent, Columbus, Ohio.

*Illinois Central—*

S. S. Morris, Chairman, Safety Committee, Chicago, Ill.

*Kansas City Southern—*

M. T. Fulton, Supervisor of Safety, Kansas City, Mo.

G. W. Smith, Safety Inspector, Pittsburg, Kans.

*Kansas, Oklahoma and Gulf—*

R. R. Stevens, Assistant Superintendent of Safety, Muskogee, Okla.

*Long Island—*

T. P. Brennan, Safety Agent, New York City.

*Louisville and Nashville—*

R. L. Pilling, Supervisor of Safety, Louisville, Ky.

*Minneapolis, St. Paul and Sault Ste Marie—*

L. P. Green, Superintendent of Safety, Minneapolis, Minn.

*Minneapolis and St. Louis—*

O. F. Johnson, Safety Supervisor, Minneapolis, Minn.

*Missouri, Kansas and Texas—*

J. V. Butz, District Superintendent, Smithville, Tex.

C. F. Colby, Safety Agent, Dallas, Tex.

J. F. Smith, Safety Agent, Dallas, Tex.

J. L. Walsh, Superintendent of Safety, Dallas, Tex.

*Missouri Pacific—*

R. H. Dwyer, Superintendent of Safety, St. Louis, Mo.

*Michigan Central—*

A. C. Hartley, Supervisor of Safety, Detroit, Mich.

*Northwestern Elevated Ry. Co.—*

John Farrell, Chicago, Ill.

## WEDNESDAY MORNING SESSION

**T**HE First Session of the Steam Railroad Section was called to order at 9:30 a. m., Wednesday, September 28, by Chairman Robert Scott.

CHAIRMAN SCOTT: We will now have the roll call by the Secretary.

(Secretary H. M. Mayo called the roll.)

CHAIRMAN SCOTT: The next order of business is the report of the Chairman.

I am going to ask Mr. T. H. Carrow to come to the Chair while the Chairman reads his report.

(Mr. T. H. Carrow took the Chair.)

**REPORT OF CHAIRMAN**

MR. ROBERT SCOTT (Superintendent, Insurance and Safety, Atlantic Coast Line Railroad): As presiding officer, I extend to all present a cordial welcome, with hearty greetings to the members, and solicit from them such aid in our deliberations as their knowledge and experience fully qualifies them to give.

The reports of the Secretary and the various committees will give you full details of the work by our Section during the past year.

It has been a great pleasure to have been associated with the present administration, and I acknowledge with deep gratitude the honor that has been mine in serving you as Vice-Chairman and Acting Chairman for a brief period.

I consider it a misfortune to our Section that Chairman Myers resigned during the year; he was such a magnetic fellow and a tireless worker. We have suffered a distinct loss in having to forego his services since the early part of the present year.

Your Acting Chairman has attempted to direct the work as best he could with such limited experience as he has had in Council matters. It has been possible to hold only one meeting of our Executive Committee during the year, although it pleases me to be able to say that there has been close co-operation between all officers and members of committees.

At this point let me thank every member of every committee for the active support given the work of our Section. It is gratifying to know that such a large number of our members are willing to give their valuable time and talents to the cause.

It is particularly pleasing to learn that all of the important railroad systems in the country have seen fit to continue the work of accident prevention since return to private operation on the first of March. From what can be gathered, some of the lines have actually enlarged upon the plans adopted during Federal control and are carrying the work forward more aggressively than ever before.

One thing that occurs to me to stress is the desirability and importance of giving more publicity to our work; this refers to the activities of the Steam Railroad Section of the National Safety Council, as well as the activities on our individual roads. The general public, also our patrons, should know of the organized efforts being made to hold railroad accidents to a minimum.

Another thing I will mention, and that is the apparent need for members of the Steam Railroad Section to familiarize themselves more thoroughly with the work being done by the various sections of the National Safety Council. I am confident that a more general knowledge of the scope and magnitude of the work will not only be educational but will also be an inspiration to many of us to become more active.

A thought that comes to me is to remind members of the fact that the same question of individual responsibility we are continually pounding into officers and employees of our roads must not be forgotten when it comes to doing the things that ought to be done in our Section of the Council. It, therefore, devolves upon every one of us to shoulder our

part of the responsibility and carry our share of the burden by working diligently at whatever we are called upon to do.

There seems to be urgent need for statistical information regarding personal injuries and their causes, and I am trusting some way may be found to gather data of this kind, embracing at least all of the trunk lines.

Now, I want to make just a few remarks about the National Safety Council, and particularly the Steam Railroad Section. I want to acknowledge gratefully to the Steam Railroad Section the service that it has rendered me. Two years ago I attended my first session at St. Louis. I knew absolutely nothing about organized efforts for the prevention of accidents. That was the place where I took my first lessons in accident prevention and that was the place where I received my inspiration to go back to my road and carry on the work, and I want to tell you, my friends, that I did receive an inspiration there and I believe it is more than worth while for the representative in safety work of every railroad to come to these meetings and meet with the good fellows and get that inspiration and go back home and spread it among the officers and employees of our individual roads.

I don't believe it ever would have been possible for me to carry on the work in any fashion at all that would have been worth while had it not been for my connection with the National Safety Council. I believe that the discussions here have a far greater value than any of us place upon them. I believe that the interchanging of ideas and thoughts, the rubbing of shoulders and the clasping of hands are the things that count, and I will tell you when you get back home you can't forget those things. You carry on your work in better fashion and you are better able to put safe practices into effect.

I am going to take the liberty of relating a story. You have heard stories that come from all sections of the globe; this one comes from the Far East, from where a great deal of the wisdom has come to us. This is a story of a mother who had a son. There was the strongest kind of devotion and love between this mother and son. Eventually, this son, as he grew into manhood, fell in love with a woman and decided to take unto himself a wife. This wife was a very exacting sort of woman. She demanded everything of this husband and she said to him one day, "You claim that you admire me and you claim that you love me and I am going to put you to the test. You have got to show me absolutely that you love me above all else in this world, otherwise, these statements and these claims that you have made to me are worthless. You must go to that mother of yours, you must cut that mother's heart out and bring that heart to me."

What did the son say? He said, "Wife, I can't do that; that would be committing murder."

The wife said, "I care nothing about that. All I care for is to have absolute proof of your love for me, and I demand that you shall bring your mother's heart to me."

The husband went and slew his mother. He cut that heart out of his

mother's breast, and going to this wife with the trembling heart of his mother in the palm of his hand he tripped and fell, and what did that mother's heart say? That mother's heart said, "Son, art thou hurt?"

Men, there is the kind of feeling you have got to have in your hearts if you make a success of this safety work.

When I first went into safety work, I thought it was dollars and cents; I thought it was saving a few fingers and a few toes, but I have found out that it is a far greater thing than that. We talk about the rights of capital, the rights of labor and the rights of humanity, but there is a greater right than that—the right of the Creator, the One that made you and the One that made me, and that is the kind of love you have got to have in your hearts if you are going to succeed in that work.

ACTING CHAIRMAN CARROW: Gentlemen, you have heard the Chairman's report and its appeal; what is your pleasure?

Mr. T. R. McCAMPBELL (Cleveland, C. C. & St. L. Ry.): I move that the report of the Chairman be accepted as a part of the minutes of this session.

(The motion was seconded and carried.)

(Mr. Scott resumed the Chair.)

Mr. MARCUS A. DOW (General Agent, New York Central Lines): The President of the National Safety Council, and perhaps the most loved man in safety work in this country, probably would have come into this Sectional meeting in preference to any other meeting of the convention today except for the fact that he has been taken sick and I understand has been taken to his home. I am sure that every member of this Section feels way down in his heart that Ralph C. Richards ought to be with us here in this meeting, and I am sure that you are all deeply apprehensive for him in this sickness which has suddenly overtaken him.

I would like to move, Mr. Chairman, that the Steam Railroad Section extend to Mr. Richards our expression of deep sympathy and the wish that his sickness is not serious and that he will soon again be able to return to his desk and take up the range of safety work as usual. I would like to make that a motion.

(The motion was seconded and unanimously carried.)

CHAIRMAN SCOTT: The next in order is the report of committees. Has the Bulletin and Publicity Committee anything to report?

#### REPORT OF BULLETIN AND PUBLICITY COMMITTEE

Mr. ISAIAH HALE (Safety Superintendent, The Atchison, Topeka, and Santa Fe Railway System): We have managed to supply the National Safety Council with enough material to get out the requisite number of bulletins, and in behalf of the incoming Committee, I am going to urge upon you gentlemen separately to do something more this next year for this Publicity Committee than you have done this last year. If you will send the subject for one bulletin that will be all that can be expected of you and will enable this Committee to carry on the work as it should be carried on. They want something new, something with a punch in it,

and I urge you to come to their relief this year and help them as you can help them.

CHAIRMAN SCOTT: Thank you, Mr. Hale. I feel that your Committee is entitled to a great deal of thanks for the work done during the year. I quite appreciate what it means to get material together for bulletins.

The next is the report of the Committee on Accident Causes and Remedies. Mr. J. E. Long is the Chairman.

#### REPORT OF ACCIDENT CAUSES AND REMEDIES COMMITTEE

Mr. J. E. Long: Shortly after the members of this committee were designated, all of the members with the exception of one and the Chairman, left the field of railroad safety work for other lines, making a change in personnel necessary. The Committee was finally organized with the following members: Mr. T. H. Carrow, Supervisor of Safety, Pennsylvania System; Mr. T. Hartenstein, Assistant to General Manager, Lehigh Valley R. R. Co.; Mr. F. W. Mitchell, Supervisor of Safety and Examinations, New York, New Haven & Hartford Railroad Co.; Mr. D. H. Beatty, Superintendent of Safety, Southern Railway System.

The first and only meeting was held in the office of Mr. Carrow at Philadelphia on July 27, with all members present excepting Mr. Hartenstein, who was unavoidably absent.

At that meeting arrangements were made to have four papers prepared, and plans made to have them discussed.

Upon taking the matter up with the Chairman of the Program Committee, however, it was learned that the program for this Congress had been completed, making it impossible for us to carry out our proposed arrangements. We were also advised that arrangements had been made to have papers prepared by other members of this section, covering the subjects we had planned. Under the circumstances we decided it would be best to abandon our contemplated program.

The members of the Accident Causes and Remedies Committee however, expect to be prepared to enter into the discussion of the address to be made by Mr. Arthur Ridgeway of the Denver & Rio Grande on "Maintenance of Way and Motor Car Accidents," the address by Mr. J. McNally of the Wabash Railroad on "Shop Accidents," and that of Mr. Baltzell of the St. Louis & San Francisco on "Transportation Accidents."

The recommendation was made in last year's report that this Committee communicate with the Statistician of the Interstate Commerce Commission for the purpose of obtaining a statement of accidents classified by detail causes. This recommendation was carried out and the Director of the Bureau of Statistics, Interstate Commerce Commission, advised us that this information was not as yet available but that Accident Bulletin No. 74, covering the last quarter and the year ended December 31, 1919, was in the hands of the printer. He was unable to state definitely when this publication will be finally issued. Your Committee suggests that all members of the Steam Railroad Section obtain copies of this Bulletin as soon as issued for the purpose of studying it, with a view to

utilizing, as far as possible, the information contained therein, for the prevention of accidents.

With reference to the recommendation contained in last year's report, relative to the development of detail causes of shop injuries, the Committee feels that in view of the difficulty of developing these causes and particularly on account of the fact that Train and Train Service Accident causes have not been fully developed or utilized, it would be well to defer action on the full development of detail shop causes until next year. A brief analysis was made of 179 reportable personal injuries to shopmen on one of our member roads and this study of the accident causes developed that the injuries occurred in the following manner:

#### ANALYSIS OF PERSONAL INJURIES TO SHOPMEN

- 45 Injured account of being struck by falling tools or material with which they were working.
- 28 Injured while using tools, subdivided as follows:
  - 20 Self inflicted injuries (not due to defects)
  - 3 Struck by tools in hands of other employees
  - 2 Defective hand tools
  - 2 Use of air hammers, drills, etc.
  - 1 Use of jacks (not defective)
- 17 Injured by falls, subdivided as follows:
  - 6 Falling from engines or cars standing
  - 6 Falling over scrap, air hose, couplers and other removable obstructions
  - 2 Falling from ladders account of ladders slipping
  - 1 Falling from scaffolding
  - 1 Falling over rails
  - 1 Killed and 1 Injured account of falling into engine or ash pits
- 15 Injured while handling material
- 14 Injured by slipping accidents, subdivided as follows:
  - 3 Slipping on snow or ice on or between tracks
  - 2 Slipping on aprons of engines
  - 9 Slipping from miscellaneous causes
  - 9 Injuries to eyes from flying particles
  - 4 Injured account of stepping on nails
  - 3 Injured account of shaker bar slipping from lug
  - 3 Injured account of ropes, chains, or cables slipping or giving way
  - 3 Injured account of handling fire rakes
  - 2 Injured while getting off standing cars or engines
  - 4 Injured while using Machinery, subdivided as follows:
    - 1 Unguarded machinery
    - 1 Cleaning, repairing or adjusting while in motion
    - 2 From miscellaneous causes
  - 2 Injured account of being struck by objects thrown from cars, engines, platforms, etc.
  - 2 Injured account of being struck by tools or other objects falling from shelves, scaffolding, platforms, etc.

- 1 Injured account of climbing over, under, or between cars or engines
- 1 Injured account of explosion of gas
- 1 Injured while using squirt hose
- 1 Injured account of being struck by engine
- 24 Injured in miscellaneous ways not otherwise specified

A further study as regards the length of service of the men injured, developed the following facts:

74.3 per cent occurred to men whose duration of service ranged from 1 to 42 years

7.3 per cent to men in the service from 6 months to 1 year

9.8 per cent to those in service from 2 to 6 months

1.3 per cent to those in service from 1 to 2 months

5.3 per cent to those in service from 2 weeks to 1 month

2.0 per cent to employees in service less than 2 weeks

From this analysis it will be noted that the majority of these shop accidents occurred to the older men in the service rather than to the new men. Possibly these figures as to length of service are not generally applicable to all roads nor do they apply to employees injured in Train and Train Service Accidents.

In conclusion, I wish to express my appreciation for the valuable assistance so cheerfully given by the other Members of this Committee, without which this report, even though incomplete, would not have been possible.

(On motion the report was seconded and carried.)

CHAIRMAN SCOTT: Next we will have the report of our Secretary, Mr. Mayo, who has served us so well during the year.

#### REPORT OF SECRETARY

SECRETARY MAYO: I didn't write a report. I want to say this, however, that during the twelve months of my official capacity it was a rather mixed pleasure. When they turned this job over to me, when I got back home I wrote Mr. Whittemore that I hadn't the slightest idea what to do. He picked up a whole lot of stuff that had accumulated that he didn't know what to do with and shot it down to me, and for a while I felt very much like the man who was called in to attend the funeral of his old friend. He came into the house and looked down at the remains and said, "Poor old Clancy. He didn't believe in heaven and he didn't believe in hell, and here he is, all dolled up and nowhere to go."

I don't know who is going to succeed me to this very interesting office, but I do want to make an appeal in his behalf to all of you and particularly you who are old in the service and who have had experience, to come across and help him out. Send him material you get out every month with an occasional letter or suggest some line of thought or action that has proved interesting in your section. He is going to need it because your Secretary has many other things to do. I wanted to get up a monthly letter each month; I always had the inclination but didn't always have the opportunity. You can make the life of the Secretary much more endurable and his assistance to the Section far more valuable,

and you will do the members of the organization a great deal of good by letting him have what you have in your dome and don't be afraid to let it get out.

I want to thank you for the various letters I have received from a number of you and I sincerely trust that my successor will give you more than I gave you, because I only gave you fifty-fifty and I ought to have given you one hundred per cent.

Mr. C. R. STAPLES (Southern Railroad): I move that the report of the Secretary be accepted, and that the advice laid down by him be followed out.

Mr. E. S. CHAPIN (Pennsylvania Lines): In seconding that motion, I want to say that I have a great deal of sympathy for our Secretary. I don't believe there is one man here but what got out something on his railroad that would be of value to this Section, and if we would just have Mr. Secretary placed on the mailing list and let him have the bulletins or whatever is published it would be a great deal of help to the Secretary and to the Section.

(The motion to accept the Secretary's report was carried.)

CHAIRMAN SCOTT: Has the Program Committee anything to report, Mr. Clark?

#### REPORT OF PROGRAM COMMITTEE

Mr. J. C. CLARK (Oregon Short Line): I have no formal report to offer. I would like to call attention to the fact though that there are only three subjects listed for discussion at the round table meeting Thursday afternoon. This doesn't mean that there are only to be those three subjects brought up for discussion. We want any one who has any particular problem he wants to talk over to bring that problem up. Mr. Harry Adams is to be Chairman of the round-table meeting and he will be very glad to receive topics for discussion from any man here.

I feel that there is no report necessary so far as the program is concerned; the program speaks for itself. We have gotten away a little bit from the ordinary practice of the last few years at least and brought in more speakers from outside.

CHAIRMAN SCOTT: Gentlemen, you have heard what Mr. Clark had to say about handing in anything you wish to have discussed at the round table. Let's not forget that.

In connection with the very able work that Mr. Clark has done in the preparation of the program this year, I want to say that it is no small task to get up a program for a meeting of this sort, and I think Mr. Clark is entitled to a great deal of credit for the very able program which he has prepared.

(On motion the report was accepted.)

CHAIRMAN SCOTT: We will now have the report of the Committee on Membership. Mr. Whittemore is Chairman.

#### REPORT OF MEMBERSHIP COMMITTEE

Mr. F. WHITTEMORE: At the close of last year, the membership of the Steam Railroad Section consisted of 129 railroads with a mileage of 216.

000, there being only two or three important lines in the entire country that had not joined hands with us in our efforts to build up a branch of the National Safety Council which would be an everlasting credit to the railroad Safety men. This year, after passing through one of the most critical periods in the history of our railroads, the membership totals 124, representing 215,800 miles of track. The lines cancelling their membership are as follows: Charleston & Western Carolina R. R., Atlanta, Ga.; Duluth, South Shore & Atlantic Ry., Marquette, Mich.; Ft. Worth & Denver City Ry., Ft. Worth, Texas; Grand Trunk Lines in New England, Island Pond, Vt.; Temiskaming & Northern Ontario Ry. Commission, 25 Toronto St., Toronto, Ont., Canada; Toledo Terminal Railroad, Toledo, Ohio; Union Terminal Railroad, St. Joseph, Mo.; Wichita Valley Ry., Wichita Valley, Tex.

As will be noted, all of these are small lines and have cancelled their memberships either because they are being operated by large trunk lines, who hold membership in our organization, or their safety departments have been abolished. While of course the loss of these lines is to be regretted, it is very encouraging to note that none of the larger lines are included in this list.

#### NEW MEMBERS

The following new members have been secured: Colorado & Wyoming Ry. Co., Denver, Colo.; Yazoo & Mississippi Valley R. R., Chicago; Gulf, Mobile & Northern R. R., Mobile, Ala., with a total of 1,900 miles. In addition to the new members, 48 railroads whose membership expired this year have renewed, and we are confidently counting on the remainder of you members to send in voucher covering renewals immediately upon receipt of notice of the expiration of present membership.

The growth of the Steam Railroad Section during the past six years has been as follows: 1915, 27 members; 1916, 63 members; 1917, 87 members, 1918, 103 members, 1919, 129 members, 1920, 124 members.

In accepting the Chairmanship of this Committee, I advised the Chairman of our Section that while I and the gentlemen selected to serve with me would gladly put forth our best efforts to increase the membership of the Steam Railroad Section, I felt that we would be quite fortunate if we were able to hold the ground gained last year, when the Safety Section of the Railroad Administration was standing staunchly behind this organization and rendering every possible assistance. The Membership Committee during the past few years, under the able leadership of Mr. Blakemore of the N. & W., has been unusually successful and that we have been able to keep our forces up to full strength through such an uncertain year as 1920 is a tribute not to the efforts of any individual, but to the Steam Railroad Section of the National Safety Council and the high ideals for which it stands. At the beginning of this year not only the safety men but all other railroad officials and employees anxiously watched developments several months, for there appeared on the horizon unprecedented conditions and the future of railroad associations, such as ours, could not be guessed at amid the noise and excitement about March first. Indeed, some of the associations, which were local propositions, were

now is safety work. We have gone through a very strenuous period when we, all of us, including the officers, have lost sight of a great many details that go to make up a good railroad. We find on the Union Pacific proper that our accidents in the last few months have grown tremendously. They have grown for a reason. We have any number of new men in the service that we found necessary to employ. These men have to be educated, and I feel responsible myself to a certain extent for letting some of the details get away from the officers.

I am going to suggest to you some of the practical things in connection with safety work as I see them, both from the view-point of the operating officer and from the view-point of the man in the service. The thing we are suffering from on most railroads, and I am speaking very frankly, is

#### ALOOFNESS OF OFFICERS

the dignified aloofness on the part of some officers. We are overlooking the fact that every man in the service (and that goes down to the call boy; I am just a little partial to that fellow) is after all a factor in the railroad. In handling these safety meetings there isn't enough interest put forth on the part of the average officer to get in touch with the man to find out what he is thinking about. I have in mind particularly this one point: We have thrown down the bars to the men, asking them to make suggestions and recommendations along safety lines. We are going to get, of course, a good many suggestions that are not practical and at times some that may appear more or less ridiculous. That is to be expected. We have let a habit grow on us that when a suggestion of that kind is offered, we simply lay it aside and say it isn't practical and let it go at that. The thing we should do is to call this man in, or go to see him and tell him why the suggestion he made wasn't practical and why the committee decided it wasn't workable. We have attempted all along to follow a policy of calling the man in or going to see him and explaining to him why his suggestion wasn't practical, but we are going to go a little further and, as far as is consistent, we are going to call the men who make suggestions to the meetings and get the benefit of their view-points and get their reasons why they made the suggestions. To accom-

#### SAFETY MAN ON EACH SUPERINTENDENT'S STAFF

plish that, it is our intention to place a safety man on each superintendent's staff, holding that man responsible for safety matters on his particular division. We have many inspectors on our railroad but they are working at random now, none of them feels that he is directly responsible for his particular territory or particular plant.

We are working on the idea of having a man on each division with the rank of a trainmaster. I don't know how practical that will be on each railroad as most of the railroads have a different system of handling their divisions, but I do feel that if we are going to get the best, each and every railroad will have to adopt a more detailed method of handling safety matters. Our trouble is we usually wait until we have a serious accident and then wake up to the fact that it is necessary to do something. It re-

minds me of a story I heard some time ago, which will illustrate my point, of an old Irishman in the track gang at one of these little country towns, that went to the picture show once a week. It only changed its reels once a week. This old gentleman went to this picture show and there was thrown on the screen a passenger train going by and a lady going in bathing. The scene showed the lady starting to go in bathing and then the next scene showed her in the water. This old Irishman came every night. Finally, the manager said to him, "Of course, we are interested in having you come, but I want to say to you that we only change our reels once a week." He said, "That's all right; I understand." The manager said, "But would you mind telling me why you come every night? We are interested in knowing what our patrons like."

"Well," he said, "you know I work on a railroad and that passenger train is going to be late some day." So it is in these safety matters. We are continuing to attend the meetings and not getting results. We are going to be too late some day and we are going to have a serious accident that might have been avoided.

In our organization in the Western territory, and it is perhaps no different from what we have on most railroads, it has been our endeavor to select men who are practical, particularly men who can and do talk the language of the average railroad man. I believe there is a mistake made in having too many statistics at our meetings. Figures are usually dry and they don't appeal to the men. My thought is, if we can, to select certain accidents at our meetings and go into details with the men as to how the accident happened, how it can best be prevented, and, where we have shops or big terminals, take the committee out in the yard and explain how the accident happened and what we should do to prevent a repetition. In other words, we have to reach the fellow now on the ground and make him appreciate the fact that we are depending on him for results. There isn't any operating officer or any set of officers that can run a railroad and run it satisfactorily unless every man in the service is loyal to that railroad and loyal to the officers. We are not going to get that loyalty by talking *at* men; we are going to get it by talking *to* them. The mistake that is made by most speakers is that they talk *at* their men.

#### LABOR ORGANIZATIONS

I am referring now particularly to men who are members of organizations—labor organizations—(and I want to say in that connection that I am in sympathy with any labor organization that is properly run; if I were a man in the service there isn't a question about where I would be. I would be in the organization) and in this connection I want to suggest to you men who are in these organizations (the fact that you are members of the Safety Committee is evidence *prima facie* that you are the average at least and perhaps above the average) that it would be well to discuss these matters in your meetings. Let's have the men understand that the operating officer has his difficulties and the more we help this fellow the easier it is going to be for all of us. I can say very frankly in our territory that we are having the best co-operation. Our men out there are everything that could be expected, and on the other

hand, we are attempting to be a little more than fair with the fellow who makes an honest mistake. I am opposed to drastic action in correcting irregularities unless such action is absolutely necessary. It is a mistake to lose an old man in the service when it can be avoided. The best answer to our troubles now is the fact that we have lost too many old men in the service. So speaking to you men who are officers, let's not overlook the fact that any man can make an honest mistake, and if it is an honest mistake, let's give him credit for it and keep him in the service.

CHAIRMAN SCOTT: There is one announcement I should like to make at this stage of the proceedings, it is in connection with the Nominating Committee. I think most of you who were present at the Congress last year will remember that it was decided by resolution on the floor that the services of the Nominating Committee would be dispensed with. By doing that, a precedent has been established in the Steam Railroad Section. You will find on the program for this Section that the Nominating Committee will make its report Friday morning. I should like to announce that as a result of this precedent that was established last year we will have no Nominating Committee this year, unless this body feels that it should be otherwise, but that the election of officers will take place on Friday morning and that the nominations will be made from the floor.

Now, the next on the program is "Safety and Time Service", a talk that we are going to have through the goodness of Mr. Webb C. Ball, General Time Inspector of the Bureau of Railroad Time Service, of Cleveland. There is nothing more important than the question of time when it comes to the operation of railroads, and I look forward with much interest, and I am sure you do, to hearing what Mr. Ball is going to tell us. Mr. Ball.

### SAFETY AND TIME SERVICE

WEBB C. BALL, GENERAL TIME INSPECTOR, BUREAU OF RAILROAD TIME SERVICE, CLEVELAND, OHIO

Self-preservation is the physical expression of "Safety and Time Service" when referred to as a human instinct—but too often disregarded in this age of life's restless activities.

To give an account of the ways and means by which the standard "System of Safety and Time Service" has been developed to make railroad standard watches and clocks play their all-important part in the safety movement of the country is the purpose of this paper.

The railroad standard watch of today is justly recognized as one of the most important "safety appliances" required in train operation. In these days of highly complex organization, it is called upon to perform a service of safety every hour and minute both day and night, and it is as constant and necessary as regular pulsations of one's heart and lungs. No more faithful or dependable companion for mankind was ever invented or devised by the hands of skilled men.

I won't go far astray when I say this faithful little machine is abused and cuffed around without any regard to giving it a square deal by careful

handling, or some encouragement for its faithful service in the way of a little oil and cleaning once a year, or eighteen months at farthest.

Lay out a dozen or fifteen railroad standard watches, and it is very easy to tell by the condition of the watches the character and habits of their owners and as to whether or not they are dependable in the performance of their duties. It inevitably follows that a man careless and indifferent with his watch, evidences the same characteristics in his daily life and vocation.

The importance of the standard timepiece to the traveling public and to the railroads is illustrated if you call upon your imagination to picture what would happen if some phenomenon were to play havoc for a half-hour period once or twice a year with the delicate mechanism of the millions of watches and clocks throughout the world.

Again, let your imagination picture an attempt to give railroads Safety and Time Service by means of the crude sun dials of the cave man, the water clocks of the Babylonians, and the hour glasses of the Greeks, and the many prototypes of clocks and watches found throughout the Middle and Early Modern Ages.

To bring the illustration nearer home, imagine the railroads being run today by means of those two famous Connecticut products, "Ely Terry's wooden clocks," and the long-wind Waterbury watch, the latter the subject of as many jokes as are "Tin Lizzies" of today.

We railroad men know by glancing at our watches, in which we have confidence, what the standard clocks and watches in Boston, New York, Atlanta, New Orleans, Chicago, Denver, San Francisco, and Winnipeg at this very moment are telling our fellow workers and the traveling public. We are also reasonably certain as to the exact present location of express trains speeding on their course over the systems we are here representing. Thirty years ago, before the present system of Railroad Time Service was inaugurated, such certainty was impossible. The trainmen were allowed five minutes leeway at junction and passing points for errors in watches.

The best watch was 18 size, 15-jeweled, flat hairspring, single roller brass escapement, garnet jewels and not adjusted except with a punch and hammer—they classed with old-time hand brakes and wood-burning engines. Fortunately, in those days there were comparatively few trains running daily in each direction.

Today the standard demanded is such that I feel safe in maintaining that few, if any in this room depend upon watches below the standard for "old watches" now in railroad service, namely, 17 jeweled, single roller, lever set, Breguet hair spring, patent regulator, and adjusted to three positions.

I am quite willing to wager, though we are not subject to time service rules, the majority have watches that meet the present requirements—19, 21, and 23 jeweled, steel escape wheel, safety double roller, 16 size, open face lever set, adjusted to five positions, plain Arabic standard dials.

## TRAVELING PUBLIC DEMANDS PUNCTUALITY AND SAFETY

The traveling public demands punctuality and safety. The increasing popularity of the extra-fare trains tempts me to modify the statement, as the primary demand seems to be "speed," but with speed, it expects safety, then punctuality.

A valuable means for this purpose is the surprise tests of the trainmen's watches which are becoming more general, as they reveal to the official to what extent the time service rules and instructions are being carried out.

Railroad people who carry standard watches and submit the same for periodic inspection as a rule appreciate their responsibility and accordingly live up to the rules of the service. On most lines four men on every train are subject to prescribed watch inspection rules—the engineer, the fireman, the conductor, and the rear flagman, and as a further safety measure, some lines require tower men, train dispatchers, station masters, and the section foreman to carry standard watches.

The duties of the watch inspectors, of whom there are several thousands throughout the United States and who are located at all important railroad points, are best described by considering the system of watch inspection more in detail. When this system was inaugurated, it was first of all found necessary to make an inventory of all watches carried by men in train service to determine the number that could be used with any degree of safety. As this work proceeded, the bigness of the undertaking began to reveal itself. It was necessary to carry on several constructive features of the work, which included the selecting and instructing of watch inspectors at Division points, preparing forms for reports, and sending out printed directions for the guidance of inspectors and trainmen.

One of the first things done was to adopt a printed schedule specifying the makes and grades of watches that possessed the qualifications demanded by railroad service. Bear in mind that in those days watch standards and grades were not followed as closely as they are today.

The defects and weaknesses of watches were made the subject of many conferences with manufacturers, who appreciated the dangers pointed out, and recognized the opportunity of securing a hitherto undeveloped field. The inevitable result was that the American railroad watch was improved to meet the progress and improvements in railroad service and safety.

With their increasing responsibilities the various railroad officials found it advisable to raise the requirements to insure the greater safety of the traveling public and meet other transportation problems. The requirements at the present time call for the comparison of the trainman's watch twice every month with standard time and the thorough inspection of each watch twice a year—thirty seconds per week being the limit of variation allowed.

A few days prior to the semi-annual inspection period, the Superintendent sends to such of his employees who are required to carry standard watches, an order to present them to an authorized company watch-

inspector. If the employee's watch is standard and in good order, the watch inspector issues "blue card" certificate to the employee and at same time issues and sends regular certificate to the Superintendent and duplicate to the General Time Inspector. These certificates have blank spaces to fill in the number, make, and grade of watch.

Simultaneously with each periodic inspection and semi-monthly thereafter, employees submit their watches to the inspector for comparison with standard clock. The ratings of watches are recorded on employees blue comparison cards by the watch inspector, which are carried by employees until the next periodic inspection, when they are turned over to the watch inspector, who issues new blue cards and sends the old cards taken up to the General Time Inspector. The blue cards also show the number, make, and grade of watch and date it was put in order. These blue cards are standard in form and color.

When an employee secures semi-monthly comparison, he signs a form on which he writes the date and rating of his watch, corresponding to record made on his blue card by the watch inspector. This form for comparison record is mailed to the superintendent on the fifteenth and last day of each month. This enables the superintendent to ascertain which employees are respecting the rules and which are delinquent so he can take suitable corrective action.

#### EMPLOYEES REQUIRED TO HAVE STANDARD WATCHES EXAMINED PERIODICALLY

Employees are required to have their standard watches carefully examined and put in good order every eighteen months. At such times the watch inspector provides the employee free of charge with a standard loaner watch in first-class condition and equal in grade to his own.

With this watch the inspector issues a standard loaner "pink card," upon which comparisons are recorded while his own watch is being put in order. The supply of loaner watches that inspectors carry for this purpose represents a considerable investment and is wholly accommodative. Some inspectors carry as many as one hundred such watches. The pink loaner cards are standard in form and color.

When watch certificates and comparison cards are received in the office of the General Time Inspector, they are very carefully scrutinized for errors, omissions, and irregularities, after which they are placed in file.

It is the policy and practice to compile the data thus gathered and furnish each operating official with a typewritten bound copy. A comparative summary covering the entire system showing the number of employees required to carry standard watches and the number of watches inspected is also prepared and sent to the head of the operating department—superintendents also get copy of same summary besides the detailed report of their respective divisions.

According to late reports the employees of the Baltimore & Ohio Railroad are carrying 11,950 standard watches and submitting the same for regular inspection. On the New York Central the number is 11,487. On the Baltimore & Ohio, 900 standard loaners were carried during a six months period, a total of 16,675 days, an average of nineteen days for

each watch carried. The corresponding figures for the New York Central are 1,190 standard loaners carried 24,363 days during six months period, an average of 20.4 days for each loaner watch carried.

| Railroads                         | Watches | Loaners | Days   | Average |
|-----------------------------------|---------|---------|--------|---------|
| New Haven Railroad.....           | 5,376   | 674     | 12,895 | 19.1    |
| Illinois Central & Y. & M. V..... | 11,096  | 665     | 13,557 | 20.3    |
| Union Pacific .....               | 5,694   | 361     | 7,402  | 20.5    |
| Chicago, R. I. & P.....           | 5,441   | 465     | 8,421  | 18.1    |
| Southern Pacific Lines.....       | 8,376   | 865     | 22,263 | 25.7    |

Records could be given on many other railroads but these few are sufficient to illustrate the extraordinary service of safety rendered..

These standard loaner records may seem large and surprising to some, but they represent the valuable emergency service of safety rendered the public, the railroads, and the employees who use them while on duty and during the time their own standard watches are being repaired and regulated.

In making appointments of local watch inspectors, consideration is given to their experience and workmanship, personal suitability, convenient location, and equipment satisfactory for carrying on the work. It may be well to emphasize the fact that the railroad employee is privileged to go to any jeweler or watch dealer for the purchase or repair of his watch. The rules require him, however, to submit his watch to the inspector who determines whether it is standard, whether it has been repaired satisfactorily, or whether the loaner watch he may be carrying is standard and keeps accurate time.

Furthermore, every safeguard is taken to prevent discrimination of any kind on account of trade prejudice. Any advice given employees as to repairs or the purchase of a new watch must be determined by the all-important factor of safety to the service.

#### INSPECTOR'S STANDARD CLOCK

Equal in importance to employees' standard watches but more fundamental is the reliability and accuracy of the inspector's standard clock or chronometer by which he keeps correct time and compares the employees' standard watches. Standard time is obtained daily by inspectors when it is sent from Washington Naval Observatory over the railroad or Western Union wires—some inspectors have ticker service installed in their offices or stores to give them the correct time every hour from Western Union Master Clocks.

Supplementing standard watches and the inspectors' standard clocks in the maintenance of correct time are the standard clocks located in train dispatchers' office and other offices where train registers are kept. These are designated by a blue enamel sign and white letters reading "STANDARD CLOCK."

These clocks are customarily placed in charge of the chief operator who receives time daily by wire from Washington Naval observatory. A record of the daily rating of standard clock is made on printed form which also provides spaces for showing when the clock is set or regu-

lated. Clocks having a variation of more than ten seconds are set to correct time and regulated.

A few figures and facts will give some idea of the vast field now covered by "Time Service." The number of watch inspectors approximates four thousand, located at terminals, lay-over and turn-around points, extending from Boston to San Francisco and New Orleans to Winnipeg.

These four thousand inspectors employ an average of two watchmakers each, totaling about twelve thousand expert mechanics whose principal duty is to look after the railroad men's standard watches.

There are in round numbers two million employees in occupations subject to time service rules and regulations. The average therefore for each inspector is five hundred employees, the maximum being two thousand and the minimum being ten. The watches of these two million employees are actually inspected twice a year and are compared with standard time twenty-four times each year. These figures show that four thousand watch inspectors handle each employee's watch twenty-four times each year, or an annual total of forty-eight million times, a most wonderful service of safety rendered humanity and commerce.

As the watch inspectors serving the different railroad systems are regarded as part of their respective staffs, meetings of inspectors from entire systems have been held annually. These meetings are called together for the purpose of getting acquainted, discussing new instructions, comparing notes and improving the service in whatever way possible along uniform lines.

The difference between the minimum standard railroad watch today and the best grade thirty years ago, in itself reveals the improvement that has been made in the mechanical constructions of watches during the last few years, an improvement which can be accepted as the watchmakers' contribution to the safety movement.

For this mechanical improvement in watches and for their co-operation in making possible standardization of grades, special credit must be given the watch manufacturer. An instance of their co-operation was given a year ago last January when the number of railroad watches scheduled was reduced from 85 to 22.

To make this reduction possible several of the watch companies reduced their number of standard railroad watches from twelve to three. Many of the \$5 grades were dropped and will no longer be manufactured. It is therefore reasonable to expect that the few grades retained will receive special attention and further improvement in their finish and adjustments.

#### PLAIN FIGURES ON DIAL

Another very important factor of safety is the dial, that part of the watch which quickly and surely reveals the correct time to the engineer, the conductor, and other trainmen. As this information is often required at night when lights are dim and obscure, it is needless to emphasize the importance of dials that give the hour and minute without any confusion of fantastic figures or freakish designs.

The figures should be twelve plain upright Arabic figures to indicate the hour points and the twelve five minute division points in the dial circle should be distinct "squares," "diamond" or "round" "dots," with the four intervening minute dashes not quite so heavily marked but distinct for easy reading. The hour and minute hands are also real factors of safety in reading time easily and correctly, the difference in shape between these two hands must be clean cut to insure reading their exact location on the dial.

Another feature about the standard dial is the position of the stem or winding crown. This should be opposite the twelve, not as with a hunting case watch opposite the three. The use of such closed-face models that have been converted into open-face watches without changing the position of the stem, has proved disastrous to life and property as a result of false reading of the time indicated. A serious error of fifteen minutes can easily result from a confused reading of such "side-wheeler" watch dials.

Inasmuch as the effectiveness of this inspection system depends upon the constant and intelligent co-operation of railroad officials, trainmen, and watch inspectors, it is with pleasure that I here record an instance evidencing this support on the part of trainmen.

An interesting case of such co-operation recently occurred when an engineer in one of our large cities discovered that the loaner watch a companion was carrying, was his old discarded watch, which he had traded in to the inspector. He immediately made special efforts to collect a number of such watches as evidence against the unscrupulous inspector and submitted the same through their Brotherhood Grand Officers to the General Time Inspector. This was good proof of the co-operation that assures safety and success of the time inspection service. The case in question was referred to our office and the inspector was immediately dismissed.

What are some of the results of Time Service as developed and now enforced on our railroads? Its effect is well known in making safe and possible our fast mail service and limited express trains. Wrecks are fortunately very few when we consider the vastness of our railroads and the large number of daily fast trains. A study of wrecks reveals the gratifying fact that few are due to defective time pieces. The Time Service System was twenty years old when the National Safety Council was organized so that we may boast of having been pioneers in the Universal Safety movement and of having made a real contribution in practical safety methods.

When the Government took over the railroads during the war, the Director General immediately set out to simplify and standardize equipment and methods. The instructions as applied to the Time Service and Standard watches were not changed in any way whatever, except to demand a stricter observance of the rules and to simplify the same through the reduction of the schedule for new standard watches.

Today railroad time and railroad watches are recognized as standard wherever safety or any other consideration requires accuracy in time. Throughout the United States the banker, the business man, the lawyer,

and the manufacturer go to the jeweler and ask for railroad standard watches—they want the best.

Railroad standard watches received a tribute during the war that should not pass unrecorded. When General Wood returned from France, he brought back word that our officers were not equipped with satisfactory watches in spite of the fact that extreme accuracy in timing the advance of the infantry during the barrage fire was essential for safeguarding the lives of our men.

The convenience and fashion of the wrist watch had unfortunately made its appeal to our officers at the sacrifice of correct time. The outcome of the recommendation of the General was that we were called upon to help meet the situation by visiting many of our cantonments and we had the satisfaction of providing more than 15,000 officers with American made standard watches just before the signing of the Armistice and these watches were turned over to our soldier boys at manufacturers' prices as a contribution toward winning the war.

Mention should be made of the co-operation given by retail jewelers and watch dealers who almost without exception have acquainted themselves with the requirements of Time Service and railroad watch inspection and have met the same on a fair co-operative spirit in their business dealings with railroad men.

#### OFFICIAL BUREAU OF RAILROAD TIME SERVICE

For the purpose of perpetuating and further improving the safety and standardization of watch inspection and the administration of the Time Service, "The Official Bureau of Railroad Time Service" was chartered in the United States and Canada in 1918. This Bureau has its principal administrative office in Cleveland with branches in Chicago, San Francisco, and Winnipeg and has a present organization of about sixty people schooled in this work. What this Bureau intends to accomplish can best be given by quoting verbatim the third Article of its Charter:

"The purpose for which said Bureau is formed is NOT FOR PROFIT OR ANY MERCHANDISING WHATSOEVER, but to reduce the element of danger in the operation of railroads caused by inaccurate time pieces, and to increase the factor of safety to the public by general supervision of the standard time pieces necessary to the safe and efficient operation of the railroads; to keep records of the performance of said time pieces under standard forms and uniform rules and regulations; to appoint and educate local watch inspectors for the purpose of inspecting and caring for the standard watches of railroad employees, and the standard clocks of the railroad companies; to see that such watches and clocks are properly inspected; to make and maintain a standard system of watch and clock rating and regulation for railroad employees and railroad companies and in general to exercise careful supervision of railroad time service."

In football, baseball, and other forms of sports we admire the excellence of effective team work. In this team-work every player is within hearing and seeing distance of his fellows. Greater than this is the national team-work of our railroads with thousands upon thousands of

employees, thousands and thousands of miles apart, working together in absolute co-operation by virtue of clocks and watches upon which they rely for correct information as to how their fellow workers in this great national team-work are keeping step, and thus faithfully and loyally performing their part in safeguarding human lives and valuable property in meeting the very necessary requirements of social and business traffic.

CHAIRMAN SCOTT: I think we have had a very interesting session here today and to all of those who did not have an opportunity of saying something, I wish to assure you that you are going to have full opportunity to get rid of that full head of steam that you brought with you before this Congress is over.

We have with us today a gentleman who came to Milwaukee upon invitation from the Chairman of this Section. I refer to Mr. George Bradshaw, and if he is in the room I would like for him to stand and let the people see that he is here.

We welcome you to our Congress, Mr. Bradshaw and hope you will remain throughout the sessions. (Applause).

ADJOURNMENT.

#### THURSDAY MORNING SESSION

**C**HAIRMAN SCOTT: Our first number this morning is "Co-operation with Railroad Labor Organizations," by Mr. Isaiah Hale.

#### CO-OPERATION WITH RAILROAD LABOR ORGANIZATIONS

ISAIAH HALE, SAFETY SUPERINTENDENT, THE ATCHISON, TOPEKA AND SANTA FE RAILWAY SYSTEMS, TOPEKA, KANS.

When it was suggested several weeks ago that there be discussed on this occasion the subject assigned to me, there was still a good deal to be said about it, notwithstanding the fact that I had endeavored to keep you gentlemen advised from time to time of developments following my initial letter to the Presidents or Grand Chiefs of the four so-called major railroad labor organizations. Even though a partial realization of our hopes has come, developments have been so widely discussed that I am embarrassed at finding myself expected to talk on a subject with which you—or at least many of you—are already fully acquainted. I shall therefore but briefly touch on this particular topic, and use the time allotted to me on another very near my heart and which I humbly offer for what it may be worth.

I shall not repeat any of the reasons leading up to my initial letters to the Big Four Chiefs. We were unfortunate about that time in being confronted by seemingly more than our share of injuries for which there was no excuse or reason; I felt forced to believe that if we were ever going to convert a certain type of men we must do so through some agency or by some means other than by mere persuasion—or any other

means previously used. While it is true that the ritual of the several organizations then, and now, provide for a discussion on safety, at each regular meeting, I had reason to believe such discussion was largely perfunctory and was not a potent influence in getting that individual interest which the organizations, the railroads, and the men so much needed. As proof of which I would remind you that it is the exception rather than the rule that an organization man will take exceptions to the operations of his partner, regardless of how irregular they may be. Our serious injuries seldom come from the *first* failure of men to comply with safety rules. Remembering that these failures must be regularly noticed by the offender's "Brother", *why is such "Brother" not entitled to recall the time when he stood before his lodge, held his right hand high and took an oath before his God that he would protect his brother in every way he possibly could, even going so far as to pledge help to his brothers' dependents, in case of their need or distress?* Do not misunderstand me, I have no wish to belittle that oath, not at all. it is uplifting and ennobling, and all that really makes life worth while, *if organization men would live up to it, but they don't do it, and never have done it—and to that extent their obligation is idle talk.* Thousands of their members have made such admission to me and down in your heart *you know* it is true. Railroadng could be revolutionized if organization men would live up to the letter and spirit of their obligation.

I was strengthened in my resolve to do something, if possible, to bring this about, by knowing that the average organization man readily will do for his organization things he might be some little time in making up his mind to do for any one or anything else. I chose the Big Four as the organization to which to make my *first* appeal because of their organization insurance. In the two years and nine months preceding my first letter, these four organizations paid out \$21,504,844.00 in settlement of what they term "claim benefits". That a very considerable proportion of this total is paid out on accident causes gave me a basis for my argument. I suggested that they forget entirely the sentimental, the humanitarian side of safety, and be thoroughly selfish—to look on my suggestion only from the standpoint of the money they could save on injury claim payments. At least two of these gentlemen had previously told me of certain of their past achievements, but I made bold enough to say to them that while they are rightfully proud of anything they did to bring about a more general observance of Rule G, in securing various safety appliances, etc., yet they would do well to remember that the brightest jewel they will put in their crown of accomplishments will be placed there when the power and the prestige of their organizations is put behind a determined and wholehearted effort forever to put a stop to the shameful disregard by the average man for the safety of either himself or his fellow workmen.

I received a most cordial response from each of the four gentlemen, all carrying a hearty assurance of their willingness to do anything humanly possible to further the safety cause, and all breathing the fervent hope that an appreciable reduction in injuries might in some manner be brought about. Our mutual friend, Warren S. Stone, Grand Chief of the Engineers was, if anything, more outspoken than the other gentlemen

in his desire to do some constructive good along safety lines, and I feel that to Mr. Stone personally I am largely indebted for the very rare privilege which was mine—a few weeks ago—of outlining my suggestions before

#### OUTLINED SUGGESTIONS BEFORE EXECUTIVES OF LABOR ORGANIZATIONS

the executives of the sixteen railroad labor organizations, then in session in Chicago. I told the sixteen executives that all I would have them do is to put "Brother" into Brotherhood. I told them frankly they would never have anything that approximates a Brotherhood until they reached the point where they put a higher value on a human life than on a dollar; till they reached the point where they spent at least a fractional part of as much time trying to safeguard their brothers, in trying to perpetuate their service, their homes, in trying to keep them here to care for and protect their families, as in trying to secure them some concession on a working schedule.

At this meeting one of the executives asked me what assurance I could give the organizations, provided they undertook the safety education of their men, that the management of American railroads would clean up their properties, safeguard conditions, and spend money liberally in furthering safety work—and, as an aside, safety, in the minds of some men, still begins and ends in spending money. I told them that while I felt sure the management of our railroads would go to any reasonable length I could give no assurance to what extent this might be, but said: Supposing the railroad managements were not in favor of the safety movement as we know it today, were not willing to spend a dollar on it or recognize it in any substantial way, does that not only emphasize the need of that greater individual interest and care which I insist your men must show?" In a word, the more hazards that confront a man, the more necessary it becomes for *him* to watch *his* step. It is a fact that railroad service today is just as safe or as dangerous as a man chooses to make it.

I recall telling the Executives of the Shop Crafts of an occurrence at one of our shops, where a young man was milling out driving boxes and in

#### DISREGARDED INSTRUCTIONS AND LOST HAND

spite of bulletin instructions that "The wearing of gloves around moving machines is strictly prohibited," in spite of the further fact that his foreman had repeatedly objected to his wearing gloves, he continued to wear them. Finally, one day, the tool of his machine caught the gauntlet of his glove and he not only suffered an injury that required the amputation of his hand, but he had it torn off the stump at the wrist and left it in his machine. I frankly told the shop executives, so I do not hesitate to repeat it here, that it is not at all to the credit of their organizations that they have made it extremely difficult for the railroads to enforce their safety rules; that while this young man did not say so in so many words he virtually told his foreman that if he wanted to cripple or kill himself he was going to do it—and his organization backed him up in it—a fact of which they ought to be heartily ashamed. I might add that if the railroad company had done nothing more for this particular man

following his disability than his organization has done, the man would have been in greater need than he is today. It was at the brow of this hill that one of the executives made his stand and wrote me that he saw in my suggestion an attempt on the part of the railroads to pass the buck of responsibility for personal injuries over onto the organizations. I frankly told him that the responsibility for injuries was not one which the Brotherhoods could fairly say all lies with the Railroads any more than the Railroads could fairly say it all lies with the Organizations—responsibility must be jointly assumed, because all that a railroad might do to improve and safeguard conditions would go for naught if the individual reserves to himself what he regards as his God-given right to do anything in any way he wants to.

The Executive already referred to later on also stated with some apparent feeling that I had been in the railroad game long enough to know that the stuff I was talking "was bunk, pure and simple"—and rather cruelly referred to my suggestion, so humbly made, as a "hobby I was riding to death". By this time I had lost some of my *humility* so I told him that I had outlined my suggestion, as originally made, to thousands of organization men on our own line, and scores on other lines, and had yet to meet the first one who had not heartily concurred in it and expressed the hope that it might meet with the approval of their executives; I asked him by what right, without a trial or even serious thought, he dubbed my suggestion as "bunk" and intimated that the thousands of men who shared my opinion were also fools; I told him that if he didn't know it, he ought to get out and mill around the members of his organization and he'd find that among them there is slowly, but none the less surely, crystallizing a sentiment that it ought to be as much the function of his organization, for instance, to undertake the education of its members, not alone along safety lines, but in other ways, to make them more efficient and proficient, to give them high ideals, to make them better neighbors, better husbands and fathers, as it is to grieve them an additional spring in the cushion under them; I told him, and again I quote: "Your predecessors did not see this vision, and you give little or no promise of doing so, but as sure as there is a God in Israel, some day—it may not be tomorrow or next year—but some day a man will follow you as Grand Chief who *will* see it, a man who will write his name across the scroll of the world's industrial history and the light of whose achievement will not only serve to darken the shadows cast by the lost opportunities of the past, but will forever point the way toward a new era in railroading, an era when all men will understand the value of an efficient, able-bodied co-worker and realize and appreciate the real worth of a friend—when brother will at last be put into Brotherhood."

#### MEETING OF EDITORS AND RAILROAD SAFETY OFFICERS

Thence I will jump over a period of six weeks, and am pleased to report that at Chicago on Saturday last, as many of you know, Messrs. Cease, Pease, and McNamee, Editors of the official publications for the B. of R. T., O. R. C., and B. of L. F. & E., respectively, met a number of the railroad safety officers. These gentlemen, speaking not only for them-

selves, but for the editor of the official publication of the switchmen, made it clear that they were very desirous of establishing a safety department and asking, in order that it might be interesting and exert a helpful influence, that at least for a time the railroad safety officers furnish them monthly any "copy" of heart-stories and details of avoidable injuries to organization men which might have come to their notice or happened on their several properties. (Here followed a detailed account of how this "copy" might be accumulated, etc.)

That this is a long step forward none will deny; it is a big, generous, voluntary act on the part of these editors, speaking for their Organizations, and will forever stand as a monument to their sagacity, their fairness, and their far-sightedness, which will endure long after less generous contemporaries have been forgotten. And even at that, I am pleased to believe that this co-operation by all concerned, which has but a single purpose, will prove but a stepping stone, not a resting place.

There is, however, one factor which, to me, has never seemed to enter into our safety work to an extent it should. Were I a psychologist I might more aptly present my views, but even without a mind that belongs to a five foot shelf of books I hope I may make myself clear. Frankly I do not believe any of us have talked optimism, good cheer, and good fellowship to the extent we should. The fundamental of Safety is a desire to live; in a word, the desire to live must be stronger in an optimist than in a pessimist. It is obvious, therefore, that what we need is not only a greater concern about our individual welfare, but more optimism—more good cheer, more good fellowship, more contentment. Pray do not misunderstand me to mean that to approach contentment we should teach ourselves to sit serenely down and be satisfied. Some one has said: "We should ever be content but never satisfied till we have made the most of our opportunities."

Our railroads have never before had so many young employees as now, and since our most fruitful field is likely among those young men and women, it should be not only our duty but our privilege so to train these immature branches as to shape properly the mature tree. Some one has said, "One of the greatest gift the Gods can bestow is the gift of Good Cheer; the ability to smile, to enjoy the laughter of others, to spread the contagion of happiness wherever you go, makes one not only a welcome guest but an actual blessing. We are so intent on making a living, so wrapped up in our selfish selves we forget we owe the world at least the courtesy of a smiling face and each other the inspiration of a cheery word and a friendly handshake." Robert Louis Stevenson once wrote "A happy man or woman is a better thing to find than a five pound note; their mere entrance into a room is as if another candle had been lighted," and, incidentally, if the man ever lived who knew the value of Good Cheer, that man was Robert Louis Stevenson, for *his* supported him through forty years of varying fortunes but unvarying ill health.

#### EFFECT OF MENTAL ATTITUDE

One doctrine I am firmly convinced we should also preach to our new men is that "Without any question, our thoughts more than any other

one agency directly fix our status in life. The mental attitude which we hold toward our work or our aim has everything to do with what we actually accomplish. If we go to our work with the attitude of a slave lashed to his task, and see in it only drudgery, if we work without hope, see no future in what we are doing beyond getting a bare living, if we see no light ahead, nothing but poverty and hard work all our lives, if we think we were destined to such a hard existence, that the Fates have been unkind to us, that the good things of life were all meant for somebody else but not for us, we cannot reasonably expect to find anything else than just what we are looking for."

"If, on the other hand, no matter how poor we may be today, we can see a better and brighter future; if we believe that some day we are going to rise above humdrum work, that we are going to get out of the basement into the living room of life where comfort and happiness await us; if our ambition is clean cut and we keep our eye steadily on the goal which we hope to reach and feel confident we have the ability to attain, we will surely accomplish something worth while. I never knew a man who believed in himself and constantly affirmed his ability to do what he undertook, who kept his eye steadily on his goal and manfully strived to reach it, who did not make a success of life. There is no other one thing which will bring so much value into one's life as that of always carrying an optimistic, hopeful attitude of really expecting that things are going to turn out well with us, not bad; that we are going to succeed, not fail; that we are going to be happy, not miserable. But if we are always putting a low rating on ourselves, constantly marking ourselves down, we may be very sure that we will never meet anybody else who will take the trouble to mark us UP, to put a higher valuation on us than we put on ourselves." I am firm in my belief that we would do well to preach this doctrine to our men—both young and old.

The greatest obstacle to our progress along this new path is the innate, if not ingrowing, selfishness which, to a varying degree is in us all. As an illustration of two types I might tell you that I attended a meeting of one of our local safety committees, along about April last. There were two shopmen members of this committee who had been paid two hours time for sitting in the meeting the one hour which took them up to 3:00 P. M., their regular hour for quitting work. At 3:00 P. M., while I was speaking, they all but broke up the meeting in getting out. I have no funny notions about myself or my very humble position; I do not expect, nor would I have our men show me any more respect than I am willing and glad to show them, but, frankly, only getting to that part of the line twice each year. I really felt that as an ordinary courtesy they might have delayed their exit the five or ten minutes necessary to let me finish. At close of the meeting their foreman told me they left at 3:00 P. M. every meeting, which never lasted after 3:30 P. M., that they had refused to stay even though he allowed them pay for any time used after 3:00 P. M., frankly saying they would not stay unless allowed time and a half for overtime. When the foreman told them he thought them unreasonable one of the men looked him in the eye and asked "Well, what in h——l is it going to get me?" The fact that we made a reduction of 25 per cent in

fatalities among our employees in 1919 as compared to 1918, that *they* might have played some little part in that wonderful accomplishment, meant nothing at all to those men.

I have ever been willing to see a measure of sanity in the mind, a measure of justice in the heart of every man, and just as I was beginning to wonder if I was wrong, if all men were selfish at heart, I was unexpectedly shown the other side of the shield.

#### ALL MEN NOT SELFISH AT HEART

Boarding one of our overland trains late at night a short time later I found in our Pullman, upon getting up the next morning, two little Italian girls, aged about five and seven; there was pinned to the dress of the elder one a letter which would have brought tears to the Sphinx, could it have read it. Briefly, it stated that four years ago the father of these children left their mother and them in Italy and came to this country to make a permanent home. He located at Cucamonga, a small town on the Santa Fe Lines just east of Los Angeles, and after four years of hard work and self denial and loneliness, such as I sometimes think only a foreigner understands, he accumulated a sufficient surplus to send for his wife and two children to join him here. The family left Italy on December 2, landed at Ellis Island December 24, and Christmas morning, while the church bells across the bay were ringing out their message of Christmas cheer, the mother of these two little girls died, and with her death all knowledge as to who they were or where they were going was lost. It was necessary for the Steamship Company to correspond with the Italian government in order to secure this information, and I would remind you that while this was being done these two babies were batted around the bull pens on Ellis Island for three months and a half. They were well on their way when I met with them in Arizona. On this car I also met the wife of a Superintendent on the Chicago, Milwaukee & St. Paul Railroad, a very charming woman, who told me, in speaking of these children, that she had never seen such tender care and solicitude shown any one in whom they had no direct interest as had been shown them by the Pullman conductor and porter, with whom we were riding. She stated she offered to get the youngsters ready for bed the first night out of Chicago, but this young man seemed to want to do it, and she told me that certainly no father ever made his own babies ready for bed and did it more modestly than did this young Pullman conductor; she stated further that six or eight times during the night she saw him come to the upper berth occupied by these children, which was directly across from hers, pull the straps more closely together so they might not fall out, and cover them up so that they might not get cold. When we came back onto the train after eating breakfast at Seligman, Arizona, a gentleman, whose face was bronzed with out-door exposure and whose clothes bore evidence of desert life, went to the news stand after leaving the dining room, and I subsequently saw by the price tags they carried, he had paid a dollar each for a little boy and little girl doll. When he took these into the car and gave them to these Italian children they clapped their little hands and jumped up and down for the very joy that

was in their hearts, this probably being the first real kindness shown them in a long time, which they understood, and when this gentleman, whom I afterward learned was a miner, turned around to leave them he seemed half ashamed that I caught him with a tear in his eye, and he said to me "My God, brother, I have spent a thousand dollars many a time that did not give me half as much pleasure as those two dollars."

Of what I want to remind you is, that when the thought first came into the mind of that miner that he might give these children a little happiness he did not, like our shop man referred to, say to himself "Well, what in the h——l is it going to get me," and he confessed to me five minutes later that the greatest happiness that had come to him in years had come through showing a kindness, *through doing something for some one else.*

I have told this little story to a good many of our men. I have said to them that it is not at all likely they will ever find themselves on a Pullman car with two Italian children going to Cucamonga, California, or that they will ever have a chance to buy such children a doll, but I have reminded them that all of them every few days, and many of them every day, have a chance to show a very much greater kindness to the children, perhaps the two little girls, of some man with whom they work, by getting the man to stop some irregular practice of his which may some day rob his children of his protecting care, and stated that whether or not they are going to do so depends entirely on whether they have the view-point of the man who wants to know what such an act is going to get them or whether they have the view-point of this Arizona miner.

As much as I dislike to inject myself into this story I cannot resist the temptation to say that about a year ago, in one of our meetings, an engineer said to me: "You were out here once, Mr. Hale, and literally tore into us fellows." I told him I was mighty sorry to know it and asked him how long ago that was, and when he told me seven or eight years, I made a confession there which I am willing to repeat here; and that is, I have barrels of the milk of human kindness in my system today where eight years ago I did not have ounces, and I have it simply because I am just beginning to realize the value of an able-bodied, co-worker, and just beginning to appreciate the real worth of a friend. To this extent I am not selfish—if I may have sown in your mind a seed that may in time grow into a thought that will bring you as much comfort as mine has recently brought me, I will gladly share it with you and be very happy in so doing.

#### TIME TO HELP IS WHEN HELP IS NEEDED

In conclusion I have long contended that the time to help a man is when he needs your help. I'm not sentimental, it is seldom I resort to poetry as a means of expressing myself, but one verse of a favorite reads:

I'm not much on philosophy—I don't know all the creeds,  
I don't know what's inside the books my next door neighbor reads,  
I haven't studied ancient tongues, my English isn't good,  
I know I say a lot of things that scholars never would,

But this is my experience, an' so I pass it on:  
The time to be a friend to a man is when he's needing one.

As a first move in this self-treatment, let me suggest that you learn to smile. A smile is described by some rhymester as

The thing that goes the farthest toward making life worth while,  
That costs the least and does the most, is just a pleasant smile,  
The smile that bubbles from a heart that loves its fellow men,  
Will drive away the clouds of gloom and coax out the sun again,  
It's full of worth and goodness, too, with manly kindness blent,  
It's a worth a million dollars and it doesn't cost a cent.

And the end is Success, and success may be something entirely different from what you think it is today. Edgar Guest says:

Success is being friendly when another needs a friend,  
It's in the cheery words you speak, not in the coins you lend;  
Success lies not alone in skill and deeds of daring great,  
It's in the roses that you plant beside your garden gate.

Success is in the way you walk the paths of life each day,  
It's in the little things you do, in the little things you say;  
Success is in the glad Hello you give your fellow man,  
It's in the laughter of your home and joys for others that you plan.

Success is not in getting rich and rising high to fame,  
It's not alone in winning goals which all men hope to claim;  
It's in the man you are each day through happiness or care,  
It's in the cheery words you speak and in the smile you wear.

Success is being big of heart and clean and broad of mind,  
It's being faithful to your friends, and to the stranger, kind;  
It's in the children whom you love, and all they learn from you,  
Success depends on character and everything you do.

CHAIRMAN SCOTT: I am sure every person in this room must have felt the inspiration that came during Mr. Hale's talk. I was very glad indeed to see the spontaneous rising of everybody in the room to show appreciation for what Mr. Hale has given us here today.

It is possible that some of you may have some questions to ask Mr. Hale as to what is expected of you when you get back home. In other words, shall the Steam Railroad Section have a committee that will collect these news items for these periodicals or shall we be expected to send the items direct to the editors of these papers?

#### DISCUSSION

MR. HALE: While it was tentatively agreed at Chicago Saturday that we should individually send to these editors a monthly contribution, it seems to me it might be very well, after giving it more mature thought, if

this Section would delegate one man—not a committee, because of the difficulties and delay in getting committees together—who will check up and follow up the laggards and put a puncher behind the man who does not respond and let him assemble this data and send it to the editor.

MR. L. G. BENTLEY (Chesapeake & Ohio): I move that you appoint such a representative to collect and check these items for the monthly journal.

CHAIRMAN SCOTT: You refer to checking the items; do you have in mind censoring these items before they are given to the press?

MR. BENTLEY: To collect these items and keep a check on them.

MR. H. A. ROWE (D., L. & W.): I had the pleasure of attending that meeting Saturday at Chicago and I know that the editors will be very glad indeed to receive the communications from the various safety men, and they suggested that the items be forwarded direct to them.

I am not disagreeing with Mr. Hale, understand, but I am just simply expressing my little thought on the matter, that in addition to sending monthly copies to the editors, we send one copy to a designated person, and we can never find a person with more dynamic force to supervise that than Mr. Hale, and he can keep check on these and find out whether each one of us is doing our fair and square duty in the matter.

Possibly the Chairman may feel a little reticent about nominating or appointing Mr. Hale now and I would suggest that that be the business of the next Chairman to appoint Mr. Hale, if he can see his way clear to do so, as the person to whom these news items should be sent.

MR. HALE: I would be very glad indeed to serve you but I am away from home two or three months at a time and because of that factor, it would not be advisable to have me because when I am on the road I am not so situated that I could handle it as it should be.

MR. JOHN T. BRODERICK (Baltimore & Ohio Railroad): Personally it doesn't seem to me at all necessary to appoint any one to handle that matter; it is a responsibility and a duty that should rest upon the individual roads to see that it is done, and they should certainly have enough interest in it to handle the matter direct. I wouldn't care to burden Mr. Hale or any one else with a responsibility or duty of that sort.

MR. E. R. COTT (Hocking Valley Railroad): If we have somebody in this organization who is responsible to see that we come up to our full requirements, and, as Mr. Bentley says, keep a check on us and see that we are doing our duty, why I think we shall get farther, and I feel that it is so important a matter that we dare not leave it to the individual members, not that I feel that any one of you might fail, but all of us have the habit of carelessness where we say we will do that tomorrow, and I second Mr. Bentley's motion that the Chair appoint a committee of one who shall have this in charge.

MR. BRODERICK: Personally, I am inclined to believe that it would be unwise for anybody to edit or determine what should or should not be sent in.

MR. COTT: It was agreed over at that meeting that it would be impossible for them to use everything that we might send them if everybody did his part. I do not mean that the party whom you might appoint under Mr. Bentley's motion should act as a censor; they have agreed to do that

job themselves; in fact, they want to. What I mean is what Mr. Bentley said, to keep a check on us and see that the items reach the members regularly.

I just wanted to correct that impression that he is not to censor these items but to see that they are collected and forwarded.

MR. BENTLEY: Since hearing the gentlemen speak, I believe that the important function that devolves upon this gentleman that I moved to appoint lies in keeping up enthusiasm and in keeping a check on these articles, not so much as in collecting them and distributing to the various magazines. Therefore, I feel that my motion should have been along the line of Mr. Hale's suggestion that he should keep a check and know whether each railroad was doing its part; not in any sense to act as a censor on material being submitted. I would like to word my motion in that manner.

MR. HALE: The trainmaster, Mr. Ceas, who did most of the talking at this meeting, made it very clear that they wanted to establish this safety department in their magazine. It was only to get it started and get into it the things that should go into it to make it effective that they asked for this help from the railroads at this time. It is manifestly evident, as Mr. Cott says, that they can't use all the stuff that we send them; they are going to cut it down and take out only such things as appeal to them, and I still think that we should have some sort of a check, not so much on this copy that goes to them, but to see that every man is responding. They are going to edit this stuff we send them and, as I said before, they will throw out a lot of stuff which is unsuitable and which they cannot run because of the lack of space.

I might offer a suggestion to the Chair, if I might, to appoint Mr. Cott, who is from the state of candidates, to this one particular job.

MR. W. A. YOUNG (Oregon Short Line): I wish to state at this time that I was a delegate to the convention which convened in this city last week, representing the International Association of Supervising Mechanics on the railroad, and they went on record as favoring the safety first movement, and I am sure they will be glad to receive and print in their magazine anything pertaining to the safety movement on the railroads.

CHAIRMAN SCOTT: It seems to me that this matter has been thoroughly cleared up and if there is no further discussion at this time we will put the question before the house.

The motion is carried.

We will now take up the next item on the program, which is "Shop Accidents," by Mr. J. A. McNally, Safety Agent, Wabash Railroad.

### SHOP ACCIDENTS

J. A. McNALLY, SAFETY INSPECTOR, WABASH RAILROAD, ST. LOUIS

In dealing with this subject I am not going into statistics but am writing this article from facts gathered from my own personal experience. In my investigation of all shop accidents that come under my jurisdiction I have found that only 7 per cent are due to unsafe conditions, thereby

indelibly impressing upon my mind the most important thing to eliminate accidents is to deal directly with the individual using all the strategic force and diplomacy at my command to break up the other 93 per cent, which are due to carelessness. In my mind there are three kinds of carelessness: Ignorant, thoughtless, and wilful. In the ignorant class we have the man who has had no experience; he should be watched closely and cautioned whenever necessary. The foreman in his department and safety committeeman should especially look out for this class of employees. Then we have the wilfully ignorant man, one who takes no stock in the safety movement, belittling those at the head, who only learns from painful experience the value of the safety movement. Fortunately this class is not large and is rapidly diminishing. In the thoughtless class we have those who from force of habit do things mechanically not seeing or thinking what is liable to happen, and this class is often responsible for the injury to other employees. The wilful class is more or less uncertain and difficult to pick out as opinions differ and statements conflict, but the number of accidents causing death and injuries shows without a doubt that experienced as well as inexperienced men are getting injured or contributing to the injury of others. The Safety Movement is one instrumentality by which these evils can be corrected. Its aim is to promote the "Golden Rule Spirit." Every apprentice boy should be taught the principles of safety from the date of his apprenticeship. He should be made to possess, enlarge, and transmit to his successor all the accumulated knowledge of his predecessor and when once a system of this kind is well grounded a new foundation will be laid and the railroad shop employees will have an additional guarantee for his preservation.

In eliminating shop accidents it is well to take up the evil that causes the largest number of accidents. We find from Interstate Commerce Commission reports, which are authentic, that the use of hand tools, apparatus, etc., are leading the list in injured with 10,467 shopmen injured last year. To cut down this number, I would suggest that a daily inspection be made of all tools in tool rooms, and a weekly inspection of all tools in private lockers. Tool room firemen should see that no defective tools are given out for men to work with. The next item that contributes to a large number of injuries is the collapse, fall, etc., of objects, with 9,613 injured in one year. When men are working overhead a drop cord with a sign reading "Men working overhead" should be placed where it could be readily seen. This would possibly cut down the number injured in this manner. Nearly every month some one is injured by heavy wrenches left on running board being knocked off or otherwise falling on men below. All concerned should discourage the practice of leaving such tools on running boards or benches where they are liable to fall and injure the workmen.

A number of cases have been reported by the I. C. C. where shop employees have been killed and injured crossing tracks, or crawling through or over cars. When necessary to cross the tracks follow the traffic rules by crossing at right angles. This gives one a better view

in either direction, besides it lessens the distance in the danger zone. If your business does not require you to be on tracks, stay off. Places where Hurdy trains are operated, men should get on and inside of coaches before it starts and stay there until it stops. Many men are killed each year attempting to get on and off moving trains. Stay off of the platforms, in case of collision you would be crushed between platform and end of car. In looking over the bulletin boards, employees should pay special attention to the safety signs. They were put there for the benefit of the employees, hence comply with their warning.

#### THE EMERY WHEEL

A word about the emery wheel. Despite the fact guards have been applied, and goggles furnished, accidents still continue. Men should approach a stone with one thought in mind—this is a dangerous article and I must be careful. Never try to grind out a wrench or any other object that is the same width of the stone or you may be a successful candidate for the hospital. Foremen should understand it is not enough to tell a man what methods are unsafe, but he should be told why it is unsafe and furthermore a safer method in doing the work.

Discard the gloves and rings working around machinery. You may not look quite so handsome or keep your hands as clean, but they will be of more use to you with five fingers on each hand. Run the fellow off who insists on distracting your attention from the machine you are running. This same fellow will not contribute materially to your support if you are injured.

When chipping protect eyes by using goggles and protect the other fellow by putting a shield in front of the work you are doing.

Calling attention to hydraulic jacks, never use nuts or any other metal to build up between the jack ram and barrel in order to support the load caused by leaky jack. The pressure brought to bear often causes these articles to fly with the speed of a bullet. Defective jacks should never be used but sent in immediately for repairs. I also wish to mention in connection with that, where shops are not equipped with electric cranes and wheels are taken out by jacking up and blocking under, that blocks for both sides be of same thickness and number,—number one on the floor, number two next and so on. A man should follow right up with blocks as engine is being raised or lowered, also a wooden wedge to be ready to slip under in case jack gives way. Never depend on jacks alone to hold weight of cars or engines. When putting in washout plugs, relief valves, or any other water or steam-tight connections you should remember many men have been killed or injured due to some thoughtless workman sticking a plug in a sheet without tightening it up. Of all the unpardonable sins this is one of the worst. If you cannot complete the job leave it out entirely, in this way you will not add to the long list of men injured by the deplorable practice of entering a plug a thread or two by hand and leaving it in that condition.

Carrying a bar, ladder, or any lengthy material on shoulder in horizontal position is a dangerous practice. Meeting some one in doorway or

cloud of steam or smoke in roundhouse, the result would be loss of an eye or face disfigured. Get the safety habit; carry them like the soldier carries his rifle.

Removing and replacing driving springs especially around roundhouses is dangerous work and should be given proper attention. I know of one man who was killed as the result of driving a block out from between spring and frame without taking up weight of engine. All employees should be taught never to remove blocks from springs or gibbs from hangers without taking weight off of springs. Be sure to finish your job well before leaving it, perhaps the nut you failed to tighten, the cotter key you left out or the one you failed to spread may be the primary cause of a serious wreck in which some one is killed or injured, and perhaps some of your own family.

#### A WORD TO THE CAR MEN

*The Blue Flag.* It is of the utmost importance that all concerned keep in mind that life or limb depends on the strict compliance with Rule 26 Standard code, also other instructions pertaining to the movement of cars undergoing repairs. Foremen in charge can and should take this matter up at their various meetings, pointing out the importance of keeping signals in good condition, properly displayed, and reporting to the proper official any case coming under their observation where the Blue Signal is not respected.

Flue blowers and boilerwashers and their helpers are often injured on account of their inexperience in handling this work. For this reason it is necessary that the foreman in charge, before permitting men to do such work, should instruct them personally as to ways and means of doing their work in safety to themselves and others. The same rule should apply to all new men coming on the job in any craft. Foremen should explain to them the purpose of the safety organization.

*Hostlers.* Men are still being injured or killed by movement of live or dead engines on account of hostlers not giving necessary warning. To move an engine without sounding bell or whistle is an exceedingly dangerous practice. No one should be permitted to handle engine except those who are fully acquainted with its mechanism. When leaving an engine they should see that throttle is shut tight, reverse lever on center, and cylinder cocks open.

There have been several accidents the past year on the use of oxygen and acetylene. I am offering the following rules for their use:

1. Handle all oxygen cylinders with care and avoid dripping them any distance.
2. Keep all acetylene cylinders away from fire.
3. All cylinders should be kept in upright position, firmly fastened to avoid tumbling over.
4. Before attaching the regulator to the oxygen tank "crack" the valves so it can be opened very slowly. A sudden opening which is difficult to avoid when the valve is stuck may cause a severe shock to the regulator which may produce very high heat due to

sudden compression and so cause an explosion, particularly if any oil, grease, or other fuel substance is present.

5. Under no condition should oil or grease be used to make up the joint. A special lubricant is provided for this purpose by some manufacturers. If this is not available use very small quantity of soap or a very little glycerine.
6. Inspect all regulators and gauges before applying to see that they are free from oils and greases.
7. Different colored hose should be used for the oxygen than for acetylene to prevent danger from interchange. Black hose is used generally on acetylene cylinders as these cylinders are as a rule painted black. Red hose is used in the oxygen cylinders as these cylinders are usually painted yellow.
8. Examine hose at regular periods for leaks by putting it in water when under pressure. This will show small pin hole leaks that sometimes cause a great loss of oxygen.
9. *Burned Hose.* The gas hose connecting the regulator with the torch is often quite long. If the burned hose is flexible rubber it can be doubled on itself and the blaze extinguished. If the hose is of the stiff or armored kind that cannot be kinked, it may be necessary to shut off the gas at the valve. For this purpose a shut off valve should be provided as close to the torch as possible.
10. Blow out new hose before applying to prevent dust being carried to torch.
11. *Oxygen Tank Valve.* Open the valve slowly but completely back of stem with sufficient force to compress the washer that surrounds the valve stem. Otherwise there will be more or less leak. Oxygen is very expensive.
12. *Regulators.* Never drop or jar regulators. Do not turn pressure on regulators without first releasing all pressure from the regulator spring.
13. *Torches.* Use care in handling the torch. The tips and other parts are easily injured. It must not be misused. It is a torch not a hammer.
14. Novices should not be employed until they have been properly instructed by one who is thoroughly acquainted with the apparatus as the gasses are very explosive and the outcome may prove very serious if operators are not properly instructed.
15. Apparatus should be assigned to individuals or skilled operators who at all times would be more familiar with the working of same. Interchanging is a bad policy.
16. Above all else, THE BEST KNOWN SAFETY DEVICE IS A CAREFUL MAN.

I also offer the following Don'ts for shop men:

MECHANICAL DEPARTMENT

Do not attempt to operate a machine unless you are thoroughly qualified in its operation. Do not work with any machine unless authorized by the foreman in charge.

Do not operate any machine until all stops and safety appliances are in position and securely fastened.

Do not clean or oil machinery while in motion.

Do not grind at emery wheels nor operate a machine from which chips are flying without using goggles.

Do not look at electric welding without using shield over your eyes.

Do not go on crane runways without knowing that you are fully protected.

When repairing motor-driven machines see that circuit breaker is out and hang sign on starting box or controller, reading: "Man working on machine."

Do not overload sling chains nor use them with ends fastened together by a bolt.

Do not stand under a load being moved by a crane or other mechanism.

When working overhead, hang a sign: "Men Working Overhead," from drop line in plain view of men on floor. This applies to repairmen working on cranes, line shafting, etc.

Use chipping screens or protectors on machines to prevent chips from flying.

Do not attempt to clamp or chuck job or change gear while machine is in motion.

Do not wear gloves, or clothing with loose sleeves, while operating machinery.

Do not place materials in babbitt pot unless you are positive that same are entirely free from water.

Do not go near or under bar material which is being turned in turret lathe.

Do not jump on or off elevators, turn-tables or transfer-tables while they are in motion.

Do not file right-handed on lathe, as it brings operator too close to chuck or carrier.

Do not use a file without a handle.

Do not allow gears to be exposed.

Do not place fingers under job to ascertain if drill is coming through.

Do not wipe drills or clean in or around motor while it is in motion.

Do not lean over boring bar on horizontal boring machine on a one-half open job.

Do not cut off bolts or rivets without holding a broom or cane to keep heads from flying off.

Do not blow out engines with air until sure that there is no one in the way.

Do not raise or move engine with a crane while any person is on the engine.

Do not move crane without first sounding gong, nor raise the hook above the limit switch.

Do not throw red hot rivets from forge fire to riveters where they may be missed and fall on some other workmen near-by.

In hardening tools in hot lead or barium chloride baths, always be

sure that tools are perfectly dry, as the dampness and moisture on the tools may cause the lead or chloride to splash and injure the workman.

Do not weld pipe or any hollow forging on both ends without first seeing that there is an air hole in one end to allow gas to escape and prevent explosion. This also applies to any forging or casting which is cored in the center and solid on both ends.

In handling material at the steam hammer, always use tongs, and always stand at the side of the forging or piece you are holding, as a piece of iron may fly and hit you if you are standing directly back of the forging.

Cold iron should not be cut under steam hammer.

When about to make a change of dies on forging machines, always be sure machine is stopped, otherwise something might fall on the pedal and start the machine running. The same applies to shears and punches.

Do not put your hands on lifting chains when working chain hoists.

Do not swing a sledge until you are sure there is no one behind you.

Do not throw large quantities of water on forge fires, as it is apt to make gas and cause cinders to blow out in your face.

Do not use files or hardened steel for drift pins.

Do not shift belts by hand.

Do not tighten washout, arch tubs, or other plugs in boiler under pressure.

Examine carefully all tools, machines, and appliances you are required to work with, and if there is anything which in your opinion is defective or unsafe, call the matter at once to the attention of your foreman, and make out safety card.

Use care when handling long material when view is obstructed and thus avoid striking and injuring a fellow workman.

Do not stand on foot-board of an engine when the engine is handling a tender or another engine without a coupler.

Do not change injectors or fire up a boiler until you know the boiler has plenty of water.

Before moving an engine, walk around and examine it and ring the bell as a warning.

Do not leave an engine standing without opening cylinder cocks, setting brake, and placing reverse gear in center position.

Do not remove gauge cocks while engine is under steam.

Do not tighten injector nuts when injector is working.

Do not disconnect injector pipes before bleeding off the pressure.

Do not unnecessarily move handle of brake valves.

In starting injectors care must be exercised to see that no one is near overflow.

#### CAR DEPARTMENT

Do not go under a car or between cars for the purpose of making inspection or repairs without first knowing that you are fully protected.

Do not go under a car which is jacked up unless the weight of the car is resting on the horses provided for that purpose.

Do not use steel bars in place of jack handles, and do not allow jack handles to remain in position after completing the jacking of a car or engine.

Do not allow tools or material to remain on cars after work is complete, as these are liable to fall off and injure some one.

When old lumber is laid aside, see that points of nails are turned down or, preferable, bent over, to render them harmless.

Do not jack a car or engine unless substantial blocking is placed under the jack and wooden shim on top of it to prevent slipping.

Do not jack a car without first blocking the wheels.

Do not smoke, nor use a lighted torch or lantern, around or near a tank car or a car bearing flammable cards.

Do not use ladders that are not equipped with anti-slipping device.

Now that the wage question is settled, the men are getting back to normal. Let's all renew our efforts to stop accidents. Let's all go forward with an unshakable purpose and a firm resolve to do our part, and by so doing gain for ourselves that coveted distinction and just reward of a grand and noble work honorably rendered.

Now, there may be several other suggestions to make, but, as a rule, they won't look at all those suggestions. They are just like a child, they have got to learn all the words before they are able to talk intelligently, and that is one reason why I put those "don'ts" in there.

Now, as a rule, all roads have had more or less trouble in the last year, some of them with an increase in accidents, and I believe it is due a good deal to the conditions that existed. The wage question distracted the men's minds but now that that is settled, the men are getting back to normal and it is our duty now to renew our efforts in this safety movement. Let's go forward with an unshaking purpose and firm resolve to do our part, and by so doing we will gain a reward for the grand and noble work honorably rendered.

CHAIRMAN SCOTT: Before we take up the discussion of this interesting paper, I should like to change the order of business just a little bit and take up the next item on the program, which is an address by Mr. Samuel O. Dunn, Editor, "Railway Age," Chicago. I doubt if there is a man in the room who is not a reader of the "Railway Age". I doubt if there is an office on any railroad but what receives this publication each week. I think it is a great honor to this Section that we should be able to have the editor of this most estimable magazine come and address us today on "Economic Phases of Railway Safety Work". This is one side of the question that has not been given a great deal of consideration by the Steam Railroad Section, but I think it is well that we, as safety men, should know something about all sides of the question, and I know of no one who is better prepared to tell us about this side of it than Mr. Samuel O. Dunn, and I have the pleasure of introducing to you gentlemen today Mr. Dunn.

## THE ECONOMIC VALUE OF RAILWAY SAFETY WORK

---

SAMUEL O. DUNN, EDITOR, "RAILWAY AGE," CHICAGO

---

Railroad transportation always has been recognized as a hazardous industry—hazardous to those working for the railways, to those using their service, and to those having occasion to go upon or cross their properties. If I remember my history correctly, on the first occasion when a steam locomotive drawing a train was run in England, a prominent statesman who had been active in securing the construction of the railway was killed.

In consequence of the clearly recognized hazardousness of the industry, efforts constantly have been made since the first railway was built to reduce the hazards and increase the safety of operation. Until within the last decade these efforts had met with greater success in some other countries—notably France, Great Britain, and Germany—than in the United States. The accident record of our railways long was bad by comparison with that of the railways of almost any other leading country, and the worst of it was that it did not improve much. Accidents increased as the mileage and the amount of business handled increased. Those who studied the problem realized that this was principally due to two causes. One was that most of our railways were hastily and poorly built into new and undeveloped territories, and the character of their construction made the prevention of accidents very difficult. The second and most important reason was that our railway officers and employees had the characteristic American tendency toward recklessness, the tendency to "take a chance" regardless of consequences. This tendency of employees, who in this respect were merely typical Americans, was so strong that even after the physical properties of many railways had been greatly improved and safety appliances of numerous kinds had been installed it was found extremely difficult to get employees to protect themselves and the patrons of the railways by properly using the facilities at their disposal.

About ten years ago the railway accident situation grew so bad that it became the subject of much agitation and of great concern and consideration by railway executives and operating officers throughout the country. One of the results was the starting of what was called the "safety first" movement. The real father of this movement on the railways, as I believe is generally recognized, was Mr. R. C. Richards, general claim agent of the Chicago & North Western Railway, who is now president of the National Safety Council. It was on his initiative that the management of the North Western began the formation of local safety committees all over its lines, composed of both officers and employees. The example set was rapidly followed by railways in all parts of the country. Not only were hundreds of safety committees organized, but many railways created safety departments in charge of able men whose duty it was to study all the conditions which tended to cause accidents and to devise remedies for them. A very extensive propaganda was carried on among employees to educate them regarding their own interests and the interests and rights of the railways and of the public concerning this matter.

## INCREASE OF SAFETY ON RAILWAYS

The results of all the work which has been done within the last ten years in installing safety devices and in educating officers and employees upon this subject are strikingly reflected in the statistics regarding railroad accidents. The latest statistics available regarding railway operations and railway accidents for an entire year are those for 1918. In the eight years from 1910 to 1918 the amount of freight handled increased 70 per cent and the number of passengers about 30 per cent. It is a remarkable fact that during these years there not only was no increase but a marked reduction in the number of railway employees and of passengers and other persons carried under contract who were killed. The number of employees, both on and off duty, killed in 1910 as a result of train operation was 3,383, while in 1918 it was only 2,781. The number of passengers and other persons carried under contract killed in 1910 was 421, while in 1918 it was only 342. This makes a total of 3,804 employees and passengers and other persons carried under contract who were killed as the result of the operation of trains in 1910, and a total of 3,123 in 1918. The number of employees killed in railway industrial accidents in 1910 was 421, while in 1918 it was 418. There was even a marked reduction in the number of trespassers killed. The figure for the number of this class of persons killed in 1910 is not available, but we know it was about 5,000. In 1918 it was only 3,255.

It is surely a high tribute to the efficiency of those who have carried on safety work for the railways that this record can be exhibited. Lest some of my friends who believe in government control should claim that the good results obtained in 1918 were due to government operation, I will say in passing that in 1917, under private operation, the number of both passengers and employees killed was less than in 1918.

While, however, gratifying progress has been made on the railways, I need hardly tell you that the number of persons annually killed and injured upon them is still much too large. The total number of all classes killed in 1918, including trespassers and those killed at highway crossings, was almost 10,000, while the total number of all classes injured was almost 175,000. When we discuss the need for safety measures we usually discuss them on the assumption that they are needed almost entirely to prevent the loss of life or the pain and suffering occasioned to their victims. Undoubtedly that is the most important point of view from which the subject should be considered. I am going to venture today, however, to call your attention to the fact that safety work has economic phases which are of very great importance.

## ECONOMIC EFFECTS OF ACCIDENTS

Almost every accident has some economic consequences. By that I mean that it either results in some destruction of property, or temporarily, partially, or completely destroys the value of one or more persons as producers. The amount of property destroyed each year in railway accidents, including both the property of the railways and of their patrons, is very large. The destruction of a large amount of property is the

destruction of the results of the work of a large number of men, and it causes directly and indirectly a diminution of the amount of necessities, comforts, and luxuries available for the use and consumption of the public. It is obvious that if all the property and all the commodities produced by men's work were immediately destroyed we should all be speedily reduced to starvation and misery, no matter how hard we worked. The destruction by accidents or otherwise of a smaller amount of the things produced by the labor of our brains and hands has similar effects which are great in proportion to the amount of the destruction.

Likewise, every accident which results in a man being killed or maimed reduces the total production that otherwise would be obtained. When a man who has just reached his prime as a worker suddenly is cut off society loses a large part of the work that has been done to rear and develop him. It gets only a partial economic return for his economic cost. When a man is compelled to refrain from work because of an accident society loses the product which would have been obtained from his exertions if he had been able to stay at work. As I have said, the number of men injured in railway accidents in the year 1918 was 175,000. If those men lost an average of four days each the total loss of working time aggregated 700,000 days, which was equivalent to the complete loss of the work of 27,000 men for one month.

To measure the results of railway accidents in economic terms of lost production, and lost opportunity for consumption on the part of the public, may seem a coldblooded way to treat the subject; and as I already have indicated, I recognize the fact that the main purpose for which safety work should be carried on is to prevent the cutting off of the lives and the pain and suffering of the victims. But to measure the results of accidents by economic standards is by no means so coldblooded as it may seem. When a man in the prime of life, with a family dependent upon him, is cut off or loses a limb the economic consequence to his family is the destruction or reduction of his income. The amount of deprivation, pain, and suffering occasioned to the families of the victims of accidents is surely comparable with the effects upon the victims themselves.

#### INDIRECT ECONOMIC EFFECTS

It is not, however, the immediate families of the victims who experience all the economic effects. The welfare of society as a whole demands not only a fair division among all classes of what is produced but the largest aggregate production of necessities, comforts, and luxuries that is compatible with reasonable conditions of work for those who do the work of society. Now, every accident by which a man loses his life, or even is temporarily disabled, reduced the amount of production that can be secured for the general good.

Railway safety work has the direct effect of reducing the amount of property destroyed and the number of persons killed and injured, and if its economic value were to be measured merely by these direct and obvious effects it would be worth far more than it costs. From an economic point of view, however, its indirect effects may be and probably

are more valuable than its direct effects. In the first place, every derailment, collision, or other train accident which occurs not only affects the trains directly involved, and the persons upon them, but also affects the operation of a large part or even all of the railroad upon which it occurs. It throws passenger trains off their schedules, delays freight trains and has other consequences which reduce the amount of traffic that can be handled and adds greatly to operating expenses. The number of collisions upon our railways in 1918 was 8,715, the number of derailments 13,568, the number of boiler explosions 239, the number of other locomotive accidents 275, and the number of miscellaneous train accidents 1,898. This made a total of 24,695 train accidents of all kinds. The damage to railway property reported as a result of these accidents was \$20,954,350, but the reduction of earnings and the increase in operating expenses indirectly due to them caused an aggregate loss exceeding by many times the value of the property destroyed. -Whatever tends to reduce accidents necessarily tends to reduce these very large indirect effects which are due to them.

#### CAREFUL WORKER IS EFFICIENT WORKER

The economic effects of railway safety work are even greater and more comprehensive than what has been said already would indicate. The principal cause of railway accidents is and always has been the failure of officers and employees to exercise reasonable care in the performance of their duties. Safety work, when properly and effectively carried on, so constantly and forcibly brings home to officers and employees the necessity for being careful in every thing they do that it changes and improves their entire attitude and habits with reference to their work. It results, when they have a thing to do, in their thinking not merely of getting it done in some way, but of doing it in the right way. Now, this improvement in their mental attitude and habits is one of the main things needed not merely to reduce accidents but also to increase their general efficiency. Usually whatever tends to make a man more careful in his work also tends to make him a more efficient worker—that is, a worker who in the long run will do more and better work than he would do if he were not careful. The effects produced by the constant inculcation of the principles of safety upon the general efficiency of the operation of the railroads cannot possibly be measured either in increased passenger miles and ton miles handled per employee, or in terms of reduced cost of handling a given number of tons one mile or passengers one mile, but that increased care by employees in doing their work does tend to increase the general efficiency of operation is beyond question.

#### SAFETY WORK AND INDUSTRIAL RELATIONS

There is one other indirect effect of safety work, and especially of the work of safety committees, to which I think attention should be called. The greatest industrial and social problem of our time is that of establishing better and more satisfactory relations between the owners and managements of large business concerns, on the one hand, and their employees, on the other. I believe that the principal reason why employers

and employees in so many of our great industries are divided into warring camps is that many business concerns have become so large that their owners and chief officers and their employees seldom come in contact with each other except when they are brought together by controversies regarding conditions of employment and wages. The owners and chief officers of the concerns and the employees have been pushed so far apart that neither class has an adequate understanding of the problems, the functions, the motives, or the desires of the other. The suspicions and antagonisms arising from this situation have a direct tendency to reduce efficiency in all industries, including the railroads, and they will never be allayed until employers and employees of large industries come to a better understanding with each other. They will never come to a better understanding with each other until new points of contact are established between them to take the place of the points of contact which have been destroyed by the substitution of vast industrial concerns for comparatively small concerns in which employers and employees worked closer together. I know of no means which actually has been tried on the railroads which is better adapted to re-establish points of contact between employers and employees, and bring about a better understanding between them, than safety committees. When officers and employees work together on safety committees they soon learn that the problems with which they are dealing are problems of mutual concern the solution of which will be equally advantageous to the railways and to the men. The employees who serve upon these committees are almost certain to get a better knowledge of the problems of railway operation and develop a more friendly attitude toward the managements and to communicate this knowledge and friendly attitude to many of their fellow employees. This again is bound to have a tendency to promote efficiency in the operation of the railroads.

On the whole, therefore, I firmly believe that the safety work being done on the railways is not merely from a humanitarian point of view, but also from an economic and social point of view, one of the most important kinds of work being done on them. From a purely economic standpoint no railway management can afford to hesitate to spend all the money that is necessary to have safety work adequately and ably done. It is, on the other hand, a kind of work which from a purely business point of view no railway management can afford to neglect. While great progress has been made in this kind of work within the last decade, it is only necessary to mention the fact that 10,000 people were killed and 175,000 injured on our railways in 1918 to emphasize that there is great need for safety work on the railways to be carried on more comprehensively, energetically, and ably than it ever yet has been.

MR. JAMES SULLIVAN (Chicago & Northwestern): I just received a message I think you all will be glad to hear that Mr. Richards is much better. (Applause)

CHAIRMAN SCOTT: We will now take up the discussion of Mr. McNally's paper and while this discussion is going on, I am going to ask Mr. Broderick of the B. & O. to take the Chair.

(Mr. Broderick took the Chair.)

## DISCUSSION

MR. CHAPIN (Pennsylvania Railway): One point that I feel strongly about in Mr. McNally's paper is that the shops should be kept clean. In one of our shops they had a system whereby all scrap material was always placed in one place at the head of the track. It was pointed out to them that the sweeper would only take material which was at the head of the track. This resulted in two things: The workman when he put down his material knew he would find it there, no matter how much the floor was cleaned, and another thing, the collection of scrap was very much easier. The sweeper kept the track space swept up of dirt and dust only and let the material which was to be reapplied stay where it was. They whitewashed the pits which increased illumination and helped to make the men feel that they were in a good place to work. I happened to be in this shop at noontime and papers and refuse from lunch boxes were placed in refuse cans. I have known the day when it was all dumped into the pit to be shoveled out by the cleaner.

Another thing, with those of us who have woodworking departments, the problem of safety treads has not been an easy one. Rubber, canvas or things of that kind may tear or rip or stretch. In some of our shops we give the tread a coat of paint, put sand on top of that, let that dry and give it another coat until you have three layers. Let that be your safety tread, and when it wears down, paint it up again. It doesn't take but a few minutes, it is cheap, serviceable, and does the trick.

MR. CHARLES JEHLIK (Chicago & Northwestern): I make it my business to see that all tools are put in good condition before they are given to the men. I see that the men have enough goggles for grinding purposes and other things. I send for those hard fellows in the shop who do not want to do what safety calls for and I tell them what safety is.

Keeping the aisles clean: I made a recommendation that the foreman go to that gang boss and say, "Read rule 736 to them." I get after all the men that I see who are not doing what is right.

I want to tell you that when you run a locomotive department, as a safety committeeman, of twenty-four engines and twenty-four stalls, attend to your own work and see that things are right so you don't lose your own job, and attend to your safety committee work aside from that, you are doing your work not for itself but for humanity, and if I have a man in the locomotive department that will not do what the safety committee wants him to do, the organization backs me, and that is Local 478, and he has got to do what is right or he cannot work. If the man can't read the language on the bulletin board, I will go to him and give him the language he wants and give him to understand what safety is; and they are going to be taught safety first by all means.

MR. SCOTT: This is merely in the way of relating a thing that has reduced shop accidents on the Hocking Valley. We have, I am pleased to report, for the first eight months of 1920, a reduction of forty-eight per cent in shop accidents. Last year in November I got out a circular to the general chairmen of the brotherhoods on our line requesting that I might meet with them and secure their co-operation for furthering

safety, and the first fellow that took me up was the president of the federated shop draft and he was one of the fellows, of course, that I wanted to reach. They set a day for me to be with them and I nearly worked my head off that night on an address. I felt that I must not make a single mistake or I might be lost and here was the opportunity which I had been looking for. I recall before going down to the meeting that night I went up into my room and shut the door and had my notes in front of me and I expect I made the room ring. I went down to the meeting and was surprised to be invited into a very small room. I assumed, of course, that I was going to address a mass meeting and there were just thirty-two men present. Well, that kind of took the pep out of me. I was taken around the room and was introduced to the gentlemen and then the president stood up and said, "Gentlemen, you will recall at our last meeting I read to you a communication from Mr. Scott, and it was agreed that we might extend to him an invitation to be present. You will remember I requested each of you to bring a list of complaints here in regard to safety and I will start here and go right around the room." The first fellow pulled out a sheet of paper and he started in and showed me where the Hocking Valley fell down on safety. I took my notes and tore them up; my address was gone. We went around that room. You know Elbert Hubbard said some people have three kinds of trouble: All they have now, all they have had, and all they ever expect to have. That was the case there that night. They brought up all the troubles they had had, all the troubles they now had, and all the troubles they expected to have. I never had such a great experience in my life. That meeting lasted until twelve o'clock that night. I understood, as I never did before, the viewpoints of those men. I was able to set them right on some things. I made a list of their complaints and went to the General Manager the next morning and said, "Here is our chance to prove to these men that we mean absolutely what we say," and we did. Since then we have had the most wonderful co-operation from the shop men, because we had that opportunity to prove that we meant just what we said.

MR. M. S. COLE (Oregon Short Line): The gentleman who just spoke hit the nail on the head. We have been mingling among our men in the shop. As an instructor, I work more with the younger boys and the younger men. We can't expect to do very much with the older men seeking employment from the other roads. When you can reach the apprentice individually, you can train him in his work and in safety first. It requires patience and it requires conscientious effort. We have eliminated, I think I can safely say, more than forty-eight per cent of our accidents in the shop.

#### ELIMINATED THE PRACTICAL JOKER

I might go back to Mr. McNally's paper. He mentioned the practical joker but he made no suggestions for his elimination. I think we can say that the superintendent of our shop very thoroughly eliminated the practical joker in the shop in this way: Two accidents occurred through just merely thoughtlessness on the part of the man who perpetrated the

joke, not knowing about it at the time as he did not intend to cause any injury, but the man who perpetrated that joke had to pay the man who suffered from the joke for every hour that he missed from his work. He had to pay him out of his own pocket, and that eliminated the practical joker in that shop.

ACTING CHAIRMAN BRODERICK: The time is rapidly passing, so we will proceed with the next paper. Mr. C. H. Baltzell, Superintendent, St. Louis and San Francisco Railroad, Fort Smith, Arkansas, will speak to us on "Transportation Accidents."

### TRANSPORTATION ACCIDENTS

C. H. BALTZELL, SUPERINTENDENT, ST. LOUIS AND SAN FRANCISCO RAILROAD,  
FORT SMITH, ARK.

My subject covers such a wide territory it is difficult to know just where and how to commence. Of course one of the principal things that we should know is whether we are becoming more careful or not.

I have checked up a number of statements, from various departments and organizations and want to present something briefly to you. For instance, B. of R. T. organization dating back to 1884 up to and including 1919, shows the greatest number of men killed in collisions to be 83 in 1903 and 1904 with a gradual decrease each year up to 1919, which shows 19 men killed. The greatest number of fatalities from making couplings are registered in 1916, 1917, and 1918, a total of 176; previous three years, 123, while 1919 shows a total of 34. In 1905 and 1906, 321 were killed by falling from trains, while the year 1919 shows a total of 78. Getting on and off trains, the largest number of fatalities was 37 in 1903 and 1904, while in 1919 three men were killed. In 1911 and 1912, 426 men were killed by being run over in switching, and in 1919 there were 121 killed.

This would indicate that men in that organization have taken advantage of the safety work and are more cautious, thereby greatly reducing the fatalities in their department.

It appears to me that railroad men generally are using more care, thinking of the danger that surrounds them and thereby greatly reducing the hazards in their work. I know on my own division for 18 months there was not an employee killed. This splendid record was broken by a fireman using a shaker bar, beating on the side of the ash pan and asking the engineer to move the engine; but in some manner the shaker bar was engaged in the spokes of a driving wheel. The shaker bar was whirled from his hands, struck him in the back of the head, and killed him instantly.

In the past nine or ten years safety committees throughout the country and safety workers generally have been extremely active in reporting and correcting unsafe conditions which in many cases were promptly handled and the hazard removed, but in my opinion the big work for all division safety committees as well as the employees, is to be alert and active in correcting unsafe practices. This is a matter that if handled in an ear-

nest, sincere manner, and never letting up on the proposition, is bound to secure best results.

The Transportation Book of Rules points clearly to rules and regulations that have been framed for the benefit of the men. Unsafe practices are frequently indulged in without a word of warning to the man doing these things until only too often it is too late to save that man from a serious personal injury or fatality. From actual experience we do not know how much good can be accomplished by taking some action on the ground in the observance of unsafe customs and practices. For instance, you take the man that has been in the habit practically all of his railroad life of adjusting couplers with his feet or hands just about time cars are to be coupled; in my opinion the proper way to handle that man is that every time another employee or division officer observes this dangerous work is to call him off to one side quietly and in an earnest and sincere manner tell him of the danger that he is running. It is all a matter of education.

It is true that in many cases men will persist in continuing these unsafe practices, but there is one thing about our safety work; in order to win we must never get out of patience, must never give up the hope or thought that a man can be brought to his better senses, and if enough attention and patience is displayed you will finally reach this man and make a believer out of him and his influence and actions in eliminating this dangerous work will have a mighty good effect on others. There are hundreds of ways on a railroad for employees to get hurt and killed and I have made it a rule and practice in handling my safety committee and division officers to instill in their minds the one thought to be constantly on the alert and lookout not only for dangerous conditions but unsafe practices.

I think every committeeman should feel his responsibility in regard to these matters. When he observes unsafe work and fails to take proper action, and later on the man indulging in that kind of unsafe work is crippled or killed, I want each committeeman that has observed these conditions to feel that to a certain extent he has contributed to the personal injury or fatality by his failure to do the thing that he had a right and the opportunity to do by getting to that man and talking with him about it. If the influence of one committeeman is not sufficient it is better to double up several good earnest workers and keep continually behind the man and you know and I know that with proper handling it is only a question of time when the employee will correct these bad habits. On the other hand, I think it is a fine thing to be continually talking to the men about cultivating good safe habits, to be thinking of the things they are doing, to realize and to appreciate the danger that does surround them, firmly fixing safe habits in conducting their work, which is far better than any rules, because habits firmly fixed do not have to be watched. In other words, habits are safer than rules, as Dr. Frank Crane in the "American" for July says: "One habit is better than a dozen rules." In the same number of the "American" a splendid article is written on "What fool thing do you do that endangers your life?" What a startling announcement that 80,000 men, women, and children are going to be killed in the

United States in the year of 1920, and about 14,000,000, according to one Insurance Company's estimate, are going to be injured, directly through carelessness, thoughtlessness, or failure to think of the danger that they are running into.

In 1917, 80,000 deaths were due to accidents. Only 22,000, less than one-third of them, were in industry. Other nations refer to America as "Careless America." Think of the appalling automobile crashes at grade crossings throughout the country! You can hardly pick up a paper that does not have an account of an automobile struck on some crossing. "Entire family wiped out," and "five killed, three crippled," are headlines that have appeared. There seems to be an insane desire on the part of many automobile drivers to beat the train over the crossing. I have personally observed them rush across in front of an engine and then stop on the right-of-way and nearly the entire party in the automobile give the engineer the laugh, because of the frightened expression on his face, knowing what a narrow escape they had. But they apparently failed to appreciate or realize the danger they had run into.

#### TRIBUTE TO THE RAILROADS

I saw a splendid tribute to American railroads and the men who run them, which was written by Edwin S. Jackson, April 11, 1920, on his fiftieth birthday, as follows:

"A railroad is not the unfeeling and relentless devourer of automobiles and little children at grade crossings described by impassioned advocates in crowded court rooms. The whistle of danger is an engineer's use of a piece of machinery, but it is also the echo of a man's thought for his own babies left at home.

"A railroad has been likened to an octopus by those who do not know the flesh and blood and personality of railroads. The soul of a railroad is Fidelity, and if a railroad is an octopus, it is an octopus with a soul.

"A railroad is a disciplined power; owning rails and cars and locomotives; engaging the highest quality of mechanical skill and expert knowledge; but the glory of a railroad is the united adjustment of its living nerves to patience, courtesy, speed, and safety."

I also want to pay tribute to locomotive engineers who, I think, are using their every effort to avoid striking automobiles. A case came up on my division last October. One of our passenger engineers on a fast train from St. Louis to Texas, while running 50 miles an hour near a small station in Oklahoma, came around a curve and discovered only a few hundred yards ahead of him three little children—one boy and two little girls all under the age of 6 years—playing on a bridge. I have never seen a man so filled with emotion as was this engineer, whose name is Arthur Davis, in describing this scene immediately after its occurrence.

#### THE ENGINEER'S STORY

"Mr. Baltzell," he said, "when I saw those little children out on the bridge and my train running at full speed and knew it was impossible to

stop the train and avoid striking them, I would have turned my engine over had it been possible to do so to keep from striking those little children. About that time a little twelve year old girl by the name of Agnes Standifer, who lives close to the bridge, hurried up the side of the 12-foot fill, ran out on the bridge almost directly in front of this fast train, took the little boy, stepped to the side of the bridge, dropped him to the foot of the bridge—fortunately no water was at this point—then stepped quickly to the little girls, got one under each arm, stepped to the edge of the bridge, and dropped off with them just as the engine rushed by."

It was a splendid display of presence of mind on the part of Miss Standifer. No one was hurt, but if that engineer lives to be 1,000 years old he will never fully recover from the terrific shock and strain that he received going through those few seconds.

I have always strongly believed that the public generally should be taken closely into our confidence and the safety work spread among the country people, small-town people, as well as throughout the large cities. Much good can be accomplished by the Division Safety Committee, which meets each month, by holding their meetings up and down the division at various points and making a community affair out of it. The business session could be held generally from 8 o'clock until noon, concluded at that time, and the afternoon devoted to a general get-together meeting with a safety thought carried as far as possible among these good people.

There is no question that observation of unsafe practices with corrective action has not been given the attention that it should have. It is very easy to slip back in matters of this kind and after division committeemen and other employees as well as division officers fail to take proper action when observing irregularities, it is only a short time until these irregularities fail to attract even their attention and there is where the danger lies. On the other hand, if our young committeemen especially, can be educated in proper manner to take some action on the irregularities and unsafe practices that come to their observation it is the most wonderful way of sharpening and strengthening their minds as well as enlarging their capacity to do things; and if they will stick to this plan they will begin to see lots of things that never attracted their attention before, thereby greatly improving themselves in many ways.

I believe that Transportation Accidents can be greatly reduced by red hot campaign on train rule meetings for each and every division held for one hour each week, even if but one rule is discussed at a time and kept in mind; that when unsafe practices are observed that some action will be taken in a sincere manner to induce that man to eliminate the bad practice, and get him to form good safe habits.

#### HOPPING TRAINS

The "boy hopping-train" habit is extremely dangerous and an active crusade has been going on for a number of years on the Frisco railroad, which has certainly shown results. It is the common talk of train and engine men as well as yardmen and others, that you don't see as many boys hopping the trains as formerly. Certainly the figures showing a de-

crease in personal injuries and fatalities under this heading are very encouraging.

You cannot take a boy by the back of the neck and scold him and perhaps tell him that he must not hop trains and get the best results. Take him off quietly, talk to him like he was a man, point out the danger, then leave it to his own judgment and honor, and nine times out of ten you have converted that boy and he will use his influence with other boys against this dangerous habit. We cannot afford to lose any of these young fellows, neither through disability nor death. I believe that the utmost consideration must be shown boys throughout this country. There are 10,000,000 boys throughout the United States between the ages of 12 and 19 and we need every one of them to make strong, healthful, self-reliant Americans.

Another important item is to make strong effort to induce men to take proper rest when off duty to prepare for next run or hours of service. So many men fail to do this, increasing liability of Transportation Accident. The most dangerous time is when a man is so sleepy and tired that he does not care nor does not think of his personal safety. The women folks at home can greatly assist in keeping this thought before the bread winner.

I am a strong believer in athletics for railroad men. I believe it makes them more healthy, happy, and efficient; besides it has a mighty good effect in causing them to take better care of themselves. Athletics played a big part in winning the World War, and it surely will play a big part in straightening out this upset world.

One big item in Transportation Accidents is the proper handling of train orders. Every man on the Division should use his personal influence to see that orders are handled according to the rules. One bad habit in which a number of operators indulge is telling the conductor or others the contents of his train orders, often misleading the conductor and others. Let the conductor read the order to the operator and operator check it carefully. Rule 210 is of the utmost importance.

Harmony and team work contribute a great deal to the interest in Safety First. Every effort should be made at all times to promote the feeling of friendship and the thought to be on the lookout in a helpful manner for the other fellow; and to eliminate entirely all selfish motives and work together for betterment and efficiency.

MR. HALE: Mr. Chairman, may I ask Mr. Baltzell if the Frisco Railroad saw to it that this wonderful heroic action of this wonderful heroine was brought to the attention of the Carnegie Commission and did she get a medal as she was entitled to?

MR. BALTZELL: I wanted to tell you some more about that. When I brought that to the attention of the committee, every man promised to do something for that little country girl. They bought her a beautiful locket properly inscribed and they told us this was to be presented to her on Christmas Eve. I said to this engineer, "Arthur, we are going to Albany Christmas Eve for this presentation." He said, "Well, I have a little Christmas tree at home." I said, "So have I, but listen, Arthur, when they get as old as you and I, Christmas trees and things of this

kind is what we do for the other fellow." He said, "Sure, I will go," and we went, and I shall never forget it. There was a little country school house, a little Christmas tree, and you never saw so many doll babies and tin horns as there was down there. We put that thing over in a wonderful way, and just think of the effect that we made in that community in the interest of safety first. What I want to do is to get a scholarship for that little girl so she can go off to some big school and have all her expenses paid, and that is the thing that is going to be done for her.

MR. HALE: Mr. Chairman, I want just to leave this word. If you can make a man understand that by his safe actions he is the real profiler, you will get somewhere. I had a roughneck switchman come to me following a talk something along the lines of my talk this morning and he said, "Hale, I didn't just get your talk last night. I guess I was a little dense and I was tired but I have been thinking it over this morning since my mind is cleared up and I know what you mean and I am strong for you and I want to shake hands with you." I said, "Now what do you understand me to mean?" He said, "Well, I am working down here in the yards as a switchman and I see my partner pull some bone and I go over and say, 'Boys, listen to me. You stop doing that. One of these days you are going to do that and it is going to cost me three dollars and twenty cents, and, damn you, I have no money for you.'" When you can make a man realize that he is going to pull some bone and it is going to cost him three dollars and twenty cents, he will see to it that the man quits.

(Mr. Scott resumed the Chair.)

CHAIRMAN SCOTT: Mr. Baltzell's paper is open for discussion.

#### DISCUSSION

MR. V. PARTIN (Ann Arbor Railway): Regarding automobile accidents, and with particular reference to the automobile driver driving up to the crossing and, after the engineer has possibly made an emergency stop of his train, giving the engineer the laugh, I want to let you all know how a case of that has been handled on the Ann Arbor Railroad. This particular engineer was coming down the track with a freight train and some parties in an automobile acted as though they were going to attempt to cross the track directly in front of the engine. The engineer made an emergency application of the brake. The automobile stopped and as usual they gave the engineer the laugh. He got down off the engine and tried to reason with them but he could not. He said, "All right, I'll take the number of your machine, turn it in to my superintendent and let him handle the matter with the Secretary of State." He took the number of the machine and sent it to me with the circumstances. I took it up with the Secretary of State who referred me to the chief of police in Flint. After taking it up with the chief of police in Flint, I found that the man had moved to Owosso. I then referred it to the chief of police at Owosso. The chief of police located these parties, called them into court and last week had turned the case over to the prosecuting attorney.

In connection with employees, it is easier, I believe, to train the man that is just entering the service than it is the old head who believes that

he knows it all. I would suggest that when you employ a new brakeman or a new fireman off the farm, have a small pamphlet of safety first rules and when he starts out to learn the road, let him take that along with him. He will read that several times.

NEVER ADMINISTER A REPROOF WHILE ANGRY

MR. D. K. RAWLINGS (Oregon Short Line): I was particularly interested in the discussion of the paper of Mr. Baltzell's on the manner in which you approach a man. I like spirit. I have tried to place before all of our committeemen the proper spirit in which to approach a man who has violated some safety rule. In many cases I think that the committeeman could have done much better if he would have walked away and left the man until he was in the proper frame of mind to approach him. I know of one instance where a man approached another man who was grinding on an emery wheel. The man had had a little difficulty shortly before he approached this man with one of the foremen and he was quite mad. When he saw this man grinding on the emery wheel he started in in good plain English to bawl him out. The result was a quarrel between the two men which brought bad feelings. The man turned around and told him in good plain English to go to hell, that he was handling that emery wheel and he knew what he was doing and he had done it for twenty-three years. He left a bad impression. If that man had gone off and got into the right frame of mind and talked with him in the right spirit, he would have been able to get his co-operation and show that man by conclusive arguments that it was necessary for him to stay on his job.

We had an engineer on a passenger train going through a town and a man in a Ford car crossed just ahead of the train. The engineer got the scare of his life. He got off his engine and got the number of the car as it disappeared. He sent the number of the car to our office and we went to the Secretary of State and found out to whom the car belonged and I made a special trip to that man's home that night. I found him with his family eating supper. I told him who I was and he invited me in and I went in and talked with him and his family, explaining to him how he had scared the engineer and how an accident might have occurred by his crossing without looking either to the right or left of that crossing. I received the heartiest response from his wife and family and a promise from him that in the future he was not going to take those chances.

MR. J. T. COLEMAN (Pennsylvania Railroad System): Regarding the question of reckless automobile driving, in the state of New Jersey, the Atlantic Division, placed a check for four days on one of its most important grade crossings and furnished the Highway Commission of the state of New Jersey with the numbers of each automobile that made a violation in passing over this grade crossing and over sixty of the number absolutely refused to obey any instructions or obey the signals. We are furnishing that to the State Highway Commissioners, hoping to bring it to the attention of the individual automobile driver.

MR. BRODERICK: The subject of automobile accidents I think is vital. On the B. & O. we have been carrying on a special campaign of this sort for the last ten months. We think it has good results. We have been

getting the numbers of automobile operators who violated the safety rules in crossing railroad tracks and sending the report to the automobile commissioner or Secretary of State as the case may be, who in turn will bring it to the attention of the automobile owner. It seems to be a question of the public being educated to the realization of the importance of taking proper precaution at railroad crossings. The installation of crossing gates and bells and things of that sort is not going to solve the problem. We had a most aggravating case on our Wabash Branch between Baltimore and Washington a few days ago which shows that the maximum amount of warning doesn't mean anything to some people. We had an automobile driver go through our crossing gates when they were down, the watchman on duty, the wigwag signal functioning, and the warning bell ringing, which meant nothing to him. There was the maximum amount of warning that could possibly be given at a railroad crossing.

MR. JOHN F. GROSZKI (Safety Agent, Oregon Washington R. R. & Nav. Co., U. P. System). I think this is one of the most important questions that is before the railroad men today. As far as our own casualties in our shops and along the right of way is concerned, I think we can manage that very well, but we have got to reach the public on the question of the automobile driver.

We have a very mountainous country. We run through all the smaller chains of the Rocky Mountain range besides the Cascade range. We have curves, we have many crossings and we have a very bad operating condition when it comes to railroad crossings, and we have tried to work on this problem.

We have gone to some trouble, some expense, and taken some time to try to educate the public along the lines Mr. Baltzell mentioned. We have gone to public schools and talked to the children. We have gone to meetings of automobile clubs and talked to them. We have talked before the Automobile Club at Walla Walla, Washington, which is one of the most enthusiastic safety clubs I have ever met anywhere and we have not had an automobile accident there for the last two and one-half years, or anywhere in that vicinity.

Another thing that we have gone ahead with is to try to enlist the newspaper editors in the community. Along our railroad I have got in touch with about 175 or 180 editors of newspapers, both daily and weekly—that includes the daily papers in the larger cities like Seattle, Portland, Spokane, and Tacoma and the weekly papers in some of the smaller towns. We run small press notices about every sixty days and in this little press notice we give two or three very bad accidents that have occurred where an automobile was smashed up and particularly where more than one person was killed, mentioning that in a few lines and then instructing the automobilist how a crossing should be made. My scheme has been this:

#### INSTRUCTIONS TO AUTOMOBILISTS WHEN CROSSING RAILROAD TRACKS

When you approach within one or two hundred feet of a crossing, put your car on an intermediate gear, then when you come to the crossing, stop. After you stop, why then look and listen. If there is no train in

sight and the coast is clear, then proceed. If the crossing is on the level, go across on intermediate, but if there is the least grade, I advise the automobilist to put his car on low gear so he will be absolutely sure to make it. If there is a curve or a cut, I advise the automobilist to get out and look, especially if there are two in the car.

We have kept that up for some time and the newspapers are giving us splendid support. Where the editors were cold and didn't want to give us support, I went down and visited them and asked them to come to our aid. One man in particular wouldn't give us any space at all. One day I got him down to the meeting and I worked our boys to take up the automobile question. The next morning that man gave us two and one-half columns about crossing accidents. What has been the result? Our engineers tell me it has done a lot of good. I want to say that on the old W. R. & M. with about 2,300 or 2,400 miles of railroad through mountainous country with very bad crossings we haven't killed a person at a railroad crossing for a little better than eleven months. That is accounted for, I believe principally, through the newspaper education and we are going to continue that.

MR. MAYO: The time is getting late. I would suggest that we take up this discussion, which is so important, at the round-table meeting this afternoon, and now proceed with the regular order of business and the election of officers.

CHAIRMAN SCOTT: Mr. Adams, will you make note of that?

Do I hear a nomination for the office of Chairman of the Steam Railroad Section for the coming year?

#### ELECTION OF OFFICERS

MR. E. M. SWITZER (C. B. & Q. Railroad): It seems to me, in selecting a man for Chairman of this Section, we should, of course, select some one who has demonstrated his interest in our interest and the interest of this Section, and it is also very important to select a man who is so situated that he has abundant opportunity to attend to the rather burdensome work that I am sure is entailed in the position. I have in mind such a man and I would like to nominate Mr. T. H. Carrow of the Pennsylvania Railroad.

(The motion was seconded and unanimously carried.)

MR. CARROW: I thank you very much for conferring this honor upon me.

I want to see the Steam Railroad Section become a great power in the work of the railroads of this country. I want to see safety men everywhere, intelligent and educated in their line. I am not particular about the language they speak, but I want them to know their business and I think there is no medium in the world so efficient as a session of this sort to bring that about.

I don't intend to speak very long but I do want to give you an idea as to what I think is involved in the true vision of the safety work in the future. You will recall last year in my address I enumerated a great many things to picture the enormous magnitude of the railroad business in this country. Today I invite your attention to the speed at which we

are going, to the increased development that you see on every hand, and, at last, draw a picture in your mind of what will happen ten years from today. The 40,000,000,000 "passenger miles" will in all probability reach a hundred billion and where one person travels today there will be three. I have never seen in my life the inclination on the part of men, women, and children all over the world to travel like there is today.

There are today approximately 9,000,000 automobiles in this country. By the most careful estimate that I can make, there will be 25,000,000 automobiles in the United States in ten years. There are public roads projected in every part of the land that will increase vehicular travel one hundred per cent and the 7,000 deaths and injuries at railroad crossings will be multiplied by three unless we, the people who are responsible for inculcating safety in the minds of the public and bringing to the attention of our officials the great principles of safety, do our full duty.

Now, let me say one thing more. Don't blame the officials; don't blame the employees, but look into your heart and your mind and find out where you have been ineffective and go to it with all the strength that you can assemble and make them understand and feel that safety work is right and that it must survive.

CHAIRMAN SCOTT: Nominations for Vice-Chairman are in order.

MR. D. B. ALLAN (Union Pacific): We have in our country a great transportation system that has been a pioneer in many things having to do with the glory of the Republic. This transportation system was a pioneer in construction West of the Missouri River. This transportation system was not built in a spirit of commercialism but sponsored by the Lincoln who looked on it as a military necessity, it was constructed with the idea that it would preserve the union of the states and as we all know, it was for that reason it was christened the Union Pacific. Gentlemen, the Union Pacific has come into this convention with thirty-five men and we have a candidate for the position of Vice-Chairman. We feel, and justly feel that if the position of Chairman goes to the East, the position of Vice-Chairman should go to the great West and it is my delightful privilege, Mr. Chairman, to present to this convention the name of Peter Groome for Vice-Chairman.

(The motion was seconded and carried unanimously.)

MR. GROOME: Mr. Chairman and Gentlemen, if there is anybody in this room that is surprised, it is myself. I knew nothing about this. It has been forced upon me. The only thing that I can say is that during the coming year I will pray that Tom Carrow won't die or resign his position.

CHAIRMAN SCOTT: The next in order is the election of a Secretary. Do I hear any nominations?

MR. E. S. CHAPIN (Pennsylvania System): Mr. Chairman, the nomination for Secretary is kind of a left-handed compliment to a fellow because you are handing him all the hard work there is. You have to have a man with a lot of pep and one who can handle the hard man. I want to nominate Mr. A. V. Rohweder, of the Duluth, Missabe and Northern.

(The motion was seconded and carried.)

MR. ROHWEDER: Yesterday morning some one said something about the possibilities of my accepting the Secretaryship of the Steam Railroad

Section and just a few minutes after that Mr. Mayo got up and made his report and told about all the hard work he had and the little support he got, but he helped it out a little bit by asking for assistance and I want to ask for the same thing now.

CHAIRMAN SCOTT: Gentlemen, I think you have done well in the selection of your officers for the incoming year...

If there is nothing further, we will stand adjourned.

ADJOURNMENT.

## THURSDAY AFTERNOON SESSION

### ROUND TABLE

HARRY A. ADAMS, CHAIRMAN

Bureau of Safety, Interstate Commerce Commission, Washington, D. C.

THE third session of the Steam Railroad Section was called to order at 2:45 o'clock, by Mr. Robert Scott of the Atlantic Coast Line Railroad.

MR. R. SCOTT: I would like to read to you a telegram just received from Mr. Richards:

"I hope the Steam Railroad Section will have the best and most interesting session in its history and that great benefit to the Safety Movement will result therefrom. I regret exceedingly that on account of my illness I am unable to be present. Please give my kindest regards to all the delegates.

"R. C. Richards." (Applause.)

I have another telegram here from Mr. William S. Wolner of the Northwestern Pacific:

"Please express to the meeting my regret on account of inability to be with you. Northwestern Pacific one hundred per cent officials and employees for safety; forty-three per cent reduction in accidents for August; fifteen per cent reduction for the current year.

"Northwestern Pacific."

As I understand it, the afternoon session is to be devoted entirely to a round-table discussion, and Mr. Harry A. Adams is going to conduct the meeting.

(Mr. Harry A. Adams presiding as Chairman.)

CHAIRMAN ADAMS: This is going to be a very, very busy afternoon, and in order that we may dispatch the business, I hope you will give good attention, and that each gentleman who speaks will confine himself to the subject. There will, no doubt, be subjects coming before the meeting that will require ten to fifteen minutes, but if all take that length of time we shall not be able to finish within the required time.

The first subject on the program is "Use of Statistics in Connection with Safety Work". This discussion will be led by Mr. J. C. Clark.

## USES OF STATISTICS IN CONNECTION WITH SAFETY WORK

J. C. CLARK, ASSISTANT TO GENERAL MANAGER IN CHARGE OF SAFETY,  
OREGON SHORT LINE RAILROAD COMPANY, SALT LAKE CITY, UTAH

There are various uses for statistics. They are sometimes used to conceal facts. They are sometimes used to prove untruths, and occasionally I am told they are used to present facts in such a way that you can intelligently carry on safety work or any other kind of work. Now I am only going to deal this afternoon with the latter phase. Statistics if properly used can be of great assistance to all safety officers. The greatest trouble, I think, at the present time is the fact that different roads are compiling their statistics on a great number of different bases. Some roads in their industrial accidents use the nine hour basis. Other roads use as a basis of comparison the accidents per one thousand men employed. In train service accidents some use a basis of accidents per million locomotive miles. Others use a basis of ton-miles. It seems to me that we should get together and agree on a uniform basis of reporting accidents.

Personal injury has usually been taken as the basis of safety work. I think that we should also take into consideration the amount of damage, but that is secondary to the personal injury feature. Now a good many of the safety officers take into consideration all personal injuries, whether there is time lost or not. A good many of the roads only take into consideration the I. C. C. standard which is to exceed three days lost time. There is a question in my mind as to how we should report for these safety departments. As a rule, any accident regardless of how much time is lost might have resulted in a lost time accident even though there was no time lost. It is a pretty hard proposition to get down to really a uniform basis.

As I take it, this discussion this afternoon is for the purpose of getting the views of the safety officers gathered here, and see if we can't get down to brass tacks. Of course, you can all see the value of having a uniform basis. At the present time I can't compare injuries on the Oregon Short Line with injuries on the D. & R. G., for example, because Mr. Ridgeway uses any injury regardless of whether time is lost or not, and he gets out a table every month showing the percentage of employees injured. I use an entirely different basis, and I can't compare my figures at all with Mr. Ridgeway's. Mr. Ridgeway is in the same territory that I am in, and I would like very much to be able to show my officers a comparison between these lines. So if we get down to a uniform basis I think that we will accomplish a very great purpose.

Another thing that I think we should do if possible is to co-operate, to a certain extent at least, with other industries so that we can make comparison between injuries of employees on railroads with injuries to employees in other industries—the steel industry and a number of others. They have a fairly uniform basis in a good many states due to the fact that the compensation laws, I think require certain standards. But there

is wonderful room here for constructive work, and I am very much in hopes that the discussion this afternoon will develop opinions on some one basis that we can settle on, and in that way get the benefit of comparative statements with other roads and with other industries.

I believe we can accomplish this purpose, and I will suggest, Mr. Chairman, if it isn't out of order, that in this connection we also consider appointing a permanent committee of the Steam Railroad Section to co-operate with other industries representing the National Safety Council to work with them during the coming year and see if we can't get down to a uniform basis of reporting accidents. I believe that would be a good thing.

MR. DOW (New York Central): I move that the subject be referred to the incoming Accident Causes and Remedies Committee for their investigation and report at the next annual meeting. (Seconded.)

CHAIRMAN ADAMS: It is moved by Mr. Dow of the New York Central and Mr. Walling of the Chicago Western Indiana that the subject under discussion be referred to the standing committee of Accident Causes and Remedies. You have heard the question, are there any remarks on the subject? Are you ready for the question?

MR. ROCKWELL (Buffalo, Rochester & Pittsburgh): I think this is a very excellent move, but it seems to me we might get action into this and get some immediate benefit by amending Mr. Dow's motion to request this committee to formulate some plan and put it in operation by January 1. Give the committee power to formulate a plan so that we can get speedy work, and I move that as an amendment to Mr. Dow's motion.

MR. CLARK: I second it.

CHAIRMAN ADAMS: Does that meet the approval of the assembly? If there are no objections we will let that be a part of the motion. Are there any objections? Hearing none, that will be a part of the motion that this committee will meet, act, and report by January 1.

MR. CLARK: I should like to state in that connection I understand the headquarters staff of the National Safety Council will be glad and willing to take care of the clerical work in connection with that. The reports could be made to the Secretary of the Section and he could forward them to the headquarters of the Council, or they could be sent direct to the headquarters of the Council. I have talked that over with Mr. Rosseland and he has assured me they would be glad to take care of any clerical work in connection with a move of this kind.

CHAIRMAN ADAMS: Are you ready for the question? All in favor of the motion as made will signify by saying "Aye". Contrary? It is carried.

MR. DOW: May I have the privilege of the floor for one moment before you proceed to the next subject? I want to put a motion and I want to do it while the temporary chairman is in the chair so as not to cause any embarrassment to the permanent chairman. This morning the Steam Railroad Section very properly, and following the usual custom, elected to office gentlemen who have shown by their ability and their hard work that they were well fitted for the positions to which they were chosen. I do not think that this section wants to adjourn from this convention

without taking some recognition of the very splendid services rendered by the acting chairman, Mr. Scott. I don't know whether any of you realize the difficulties that beset a man who has to take up the reins of the chairmanship of a section of this kind within a few weeks before the annual convention, without having had his hands on the work, or having had experience in the ways of the sectional work up to the time of Mr. Myer's resignation a short time ago. In spite of the difficulties under which Mr. Scott has been working we all know the splendid and efficient manner in which he has gotten this Section together and conducted the meetings, and I want to propose to you that we signify our appreciation of Mr. Scott's services as Chairman of this Section by a rising vote of thanks.

(Rising vote of thanks and applause.)

Mr. Scott: It pleases me very much. Fellow-members of the Steam Railroad Section, to hear these remarks offered by such a prominent and active member of this section as Mr. Dow, and I want to assure you that I appreciate fully everything that has been said. I have done my best so far in the discharge of my duties, and I am very glad to know that my services are appreciated. I thank you.

Mr. Chapin: I think it is only fair that we should also express our appreciation of the difficult duties accomplished by our Secretary, Mr. Mayo.

CHAIRMAN ADAMS: Those in favor please rise.

(Rising applause.)

CHAIRMAN ADAMS. Order of business No. 2—"Competition in Safety Work." This discussion was to have been led by Mr. Ralph C. Richards, who we all know is temporarily out of commission, and I am glad to say that it is not serious. In his stead I am going to call upon a gentleman who was a long time associated with him in the safety work on the Chicago and North Western Railway, a gentleman whom you all know well, and who was your regional supervisor of safety, and now secretary of the Chicago Local Safety Council—Mr. Harry J. Bell.

### COMPETITION IN SAFETY WORK

HARRY J. BELL, SECRETARY, CHICAGO LOCAL SAFETY COUNCIL, CHICAGO

Mr. Richards had made some inquiry about the matter of awards given in connection with competition in safety work. He took the matter up with 76 steam railroads, and out of those railroads 41 were against the plan of making awards; 32 were in favor of it, and 3 were doubtful, so that you see there is quite a divergence of opinion as to the propriety of making awards or not doing so. Personally I know that Mr. Richards is in favor of that plan. I, too, am in favor of it, because experience has taught me, as it doubtless has many of you, that competition is really the spice of almost everything. They say that there is a necessity for competition between railroads which was the reason that railroads were returned to private operation, and perhaps that is true.

Now a good many roads do make awards regularly. That is on some

yearly competitive basis such as a safety banner, a vacation period to the committee on the division of the road or in the shop of the road which makes the best record, etc. Just how much merit there is in those different plans, relatively, you are perhaps just as good a judge of as any one else. It seems to me the theme of what I would like to get before you is the necessity for competition from the standpoint of creating not interest but enthusiasm. Interest in this work, I am coming to believe more every day, isn't what we want—or rather it isn't enough. We must have enthusiasm. We can't go on in our safety work or in our safety committee meetings and do the same thing in the same way endlessly. We have got to change it. We must provide an incentive, and I don't know any better way to provide that than by competition of some kind, and when you have competition it is, of course, natural that an award of some kind be made. Just in passing I would like to say—because that remark makes me think of it—that the Northwestern for years has awarded a safety banner to the division of the road, to the shop of the road, and to the terminal of the road which makes the best record in accident prevention during the year. To the members of the committee on that division or in that shop or in that terminal that win the banner is awarded annual transportation on the system for themselves and families.

It seems to me that that plan is a very constructive one because it gives the men something very tangible to work for, and when there is tangibility about it, of course there is value from a great many standpoints. It seems to me that in thinking about this matter there is a great deal of value in what Mr. Samuel O. Dunn said to us this morning in that wonderful address of his, because of the fact that if we are going to create that interest not only in the men but in the officers of railroads in allowing and authorizing this work to go on as it should go on, as it must go on to succeed, then we have to provide some very definite incentive.

I venture to say that if railroads were to undertake an advertising campaign, and instead of advertising that they have steel cars and automatic signals and automatic stops perhaps, and things of that kind, they would advertise that their road is the safest railroad from the standpoint of prevention of accidents, not only to passengers but to every one who has contact with their property, they would mighty soon get action in accident prevention on the right basis, because then it would be regarded as a fundamental part of the business of every railroad.

I have often thought of the plan of each railroad of large mileage holding an annual safety congress of its own. We have seen that demonstrated during federal control of railroads in connection with accident prevention drives.

I remember going over to Indianapolis. I think it was, about two years ago to attend such a meeting which Mr. Dow held, when two or three members of the Safety Committee on the railroad were brought into Indianapolis to attend a big safety congress for the day. I am sure that a lot of value was obtained from that plan. It seems to me that a very constructive plan of developing competition in safety work should be one whereby each road would hold such an annual congress, and let go to

that annual congress the men on each of your safety committees, or the two or three men on each safety committee who really did the best work as safety committeemen. I think that is an opportunity and a privilege to attend that annual congress that any man would look forward to, and in that method you would develop the necessary competition that you must have in this work.

**AWARD SHOULD BE BASED ON UNUSUAL SERVICE**

I believe that in making any award for a competition of any kind, the award ought to be based not on usual, ordinary service, even though one man on a railroad does that service, but it ought to be for something strikingly unusual. I don't care whether it is for maintaining the safest tractor, for doing the best job of inspecting and repairing box cars, or what not, but it ought to be for something strikingly unusual, because when you make an award for a service which is only casual or incidental or customary, it destroys the incentive in the other men, because they appreciate that something is wrong with the method if a man can get that award without doing something unusual to accomplish the result.

Now, of course, it is well to say that a man, no matter what his job on a railroad, ought to be a safe man. He ought to follow safe practices and principles and things of that kind as a means of protecting himself, and therefore he shouldn't get any reward. But really the award for unusual service after all would be based on not what a man did for himself but on what he did for the other fellows in his department or his division or in his shop. People have said also: "Why make an award for so humanitarian a service as accident prevention service"—and that is all right theoretically, but when you get right down to brass tacks, Gentlemen, you have to look in the face of the fact that we are not getting the best results in accident prevention in many instances because we don't provide the incentive, and whether it is good business or bad business, whether it is proper or improper it seems to me doesn't count so much as the fact that what we are concerned in is the stopping of people being killed in industry, and we must go the most direct route to accomplish that result.

We had up here yesterday from Chicago some twenty high school boys, sent up here to get some enthusiasm out of attending this conference, and believe me, they got it. Those high school boys call themselves not optimists or pessimists but "peptomists". They have been made now so full of pep by reason of having attended this Congress that they are going to put pep into the entire high school aggregation in Chicago, in number some 40,000 boys and girls. Now that wasn't accomplished by our telling these boys about the fact that there was a big Annual Congress on up at Milwaukee with three or four thousand people in attendance, and safety parades, and the town decorated and all that. We brought them here to show them what it was like. Now we gave these fellows something to think about. We brought them up here and demonstrated what an annual congress is like, and because of it we not only have secured a lot of interest on the part of those boys before they came here, but we are going to have lots of it in the time to come.

I don't know of anything in connection with railroading that is going to replace so thoroughly the sometimes reported "lost morale" among railroad men as real accident prevention work. Mr. Dunn in a very wonderful way brought out that point this morning. Now we can't do this kind of safety work that Mr. Dunn and you and I and all of us know ought to be done without enthusiasm.

I don't know of anything that has ever been done in railroad service that developed so much interest and enthusiasm and co-operation in connection with the prevention of accidents as those national railroad accident prevention drives, and the similar "no-accident weeks" which were conducted before that time.

I just wanted to say, therefore, in closing that we must absolutely unequivocally develop on the part of the railroad men of America, not interest—we have that—but enthusiasm. We want lots of it. We want it on the part of the total working force, and I believe that the real method of getting that is by developing competition through awards of one kind or another, and the sooner that we do develop that competition and make our plan as variable as possible so that there will be no monotony, the better results we are going to get in conserving the lives and limbs of the railroad men of this country.

#### DISCUSSION

**CHAIRMAN ADAMS:** In the last national drive I think there were several regions that put up awards. I know of three—the Central Western Region, Northwestern Region, and the Southern Region, but in the Central Western Region the largest railroad that was competing in that drive and that won the first prize was the Union Pacific. We will hear from Mr. Groome of the Union Pacific.

**MR. GROOME:** When it was announced in the Central Western Region that the regional director was going to give three banners for the different groups of railroads that made the best record during that drive and the news was conveyed to the officers and employees of the different lines, I noticed almost immediately a keen competition among the different divisions, the different shops, the different classes of employees, and when we were almost certain that our railroad was leading in the group of railroads that had more than 5,000 employees—and this information was looked for with interest every 24 hours—I advised every officer of the railroad from the Federal manager down just where we stood. Now after it was announced by Mr. Adams that Mr. Holden was going to make this award of a banner, I think we went eight straight days without a reportable accident, which shows in itself that the men did take more interest when they found out that they were being compared, that they had a chance to win something that other railroads were in competition for.

I was constantly in receipt of telegrams and letters of inquiry for several days after the drive was over, wanting to know if we had won the drive, which demonstrated to me anyway that an award of some kind keeps up the interest in safety.

**CHAIRMAN ADAMS:** One of the lines that participated in the national accident prevention drive and won a banner was a road with less than 2,000 employees—the Chicago and Western Indiana—Mr. Walling.

**MR. WALLING:** Personally I have always been a little doubtful about this giving awards for work of this kind, so that when the plan was announced of giving a banner to the roads that made the best record in that no-accident drive, I was a little dubious as to just how it was going to work out. I will have to admit, however, that it did have a very stimulating effect upon the officers and employees of our particular line. We found—just as the gentleman from the Union Pacific has said—that there was a great deal more interest among our men after the notice was given that there would be a banner awarded to the successful road. We found that every day the officers and men along the line were anxious to find out how they stood and how their nearest competitor stood. So I believe that it is a good thing, as Mr. Bell has expressed, that we have interest, but we need more than interest, and that is enthusiasm.

**MR. WHITEMAN (Bessemer & Lake Erie):** I would like to hear from the people who didn't win the banner to see whether or not there was any letting down on the part of their men after they found out that they had lost. One of my friends told me that in putting competition on with his company, as soon as a man found out that the competition took in his line he became interested—they were going to offer a bonus of some kind to each conductor, for instance, who didn't have an accident—but as soon as a conductor did have an accident then he didn't care whether he had any more or not. I would like to know if these people who lost had that experience.

**CHAIRMAN ADAMS:** Mr. Whiteman, it is the chair's intention to put on the affirmative first and then give the negative an opportunity. I would like to call on Mr. Scott, who is in the Southern region and had a great deal to do with the silver cup that was given.

**MR. SCOTT:** I don't know what I can tell you about awards. We tried our best to get that cup but we didn't get it. I thoroughly believe that you should stimulate the employees, to do their best in competition of that sort. I am thoroughly convinced that the award system is all right.

**MR. GROOME:** On the Union Pacific system, we have instructions to report to the vice-president of operations on Saturday morning to discuss a plan for the purpose of going over safety banners to be awarded in connection with safety first activities on the system. Now we don't know exactly what this plan is that the president or vice-president has, but evidently they have some faith in the banners from the fact that I understand they are going to award one to the unit—the Oregon Short Line or the Union Pacific, etc.—that makes the best record in safety for some period—also, banners to the division on each one of those units that makes the best record, and perhaps the shops or terminals that make the best record.

**CHAIRMAN ADAMS:** Mr. McAndrews, the roadmaster on the Chicago and North Western, I understand, has some views along this subject.

**MR. P. J. McANDREWS:** I shall speak to you briefly from the viewpoint

of a man on the road among the men, as to the views of the men on these awards that are granted in competition in safety work. It has been my fortune to have been roadmaster on two divisions which during my period there won the banner, and as most of you know, the roadmaster should and usually does come in contact with more of the employees outside of the large terminals than perhaps any other subordinate official, and we do get the view-point of the men in matters of this kind.

I find that competition stimulates interest in the work. It makes the safety work more intensive, and that is evidenced in the work of the chairman as well as the various members of the committee in performing their duties. On the division which won the banner for the Chicago North-Western Railway, our chairman followed every case rapidly to a conclusion, and no reported case of unsafe practices or unsafe conditions was allowed to lay dormant for any length of time, and the result, we believe, was evidenced in that we made a great record on that division. I find that the members of the committees who have won these awards become very active safety men ever after. Of course, in the progression of membership we may be replaced on the committee, but we never lose interest.

I believe that the annual transportation award on the system to the members not only stimulates the member himself but arouses interest among the members of his family, and in the neighborhood, and has a far-reaching effect in that way. Mr. Bell told you that it was necessary not only to have interest but enthusiasm, and I believe, therefore, that the award of a banner and various other matters that go with it arouse this enthusiasm and keep up the interest until the Safety Committee members reach that state which we should all reach in time of having within our heart that feeling for safety which Mr. Dow told us of so eloquently on Tuesday afternoon, I believe, and which I believe every member of this Section has felt gradually coming to them from year to year as they attended the various sessions.

We are all far better safety men after some years of experience than in the beginning of the work, and I am a firm believer from my observations among trackmen, trainmen, enginemen, and stationmen of the results of these awards, that it does serve to stimulate interest and it does help to lead them along till they get to that stage where they don't need awards any longer and the real incentive then is the inner consciousness, the heartfelt desire to be good safety men.

CHAIRMAN ADAMS: Gentlemen, there is just one other that I should like to call on. The Panhandle and Santa Fe, a part of the big Santa Fe system, won the banner in the Central Western Region for making the best record—that was 100 per cent—of the smaller lines, and I would like to have you listen to Mr. Hale of the Santa Fe.

MR. HALE: I don't know what I can say except to reiterate what Mr. Groome has said and what has been said by a number of others here. I haven't always been a convert to this reward idea but I am getting around to where I am beginning to think it is a pretty good thing. I know in that particular field everybody was very proud of the fact that we won that conspicuous place. I took the banner out to Amarillo and made a formal presentation in behalf of Mr. Adams and Mr. Holden and gave

it to Mr. Parker, our Vice-President and General Manager. He brought the people in from all over the line. We followed this little formal ceremony with a dance in a large hall near-by.

I do not think we should bribe a man to get him interested in safe work, but rather offer something as a reward for faithful service.

**CHAIRMAN ADAMS:** Is there any other gentleman who would like to speak on this subject?

#### **REWARD SHOULD BE BASED ON ACCIDENT PREVENTION RECORD**

**MR. J. C. CLARK (Oregon Short Line):** As Mr. Groome just told you there is something of this nature coming up on the Union Pacific System and since I have had the information that we are to meet Saturday for the purpose of discussing this question, I have been turning over in my own mind some of the problems that will have to be met and it seems to me that there is only one object to be attained, that is to get the enthusiastic support of all the employees and officers. The question is how can this best be accomplished. We can make an incentive for each individual to do his best in safety work by offering an individual reward. About the only way that can be done, I believe, is by offering a reward of some nature for the individual who makes the most practical safety suggestion. That system has been followed on a certain railroad in the United States, not a member of this Council, however. My observation is that it has not worked very successfully, although the record of that line is exceptionally good in safety work. It seems to me, however, that the only logical way to award the banner is to base that reward on results to be obtained. In other words, it should be based on the accident prevention record rather than on the number of suggestions offered. In order to establish the reward on that basis, you have to take it away from the individual and it would have to be offered to the shop or the division or the unit of the system. Now, the question in my mind is which way are we going to get the best results. There is no doubt but what the individual who takes the greatest interest in safety should get recognition but how can you give a reward to the individual and still base your reward on the results to be obtained.

I should like to hear what the experience has been of roads that have tried different plans. Frankly, I am in doubt as to the best plan.

#### **B. & O. METHODS IN OFFERING PRIZES AND REWARDS**

**MR. BRONERICK:** I will try and answer Mr. Clark's question. We, the B. & O., firmly believe in offering prizes and rewards, if not done too frequently. As a matter of fact, we have already arranged for an accident campaign beginning October 18, which will run for thirty days. We shall put it on a competitive basis on the grounds that it will compare with the same period of last year, and we shall give a dinner to 100 men on the successful division. We divided that between our Eastern and Western lines. We also give a banner to the successful division. We also intend to offer twenty-five, fifteen, and ten dollars respectively for the three best articles submitted to our magazine on "Accident Prevention".

tion"; this contest is open to all employees of the railroad. The competition for the dinner and the banner, of course, is restricted to the divisions, and the division having the best showing, of course, is the successful one. We have found that to be very beneficial; as a matter of fact, we had a similar campaign last year. Our management did not deem it desirable to conduct it for less than thirty days because they didn't think the results could be shown in a less period.

MR. H. M. MAYO (Southern Pacific): The question was suggested some time ago on one of the roads as to the individual prizes for suggestions. I understood that when they put that into effect the result was that some of the committees were swamped with suggestions and ninety per cent of them were not of a practical nature.

On a certain railroad that operates this method, and has been operating it for some time, I made a comparison of its figures with mine and in spite of what they were doing with their rewards, the figures on my line were just seventy-six per cent better and we gave no rewards whatever.

I would like to ask if, when a reward is offered for a certain period, there is not a slump after the end of that period.

If we could establish a reward for service rendered based upon actual results covering a period of time when these results would really indicate something, cutting out rewards for individual suggestions but basing upon actuality, there might be something in it, but I question, pardon me for that, Mr. Broderick, whether the stimulation which will follow a campaign like yours would be permanent.

MR. BRODERICK: Last year after the National Safety drive was over we, on our own initiative, undertook to continue the campaign for thirty days longer and we made better showing than we did with the National drive.

MR. H. C. HUNTER (Union Pacific): In answer to Mr. Mayo, I just refer to the year's record in the Central Western Region; the standard of the roads during the National Drive was practically the same as over a twelve month period. I believe that our period should be longer, and those of you who were in Cleveland last year remember that I said I didn't like the short period of accident prevention, that if it was worth anything it was worth carrying on indefinitely.

MR. GRODZKI: During these accident drives the Union Pacific system was split into two regions. The Union Pacific proper was in the Central Western Region and got the banner and our own end was in the North and we got the other banner. During that time the General Manager came in one day and said to me, "Grodzki, I was out on the line this week and every place where my car stopped the trainmen, the brakemen, the switchmen, and everybody came running up to the car and asked, 'How do we stand today, Mr. O'Brien?'" Now, that in itself reflects that men are going to strive for a prize. It is in the blood of every American to try to excel and especially if something is offered. However, in addition to the banner I think we should give some recognition to the individuals that helped to make it a go and a success; like, for instance, Mr. Bell's suggestion a moment ago of giving annual transportation to the employees or the safety committeemen of that particular section that make this

bull's-eye. I think that is something that we should consider in addition to a banner. Moreover, I believe it is and will be of greater advantage to make this reward for a little longer period than thirty days, say make it ninety days or six months.

MR. E. S. CHAPIN (Pennsylvania Lines): Along the lines of the last speaker, I believe the competition would be better by having one set of prizes for this week or this month or this two weeks or this three months and when that prize is won, move on another prize and let somebody else get a crack at that, and then move on and let somebody else get it. The idea is always to have a prize up all the time and get as many people interested in that as you can.

CHAIRMAN ADAMS: I would just like to say one word on that subject myself. During the period of Federal control, the regional supervisors carried on just about as much competition as the individuals did, and Mr. Bell, who is located in Chicago, was a mighty smooth artist at that work. He tried to put one over on me in the National drive and he did put it over for a few days. He had Mr. Aishton agree to furnish two beautiful banners costing \$150 to the two highest roads. On the fourth day from the end of the drive I went to Mr. Holden of the Western Central Region and said, "Mr. Holden, this Northwestern bunch is slipping one over on us. They are giving two fine banners." He said, "Adams, we will give three and go one better." We did give three. One to a road of over 2,000 making the best record, one to a road under 2,000 making the best record and one for the terminal that made the best record. I wired some sixty odd safety men four days before the drive ended and that message must have stimulated everybody because the last three days of that two weeks were the best days that we had during the two weeks' period. We had less accidents those two weeks, so there must have been something that intensified those men.

I think to give a banner is an excellent idea and I believe it should be hung up as the results of the year, and the special campaign of one week would be one simply to spread the gospel and stimulate the work.

#### REWARDS NOT NECESSARY

MR. A. W. SMALLEN (Chicago, Milwaukee & St. Paul R. R.): In regard to the banner and various prizes that have been considered for distribution, I don't agree with you gentlemen that the reason you made such a wonderful record was on account of the banner. I don't think the banner had anything to do with that record at all. That record was made by the loyalty of the men to see their own railroads finish first. I believe they would have made the same record if you hadn't offered anything. The fact that they were in a contest to make a showing in the United States was an incentive for them to make a record.

Have we lost our knack of making the movement attractive? We have been in this business about nine years and it is just here lately that I am beginning to hear talk about giving prizes to committees. Personally, on our railroad I think that by paying the men for all the time they spend at the meeting and also allowing them all expenses that they contract by attending, is plenty of reward if they have the proper enthusiasm.

The banner might be all right for a short while but where you do it for a steady diet it isn't going to be long until it won't be attractive. It shouldn't be difficult to get the support of our men. On our railroad we don't have to do that and I don't believe there are many railroads in the United States that have any better records than we have. There may be a few smaller railroads in the United States that have a better record, but I am now speaking of the large railroads, and we have yet to hold out any inducement to our men other than being truthful to them and doing what is right and proper.

MR. S. BREADY (Pennsylvania Railway): During the accident drive on the Delaware Division of the Pennsylvania, and it is being continued with success now, it took the same period of the year before and divided the dates up into innings, arranging a bulletin in the form of a score board, and for every accident over three days, under that date appeared a zero. For every date in which they had no accidents, they put "1". They carried that out during the entire drive and added the total number for 1918 and 1919 showing which team won. They carried that out with considerable success. The men are very anxious to get to the bulletin board to see what the score is of this month compared with the same month the previous year.

CHAIRMAN ADAMS: We have two more subjects on the program. Is there anything further to say on this subject?

MR. CARROW: I move that we proceed to the next subject.

(The motion was seconded.)

CHAIRMAN ADAMS: I would like to read a message that we just received.

"Wabash representative should give good account of our activities past year. My inability to meet with the session on account of being in St. Mary's Hospital is a very keen disappointment as I had hoped to be present. Best wishes.

"F. Myers."

MR. CARROW: I move that the Chairman of this meeting be directed to communicate with Mr. Myers and convey our heartfelt sympathy on account of his indisposition and our regret at his inability to be here.

(The motion was seconded and carried.)

CHAIRMAN ADAMS: The next order of business is, "Duty of Safety Committee Members." This discussion is to be led by Mr. Marcus A. Dow, General Safety Agent, New York Central Lines.

## DUTY OF SAFETY COMMITTEE MEMBERS

MARCUS A. DOW, GENERAL SAFETY AGENT, NEW YORK CENTRAL LINES,  
NEW YORK

There is something I wanted to say about the last topic under discussion in regard to stimulation in safety work.

We haven't used the system of rewards that has been discussed here but it may interest you to know of a plan we tried out among our safety committee members which consisted in giving the members of all the committees a banquet at the largest city on the railroad. We gave one

on the Big Four at Indianapolis and one in New York on the New York Central Lines. On a certain date we brought every member to Indianapolis, the General Headquarters of the Big Four, and during the hour from nine o'clock in the morning until noon, the committees adjourned to rooms that had been set aside in the hotel to hold their regular monthly committee meetings. At twelve o'clock noon they adjourned to the banquet hall where we gave them a first-class spread. We secured some of the best artists and we gave them an hour of real fun and entertainment. Following that we spent the rest of the afternoon in a sort of safety conference, such as you are conducting here, the General Manager acting as toastmaster, and outside of myself the only other speaker on the program were representatives from each one of the employee organizations. The plan was so successful that we have repeated it on the Michigan Central Railroad and on the New York Central later. It elicited so much favorable comment that last year at the time of the National Railroad Accident Prevention drive we concluded to extend the plan similar so that all the employees and their families could have the benefit of it and so we started out with a series of twenty-nine safety rallies in each one of the large important cities on the system and we took along a singing cabaret and several vaudeville entertainers on the trip and we opened up these rallies with one of our first-class shows, just as good as they pay one dollar to see anywhere, and followed it up with one of our safety lessons including a lecture by myself and picture film and we found that that combination of giving the men a good entertainment followed by the safety lessons was certainly greatly appreciated.

The theaters we employed in all these twenty-nine cities were packed to capacity. We had to turn hundreds away and in some of the towns we were obliged to start the first performance at seven o'clock and hold a second one at nine to accommodate the crowds.

It was so successful that on November 6 I am starting out with the same sort of a vaudeville outfit and we are going over the entire system with another four weeks' tour, holding thirty safety rallies.

Last year I talked to 60,000 employees and their families during those four weeks and this year with additional towns and theaters we have engaged, we expect to reach at least 80,000.

#### DUTY OF SAFETY COMMITTEE MEMBERS

One of the first duties of a safety committeeman is to report unsafe conditions, but I don't think it is necessary for me to say very much about that feature of the safety committee man's work because the first thing that any safety committee man is going to think about is the correction of some unsafe condition that he has in mind which he thinks ought to be corrected.

I am taking for granted that you attend the meetings of your safety committees and help to inspire your safety committee men with your words of wisdom and your instructions as to the methods they should pursue in carrying on their work, so I am going simply to give you one or two illustrations of the way we endeavor to impress our own safety committee men with the thought of service to their fellowmen in con-

## **SAFETY CONGRESS**

nection with the correction of unsafe conditions. I think that the first thing to impress upon the committee members is that unsafe conditions must be reported promptly so that action or correction may be made before some one is injured, not waiting even for the meeting of the divisional safety committee, if it is a glaring hazard and where an accident is sure to happen to the first person to come along and come in contact with it. It doesn't do any particular good to lock the barn door after the horse is stolen, neither can you put a man's leg back after he has lost it, nor can you compensate for pain and suffering of a broken limb by simply fixing up the thing that caused it, and say, "Well, anyway no one else is going to get hurt there." Of course, I don't mean to say that it does no good to correct an unsafe condition after an accident happens—it is necessary to do that to prevent the recurrence of the accident—but you must impress upon the safety committee man from the very first instant of his appointment on the committee that he must lose no time to correct the unsafe conditions, that he must be alert and watch for those conditions and get them corrected before some one is hurt.

### **CORRECTION OF UNSAFE PRACTICES**

The second suggestion is regarding the correction of a specific unsafe practice in which the committee man may observe some of the employees indulging.

At a recent meeting of one of our committees a brakeman was called on and asked what he had done in the interest of safety aside from the correction of unsafe conditions that had been discussed at the meeting. He got up and he told this story: He said that he was down in the railroad yard a few days before and a drawhead was pulled out of a freight car and the conductor of the train wanted to couple that car back onto the train by means of chains, so he signaled the engineer to back up the rest of the train to this car. He didn't want to hit that crippled car too hard and perhaps kick it away a foot or two which would necessitate a second attempt and perhaps consume another minute's time, and so to save that minute's time this conductor went in between those cars just as they were about to come together, stooped down, took hold of the anglechuck on the end of the moving car, intending to turn it so as to stop the train just right without taking the risk of kicking the other car away, thereby running the risk of having his head crushed to a jelly. This brakeman said, "My heart stood still for a moment, then I jumped forward and grabbed him and pulled him out and said, 'Say, old pal, do you realize the risk you are taking of making your wife a widow and your children fatherless?'" The conductor thanked him and swore he never again would take such a chance.

Now, my friends, that is the sort of co-operation on the part of safety committee members that is needed to make the safety work a complete success. You must drive the thought into your safety committee members that the mere slogan "Safety First" counts for nothing unless they realize the full meaning of those words. They must realize that these two words, Safety First, stand for a principle and if they believe in that principle,

if they believe it is good, and if they believe it is better to be careful than crippled, if they believe it is better to eliminate the unsafe practices than it is to make widows and orphans and cause all the attending suffering and hardship and sorrows that accidental injury brings, if they believe in that, then they must rally to the support of that principle, not only by correcting the unsafe conditions, not only by being careful themselves, but by doing a constructive, co-operative, and everyday work in bringing their fellow employees to the support of that principle and that they can best do by talking, talking, talking safety in a forceful emphatic way to employees with whom they come in contact in their daily work.

#### HEART TO HEART SAFETY TALKS

The third proposition is along those same lines, not necessarily waiting until they observe a fellow employee indulging in some unsafe practice to talk to him. We have had a rule for some time in our safety committees requiring every member of a committee, after the rest of the business of the committee has been completed, to get up and give the names and addresses of at least two employees not members of the committee to whom they have given a heart-to-heart talk on the subject of safety since the last meeting. You would be surprised at the way in which that idea has developed among the safety committees on the New York Central Railroads. A short time ago the superintendent of one of the divisions, the chairman of the committee, wrote a letter to all the members of his safety committee and asked them if they would send to him a letter containing suggestions as to how the safety work on the division might be improved and the general tenor of the letters of every one of those safety committee members of the roads were along the same lines, to get after the unsafe practices. Now, a few years ago we would have been astounded if we had received any such bunch of letters from a safety committee, but every one of those members had that thought imbedded in his mind of talking safety to his fellow men, getting them to eliminate the unsafe practices. While the rules of our committees require that they furnish the names of two men to whom they have given these heart-to-heart talks, you would be surprised to know that there are some men who come in with a list of twenty-five or thirty names of men to whom they have talked along safety lines.

The other day I talked over in the general session and said something about creating an atmosphere of safety among the great rank and file of the workers, and it does seem to me that the great majority of accidents to railroad and industrial employees can only be prevented when all the employees and all the officers get together and create an atmosphere of safety, an atmosphere of carefulness, an atmosphere in which the germs of carelessness cannot live, and that is only going to be accomplished by the exercise of leadership on the part of those who have the privilege of leadership, that means the officers, the division officers, the higher officials, the superintendent, the foremen, and it also means the safety committee men because there, in my opinion, is where the safety committee man has the greatest opportunity to do real constructive work in safety, that

is by having the safety man, the superintendent, or whoever instructs him in his work when he starts out, to instill in him a spirit so he will go out and exercise real leadership in safety work.

#### **SAFETY WORK SPOILED BY WRONG METHOD OF APPROACH**

The safety committee man must, however, be very careful as to his methods of approach when he talks to his fellow employees on the subject of unsafe practices. A safety committee man may spoil his work entirely by a wrong method of approach. Let me tell you of one little instance illustrative of what I mean. In a certain yard near a roundhouse, an engine man, a member of the division safety committee, was walking along and he observed a depression near the lead track which he considered was a stumbling hazard and liable to cause injury. He saw a hostler working near-by and he addressed him, if I am able to repeat the language correctly, somewhat along these lines: "Hey, you redheaded-son-of-a-sea-cook, bring a shovel over here and fill up that hole; what do you mean by leaving a condition like that laying around here?" Mr. Hostler, who had a very human interior inside of his grimy exterior answered Mr. So-and-so in three choice familiar words. The engineer realized the mistake he made and went over and got the shovel himself and filled that hole and the hostler saw him do it and he felt very uneasy. About an hour afterwards he sheepishly walked up to this engineer who was in the vicinity and said, "I am sorry I didn't fill up that hole but I didn't realize that you were trying to prevent some one from getting hurt." There is just an instance where a wrong method of approach spoiled the intention of the safety man. The committee men I think should be impressed that in giving their talks it must be done in a friendly manner; there must be no wrangling nor spirit of antagonism in carrying out this work.

#### **CORRECT THE LITTLE THINGS AND REDUCE THE GREAT TOTAL**

Another point that I should like to mention is that the committee man must be impressed with the fact that his duties will consist very largely, if he is to be a successful committeeman, in the correction of little things. When a train is wrecked and a number of passengers or employees are killed in one of those deplorable accidents that occur now and then, we read about them in the newspapers under great glaring headlines and every one is appalled at the great sacrifice of life and limb that occurred in that accident; but I say to you, and you must convey to your safety committee members this same information, that the great majority of injuries to railroad employees do not occur in these so-called big accidents but they are in the single, solitary tragedies that occur day after day, almost hour after hour, with ceaseless regularity and from apparently trivial things that could have been corrected without any great effort on any one's part. A board left lying on the ground with a nail sticking up in it may seem a little matter hardly worthy of consideration, the committee man or any other employee may observe that condition and walk around it and not be injured; but another employee not so fortunate as

he may not see the nail and step on it and badly injure his foot. The part of a coupler left lying on the ground close to a track where it forms a stumbling hazard may appear to your newly appointed committeeman a trivial matter and hardly worthy of his attention because he is looking for bigger game, but suppose some employee should come along riding on a car, perhaps in the dark, alight from the car, and stumble over that obstruction, and fall sprawling under the wheels to be dragged out a helpless cripple, to be for all his days, if he lives, a burden to himself and to his family, a poor unfortunate wreck of a human being who has been wracked by pain and soured by the bitterness of his lot, and all because some thoughtless, careless fellow employee left material lying where he knew it should not be and did not take the time or did not think to remove it. Can that still be a little matter? No, indeed; we all know it would not, but that is the thing that you must impress upon your safety committee member that he must look after the little thing that will come to his attention and observation every day, because it is those little things that go to make up the great total of accidents among the railroad employees.

To sum up then, it seems to me that there are a few cardinal and important points that must be impressed upon the safety committee members as to their duties. First, that they must observe and correct the unsafe conditions; second, that they must report and take up for correction those conditions promptly and before some one gets injured; third, that they must watch for and correct the fellow employee whom they saw indulging in some specific unsafe act which their judgment tells them is liable to cause an injury; fourth, that they must help to create the atmosphere of safety among the great rank and file of the workers by their personal effort, by word of mouth, and then by force that will come from the faithful service of a heart; fifth, that they must remember that it is the little things that they can correct and thereby obtain the biggest results in the aggregate in their safety work.

Make your committee men feel that they had a very definite responsibility in the recent great war. The aeroplane scouts were the eyes of the earth. They were trained to scent danger and they were continually flying back and forth over the enemy lines and back areas watching for the slightest move on the part of the enemy that might send danger on to our troops, likewise is the safety committee member the eyes of the great army of railroad workers, and they, too, are trained to scent danger and they must be trained to be ever alert, quick to observe the danger, whether it be an unsafe condition or an unsafe practice, and get after it and correct it before a fellow employee is seriously injured or killed.

#### DISCUSSION

MR. J. A. McNALLY (Wabash Railroad): Mr. Dow remarked that he was in the habit of having his committee men name the men to whom they had talked during the period from one meeting to another, which I think is very good. We have been following the custom of having our

committee men tell the number of men they talked to but I believe to give the names of the men to whom they talk is better. It is a whole lot like the minister that took up his duties in the congregation that was new to him and his first meeting with them was a mass meeting. He said, "I hardly know whom to talk to and what to talk about, but I am going to ask one question. I want every man in the audience to stand up who has read the 17th chapter of St. Mark." About twelve men stood up. He called them all up around the platform in front of him and said, "I have found out to whom I must talk. You men are the men to whom I will have to talk, because there is no 17th chapter of St. Mark." (Laughter) That is the idea in the safety movement; we want to know whom we are talking to. Is it necessary to talk to the same man continuously or is it necessary to get off that fellow and get onto somebody who needs it?

Here is another incident that happened and there is a man in this hall who will vouch for this. He saw a man shoving a drawbar over with his foot. He ran up to him and jerked him back and said, "Here, that is wrong. shove that bar over with your head."

"Why with my head?", he said.

"Well, use your head for something."

MR. CHARLES JEHLIK (Chicago & North Western): I don't approve of sending a letter to the dangerous man working in the shop. That isn't my motto. My motto is to get right after the man and say, "Here, you are dangerous and you have to do better." Use your diplomacy with this man according to his ability. There is a way to do these things.

I have gotten good results in handling men in the shop. When a new man is hired (and I don't have to be told he is a new man. I keep my eyes open and I can tell he is a new man just the same as anybody could tell I was a stranger in a new part of the country.) I go up to this man and tell him that we want safety first, that I am a safety committee man and the chairman of the investigating committee and I want him to do all he can to help Jehlik get the banner for the Chicago and North Western. Then I say, "Will you do it?" He can't help but say, "Yes". If he says, "No". I will take a committee of three men over there and get him in a corner for about five or ten minutes and we will tell him he has got to, and if he doesn't consent to that, we will report to the superintendent and he will give him the rest and I think he will make a man of him. I think that is the best cure for a new man, a green man that comes into the shop. I don't believe in writing letters to a man when he is in a shop; by the time you write that letter and he gets it, that man may kill a dozen or two. Tell him right there.

If I go down to a terminal depot and see something down there that isn't safe, I will look up somebody that will make it safe. Your place as safety committee man is not only in the position you hold; you can take it home with you; you can give it to your next door neighbor; you can give it to your president or your minister, or bolsheviks or anarchists.

MR. HALE: We have only a minute or two but I really feel it would be a very great misfortune and personal loss to you if you got out of here without having one of my colleagues, Mr. Andy Murphy, Yard Track

Foreman, Kansas City, tell you in two or three minutes why he is a good safety committee member.

Until he sent in his resignation a short time ago he was Vice-President of the National Maintenance Association.

MR. ANDREW MURPHY: I have heard a great deal of talk on safety plans since I have been up here and I am going to say that I have learned a lot. It has been a school of instruction for me.

I want to say something in regard to the prize business as discussed here today. Any man who is a good American citizen and has got the future of the rising generation in his heart ought not to need a prize to make him a safety first man, and ought not to need a prize to make him active in our work. When I find anything that I think isn't safe for my fellow man, I don't wait to go and ask somebody else to fix it, but I do it myself. There is a safety committee meeting every month; I don't have a little book with a little writing and say, "I saw a hole around here and it ought to have been filled up." When Murphy sees a hole, he goes and fills it up.

Our friend Hale came down through our country and you know wherever he goes he always gets the people on his side. He made a great talk on safety, as he always does, and he not only got the Santa Fe employees interested but he got everybody interested, the women, and the children too.

The safety first movement right now is education. The safety first movement will be taught at the family altar, where it ought to be taught; it will be taught in the public schools and it will be taught in the churches. Heretofore, the minister, or the priest, if it may be, laid down the plan whereby you might save your souls, but the safety first movement lays down the plans whereby you may save your body and your soul.

CHAIRMAN ADAMS: If there is nothing more to come before this round table meeting, we will adjourn until nine o'clock tomorrow morning.

ADJOURNMENT.

---

## FRIDAY MORNING SESSION

CHAIRMAN SCOTT: The first number on the program this morning is, "Maintenance of Way and Motor Car Accidents," to be presented by Mr. Arthur Ridgway.

## MAINTENANCE OF WAY AND MOTOR CAR ACCIDENTS

ARTHUR RIDGWAY, ASSISTANT CHIEF ENGINEER AND SAFETY OFFICER,  
DENVER AND RIO GRANDE RAILROAD, DENVER, COLO.

Because of the general character of that class of men which furnishes most of our track labor, and because of the particular kind of work demanded of such men, a high probability of accident among maintenance of way forces is apparently a perfectly natural assumption. These men have no particular vocation, for the wages offered are usually unattractive

to individuals who have made a specialty of any kind of work. Isolation attendant upon the necessity for their distribution along the line of railroad and away from the centers of population contributes very materially toward limiting the available supply to a class of persons who are forced to accept any kind of employment as a last resort in eking out a bare livelihood. The class of men from which maintenance of way forces are necessarily recruited is no less influential in an assumption of high probability of accident among them than a consideration of the character of work which they perform. The materials handled are ponderous, bulky, and exceedingly rough and coarse on the exterior. The hand tools manipulated are necessarily heavy and permit of little latitude of design for convenience and facility of the workman. Moreover, of such kind is the work as to prohibit to a marked degree the use of mechanical devices of a sort to conserve animate energy.

Relatively high probability of accident among these workmen is, however, not a fact and such an assumption is decidedly erroneous, for reliable figures show conclusively that the per cent injured among maintenance of way forces is considerably lower than among railway employees as a whole. For example, a record of two years shows an average of 26 per cent less injuries per one hundred men employed in this department than the average of all the railroad forces combined. Again, the same two-year period shows that in the maintenance of way forces there were 62 per cent less injuries per one hundred men employed, or less than half as many as among all the other so-called unskilled railroad laborers. While this statement is not indicative of the relative immunity from injury of railway maintenance of way forces as compared with other industrial pursuits, it does show that in so far as railway employees as a whole are involved, the maintenance of way men, contrary to expectations, is decidedly less likely to be injured than the average railroad worker.

#### MOTOR CAR ACCIDENTS

To be of any practical value, an analysis of the subject under discussion would seem to demand a segregation of motor car accidents from other kinds in the maintenance of way department. Comparing the two general classes we find that motor car accidents comprise about 14 per cent of the total, and all others, therefore, about 86 per cent. The motor car accidents may be conveniently grouped into four typical classes and their respective frequency compared thus:

|                                 |             |
|---------------------------------|-------------|
| Collisions with trains.....     | 37 per cent |
| Men falling off cars.....       | 32 per cent |
| Derailments .....               | 26 per cent |
| Collisions with other cars..... | 5 per cent  |

An analysis of these four groups leads to the assignment of primary contributory causes as follows:

Collisions with trains—Speed and carelessness

Men falling off cars—Speed, carelessness, and limitation in design of cars

Derailments—Speed, carelessness, and limitation in design of cars

Collisions with other motor cars—Speed

There are thus shown to be three principal contributing factors of which one, speed, is common to all four groups. Perhaps excessive speed in the use of cars can be very largely, if not entirely, attributed to that human instinct common to all mankind which may be described as an almost uncontrollable passion to utilize to the utmost all power and authority vested in the individual. For instance, if a man is given the power of propulsion to travel without inconvenience thirty miles an hour, he will never move at less velocity. The case of the automobile is an illustrious example.

As to the limitations in the design of cars, much may be said. Lightness is the first requisite, for to be of any use at all workmen's cars must be so limited in weight as to be easily handled on and off the track by the number of men they are designed to carry. On the other hand, this very limitation in weight militates against immunity from derailment since many derailments may be ascribed to light weight as a contributing cause. Again, limitation in weight is inseparable from restricted dimensions which necessarily curtail seating and tool carrying capacity both in magnitude and distribution throughout the space available therefor. In fulfilling the fundamental essentials, the designer is also handicapped in properly disposing of the matter of hand holds and grabirons, while provisions for the various forms of tools, separate and apart from their weight, is indeed a serious study. Moreover, the adoption of either the direct or indirect method of drive carries with it a sacrifice of some of the advantage of the other.

The carelessness factor in most motor car accidents is manifested in disorderly seating of men, hasty and thoughtless loading of tools, inattention to car and contents while under way, and wanton disregard of the danger of imperfect flag protection.

#### OTHER MAINTENANCE OF WAY ACCIDENTS

Turning now to a consideration of other maintenance of way accidents in distinction from those attendant upon the use of motor cars, we find the most frequently recurring accidents listed in their order of frequency to be as follows: Struck by flying objects; use of tools not defective; eye injuries; struck by falling objects; use of tools in hands of others.

Among the flying objects which carry destruction in their path may be mentioned spikes not firmly started before a full swing blow of the maul is delivered, nuts cut off track bolts with a chisel or knocked off with a maul, and articles thrown or falling off passing trains.

The unskilled use of non-defective tools such as picks, claw bars, shovels, adzes, and track jacks contributes a very large share of resultant injuries.

Eye injuries originate largely from mushroomed chisel heads, improperly tempered cutting edges, dust and metal scale.

Many of the injuries resulting from falling objects are incurred during the loading, unloading, or otherwise handling materials of one sort or another.

The erratic swinging of picks and mauls and the careless manipulation

of shovels are responsible for a very considerable number of injuries inflicted by tools in the hands of others.

Of all the injuries suffered by maintenance of way employees, more than one-third—35.6 per cent to be exact—are to be found in injured hands and feet, in the proportion of about two in the hands to each one in the feet. A most prolific source of injury to the fingers is in the use of the claw bar when pulling inside spikes. Perhaps the claw is worn and the foreman hasn't taken the trouble or had time to send the bar in for reforming; or perhaps the workman doesn't use care in getting a good bite on the spike; or perchance the spike head is snapped off, but whatever the reason, a wild hard pull often sends the handle end of the bar crashing down on the opposite rail with only a human finger to absorb the impact. Another deep-rooted origin of injury to the hands is to be observed in the many slivers, jagged edges and rough surfaces with which maintenance of way materials abound. Again, maintenance of way materials are of necessity weighty and large in size. Stored in piles or nested in transportation they present no opportunity for a hand hold. The slightest opening between units serves as an invitation to a workman to thrust in his hand and the outcome is often a crushed finger.

Occasionally a man cuts his foot with an adze or strikes it a glancing blow with a maul, but by far the majority of foot injuries occur through the dropping of some heavy object on the toes. Very often this is the result of some spontaneous action of one or more of his co-workers without advance warning. In the handling of railroad materials, the units of which require the combined effort of two or more men, lack of unity of action or movement is almost sure to result in some sort of accident.

#### REMEDIES

A conclusion without a discussion of remedies would be reprehensible. The only absolute cure for excessive speed in the use of motor cars is to render high speed impossible in the design of cars, and notwithstanding the disadvantage of limiting the speed of all cars to a predetermined rate, safety interests apparently demand such limitation.

Through co-operation with manufacturers of cars in the details of design will accomplish much toward a universally satisfactory type of car, and it will surely open a way for a judicious choice of the lesser of any two evils of design.

There is but one wholly effective remedy for curing the most pernicious practice of moving motor cars without flag protection, and that is to require such movements to be conducted under the standard train order system. We are forced to the conclusion, however, that because of the delicate questions involved, this plan is impossible of adoption and that there remains the only alternative of enforcing a rigid requirement of adequate flag protection. To accomplish the desired results, this requirement must be exacted under the most stringent discipline and even trivial violations thereof subjected to extremely careful scrutiny. Perhaps there is no more effective means to the end sought than in justifying these severe disciplinary measures by emphasizing without stint the constantly impending danger involved in unprotected car movement. The unsys-

tematic loading of men and tools, primarily due to simple thoughtlessness, can generally be eliminated by patient and specific admonition.

The most potent instrument in combating the persistent menace of other maintenance of way accidents is available in the form of a prudently administered campaign of education; in fact it is about the only recourse. There is in this suggestion no intended implication that these men of brawn are necessarily of inferior mentality, for no one human is superior to any other outside their respective spheres of mental activity. It means simply that thus far no educational opportunities have been available. Briefly stated, they have never been told. Herein lies the golden opportunity, for first teachings are always lasting in developing character-forming habits. It may be that verbal dissemination of information through personal contact between officer and men seems the proper course to adopt, or it may be considered advisable to use the medium of the printing press, but whatever plan is adopted, the whole propaganda must be administered in homeopathic doses so to speak. Any complete set of rules and regulations, or even any compendium of advice, if at all comprehensive, would appear so formidable as to be repugnant to the men and thus defeat the very purpose of the promulgation. Nor can the ultimate end be accomplished at one fell swoop. Education, like the formation of character, is a process of evolution and involves the element of time in its assimilation. No astonishingly precipitate results, therefore, should be expected, but rather should commensurate returns be looked for only after months or years of effort. The essence of the safety work consists in the meeting on common ground of the teacher and the taught. Any other attitude is sure to be productive of a failure worse in its effect than entire absence of interest. Success is assured only to the extent that patience, forbearance, and kindness pervade all activity in this direction.

Finally, the "tide in the affairs of men" is at flood. Education in safety matters opens the door for the promulgation of "Americanism", for the development of good citizenship, and for service in humanity's cause.

#### DISCUSSION

CHAIRMAN SCOTT: You have heard this very valuable paper from Mr. Ridgway, and he must be an authority on this subject, or he could not have presented it to us in the manner in which he has done.

I am going to take the privilege of undertaking to direct this discussion so that we can get as much out of it as we possibly can. We are all here to get ideas. We can go back home full of enthusiasm and inspiration, but we must have ideas to put this thing over.

We have heard this paper of Mr. Ridgway's on "Maintenance of Way and Motor Car Accidents." He tells us that fourteen per cent of the accidents are attributable to causes of that sort. Now, let's see if we can't get something out of this paper and take it back home and cut down the fourteen per cent.

#### SAFE SPEED FOR MOTOR CARS

Let us take up first the subject of speed. Mr. Ridgway has told us that we must co-operate with the manufacturers to see if the speed of

these cars cannot be reduced, because if they are geared up to sixty miles an hour the man who is operating the machine is going to run it sixty miles.

Now, let's have a full and free discussion. If any man in this room has a thought or idea that he can give us let's have it.

MR. E. S. CHAPIN (Pennsylvania Lines): Whatever you decide here that you would like to have incorporated into your engines or motor cars, I should be glad to place it before the Engineering Section. That is the kind of work the Engineering Section is looking for.

MR. W. A. YOUNG (Oregon Short Line): I note in the remarks that a great many accidents are due to falling off of motor cars. We on the Oregon Short Line have adopted the safety hand rail which I am sure will be a great benefit to all employees. I think as a means of safety it ought to be universal throughout the United States that the safety rail be put on motor cars.

MR. McNALLY: I have had considerable experience for the last sixty days with motor cars, in view of the fact that I have gone over almost the entire Wabash system, and I find a good many of our accidents are due to speed, and that is a good thing for the Engineering Department to consider.

These grabirons on the motor cars are a very good thing and we are equipping them now as fast as we can. The only serious accident we have had this year was the death of one of our section men. Unfortunately, this car was the only one on the division between Kansas City and St. Louis that did not have the grabirons on it.

We have on the back end of the car a little slot to put the toe of the jack in to keep it from falling off. We also put a tool box on the side of the car. I don't know how many of you men will approve of that but we have found it has done away with tools falling off and derailing the car. The box is not quite as long as the car, it reaches about half-way over each wheel. That gives you a chance to carry all your tools on the outside of your car and gives plenty of room for the men to ride.

Another thing, it is necessary to educate men on flagging. We had an engineer turn in a card and letters all in view of the fact that he got a flag that caused him to go off the track where they had a rail up. This man stood on the track with a red flag in his hand, with no stick on it, waving it like this when he could see the engineer in the white of his eye. His body acted as a background and the engineer couldn't see anything until he was right on him and the consequence was he went around the curve and went off. Fortunately, no one was injured.

We had another complaint from an engineer where a section man had given him the high ball with his red flag. We asked this foreman if they instructed their men how to flag when they sent them out. "Sure, we always send out an old man," he said. I said, "If you are in the least doubt as to whether these men know how to flag, have them go down the track and show you what they are going to do when a train comes down the track." It is necessary for these men to have a flag on a stick at all times, also torpedoes, and they should give an engineer the full benefit of the flag clear across the track.

MR. W. J. ORR (Toronto, Hamilton and Buffalo): All our men are supplied with first-aid boxes and I instruct them in safety and first aid before I place the box with them and they are supposed to carry those boxes on the cars.

CHAIRMAN SCOTT: I should like to get some information for the benefit of myself and others here with reference to the rate of speed that is permitted under the rules of some of the larger systems represented here this morning.

MR. TABERT (Chicago & North Western): We, on the North Western, have a rate not to exceed twelve miles per hour.

MR. ADAMS: If you recall, last year we took up practically a half day in discussing the speed of motor cars. It was a subject in which much interest was manifested and there was finally a resolution put through that the Steam Railroad Section, or the Executive Officers of the National Safety Council would handle this some way with the manufacturers restricting the gear to a speed of fifteen miles an hour. It occurs to me that something should have come from that action. Now, if we are to meet annually and discuss the same subject over and over and then not put it to a final conclusion, it seems to me it is "love's labor lost."

MR. RIDGWAY: I should like to ask the gentleman from the North Western how he restricts the speed to twelve miles per hour?

MR. TABERT: We have our cars adjusted that way.

MR. W. E. DEBLER (Union Pacific): We have a speed limit of twenty miles per hour where the track is not obstructed in any way from the view of the operator, and as far as accidents are concerned on our railroad, a very small percentage are due to excessive speed. I don't believe that motor cars should be turned out by a manufacturer that will only produce fifteen miles per hour. There are times with a speed of twenty miles per hour you can get away from a train or some accident which would occur if you did not have the speed. As far as motor cars are concerned at the present time, I don't think that they are able to go much over thirty or thirty-five miles per hour with a gang. They will do that light, but with a gang their horse power is very limited, and I would suggest that the matter of speed be discussed along that line.

#### SERIOUS MOTOR CAR ACCIDENT

MR. A. V. ROHWEDER (Duluth, Missabe & Northern): The matter of speed on motor cars out in our territory has been discussed several times. We had perhaps one of the most serious motor car accidents, in fact two of them, this year in which five of our employees were killed on one road and it wasn't due to speed.

The gentleman that just spoke brought out a point that I think ought to be considered. Out in the Western country where you have long fills and hard places to take a car off and you are ahead of a train, if you can get twenty-five or thirty miles an hour out of a car you perhaps can get to a place where you can take the car off conveniently, especially where you have only two, and in some cases only one man on the car, due to the shortage of help.

Another thing, you will find if you gear a car down the fellows can change the speed readily when they get next to it.

Undoubtedly, it will be of some value to give you briefly an account of the accident in which we had four employees killed and eleven people injured. It occurred in this way: On July 26, Sunday night, there were two motor cars on our line and the portion of the line on which the accident happened is single track. One bunch of the fellows had been up to a ball game, a distance of about thirty-five miles, and they were coming home. It was a clear moonlight night and they were going at a pretty fair rate of speed. The other bunch was a bridge gang who had been over on the main line repairing a bridge and were returning to their terminal. About 10:30 or 11:00 o'clock they came together head-on in a cut. It was found that the accident was due to two causes. Neither car had a light on it, and there is a rule prohibiting the use of motor cars for any other than company business by employees.

We had always expected every man in the section gang, or any one else operating a motor car, to use a hand lantern, and we found upon investigation after the accident that in a large number of cases that lantern would go out, due to the vibration of the car. We are now equipping all motor cars with a presto light tank, the same as on the old original Ford, with a red light to the rear and a white light to the head end. We found that that was the only practical way in which we could be assured of a light on those cars. We have also put on a metal flagging equipment case containing torpedoes and a flag.

CHAIRMAN SCOTT: We all know that resolutions are fine things, but we want to know if there is any railroad represented here that has by educational methods or mechanical devices been able to limit the speed at which the motor cars are being operated on his railroad.

MR. JOSEPH T. PRATT (Reading System): All cars purchased by the Reading do not exceed a speed of twenty miles an hour.

MR. R. L. FILLING (Louisville & Nashville): The L. & N. runs fifteen miles an hour. It is an educational feature. They educate the men in that line and have issued instructions to all section men having charge of motor cars. I don't think it is advisable to change the speed on any car, any more than it is to remove the whistle from an engine to keep the engineer from whistling whippoorwill.

MR. CHAPIN: May I ask whether any of the cars are equipped with anything like a speedometer so if the men are told to keep fifteen miles an hour they would know they are at that speed?

MR. T. R. McCAMPBELL (Cleveland, C. C. & St. L.): I think the problem of speed on motor cars is pretty much a matter of education. Now, the M. and W. Department of our railroad regulates the speed of motor cars to twenty-five miles an hour through the rural regions and ten miles an hour through cities and towns and that speed must prevail at highway crossings where the view is not absolutely good. Our superintendents have asked their safety committee men especially on motor car accidents, to report specific violation of speed rules. I believe that is the only solution for the regulation of speed of motor cars. We have grades on our railroad, and I presume other lines have also, where we maintain as low

a speed as twelve miles per hour. It would be a difficult problem for the motor car to reach the top of the grade when only running ten miles an hour at the bottom unless it had a powerful engine.

Some one suggested having a speedometer. We who are old in train service know what we used to do with speedometers and recorders. You can always adjust those things. The man who works with those things soon becomes as familiar with them as the man who manufactures them. I believe the solution is through education.

CHAIRMAN SCOTT: Is there any one here who has anything to say in a general way on this motor car question?

MR. CARROW: I should like to ask, Mr. Ridgway, what effect the safety movement has had on you and what effect you predict it will have on officials of railroads in respect to making them appreciate the importance of paying attention to the details which heretofore, I believe, are generally considered to have been overlooked by those high in authority.

MR. RIDGWAY: Since I have been placed in charge of safety work on our line, there have been thousands of little things of a dangerous nature that have come into my mind that never were thought of before. The same is true of the men. They see a multitude of little things that they never saw before.

MR. CARROW: I want to ask one more question. Do you feel that the time that you devote, or the time that any other officers devote is of sufficient importance to counteract or overbalance the good that is derived from any attention that they might pay to safety work?

MR. RIDGWAY: I can answer that in just one word: Infinitely.

CHAIRMAN SCOTT: It seems to me that we have all profited by this discussion and by the presentation of Mr. Ridgway's paper, and unless there is something further to come before the meeting in connection with it, I should like to know the pleasure of this body with reference to this particular paper.

#### SEASONABLE EMPLOYMENT SHOULD BE DISCONTINUED

MR. P. J. McANDREWS (Chicago & North Western): There is just one little thought that occurred to me in connection with this address by Mr. Ridgway. We have heard a great deal about the old man getting injured and the new man taking his place, leaving a hazard for the rest of the employees. One thing has been carried out in the maintenance of way work that brings about this very result without the men getting injured and that is seasonable employment. In the Road Masters' Association, of which I happen to be an officer, we have been for a number of years recommending that seasonable employment be discontinued wherever possible to do so and it can be done on a large percentage of the lines of the United States. The old practice of the general manager coming down the first frosty morning and laying off all the section men and compelling that section foreman to employ a new crew next year ought to be stopped, because that gives us new men every spring and increases the number of accidents because it has produced a whole lot of inefficiency. Get your men working the year 'round.

**MR. RIDGWAY:** I want to say amen to all that Mr. McAndrews has said. Perhaps one of the most able addresses ever given before the Steam Railroad Section was that of yesterday by Mr. Dunn of the "Railway Age." Mr. Dunn is an enthusiastic advocate of continuous employment.

I want to corroborate what Mr. McAndrews has said to this extent: That there is no one thing that we can do that will reduce accidents in the Maintenance of Way Department more than by giving continuous employment to these men who do our hard labor.

I believe that the influence of this Steam Railroad Section would be felt very materially by the management and by the executives of railways if we could in some way express our opinion to the effect that one of the most efficient ways of reducing injuries of maintenance of way employees would be in continuous employment.

**MR. BROPHY (Union Pacific):** I agree that education is a prevention of accidents, and in regard to the speed of motor cars, I am not in favor of the manufacturer turning out a motor car for us with a limit of speed, as I believe that our section foremen and all our supervising officers understand what safety means in regard to speed. Another question in the operation of motor cars and that is the movement of a car on a double track while a train is passing. All our cars stop and the men get off while a train passes to avoid anything falling from the train and striking them if they were on the car. I have spent a good deal of time on motor cars. I suppose that I covered not less than 500 miles a month and I find that the men out on the track operating cars are operating at a safe speed and under flag protection. That is education.

Speaking about new men coming on and not understanding the methods, every foreman of the bridge and building department on our division has instructions to explain to the new men the first morning they come to work the dangers that they might encounter by unsafe practices in the operation of motor cars or any other tool that they might use, and it is education and confidence of the men in safety operation on your railroad that gets results.

(It was voted that Mr. Ridgway's report be accepted and placed in the Proceedings, with a vote of thanks.)

**CHAIRMAN SCOTT:** I am going to ask our new presiding officer, Mr. Carrow, to take the Chair.

(Mr. Carrow took the Chair.)

**CHAIRMAN CARROW:** It affords me great pleasure to introduce to you Mr. W. P. Borland who will now address you.

**MR. W. P. BORLAND (Chief of Bureau of Safety, Interstate Commerce Commission, Washington, D. C.):** I feel it a great honor and a pleasure to be permitted to address you today upon the safety work of the Interstate Commerce Commission, because it gives me an opportunity to clear up some misapprehensions about the scope and purpose of the safety work of the Interstate Commerce Commission.

The Bureau of Safety of the Interstate Commerce Commission is concerned with the enforcement of law. The scope of its work goes to the proper administration of those laws. Outside of that field it has no duty to perform and just the moment it gets outside of that field it is liable

to get its fingers burned, so we keep clear. We continually get complaints about safety conditions of all descriptions existing upon all railroads of this country over which we have absolutely no jurisdiction. We can do nothing with them whatever because when we get through enforcing our laws, we are done; and the minute we attempt to do something which the law does not empower us to do, why we are liable to get in bad. The only thing we can do when we get these complaints about safety matters, unsafe conditions rather which exist, that come outside of our jurisdiction, is to refer the parties making those complaints to the safety organizations of the various railroads and we hope they will take care of them.

## **SAFETY WORK OF THE INTERSTATE COMMERCE COMMISSION**

**W. P. BORLAND, CHIEF, BUREAU OF SAFETY  
INTERSTATE COMMERCE COMMISSION, WASHINGTON, D. C.**

There are two bureaus of the Interstate Commerce Commission which are directly and primarily concerned with the question of safety in railroad operation, namely, the Bureau of Safety and the Bureau of Locomotive Inspection. The activities of the Bureau of Safety are divided into four sections:

1. Enforcement of the safety appliance law
2. Enforcement of the hours of service law
3. Investigation of accidents
4. Investigation of block signals, automatic train stops, and other safety devices

As its name implies, the Bureau of Locomotive Inspection is charged with the administration of the locomotive inspection law.

### **THE BUREAU OF SAFETY**

The organization of the Bureau of Safety includes fifty-four inspectors; forty-two of them are safety appliance inspectors, ten are hours of service inspectors, and two inspectors whose principal duties are the investigation of signals which have been involved in accidents and of safety devices of various forms which are presented to the Commission for consideration. The services of all these inspectors are utilized for the investigation of railroad accidents, and for other special investigations as required.

### **THE SAFETY APPLIANCE LAW**

The original safety appliance act was passed in 1893 and was amended by subsequent acts in 1896, 1903, and 1910; and under a provision of the act of 1910 the Commission in 1911 issued an order prescribing standards for safety appliance equipment, which standards became fully effective March 1, 1920. The federal requirements for safety appliance equipment on cars and locomotives now cover practically all appliances

which are used by train service employees in making up and operating trains, including power brakes, hand brakes, automatic couplers, grab-irons, handholds, hand rails, ladders, sill steps, running boards, foot-boards, and similar devices as applied to cars and locomotives of different types, the number, dimensions, location, and manner of application of these appliances being specified.

The safety appliance inspectors are assigned to certain prescribed territory; for this purpose the United States is divided into twenty inspection groups and two inspectors are assigned to each group; two of the inspectors are not permanently assigned to any territory but are detailed for services where conditions may require special attention. These men make regular inspection of equipment, the results of which are tabulated and also promptly furnished to each railroad company on whose lines the inspections have been made in order that an accurate check may be had upon safety appliance conditions on each line and if necessary corrective measures may be taken. In cases where the requirements of the law are being flagrantly disregarded, the inspectors secure evidence of violations of the law, upon the basis of which prosecutions are instituted in the federal courts.

In this manner there are inspected annually approximately one million freight cars, and twenty-five or thirty thousand each of passenger cars and locomotives. The following tabulation summarizes the results of this inspection work for the past six fiscal years.

|                 | 1915      | 1916    | 1917      | 1918      | 1919      | 1920    |
|-----------------|-----------|---------|-----------|-----------|-----------|---------|
| Freight cars:   |           |         |           |           |           |         |
| Inspected       | 1,000,210 | 908,566 | 1,100,104 | 1,059,913 | 1,023,942 | 864,775 |
| Defective       | 47,754    | 33,715  | 40,123    | 41,563    | 37,893    | 39,698  |
| Pct. defective  | 4.77      | 3.72    | 3.64      | 3.92      | 3.70      | 4.59    |
| Passenger cars: |           |         |           |           |           |         |
| Inspected       | 33,427    | 27,220  | 29,456    | 25,732    | 23,712    | 19,849  |
| Defective       | 954       | 496     | 252       | 145       | 92        | 153     |
| Pct. defective  | 2.85      | 1.82    | .85       | .56       | .39       | .77     |
| Locomotives:    |           |         |           |           |           |         |
| Inspected       | 38,784    | 31,721  | 37,199    | 33,806    | 30,707    | 23,883  |
| Defective       | 1,575     | 1,161   | 1,003     | 740       | 566       | 570     |
| Pct. defective  | 4.06      | 3.66    | 2.69      | 2.18      | 1.84      | 2.38    |

The express purpose of this legislation is to promote the safety of travelers and employees on railroads, and with respect to employees this purpose is accomplished by establishing proper standards for safety appliances, providing uniformity in this equipment and requiring it to be properly maintained. While it is impossible accurately to tabulate the beneficent results of this legislation, it cannot be doubted that there are thousands of men now actively engaged in useful railroad service who would have been maimed or killed if this law had not been enacted and properly administered. A reference to accident statistics, particularly coupling accidents, is illuminating, as shown by the following tabula-

tion covering the years 1893, when the original law was passed, 1900 when the original law became effective, and 1918, the last year for which statistics are available:

|                                                     | 1893      | 1900      | 1918 <sup>1</sup>        |
|-----------------------------------------------------|-----------|-----------|--------------------------|
| Number of trainmen employed                         | 179,636   | 191,198   | 226,936 <sup>2</sup>     |
| Total casualties to trainmen                        | 20,044    | 18,967    | 44,550                   |
| Total coupling casualties                           | 9,063     | 3,991     | 2,972                    |
| Percentage, coupling casualties to total casualties | 43.33     | 21.04     | 6.67                     |
| Tons carried one mile per trainman employed         | 520,987.5 | 740,589.1 | 1,738,223.1 <sup>2</sup> |

<sup>1</sup>Calendar year; casualties to trainmen on duty resulting from train accidents and train-service accidents.

<sup>2</sup>For year 1917, trainmen employed on Class I roads only.

#### THE HOURS OF SERVICE LAW

The hours of service law, enacted in 1907, limits the hours of service of railroad employees engaged in or connected with the movement of trains to sixteen hours within any twenty-four period, and provides that an employee who has been on duty continuously for sixteen hours shall not be required or permitted to go on duty again until he has had at least ten consecutive hours off duty; an employee whose period of duty has been broken but who has been on duty sixteen hours in the aggregate in a twenty-four hour period must have at least eight consecutive hours off duty before he can resume duty. Train dispatchers, operators, and other employees who use the telegraph or the telephone for transmitting or receiving orders pertaining to or affecting train movements are limited to a maximum period on duty in any twenty-four hour period of nine hours at continuously operated offices, and of thirteen hours at offices operated during the daytime only, except that in case of emergency they may be permitted to remain on duty for four additional hours not exceeding three days in any week. Certain additional exceptions are also provided by the terms of the law; the law does not apply to wrecking crews, or in case of casualty, unavoidable accident, act of God, or where the delay was the result of a cause not known to the carrier or its officer at the time the employee left a terminal and which could not have been foreseen.

There are nine hours of service districts, one inspector being assigned to each group, and one unassigned inspector is detailed wherever his services are required. These inspectors periodically check the railroad companies' records of the time on duty of employees subject to the law, and when circumstances require punitive measures, they procure evidence of violation of the law upon which prosecutions are instituted. Numerous complaints alleging nonobservance of the law in specific practices or localities are received by the Commission, and these complaints

are referred to the hours of service inspectors for investigation and report.

As previously noted, the terms of the law permit so-called excess service under certain conditions, and in conformity with an order of the Commission the carriers furnish monthly reports, under oath, of cases of excess service which have occurred on their lines, together with the reasons therefor. These reports are tabulated and annual statistical tables are published, the instances of excess service being classified according to causes. The following tabulation contains data relative to cases of excess service reported for the past several years.

| Year | Total Number of Railroads Filing Hours of Service Reports | Number of Railroads on Which Excess Service Was Reported | Number of instances of service in excess of the limitation prescribed by law |                     | Total instances of excess service reported |
|------|-----------------------------------------------------------|----------------------------------------------------------|------------------------------------------------------------------------------|---------------------|--------------------------------------------|
|      |                                                           |                                                          | Employees in train service                                                   | Telegraph operators |                                            |
| 1913 | 1,194                                                     | 455                                                      | 269,392                                                                      | 31,094              | 300,486                                    |
| 1914 | 1,238                                                     | 419                                                      | 136,631                                                                      | 25,650              | 162,281                                    |
| 1915 | 1,186                                                     | 451                                                      | 63,248                                                                       | 14,013              | 77,261                                     |
| 1916 | 1,189                                                     | 443                                                      | 79,046                                                                       | 19,266              | 98,312                                     |
| 1917 | 1,146                                                     | 487                                                      | 106,740                                                                      | 28,773              | 135,513                                    |
| 1918 | 1,086                                                     | 424                                                      | 206,184                                                                      | 58,237              | 264,421                                    |
| 1919 |                                                           |                                                          | 82,620                                                                       | 67,773              | 150,393                                    |

#### INVESTIGATION OF ACCIDENTS

Under the accident reports act of 1910, the Commission has been investigating and reporting upon serious railroad accidents for the past ten years. The law authorizes the Commission to prescribe the method and form of reports of accidents to be made by the carriers, and provides that it shall have authority to investigate collisions, derailments, or other accidents resulting in serious injury to persons or to property, and make reports thereon, including statement of cause and such recommendations as the Commission deems proper.

Under an order of the Commission, the carriers are required immediately after the occurrence of a collision, derailment, or other accident resulting in the death of one or more passengers or employees on or about trains, engines, or cars, to report the same by telegraph to the Commission. These telegraphic reports are referred to the Bureau of Safety; if a report indicates that an accident is of sufficient consequence to warrant investigation by the Federal Government, or if it appears that an investigation would develop information regarding operating conditions or practices concerning which recommendations looking toward increased safety in railroad operation should be made, inspectors who may be located near

the scene of the accident are assigned to conduct an investigation. Investigations are usually held jointly with railroad officers and, when investigations are made by the state authorities, with representatives of the state commissions as well. When question is raised as to the proper operation of signals or other devices, or when an accident has resulted from a broken rail or failure of other structure or material, engineers of the Bureau who are qualified to deal with these technical problems assist in the investigation and conduct of such tests as may be necessary to establish the cause of the accident.

Reports upon accidents investigated are prepared by the chief of the Bureau of Safety and after approval by the Commission are transmitted in each case to the president of the railroad on which the accident occurred. In the case of the more disastrous accidents, and when operating conditions and practices disclosed by the investigations present lessons of general application, the reports are printed in full and promptly made public. And all of the accident investigation reports are published in condensed form in quarterly summaries of accident investigation reports.

It is difficult to form even an approximate estimate of the far-reaching importance of impartial and thorough investigation of accidents and the publication of complete, unbiased reports. About ninety or a hundred accidents per year are investigated. In numerous instances, operating conditions and practices have been found to prevail which were likely to lead to accidents at any time, and specific recommendations to eliminate these dangers have been made. In some cases, inadequate or ambiguous operating rules have been disclosed, as well as antiquated methods of operation in effect; signals inadequate or not maintained in proper operating condition and in a few instances being flagrantly disregarded; employees occupying responsible positions in train service who have not been properly instructed and examined on the rules; lax supervision, and the safeguards intended to be provided by operating rules not being fully utilized; track not properly maintained; and the maximum speed limits too high for track elevation provided on curves. Investigations of materials which have failed in service have disclosed conditions in rails, wheels, and axles which require thorough study not only of specifications, composition and manufacturing processes but also of the effects of loads and stresses to which they are subjected in service. In respect to rails alone, extended researches have been instituted and are now in progress concerning the conditions which produce transverse fissures, split heads, shattered material, crescent-shaped base fractures, and wheel-burnt rails, as well as to determine methods of detecting and reducing or eliminating these defects.

Much of the value of this work results from the publicity given the reports. Not only are the specific conditions investigated which have led directly to an accident often readily capable of correction, thereby materially increasing the safety of railroad travel and operation on these lines, but inquiries and correspondence, as well as articles and comments which appear in railroad magazines, indicate that these published reports are widely read and scanned with care for the purpose of apply-

ing the disastrous and costly experience of roads on which accidents have occurred to other lines where similar conditions or practices may be found, with a view of taking corrective measures to avert possibility of similar accidents.

#### INVESTIGATION OF SAFETY DEVICES

In 1906 the Commission was directed by a joint resolution of the Congress to investigate and report in regard to the use of and necessity for block signal systems and appliances for the automatic control of railway trains, the scope of this investigation subsequently being extended to include any devices or systems intended to promote the safety of railroad operation. For a period of five years, from 1907 until 1912, this work was conducted through the instrumentality of a board of engineers known as the Block Signal and Train Control Board, while since 1913 it has been performed by the Bureau of Safety.

The method of procedure consists of an examination of plans of each device presented for consideration and the formulation of an opinion which is transmitted to the proprietor; if the device is in use or if an experimental installation is made, it is inspected and, when deemed desirable, practical tests are conducted. In some cases reports regarding the tests of devices are transmitted to the Congress by the Commission.

In round numbers, twenty-five hundred proposed safety devices and systems have been examined, including many forms of devices intended to be used in the construction and operation of railroads, and certain devices, principally automatic train control devices, automatic connectors and brake devices, have been tested under service operating conditions. Block signal statistics are compiled and published annually; these reports indicate that the block system was in use in 1906 on 48,743 miles of road, while on January 1, 1920, the mileage of road operated by the block system had increased to 101,884 miles.

#### BUREAU OF LOCOMOTIVE INSPECTION

The Bureau of Locomotive Inspection of the Interstate Commerce Commission was constituted by an Act of Congress of February 17, 1911, its direct purpose being to promote the safety of employees and travelers upon the railroads.

Its organization consists of one chief inspector, and two assistant chief inspectors, appointed by the President and confirmed by the Senate, whose duties are to direct the work of the inspectors and see that the laws, rules, and regulations promulgated thereunder are fully carried out. This law also provides that the United States and the District of Columbia shall be divided into fifty locomotive inspection districts, and that one inspector appointed by the Interstate Commerce Commission, as provided for in the Act, shall be assigned to each district.

This law was passed by Congress as a direct result of the many serious boiler explosions and other failures of the locomotive boiler and its ap-

purtenances, causing serious injury and death. On March 4, 1915, it having been brought to the attention of Congress that many accidents were due to the failure of many parts and appurtenances of the locomotive and tender, the Act of February 17, 1911, was amended, its provisions being extended to cover all parts and appurtenances of the locomotive and tender.

There are approximately seventy thousand locomotives in service in the United States which come under the jurisdiction of this Bureau. It was recognized that the most effective means of preventing accidents due to the failure of the locomotive and its appurtenances was through periodical inspections, tests, and repairs; therefore, the law requires that such inspections and repairs shall be made at stated periods and a sworn report, covering the condition of the locomotive and the repairs made to all defects found before it is again returned to service.

These reports total approximately 840,000 per annum, and are checked by the district inspectors as well as in the office of the chief inspector, in order to determine whether or not the requirements of the law and rules are being complied with, after which they are filed in the office of the Chief Inspector for reference. A transcribed report of the defects approaching violations of the law, disclosed by the Inspectors of the Interstate Commerce Commission in the course of their regular work, is furnished to the chief operating officer of the carriers, so that they may be fully advised of the conditions of their locomotives.

The rules and regulations require that each locomotive boiler shall be so constructed and maintained that it will have a suitable factor of safety, and that a specification card containing certain calculations, drawings, and other data necessary in determining the safe working pressure be filed for each locomotive boiler before being placed in interstate service. These specification cards are carefully checked by competent mechanical engineers in the office of the chief inspector, to determine whether or not the boiler meets the safe requirements.

The law requires that each inspector appointed under the Act shall make personal inspection of the locomotives under his care from time to time, as may be necessary fully to carry out the provisions of the Act, and as may be consistent with his other duties. His first duty, however, is to see that the carriers make inspections in accordance with the rules and regulations established or approved by the Interstate Commerce Commission, and that the carriers repair the defects which such inspections disclose, and makes it obligatory upon the inspector that, whenever in the performance of his duty, he finds any locomotive or apparatus pertaining thereto not conforming to the requirements of the law and rules, he shall notify the carrier in writing that the locomotive is not in serviceable condition.

It further provides for an appeal from the inspector to the chief inspector, and in turn to the Interstate Commerce Commission, in case the carrier believes an injustice has been done by the inspector.

The following table shows the number of locomotives inspected by the Commission's inspectors under the amended Act; the number found de-

fective; the percentage of those inspected found defective; the number ordered out of service; and the total defects found, for the fiscal years ending June 30, 1917, to June 30, 1920, inclusive:

|                                 | 1920   | 1919    | 1918   | 1917   |
|---------------------------------|--------|---------|--------|--------|
| Number of locomotives inspected | 49,144 | 59,772  | 41,611 | 47,542 |
| Number found defective          | 25,497 | 34,557  | 22,196 | 25,909 |
| Percentage found defective      | 52     | 58      | 53     | 54.5   |
| Number ordered out of service   | 3,774  | 4,433   | 2,125  | 3,294  |
| Total defects found             | 95,096 | 135,300 | 78,277 | 84,883 |

This law requires that in case of an accident, resulting from failure from any cause of a locomotive or tender, or its appurtenances, resulting in serious injury or death to one or more persons, a statement forthwith must be made of the facts of such accidents by the carrier owning or operating said locomotive to the chief inspector, whereupon, the facts concerning such accident shall be investigated by the chief inspector, or one of his assistants, or such inspector as the chief may designate for that purpose, and that the part affected shall be thoroughly examined and a detailed report of the cause of the accident made, and that such reports shall be made public in such manner as the Commission deems proper.

During the nine years that this law has been in effect, the Bureau of Locomotive Inspection has investigated 5,892 accidents, which caused the death of 450 persons, and the serious injury of 6,678 others, due to the failure of some part or appurtenance of the locomotive or tender, including the boiler. The great majority of these accidents could have been prevented by proper means, well known to qualified officials and employees in charge of the operation, inspection, and repairing of locomotives.

A summary of the accidents and casualties caused by the failure of locomotive boilers and their appurtenances only, for the year ending June 30, 1912 (the first year of the existence of this Law), as compared with the accidents and casualties occurring from like causes during the fiscal year ending June 30, 1920, shows the substantial decrease of 47 per cent in the number of accidents; 48 per cent in the number killed; and 49 per cent in the number injured, notwithstanding the strenuous period of reconstruction through which the country has been passing, which very clearly establishes the wisdom of the requirements of the law and rules.

In the work of the Bureau of Locomotive Inspection, attention has from time to time been directed to certain conditions which have contributed to overheated and damaged crown sheets, as a consequence of which a series of comprehensive tests has been conducted to determine the effect of the circulation of water in the locomotive boiler on the water indicating appliances, with respect to their correct registration.

Through the surprising conditions disclosed, and the information obtained, it is expected that material aid will be rendered the carriers in reducing or preventing such damage.

## INCREASED POWERS WITH RESPECT TO SAFETY

The Transportation Act, 1920, materially increases the powers of the Commission with respect to safety matters. Section 26 of the amended Interstate Commerce Act provides in part as follows:

"That the Commission may, after investigation, order any common carrier by railroad subject to this Act, within a time specified in the order to install automatic train-stop or train-control devices or other safety devices, which comply with specifications and requirements prescribed by the Commission, upon the whole or any part of its railroad, such order to be issued and published at least two years before the date specified for its fulfillment. . . ."

The administration of this section of the law is now before the Commission for consideration, and plans for carrying out its purposes are being formulated.

It is probable that a great deal of progress will be made in the near future in the installation of automatic train-control devices on selected lines in specified locations for the purpose of developing these things to prevent these harrowing collisions which we have been experiencing for quite a number of years due to the failure of the engineer probably to obey signal indications.

CHAIRMAN CARROW: A writer whose name I am not familiar with once said that the world doesn't need so much to be taught as it does to be reminded. We have got to the point where the world needs to be reminded, and Mr. Borland's résumé of the Interstate Commerce Commission was very appropriate at this time.

I want to call your attention, in his address, to the remarkable fact that coupling accidents were reduced from forty-three to seven per cent or one injury in every nineteen to one in every seventy-five. You must admit that that is one of the most remarkable improvements that ever has been made in the history of industrial development in this country.

Now, I want to call your attention to a discovery that has been made and is being perfected and when it is perfected it will excel in its effect anything that was ever done by the automatic coupler and that is automatic precaution. When we get the minds of officials and employees of the railroads and in every other line of work so that they automatically keep out of danger, so that they get in tune with a certain sort of atmosphere that deflects them from the course of danger, then we shall even excel the record of the automatic coupler in preventing injury and death.

There are a lot of things that I should like to say about Mr. Borland's address but it isn't for the Chairman to do that. However, there is an indication of a gradual persistent progress in the mechanical and physical development and maintenance of the railroads of this country that should give every man encouragement who is interested in the safety work. Now, when we supplement these wonderful physical developments with the effort that is being put forth with the mind, I have no hesitancy in predicting that the thing we are all working for will be realized.

Mr. Borland's paper is open for discussion.

## DISCUSSION

MR. M. SCANLON (Duluth, Missabe & Northern): In shifting cars into the yard the headlight must be turned on. When we are shifting these cars in, there are men working on other cars and the headlight blinds them so they can't see and they have to stop work. I should like to know if we couldn't get an amendment to that law so that we could put the headlights out so the men could continue to work, because the men are standing on a very small piece of iron and it is very dangerous.

CHAIRMAN CARROW: Your question, I believe, is directed to Mr. Borland.

MR. BORLAND: I didn't make the law and I can't amend it.

CHAIRMAN CARROW: I presume, if I gather your remarks in the beginning of your talk, that your exclusive function is enforcing the law and you take no steps to have the law amended.

I should think that is a rather hard question to answer. I don't know whether this Section is in a position to receive a motion to take some action looking to the modification of that law or whether the Interstate Commerce Commission is in a position to make modification under certain circumstances. Has anybody a suggestion? Mr. Adams, you are versed in the law.

MR. ADAMS: I know of no way that you can repeal or modify any act that the Interstate Commerce Commission has set about to carry out unless it is done through Congress. If there is a particular condition that the gentleman might have on his line, I would suggest that he consult his Congressman, and I might add that he is liable to have a big fight on his hands.

CHAIRMAN CARROW: I would suggest, my friend, that you take the matter up with your superior with a view of his taking the regular course and presenting the matter to the proper official of your state or the United States.

MR. GROOME: I have found in safety meetings that a small proportion of members of our safety committee bring in suggestions wherein they want to create certain conditions that are not permitted by the rules of the Interstate Commerce Commission which are laws. I have steadily stood to the point that we are not in a position to change existing laws of this country. Mr. Adams, when he was regional supervisor of safety in the Central Western Region, had a good many cases of that kind.

I can bear Mr. Borland out in what he has said in regard to the investigation of accidents. I am perhaps the only railway officer in the Steam Railroad Section that served an apprenticeship in the safety section of the Interstate Commerce Commission. I was inspector under Mr. Belnap for five years and I know something of the class of accidents that we investigated. We found in many cases a disregard of the rule both by officials and employees.

## IMPORTANCE OF UNDERSTANDING RULES

In regard to the rules, there is nothing more important than a rule book. On our railroad, the Union Pacific System, we have train rules' examiners on every division. Before any man in the train service, the

engine service, the maintenance of way department, the telegraph service is permitted to go to work, he is very thoroughly examined on the rules. Now, they don't sit down and write the answers to all the questions to be checked up some three or four months afterwards; they must go through this examination and be re-examined until they pass with thorough understanding of the rules. A big accident happened a number of years ago when I was with the Commission, and it was on our railroad, by the way, and not a man that was brought into that investigation would admit that he did not have a thorough understanding of Rule 9, one of the most important in the book. That was brought about by thorough examination. If we would insist on a thorough examination of our men and the best observation of rules, there would not be so many of these rear end and head end collisions that the Interstate Commerce Commission finds necessary to investigate at this time.

CHAIRMAN CARROW: Does any one wish to discuss further Mr. Borland's paper?

MR. F. M. METCALFE (Northern Pacific): I don't think you are giving Mr. Scanlon's question enough consideration. He will have to go back to his men and say the Safety Section didn't do anything that they didn't have power to change the law. Couldn't they get an exception from the Interstate Commerce Commission to waive the rule in that particular case? He will have to go back to his boys and say "I couldn't do anything for you, boys; you will have to have that light in your eyes." I think we ought to give it a little more consideration.

MR. BORLAND: Mr. Chairman, so far as the inspectors of the Interstate Commerce Commission are concerned, they have no power to waive any provision of the law. The duty of the Interstate Commerce Commission is to enforce the law as it is written; that is what we are there for.

Now, with respect to this particular situation, I don't know of any law that requires a situation of this kind to exist. There is a law that requires the electric headlights of certain prescribed candle power which would permit an object the size of a man to be seen within eight hundred feet in advance of the engine. There is no particular law that I know of that requires that headlight to be kept burning in the situation which this gentleman speaks of. If there is such a law, I don't know anything about it.

MR. A. V. ROHWEDER (Duluth, Missabe & Northern): That condition exists up on our line and was brought up in one of our safety committee meetings. It is an Interstate Commerce law, Rule 31. It says that you shall have a headlight displayed, as Mr. Borland said, on the front or rear end of a yard engine. It is the general understanding by our law department that it is necessary under the Act to keep the headlight burning on a yard engine shoving up on a dock. Now our dock is nearly a mile long and is illuminated as bright as day. We have four or five hundred men working on top of those cars all the time. This bright light shining over the top of those cars is one of the worst conditions on the road on account of blinding these dock men and the legal department hesitates in allowing any bulletin to be put out to engine men

giving them permission to shut the headlight off when the engine is moving on or off the docks under existing rulings from the Commission.

Now, the Commission did, some time ago, give permission or modified its rulings on Rule 31 to the effect that in connection with road service an engine or train meeting another on the road could shut off its large electric headlight and turn on the dimmer light so as to cut the blinding effect. Mr. Scanlon undoubtedly brought that up in the hope that this Section would request the Commission for a ruling that would take care of this.

MR. JAS. SULLIVAN (Chicago & North Western): Haven't they got a dimmer on that headlight? All it requires is a headlight.

MR. ROHWEDER: The law requires a headlight of a certain candle power. It doesn't give you authority to cut it down to a dimmer light.

MR. SULLIVAN: They do it in yards, why not at docks?

MR. ROHWEDER: That is in violation of the law, though.

CHAIRMAN CARROW: I know that on nearly every railroad they dim those lights in the yards. I am not speaking as an operating man but I should think that a dock would certainly be in the category of a yard from an operating standpoint.

MR. ADAMS: It occurs to me that Mr. Scanlon might get some relief if he will address Mr. Pack, the Chief of the Bureau of Locomotive Inspectors, and set out his case.

During my term of office as regional supervisor there were a great number of complaints from yard men about this blinding effect; these were handled by Mr. Pack but I don't believe there was any relief secured on account of the law, so it occurs to me the only thing Mr. Scanlon can do at this time would be to address Mr. Pack on the subject, outline his case and ask for relief in the premises.

CHAIRMAN CARROW: It seems to me the thing is settled satisfactorily.

MR. BRODERICK: I make a motion that Mr. Borland's paper be accepted.

(The motion was seconded and carried.)

CHAIRMAN CARROW: The next order of business is not on the program but is one that deserves and merits a great deal of attention. So far as we are personally concerned, the grade crossing situation is perhaps more serious than any other one feature of accident prevention work on the railroads of the United States.

#### GRADE CROSSING SITUATION

MR. BRODERICK: This question has been discussed more or less during this session but perhaps we don't all realize its vast importance. As a matter of information and to show you the trend of things, just a few days ago there was a bill introduced in the legislature of Maryland compelling the railroads of that State to install a special electric signal at every grade crossing in the state, regardless of whether it was a state highway or a country road. The originator of the bill proposed that the expense of this signal should be borne half by the motorists of the state and the other half by the railroads. He estimated that the device would cost between three and four hundred dollars for the material itself and a

like amount to install it, or between six or seven hundred dollars for device at each crossing. His idea was for the motorist to be taxed five cents and on that basis with 100,000 motorists in the state, they would contribute approximately \$50,000 and the balance of the expense would be met by the railroads. We looked into the thing a little bit and it was thought the estimate would be more than double what he said, so you can see where the railroads would get off on a proposition of that sort. Just as a matter of information we have in the State of Maryland a total of 834 grade crossings. We have on the Baltimore and Ohio alone 28 crossings, so we are very vitally interested in that matter.

The automobile club of Maryland was asked to look into the question and express an opinion on the subject. I attended a luncheon of the board of governors of the automobile club and they were more or less interested from both sides. They thought, of course, it was an obligation resting upon the railroads in that connection and they were likewise interested in the motorists, but they passed a resolution to the effect that they did not approve of the proposition and if it was presented they would appoint a special committee to investigate the matter and look into it thoroughly and be in a better position to handle it. It will likely come up in the next session of the Legislature, in 1922.

Gentlemen, you all realize that this matter of automobile accidents at grade crossings is a serious menace. The installation of signals at crossings is not going to prevent accidents.

It seems to me it would perhaps be proper to suggest that a special committee be appointed to handle this particular question. I don't know of anything that this whole Council could do with the idea of helping public safety more than to reduce grade crossing accidents of automobiles. It seems to me it is a serious problem and one that should be given serious thought.

My idea was that a special committee be appointed from the different sections of the Council, consisting of a representative from the Steam Railroad Section, one from the Electric Railway Section, one from the Automotive Section, one from the Industrial Section, and one from the Public Safety Section. If some action were taken in that direction it would put the National Safety Council on the map showing a vital interest in public safety.

#### STANDARDIZATION OF TRAFFIC LAWS

MR. GRODZKI: I am heartily in accord with what Mr. Broderick has said and if I had gotten up before he did I should have said practically the same. The Public Safety Section of the National Safety Council has already, since the Cleveland convention, a committee on standardization of automobile traffic laws. There was a convention in San Francisco the month of August of the National Traffic Officers' Association that started to consider national traffic laws. They appointed a committee that is going to meet in Cleveland some time the latter part of this year, and I believe, it would be the biggest mistake that we ever made if there were not appointed before we leave this Council meeting a committee such

Mr. Broderick mentioned. I believe this committee should get in touch with the other committees on traffic laws. Sooner or later we are going to have universal traffic laws. I find that the traffic laws here on the streets are different from what they are in any other cities. These universal traffic laws are going to be put through and unless the Railroad Section gets in on its share, we are going to fail in one job that we should do from the railroad standpoint.

(Mr. Scott resumed the Chair.)

CHAIRMAN SCOTT: After listening to this discussion, I take it that it is quite generally felt that the incoming administration should look into the appointment of this special committee to deal with the subject of grade crossing accidents. I don't think it is necessary to have a motion to take care of this; I am quite sure that the new Chairman will see that this is well taken care of.

MR. BRODERICK: How shall we know what action is going to be taken on this subject; will any action be taken before this Section adjourns?

CHAIRMAN SCOTT: My understanding of the constitution and by-laws is that the Chairman is empowered to appoint all committees.

MR. BRODERICK: We have talked more or less about this and we are urging that something be done, but we don't know that it will be done.

MR. H. C. HUNTER (Union Pacific): I ask the unanimous consent of this assembly to have the Chairman appoint such a committee as outlined by Mr. Broderick and Mr. Grodzki.

MR. GRODZKI: Could a committee be appointed by the Chairman before we adjourn so that some action might be taken before we leave Milwaukee?

CHAIRMAN SCOTT: Let me explain for a moment. As presiding officer at this meeting, I do not feel that it would be proper for me to appoint a committee that is to act under the incoming Chairman. If the gentleman who just spoke will present a motion in regular order and if it is duly seconded, I will take great pleasure in putting it before the meeting, and if that motion is carried, I believe that the incoming Chairman will see that everything is done that should be done to handle this question in a satisfactory manner.

MR. HUNTER: I will make such a motion as outlined by our present Chairman.

(The motion was seconded.)

CHAIRMAN SCOTT: I believe you all understand the motion. It is that the incoming administration will appoint a committee to deal with this particular subject in a manner which has been outlined. Are you ready for the question?

(The motion was unanimously carried.)

CHAIRMAN SCOTT: Mr. Carrow, will you please make note of that? Mr. J. C. Clark came to me during the early stages of this meeting and said that he and Mr. Talbert would be found, in case we wanted them at any time, in the Public Safety Section. We sent our Secretary to the Public Safety Section to look for them but they are nowhere to be found. Under the circumstances, and in view of the fact that the hour is drawing near when we should adjourn, because I understand that many of our delegates

are leaving on an early afternoon train, I think it is quite in order for us to wind up the business of the Ninth Annual Meeting of the Steam Railroad Section of the Council.

Before entertaining a motion to adjourn, I have just a few words to say. I want to appeal as strongly as I can to every member of this Section to support all of the committees in every way possible in the development of every subject that is assigned to them. I would appeal particularly to you to aid the Bulletin Committee. I know what the Bulletin Committee is up against. I served on that Committee year before last and I know that it is a very difficult matter to put out high class bulletins unless they get the right support from the membership.

Now, one other thought. I know from experience that when a man comes a long distance to attend a meeting of this kind he likes to feel that he is going to take something back home with him. One thing that I have missed more than anything else in this meeting is copies of the papers and copies of the committee reports so that we can take them back home to discuss and to utilize to the best possible advantage without having to wait sixty or ninety days for the proceedings to be published. I would like to have some expression from those in the room as to whether it is advisable to recommend to the incoming administration that at our next meeting we have advance copies of all committee reports and other papers that are to be presented for consideration at the next annual meeting.

MR. M. S. COLE (Oregon Short Line): This is the first meeting of this kind that it has ever been my pleasure to attend. Now, I came here with the purpose or with the intention of carrying back as many notes and ideas that I could gather here at this Council and I am going back full of them. I am going back more enthusiastic for a better safety campaign on our system. I, for one, would be glad to receive an advance copy of all papers and reports. It would help me and I know it would help the rest of the boys who came here with me. I believe we could put over a better safety campaign if we had these advance copies.

I would like to go on record as favoring advance copies. I make that as a motion.

MR. GRODZKI: I second that motion.

CHAIRMAN SCOTT: The motion has been made and duly seconded that we go on record as recommending to the incoming officers that advance copies of committee reports and papers be at the disposal of members at the next annual meeting of this Section.

MR. CARROW: May I amend that motion to have a little leeway? That the Chairman of the Program Committee use some discretion in the publication of them for this reason: That the expense would fall upon the members of the Council and if we published all of the papers, it might be a burden heavier than we could bear. It seems to me there ought to be some leeway.

CHAIRMAN SCOTT: As I understand the motion, Mr. Carrow, it is purely recommendatory. It is not mandatory.

I happen to be a member of several other organizations and at our annual meetings, as a general rule, the man who prepares a paper and

devotes a lot of time to it is very proud of his product and they are quite willing to furnish mimeographed copies of their papers, and I think if we will offer that suggestion it will eliminate quite a lot of expense.

You have heard this motion. Are you ready for the question?

(Upon vote the motion was unanimously carried.)

CHAIRMAN SCOTT: Now, if there is no unfinished business and no new questions to come up, I think this Section should go on record as offering a vote of thanks to the city of Milwaukee and the very able committee that has been looking after us while we are here. What is your pleasure with reference to that?

MR. W. J. OER (Toronto, Hamilton & Buffalo): I would like to move that a vote of thanks be extended to the Chamber of Commerce, or whatever it was that invited the convention here, for the hospitality received.

MR. CARROW: I would like to add to that motion by indicating our special appreciation of our old friend Anderson, who was largely instrumental in putting this thing on the map.

(The motion was seconded.)

CHAIRMAN SCOTT: I had no idea, Mr. Carrow, of letting that escape, because if there is anyone who feels devoted to Charley Anderson, it is the Chairman.

Now, let's have a rising vote of thanks to the city of Milwaukee and to the committee on arrangements and entertainment.

(A rising vote of thanks was given.)

CHAIRMAN SCOTT: I want to assure every member of the Steam Railroad Section of my hearty appreciation of the honor that has been mine to preside at this meeting, and that I have the most kindly feeling for every one of you, and I hope to see you at the next annual meeting of the National Safety Council.

MR. W. L. BOSLOOPER (New York Central Lines): We have had many votes of thanks extended to various men during this convention. Now, if you will permit me, I am going to suggest something out of the ordinary, that, in view of the able manner in which the business of the Steam Railroad Section has been conducted during the meetings of this Congress, we give three cheers for our Chairman, Mr. Scott.

(Three rousing cheers were given Chairman Scott.)

CHAIRMAN SCOTT: Gentlemen, that is the most encouraging thing I have heard since Mr. Dow offered some kind remarks in my favor yesterday afternoon, and I appreciate the good feelings and the three cheers very much indeed.

ADJOURNED.

## **Textile Section**

**H. L. ROBINSON, Chairman**

Manager, Employment Service Department, Crompton and Knowles Loom Works, Worcester, Mass.

**A. E. CONRATH, Vice-Chairman**

Chief Inspector and General Foreman, International Harvester Company, St. Paul, Minn.

**IDA MAY WILSON, Secretary**

Lowell, Mass.

---

### **WEDNESDAY MORNING SESSION**

**T**HE meeting convened at 9:45 A. M., Chairman H. L. Robinson presiding.

**CHAIRMAN ROBINSON:** Our first point of business is the appointment of a nominating committee and I would like to appoint Mr. Beyer, Mr. Stoll, and Miss Brown. You will meet some time today and report at the meeting tomorrow morning on officers for the coming year.

We feel this year that our secretary has earned her salary. We have not only worked her at our meetings, she has been very constant in attendance, but we also had the nerve to ask if she would present a paper at the Congress. Miss Wilson has been connected with the Bay State Cotton Corporation, but is now a free lance and has had considerable experience in textile mill work. She has had to preach safety to the executives and then sell it to the operatives. She has taken as her subject "Selling Safety to Executives and to the Workmen in a Textile Mill" and I take great pleasure in introducing our Secretary, Miss Wilson.

### **SELLING SAFETY TO EXECUTIVES AND EMPLOYEES**

**IDA MAY WILSON, LOWELL, MASS.**

The textile industry has for so long been considered a low accident hazard that it is difficult to convince some production executives that there is anything important to be done in the line of safety work. It is a general proposition they believe in safety measures, and say that

such measures are all right for machine shops and the like, but unnecessary in a textile mill. When it is pointed out by the accident insurance carrying company that a safety committee properly organized and stimulated, and weekly mill inspections for accident hazards, will lower insurance costs, the idea that there may be something of value in the safety movement, even in a textile mill, is likely to germinate. More than 100 textile mill memberships in the National Safety Council attest the growth of this idea. Accident compensation laws and the nationwide safety campaign of the National Safety Council have given many manufacturers a new outlook on safety work.

#### PREREQUISITES FOR ESTABLISHING EFFECTIVE SAFETY WORK

Prerequisites for establishing effective safety work are the same as for establishing an effective industrial relations department. Every division of the Industrial Relations Department has an important bearing upon safety. The same spirit motivates all sincere effort in safety and in other parts of the industrial relations field. If the mill management is resistent and is sincere in expressing a desire to make working conditions more nearly fair and safe, and workers more nearly content, the task of getting the safety idea over to the manager is comparatively easy. Starting with the promise that a mill has this type of management, we may consider ways of getting the safety idea across.

The first prerequisite is to have in the mill a man or a woman who is keenly interested in the safety movement, and eager not only to arouse enthusiasm but to sustain it by persistent effort. In the larger mills the production superintendent is usually so busy getting out production that he cannot give the necessary time to prepare himself for working out satisfactorily any part of the industrial relations (or service) field. When once he understands its value in helping him to speed production, he will give whole-hearted co-operation. In textile mills of 5,000 or more employees one man should devote his entire time to safety work. In smaller mills the industrial relations or service superintendent assisted by safety committees of executives and employees can do efficient work. But in every mill there should be some one who has ready access to the manager of the mill, and sufficient time to make plans and develop the safety spirit.

Recently a mill man when asked if he had organized a safety committee replied lightly, "Oh, yes, three times so far this year. We keep forgetting to meet, so whenever our accident insurance company gets after us we organize again."

#### ALERT EXECUTIVE NECESSARY TO SUCCESSFUL SAFETY COMMITTEE

This reply shows that there was no one on the job. A well-organized and smoothly-running safety committee that does steady and effective work always has in the back-ground an alert executive who organizes, energizes, and follows up every detail of the committee's work. A mill man recently said of a smoothly-running service department, "Anybody

can read out of a book how to organize committees, install centralized employment, start physical examinations, and do all the rest of such department's work." So can any one read out of a book how to make yarn and cloth from cotton or wool, what machines to buy and how many of each, the machine lay-out, and the number of workers required to operate these machines. Any one can start a cotton mill, but somewhere in the organization it is our theory that there should be an experienced cotton mill production executive, otherwise the man who has built a mill according to rule will suffer failure. It takes more than a book to start to make a successful safety committee.

The second prerequisite is careful planning. Every time a safety committee has to be resuscitated the task increases in difficulty, and the employees take less interest in the organization. Unorganized safety work amounts to little. To make the work successful there must be careful planning in detail, and some one back of these plans to carry them on. A carefully drawn plan of the proposed safety work by one who has made a study of approved methods is an excellent way to convince the executive in charge of the mill that safety work is feasible for his mill.

Not less essential is faithful follow-up of organization plans. The average executive is not different from the average mill employee in that he wants to be shown that the plan is working out. An excellent way to convince him is to remind inspectors of their duties, help in making the inspections and the inspection reports, supervise the investigation of accidents, transmit accurate reports to the insurance company and to the safety committees, place the blame for each accident squarely where it belongs, plan each committee meeting so that it will go on with enthusiasm that will make every member look forward to the next meeting, and to trail committee recommendations to ultimate action. Follow-up well done is itself one of the best ways to get the safety spirit over to executives and employees.

#### CONDENSED REPORTS OF ACCIDENTS HELP

A condensed weekly or monthly report of accidents, their causes and the committees' recommendations for eliminating these causes will help make the man at the top believe in safety as he does in production. And these reports will help the committees to discover the high percentage of accidents that they have agreed were preventable by exercise of carefulness. The reports may be passed down to the superintendent and the overseers, and copies of them may be posted on the safety bulletin board. Summaries of inspection reports may be made by departments and treated in the same ways. Exhibits of the shuttle or other tool that caused an accident with the committees' recommendations for preventing a recurrence of the accident, will prove effective. Presumably even in mills where cotton is studied, but not the workman, and where methods of employment and handling labor are still those of a by-gone century, traditional indifference towards the human factor will gradually be overcome.

## KEEP MANAGER ABREAST OF SAFETY NEWS

It is important to keep the manager and yourself abreast of safety news. Few managers in long established industries want to try untested methods. And they look upon all the things they do not know about as untested. Any innovation meets with opposition from some one, and the manager ought to know enough about it to back it when occasion arises, as occasion surely will. The safety supervisor should see that the manager is familiar with the points in favor of the innovation. The preliminary proof of the value of a proposed change in favor of safety should be strong. "We have never done that" is likely to begin and end any but a progressive mill man's reply to a suggestion for a change of even a trivial character. If certain machines in the mill should be guarded, cuts of new machines of the kind, with guards, will interest him. Such cuts may be found in textile magazines, insurance company's publications, machinery catalogs, and the Textile Safe Practices pamphlet published by the National Safety Council. Facts, methods, and standard practices should be placed before him. Marked paragraphs of safety news from other mills may be culled from the same sources and from the NATIONAL SAFETY NEWS. Newspaper accounts of accidents to textile operatives require no comment to convince managers and men that there are hazards in a cotton mill, and that it is a constructive service to reduce them to a minimum. If a manager does not willingly read anything he can avoid, a typewritten summary of essential facts in the articles mentioned will be more likely to receive attention.

Persuading the manager to do a definite part of the safety work himself will solicit his interest. If a carefully drawn plan for a safety meeting of superintendents and overseers is given him with the suggestion that he call the meeting and preside at it, his attention will be focused on safety, and when once this is accomplished he will get behind the safety movement. If overseers are asked to give a list of names of those in their departments who ought to make good committee members, they will take a measure of responsibility for the success of these men in safety work.

In developing any phase of the industrial relations work, its bearing on safety may be pointed out. This tends to advance the immediate project and to fan the safety spirit. As an illustration, in preparing the soil for sowing seeds of a morning lunch service throughout the mill, both lunch and safety causes are promoted by showing that experiments and studies prove that the hour of the greatest fatigue coincides with the hour of greatest accident frequency. It follows that whatever will renew vigor will promote safety, good will, and production.

## EXPANDING THE HEALTH DIVISION

In expanding the health division of the industrial relations work beyond the narrow confines of first aid, the logical first step is to secure a socially-minded nurse or Red Cross First-Aid graduate who is willing

to develop into wider usefulness. Then it is easy to link health and safety in the mind of the manager by citations dealing with risks involved in employing for machine work men and women with bodily ailments that a physician's examination would have revealed. Proper physical examination succeeded by careful placement, and by the patient painstaking follow-up of the right kind of nurse or First-Aid worker will appeal to most managers as one of the strongest safety measures. If a dentist can discover the cause of a man's partial incapacity for work, why not employ a dentist? If an oculist can learn the cause of continuous bad work, why not have an oculist examine operatives' eyes and correct defects? The work of the mill physician, dentist, and oculist is safety work. The give-em-hell treatment of employees who make mistakes must give way to an attitude of helpfulness shown in preventive measures before any one can take seriously the utterances of mill officials who use their service departments solely for selfish ends. The subject of health is the Old Faithful for the newspaper man, for everyone is interested in health. Seeds of the project to develop the health division of the Service Department are sure to lodge eventually in fertile soil. Why not sow at the same time seeds of the safety idea? Obviously, all intelligent health, hygiene, and sanitation work is safety work.

#### CENTRALIZED EMPLOYMENT IS SAFETY WORK

Centralized employment as a means of saving the time of product men, and upgrading the personnel, is safety work. In laying before an open-minded mill manager reasons why thousands of progressive companies throughout the country have successful centralized employment, the industrial relations superintendent can advance this idea by showing the Safety values in proper interviewing; right placement; detailed information regarding wages, rules and privileges; proper introduction to the job; and friendly, frequent follow-up. By these methods in a centralized employment bureau the employment supervisor should be able to eliminate many risks both to the mill and to the new employees.

And so we might continue with all other divisions of the industrial relations work—wage adjustments, settlement of grievances real and fictitious, shop committees, honest insurance administration, review of discharged and released employees' reasons for leaving, Americanization, housing, training schools, mutual benefits, co-operative stores, promotion of recreation and home welfare work. Each in a very real way is safety work. To further any one of these, its safety aspect may be considered to the advantage of both causes.

#### SAFETY WORK IN MILL NOT UNDER RESIDENT MANAGEMENT

So far we have considered ways to get the spirit into mills where there is a resident management sincere in promoting service features. Unfortunately many safety men work in mills of another type—the type that enlists the services of a safety man merely because the insurance company demands it. Or perhaps the mill is not under resident management, a

the agent has a service or safety man hurtled into his mill from the office of the general management for reasons not easily deciphered. This complicates and delays, but in itself does not preclude success, provided that the agent is fair, and the holding company sincere. A company is known by its representatives, and if it continues knowingly to retain a single dishonest representative, the sincerity of the general management does not exist except in officials' adroit use of words in public utterances. If a company's representative is either a human shark or a jellyfish, the operatives' need for safety work is great, for the policies of the agent are sure to be reflected in the executives throughout the mill. The safety man will need to have unquenchable faith in his work, and the pluck and the courage of ten. He can win the employees and find his reward in what he accomplishes for them; he cannot perform the miracle of changing an unprincipled person into a real man. The appeal must be lowered and restricted to the agent's self interest in reducing insurance costs, working hours lost, machine idleness, and labor turnover. The safety spirit will not live in a mill where the mill agent is incapable of understanding or feeling it.

In getting the safety spirit to permeate the operatives, the methods are the same as those for an open-minded manager. Most employees are open-minded on the subject of safety. Just as they instinctively like any one who takes care of their injuries after an accident, they like anything that tends to keep them from hurting themselves. The manager, superintendents, and overseers are usually former operatives who have come up through the mill. There are probably employees who could take their places if they were given the opportunity. There never has been an equitable distribution of opportunities, and efficiency is not the sole basis of promotion in textile mills. Whatever is rational for convincing the manager is applicable to the other executives and to the employees. It seems pertinent to suggest here that the service worker who resorts to wheedling and flattery to win either executives or men is a detriment to the work and should be replaced. The do-it-for-me urge and the aren't-you-wonderful propaganda spring from a desire for personal popularity at grievous cost to safety work. Sincerity, and frank presentation of the cause on its merits builds an enduring foundation. The manager who has to be "worked" for every concession to the safety program suffers from mental absenteeism and, like the one who tries to work him, ought to be replaced.

#### GIVE EMPLOYEES A PART IN SAFETY WORK

In these days of dis-ease in all ranks, men have a decided inclination to do for themselves what has always been done for them. For some occult reason the man who has risen from the ranks to the top is likely to be the most skeptical about the ability of those still in the ranks to initiate ideas or make recommendations on matters of mutual concern. Only recently have employees had representation on safety committees, and in many mills even now they are not permitted to have their own safety committees. To get the manager interested in safety work, we give him

a part of it. Why not do the same with employees? At least half of weekly safety inspections can be made by members of the Employ Safety Committee on mill time. Every accident in a department can be investigated by the members of the safety committee from that department. Committee members, as well as executives, who have made inspections, investigated accidents, and made recommendations become enthusiastic in safety work and follow eagerly the course of their efforts. When their recommendations are acted upon, and due credit is given, they are safety enthusiasts.

Executives and employees like to take pictures of what they believe to be the safe and the unsafe way to perform operations in their departments, and they are willing to have their pictures taken in the case of saving other operatives from bodily injury.

They like to make rules to govern the safe running of their machines. And who else is so well qualified? If simple, clear rules made by the executives' Safety Committee and the Employees' Safety Committee are printed in an attractive booklet in the languages most used in the mill, they will be highly prized and often read.

The executives and employees, after being provided with cuts of guard standard practice pamphlets and the like, will together study out the best guards for the machines they know so well, and when those guards have been installed, they will see that they are used, because they believe in guards of their own selection.

#### **SAFETY BULLETIN BOARDS**

If one man on the Employees' Safety Committee is responsible for weekly or perhaps daily changes on the safety bulletin boards, not only will this part of the program be carried out, but it will enlist the support of its sponsor in the whole safety movement. The bulletin board should be attractive and used exclusively for safety news, pictures, brief stories and comparative accident experiences of departments.

#### **SAFETY MEETINGS**

After the Employees' Safety Committee is a going concern, a different member may be appointed as chairman for each meeting. He will probably need the help of the service or safety worker in planning the meeting, but his responsibility of carrying out the plans that he has had part in making, and the honor of presiding, give an opportunity for self-expression in leadership that deepens his ardor in safety work.

The exceptional outside speaker can interest an Employees' Safety Committee, but members say they get more out of regular meetings, where they can take up the reports of inspectors and of accidents, make recommendations, learn what other mills are doing in safety work, and consider both their progress and the problems for which they have as yet found no solution.

A general safety rally of executives and employees with a stirring brief talk followed by interesting moving pictures with a safety theme will help, but much depends upon the choice of speakers, thorough planning

and personal announcement of the meeting through safety committee members to every employee in the mill.

It has proved to be a good idea to invite one or more members of the safety committees to go with the service or safety supervisor to meetings of the nearest safety council, when programs of those meetings look promising. It is with reluctance that some managements will pass such opportunities down the line. It is traditional with mill officials that the broadening contacts which such trips afford ought not to go below the rank of superintendents. But after this traditional autocracy has been penetrated once, the next trip is more easily arranged.

#### COMMUNITY SAFETY

Safety work with executives and employees must not become static. It depends on contacts for effectiveness and must always reach out toward greater achievement. As there is in everything that changes, one fixed member, so the spirit of social justice that prompts all sincere safety work will endure through changes of managers, methods, and motives, and will reach its fullest expression when industrial policy is clear-headed fairness. This spirit cannot be confined to any one industry or group of industries, but it will reach out until it permeates the city, the school, the home and every individual in the home. And it may be that when the community interests are known to be identical with industrial interests, when the human problem is recognized as a community problem as well as an industrial problem, we shall find the conflicting elements of today's restlessness meeting on the common ground of Safety with the knowledge that they have but one cause and one purpose.

CHAIRMAN ROBINSON: I think we all got some new ideas from Miss Wilson. In order to give every speaker a chance, we will postpone discussion until after the last address.

Mr. Clark, editor of the "Textile World Journal," notified me that at the last minute he found he couldn't get away, so he sent me his paper and if you will pardon the lack of knowledge of his intentions on my part, I will try to read it, though if Mr. Clark were here himself, it is needless to say he would be better able to put it over and more clearly. I think that the paper coming from a man who is in the textile publishing end will have more effect on the various mills than a paper coming perhaps from a certain kind of a mill, that is, a mill that does all cotton work, for example, because that would only reach the cotton people.

The "Textile World Journal" and those textile magazines reach practically every kind of textile industry and therefore it will be much more widely read by the mill agents, men who are in authority, than any other paper we could get. With that in view, we asked Mr. Clark if he would give us a paper at this Congress and he consented. If you will bear with me a few minutes, I will read it. There are some very good statements and I think there will be a good chance for some questions and discussion, not questions on Mr. Clark's ideas, but answers to his statements as to how it is done in other mills and how the difficulties were overcome.

## IMPORTANCE OF CONTRIBUTORY CAUSES OF INDUSTRIAL ACCIDENTS

C. H. CLARK, EDITOR, "TEXTILE WORLD," NEW YORK

The first organized safety work in the textile industry of which I have personal knowledge was inaugurated in 1914 by the Pennsylvania Committee on Safety Appliances, and was confined almost wholly to the development of special guards and locking devices for various types of wool and worsted machinery, including dyeing and finishing machines. Practical manufacturers and workmen served on the sub-committees having direct charge of this work, and their illustrated reports were published by Textile Manufacturers' Journal in twenty-seven separate articles appearing during the year ended November 1915. Many of the safety devices developed and recommended by that committee have been adopted very generally by machinery builders and manufacturers. It is a notable fact, however, that legislation has not been enacted in the State of Pennsylvania making obligatory the use of any of these textile safety devices.

It is since that date that the administration of workmen's compensation laws, and the organized safety campaigns instituted by the National Safety Council, and the casualty insurance companies co-operating with it, have awakened large numbers of textile manufacturers to the humanitarian need of systematic safety work and to the advantage and satisfaction that they may realize therefrom. During this period I have been impressed by the fact that those mills that have gone to extremes in safeguarding of operative machinery, shafting, etc., frequently have reduced accidents as much, nor earned as low insurance ratings, as mills that have paid relatively little attention to such details. This raises a query as to whether the accident hazards of operative textile machinery were not being unduly emphasized by the casualty insurance companies and by those who are directly responsible for safety work in our textile mills.

### IS TEXTILE MACHINERY HAZARDOUS?

It needed only a casual study of the situation to show that, in the industrial compensation rating schedules of certain states and in the accident report forms that are commonly used, there was ample ground for this suspicion. For the existence of such procedure, however, the blame rests quite as much upon textile manufacturers as upon state compensation boards and the insurance companies. To the members of a state compensation board a machine seems to be a machine, whether it be a spinning mill or a braiding machine; the one being a highly hazardous piece of apparatus requiring the services of several men, and the other being relatively fool proof and dozens being easily and safely operated by one person.

For the purpose of illustrating the hazardous nature of the textile industry I was told by one safety expert that 61 characteristic mills employing 33,393 operatives had 119,078 machines, or 357 machines for a hundred employees. In Massachusetts during one year, he says, there were 573 gear accidents in cotton and woolen mills alone, which were r

than half of all the gear accidents reported in all of that state's industries. During the same period the special machinery peculiar to cotton and woolen mills caused 3,177 accidents. For one unacquainted with the textile industry the natural assumption to be drawn from such statistics is that it contains a large amount of extra hazardous machinery. Suspecting that the statistics responsible for these conclusions may have been the cause of error, certain standard reports were examined and considerable basis for this suspicion was found.

In the 1919 edition of "The Industrial Compensation Rating Schedule" for the State of Pennsylvania the "normal ratio of machines to employees" for various branches of the textile industry are given as follows: Cotton and linen goods, 2.1; woolen goods, 1.4; carpets and rugs, 1.0; silk goods, 1.5; knit goods, 1.7; narrow fabrics, 2.7; jute and hemp, 1.2; finishing textiles, .7. The ratio of machines to employees given by the same schedule for other industries that are commonly regarded as equally or more hazardous are as follows: Smelting, .15; steel work, .25; rolling mills, .30; foundries, heavy, .25; foundries, iron, .4; machinery manufacturing, .7; automobiles and automobile parts, .4. In view of the fact that it is common practice in making out accident report cards to emphasize the direct cause of the accident, or the immediate physical instrumentality which produced the injury, it is not surprising that those lacking expert knowledge of textile conditions should interpret this misleading statistical data to the detriment of the textile industry.

#### ACCIDENT REPORTS SHOULD BE SPECIFIC

As an illustration of the relatively small number of textile mill accidents of which the immediate or direct cause is textile machinery, and as an illustration also of the failure of standard accident report blanks to give sufficiently specific information regarding contributory causes, the following report, of a large group of textile mills, appearing in the Executive Series of bulletins published by the Textile Section of the National Safety Council, may be considered as typical:

|                                                 |     |
|-------------------------------------------------|-----|
| Textile machinery .....                         | 276 |
| Hot parts .....                                 | 1   |
| Set screws, keys, etc.....                      | 7   |
| Belts, pulley .....                             | 25  |
| Chains, sprockets .....                         | 5   |
| Cogs, cams, gears.....                          | 20  |
| Rolls .....                                     | 18  |
| Shuttles .....                                  | 41  |
| Other parts .....                               | 159 |
| Elevators .....                                 | 1   |
| Other machinery .....                           | 2   |
| Explosives, fire, matches, steam, etc.....      | 23  |
| Chemicals, corrosive substances, and fumes..... | 13  |
| Falls of persons.....                           | 52  |
| Stepping on objects .....                       | 6   |
| Striking against objects .....                  | 95  |

*Textile Section*

1299

|                                                                       |              |
|-----------------------------------------------------------------------|--------------|
| Falling objects .....                                                 | 5            |
| Objects being handled (dropping materials, strains, cuts, etc.) ..... | 305          |
| Hand tools .....                                                      | 172          |
| Particles in eye.....                                                 | 95           |
| Animals and vehicles.....                                             | 12           |
| Miscellaneous and doubtful.....                                       | 108          |
| <b>Total .....</b>                                                    | <b>1,165</b> |

Appended to the bottom of the bulletin is the important admonition to "Analyze the cause of accidents in your plant, then apply suitable remedies." The only analysis that the author of this bulletin appears to consider important is that which pertains to the 276 accidents caused directly by the textile machinery. This analysis is given in another bulletin as follows:

|                                           |     |
|-------------------------------------------|-----|
| Adjusting and repairing .....             | 47  |
| Cleaning and oiling.....                  | 32  |
| Starting and stopping.....                | 15  |
| Flying machine parts .....                | 30  |
| Breaking of machine.....                  | 3   |
| Working around machine.....               | 132 |
| Passing by machine and miscellaneous..... | 17  |

I think it will be acknowledged that, of the last-named accidents only 33, or those due to flying machine parts and breaking of machines, might not have been due to some important contributing cause, which, if eliminated or avoided, might have prevented contact with a textile machine. Most of the other accidents caused directly by textile machinery, together with a large number of the other 1,165 accidents whose contributory cause is not specifically defined, might have been due to something entirely outside of the machines, and that these "somethings" will never be eliminated so long as specific definitions of contributory causes in accident report blanks are neglected, and the attention of safety committees and campaigns is concentrated upon direct causes.

**CONTRIBUTORY CAUSES**

It is my contention, based upon experience and investigation, that considerably more than 75 per cent of the accidental injuries in textile mills have their important contributing cause in the condition of floors, in imperfect natural and artificial lighting and in the physical condition of operatives.

In an address before the International Association of Industrial Accident Boards and Commissions in 1916, Dudley M. Holman, then a member of the Industrial Accident Board of Massachusetts, and a recognized authority on accident statistics, stated that, as a result of intensive study of nearly 350,000 accident reports during the past four years he had reached the conclusion that only 15 to 25 per cent of accidents could be prevented by safe-guarding machinery and other danger points, and that

from 75 to 65 per cent could be prevented by education and personal fitness. It is quite true that Mr. Holman in his address placed the greatest stress upon the importance of what he called "moral and physical hazards", but he presented some striking statistics and testimony regarding the serious nature of the slipping, tripping, and falling hazard, admitting that the lack of uniformity and completeness in the tabulation of accident statistics had rendered it impossible accurately to gauge the relative importance of this hazard. He presented figures compiled by the Ohio Industrial Commission for the year ended June 30, 1915, showing that, of 6,350 accidents, presumably confined to wood-working establishments, 3,595 were directly due to slipping, stumbling and falling on stairs, floors, etc.

Although not so specified it is apparent that a large proportion of the other accidents, whose direct cause is assigned to cranes, belts and pulleys, planers, joiners and saws, may have had their contributing cause in the dangerous condition of floors or in floor lighting.

#### ADEQUATE STATISTICS LACKING

My inability to produce conclusive statistics to demonstrate the importance of the condition of mill floors and mill lighting as contributing causes of textile accidents is due to the lack of such statistics. The importance of accident statistics as the basis of safety education is generally acknowledged, and if poor floors and poor lighting can be demonstrated to be more hazardous in textile mills than textile machinery, then the development of some simple method by which such important contributory causes of accidents may be listed adequately cannot be avoided. Ask any superintendent, overseer, or intelligently observant operative in a textile mill to give the initial causes of accidental injuries in the mill that have come directly under their observation, and in nine cases out of ten I feel confident that it will not be a machine, belt, pulley or shafting that will be designated, but either the condition of the floor, something on the floor, poor lighting, or the physical status of the injured. Of six serious personal injuries that came under my observation while I was engaged in textile mill work only one was directly traceable to a machine or to the physical condition of the injured; the others were caused indirectly or initially by slipping on wet or oily floors, by tripping over a truck, and by stepping on a roving bobbin. The obsession of one cotton-mill agent, for whom I worked, was clean floors, not only free from dirt and oil spots, but also clear of bobbins, spools, trucks, and other obstructions; some other mill agents laughed at him for the expense incurred in sweepers' wages, and in the time taken by the operatives in keeping clean their section of floor space, but it is a notable fact that that particular mill had remarkably few personal injury cases. Most of the rooms in this mill were well lighted both naturally and artificially, but, had the lighting been poor, the fact that floors were well constructed, were kept immaculately clean and always clear of obstructions about the machinery, would have still reduced accidents from so-called contributory causes to a minimum.

**CLEANLINESS, ORDERLINESS, AND LIGHTING**

It is not my purpose to criticize the valuable work that has been done to eliminate or minimize the hazard of operative textile machinery; this was safety work that had to be done at some time, and the majority of machinery builders and manufacturers are happy that so much progress has been made in so short a time, despite the large expense involved. The application of guards and locks to most textile machinery has progressed as far as safe and practical operation would seem to warrant; to go to the extremes advocated by some safety authorities is impractical and unnecessary. By the concentration of equal effort upon the elimination or minimizing of contributory causes due to the physical status of operatives, and to the condition of mill floors and lighting will prove far more effective eventually in reducing personal injuries in textile mills and other industries to the lowest practicable minimum.

Make the safety slogan for the coming year "Clean and Clear Floors and Plenty of Light" and there cannot fail to be a far more marked decrease in industrial accidents than has resulted from the adoption and application of all varieties of textile machinery, guards and locking devices, and the cost of such a campaign is negligible. It has been said that the safety problem is fundamentally psychological, and that what needs most to be done is to make men think in terms of safety. Keep your floors clean and unobstructed, and your rooms well lighted and it will make it possible for your operatives to think directly in terms of safety. By minimizing or eliminating contributory causes of industrial accidents you will make it possible for your operatives to concentrate upon the very few really dangerous sources of accidents in textile mills.

**CHAIRMAN ROBINSON:** I think that is going to be a paper on which we can get some good discussion after this is over.

We have for our next speaker a man who is Safety Engineer of one of the largest textile mills in the East, and a man who has had considerable experience in the safety game, not only in his own mills but throughout the section of the country where he is employed, and I take considerable pleasure in introducing Mr. C. H. Stowell.

**SAFETY ORGANIZATION FOR A LARGE TEXTILE PLANT**

**C. H. STOWELL, SERVICE DEPARTMENT, PACIFIC MILLS, LAWRENCE, MASS.**

In the formation of a safety organization for a textile plant of more than four or five hundred employees, the most important facts to be considered are that there is no standard or ready-made organization that will fit all plants and that a form of organization that is perfect for one plant may be of no use to another. The larger a textile plant is and the more varied the work done, the farther away from any standard the organization gets.

A successful organization must provide for representation of all departments, however small, and so arranged that any individual in the plant, whoever he may be or wherever he may work, will have an easy

method of getting a recommendation before the proper committee. It must also be such that any information going down from the top through the organization will reach all employees.

The membership of the various committees should be truly representative, that is, they should contain the proper proportion of employees to cover the variation in sex, nationality, skilled or unskilled workers, etc. On workmen's committees there should be no members ranking higher than section hand.

The members of safety committees should be carefully selected. Wherever it is possible they should be elected by the employees. If this is done, more interest will be taken in the committee work. Care should be taken to make sure that all classes of employees in a department have a chance to be members.

#### THE PACIFIC MILLS SAFETY ORGANIZATION

The simplest way in which I can bring before you my ideas as to the best form of safety organization will be to describe the organization we have at the Pacific Mills in Lawrence. The plant there consists of three Departments: Cotton, Worsted, and Print Works, employing 7,800. The work done includes cotton and worsted manufacturing, printing, dyeing, and finishing.

The present safety organization dates from July 1, 1919. Previous to that time considerable accident prevention work had been done by each superintendent through his overseers and the accident rate for several years had been lower than the average textile plant.

The head of the organization is the Agent and all matters which go up through the various committees without being settled are submitted to him for final decision.

Next to the Agent is the Committee of Superintendents, consisting of the superintendents of the Cotton, Worsted, and Print Works Departments and the Assistant Agent. All matters affecting the whole plant come before this committee and matters of general policy in regard to the organization are formulated.

#### DEPARTMENTAL COMMITTEES

Each department has a separate organization. In the Cotton Department there are three committees. The Overseers' Committee consists of the superintendent, assistant superintendent, all overseers, and the foreman of the repair shop. The Workmen's Committee consists of eighteen employees, who must be section hands or lower in rank, selected in such a way that all departments are represented. The Inspection Committee is a sub-committee of three elected by the Workmen's Committee. The organization at the Print Works is similar, but is larger, the Workmen's Committee consisting of thirty employees.

Conditions in the Worsted Department make necessary a somewhat different organization. At the top is the Superintendent's Committee consisting of the superintendent, three assistant superintendents and the master mechanic. The department is divided into three parts, Manufacturing,

Finishing, and No. 10 Mill, which is a separate plant a quarter of a mile from the rest of the department. Each of these divisions has its own organization headed by an assistant superintendent. The membership of the Workmen's Committees is eighteen for Manufacturing, nine for Finishing and twelve for No. 10 Mill.

The committees of the employees meet every two weeks, being allowed half an hour at the close of the day. The Overseers' Committees meet every two weeks, the meetings being considered as part of the duties of the overseers. The Superintendent's Committee of the Worsted Department meets at the call of the chairman. The Committee of Superintendents meets every four weeks.

#### THE SAFETY ENGINEER'S DUTIES

The safety engineer is a member of all committees, has general charge of safety matters, regulations of the State Board of Labor and Industrial elevator regulations, and liability insurance matters. His office handles the accident reports and correspondence relating to them and keeps records of all the committees.

The terms of the members of the various workmen's committees are so arranged that one-third are appointed each month for a term of three months. In this way it is made sure that there are enough old members on the committees at all times so that the business may be carried along without interruption. The object of making the term only three months is to give a large number of employees experience on the committees with the resulting education in safety. Women are given proportionate representation.

The method of procedure with the committee is for each inspection committee to make a thorough inspection of its own department once a month and report to the Workmen's Committee of which it is a part. The Workmen's Committee considers the recommendations made and, if approved, they are submitted to the Overseers' Committee. Matters which cannot be settled here are referred to the Committee of Superintendents except in the Worsted Department, where they first pass to the Superintendent's Committee. It is the general policy to dispose of the recommendations as low down in the organization as possible.

On all recommendations a definite answer is returned to the committee in which the suggestion originated. Either the recommendation is approved and the work done or the reason given why it cannot be approved. In some cases a substitute may be offered. During the first year of our organization more than 800 recommendations were made by the various committees and it was only found necessary to disapprove about twenty.

It will be noticed that with us all men in executive or supervisory positions are permanent members of the safety organization. If an organization is to be successful it must be part of the plant and not treated as a hobby or necessary evil.

As a means of encouragement for the committees and to keep up the interest, there must be action on the recommendations within a reasonable time. Most of the matters brought up by the committees are in the

nature of minor repairs which can be done within a short time. If these can be reported at the next meeting as finished, the effect on the committee is very good, as the members feel that they are accomplishing something. On the other hand, a committee is easily discouraged if its recommendations have no apparent effect.

You know from your own experience if you see something about the plant that needs to be remedied and you make a suggestion and then in a few days you feel that that suggestion has been carried out, it encourages you to be more careful with your suggestion. That is the way with our committee. We try to get the work done as quickly as possible.

During the past winter, it has been difficult to do this work on account of trouble in getting material and getting help, but in all of these 800 recommendations of which I spoke, at the present time I think we can say that at least eighty per cent have been completed. Those vary all the way from two or three boards in the floor that may need nailing down to guarding a whole set of machines, but we don't depend upon our safety committees to keep the plant safe. I don't know that it would be well to tell them so, but we don't. We depend upon the overseers and our own safety engineer's office and it is very seldom—I don't think it has ever happened—that any committee has made a recommendation regarding a machine of which we have not already in our office, a report as being previously recommended by the safety department. Probably you will have the same trouble in your mills. It is difficult to get this work done. The mill is run to turn out cloth; that is the first object and that is what I try to have the men working for me keep in mind—that the mill is run for a purpose and everything must tend toward that end.

Now in a great many plants it has been said that there was opposition at the present time. In our plant I don't think there is any overseer or man in charge of the work who would be willing to see this safety organization discontinued. In fact I think there would be a great deal of opposition to any such suggestion. That wasn't the case when I first started with the organization, however. I have about seventy-five overseers to deal with and out of that number when I first started in, I doubt if there were more than a dozen who cared very much about this safety work. I made it a point to go to each overseer and work on him until I had him with me and I had to use various methods of doing that.

In some cases I find that an overseer had been trying to get some kind of safety work or something related to it into his department and couldn't seem to make any progress on it. In that case I had to take it up with the committees and get it done, having that overseer with me. It took me pretty nearly a year to make sure that I had every overseer with me. We had baseball, and "mill nights" at the Y. M. C. A. The men played pool and had races and various other things. Those things when brought before the committees, were brought up at the beginning of the meeting and we would get the employees talking about something and when we got through with them and got to talking about safety, we had them talking and went onto the other subject.

The principal difficulty is to get the safety committee to talk. They are willing to sit there and listen but it is hard in many cases to get them

## *Textile Section*

to say anything. One way in which we get them started is to call a report from each department, to ask how his department is and if there is anything he wants to suggest. In that way we get them started.

### DISCUSSION

**CHAIRMAN ROBINSON:** I think a great many questions have been brought up that we should like to discuss. I am particularly interested in Stowell's talk for the reason that I have had difficult work in my own on safety committee work and I think that the safety committee organization is something that every concern has to buck up against and started and in my own opinion it is one of the biggest difficulties out of selling the management. In our concern I had the management before I started but getting the workmen sold was different. One of the best ways is through safety committees.

Another point in Mr. Stowell's talk that it is well to emphasize, is more can be accomplished by personal solicitation of the overseers than by sitting in the office and writing letters. So many safety men think they get a good mahogany desk and can dictate letters to a stenographer about safety conditions, they will accomplish safety work. I have never known a safety man who stuck to the office or a safety supervisor who was an office chairman that made a success of safety work. You have to go out and get that personal acquaintance with the foreman.

I find in my own case the best way to get next to the foremen and overseers is to attend meetings of outside interests. If they have a field or anything like that, I am always willing and ready to go out. If they have a ball game, I am ready to play. If they want some games, I am ready to enter into them as heartily as they do. In that way you get to know the human fellow outside of the business end and when you go to him in the shop and say, "Well, Bill, there's a fellow over there that is doing an unsafe thing. Don't you think that he could be cautioned or could get him to do it a little differently?" Why, nine cases out of ten that foreman is with you simply because you are not doing it in a dictatorial way. You can see things that perhaps he, being so close to them and being so used to seeing them done, has passed over time and again and in the future he will be watching for those things.

Mr. Stowell has emphasized that fact of personal solicitation very nicely and I will leave it to the meeting if they want to question Mr. Stowell. If so, you can present your questions to him or you can ask questions about any of these other papers. I would recommend that personal experiences be given. I think that is one of the best means of discussion. If somebody can get up and tell what they have done, it will give you a chance to go home with some new ideas.

**MR. STOWELL:** We are here to get all the information we can and it seems to me that there is no need of sticking strictly to the subjects announced. If there is any information I can give, I will be glad to give it. There is one thing about overseers. If there is an overseer that is in opposition to the safety organization or any man or any employee in a mill who has charge of work, I don't say to myself, "What is the mat-

with that man? What is wrong with him?" I am more inclined to say. "What is the matter with the Safety Engineer? Why hasn't he got that man with him?"

**"INFORMATION FOR NEW MEMBERS OF SAFETY COMMITTEES"**

I try to work on that basis and then go after the men and get them. Possibly you would like to criticize this little book of instructions we give the employees. This is very carefully written. I went over that dozens of times before I had it printed. It does fit us. Maybe it won't fit all mills. There is one thing here in particular that some have criticised. At the bottom of the first page inside where it speaks about bringing the matter before the overseer before bringing it up in the committee, you would judge by reading that over, that we were trying to interfere with the members of the committees in what they want to bring before the committees, but that is not the case. We find we get better results in every way by getting the members of the committees to go and talk to the overseers, explain what their suggestion is going to be to the committee and get any information or any word that he could give them on it because we get better co-operation from the overseers since we began to do that, than we did before.

Our overseers, we believe, are high-grade men. They take pride in their departments. They want them to be the best departments in the mill and if they find that some of these things are coming up in this way, they try to think up methods of overcoming the objections or complying with the suggestion of a member of the committee. Then when they have their own overseers' meetings, they are prepared to speak about it and give intelligent information to their own committees and then we have the records of the workmen's committees written out. The stenographer makes extra copies and sends them to the superintendent or the assistant superintendent in the worsted department and he takes the copies and cuts them up into strips and gives the overseer of the department concerned, any recommendation which concerns him. Then before the meeting of the overseers, he can look that matter up and he is all prepared to state his opinion and give whatever information he can.

We vary from that rule on the inspection committee. They are expected to go through the plant and see the actual conditions and report them and we don't want them to talk to the overseers unless it is on some small matter that can be remedied right away, so there is an indirect way in which a member can bring the matter before the committee without going to the overseer by calling the attention of the inspection committee to it as that committee goes through the department.

**INSPECTION REPORT FORMS**

**MR. A. J. DRESKA** (Paramount Knitting Co., Waupun, Wis.): I would like to ask Mr. Stowell if he has a regular form for the inspection committee.

**MR. STOWELL:** We have no form for the inspection committee. My assistant was rated as safety inspector and makes a weekly inspection of

the plant and fills out the form which the rating bureau of Massachusetts requires. It completely covers the whole plant but the form of report for the workmen's committees is simply keeping the minutes the same as you would keep them for any committee. We keep the actual minutes of the meeting and each recommendation brought up there is numbered and is put on a card index so that no recommendation is ever lost and must be accounted for in some way. It either goes up to the top and is disapproved and goes back to that committee, or the work is done and at the next meeting of that committee, a report is made on every recommendation to that committee reporting what action has been taken on it.

CHAIRMAN ROBINSON: Is there anybody here representing a conference which does have a regular inspection blank for their committees with certain specified questions?

MISS WILSON: I tried the plan of having typewritten a list of the points that the employees' committee will take up and I tell them to take up any others that come to them, not only for safety but sanitation, and I found that to be very, very helpful. They don't know what to look for unless they are told.

CHAIRMAN ROBINSON: In other words, you give them a hint of what they should be on the lookout for.

MR. DAVID S. BEYER (Liberty Mutual Ins. Co.): The insurance companies give an outline of the information for which the safety committee should look, on a regular printed form.

MR. JOHN RENNIE (Joseph Bancroft & Sons Co., Wilmington, Del.): Mr. Beyer has spoken of a form. We use that form all the time and find it very successful. The questions that are supposed to be given are filled out regularly and they cover practically everything in the plant.

There is just one question that I haven't heard discussed at this meeting and that is a school for foremen that is outside of the plant altogether.

We found last winter that that was a very successful thing in Wilmington. The Delaware Safety Council, in connection with the National Safety Council, formed a school for foremen and all the industries in that district have foremen at these meetings and ninety-five per cent of our men were there. All last winter at these meetings they broadened the thing out considerably.

CHAIRMAN ROBINSON: Along that connection, Mr. Rennie, we carry on the same school in Worcester, a foremen's school.

#### WORKMEN'S COMMITTEES

MR. STOWELL: I was going to state in regard to the blank to be filled in, we tried that for a few weeks at first but it was too much for the committee to attend to. They paid more attention to the blank than to the inspection, so we covered that by having the safety inspector go with the committee, giving them any help or information they want, and then brings up another point that I forgot to mention.

A first I attended the meetings of the workmen's committee myself, but I found that the members of those committees considered that I was re-

representing the management and they wouldn't talk as freely as I wanted them to, so instead of going to the meetings myself, I send my assistant and he acts as chairman of the meetings and we get better results in that way. I attend meetings of the overseers.

CHAIRMAN ROBINSON: In relation to committees, I want to give you an experience I had when I started out. I had a general workmen's committee which took in the whole plant. I found there was a lack of interest and in analyzing the cause, I found the reason was that we would have the committee talking wood-working safeguards in our plant and the members of the committee who were from the foundry or from the machine-shop were not interested. Therefore I split my safety committees up so I have men now representing only that kind of work.

In the textile mill, of course, you have got a little different condition, but I should say that the best plan in my own experience would be to take your people that are doing the weaving and have a weavers' committee, then a loom fixers' committee and the mechanical department separate. I don't know whether anybody has tried that in the textile mill but we found in our mill that the best way was to have the committees divided so that they considered their own particular hazard and gave them a chance once in six months to inspect the other departments to see what they could find. It caused a little rivalry and a little interest but they preferred just to talk their own hazards and not talk the hazards of the other parts of the shop.

MR. ALFRED BURNS (West Boylston Mfg. Co.): You have just spoken of a thing I was thinking about. Mr. Stowell says a committee of three of the workmen's committee form a sub-committee of the inspection committee. Well, I don't think they are quite qualified, for instance if they are weavers, to speak or look for dangers in the card room or spinning room or twisting room. I think as you said, a committee from each one of those rooms should inspect their own department.

MR. STOWELL: The reason that inspection committee is a sub-committee is because the workmen's committee is too large to go through the plant. We wanted the committees large enough so that every possible department would be represented, but of course, we couldn't send those full committees through the plant. This sub-committee reports to the workmen's committee, and there are on that workmen's committee men who are loom fixers or weavers or who work in all parts of the plant and they are qualified to pass on any matters that come up in their own part of the plant and we try to cover it in that way. The only reason for that inspection being a sub-committee is to make it a committee that can be reasonably handled.

The nurse also, wherever possible, goes with this inspection committee and inspects the sanitary conditions.

CHAIRMAN ROBINSON: Mr. Stowell, are those three members of the inspection committee always the same men or do they differ at each inspection?

MR. STOWELL: This inspection committee is actually elected by all the workmen's committee. They can put on that committee anybody they desire and when the term of any member of the inspection committee ex-

### *Textile Section*

pires, that makes a vacancy and that is filled by the workmen's committee. A member may serve on that committee a month or maybe two months, but usually we find where an employee goes on to that inspection committee for a short time, say a month, he is apt to be re-elected to the workmen's committee and then re-elected on the inspection committee so the average time is anywhere from one month to four months. Of course it requires one trip around the plant by the members of the inspection committee to get familiar with the plant and to be of any use to the committee. That is why we make the term three months. We tried two months at first but that wasn't long enough. We have always found there is quite a strong desire to become a member of that committee because of the opportunity of seeing the rest of the plant.

All textile mills have employees who have been with the plant for possibly forty years and have never seen much of the plant outside their own department and for that reason, many want to get on this inspection committee and in that way we get good men.

MR. B. G. RUMSEY (Standard Textile Products Co.); We have divided our workmen's committee into a certain number of portions and divided the plant into a certain number of zones and at each inspection, each zone is inspected by a certain portion of the workmen's committee. This is alternated in each inspection which brings every member of the workmen's committee into the entire plant. They can go through the plant and look it over in one-fifth the time; that is, there being five groups moving over five zones. They go in rotation. Each particular member of the committee gets around the plant looking over the entire plant during the course of service. We have found that quite interesting. There is a little rivalry watching for the inspection committee's next trip, that is to say that the people going through on an inspection trip don't want to leave any loose ends to be picked up by the next group. They want to make it clean cut. It has been quite successful.

MR. STOWELL, I had one question in mind in regard to having all overseers serve on the committee. That means that all the overseers are at some certain portion of the day, once every two weeks, away from their departments, grouped at one place. Have you found a suggestion or thought that there might be a little hazard in that? If some emergency came up, such as a fire, leaving the department to husk for themselves for the moment without the overseers? Has it ever disturbed you at all?

MR. STOWELL: That has occurred to us but in order to answer that I will have to brag a little about the Pacific Mills. It is the policy of that plant to have the departments organized in such a way that the overseer can leave at any time but of course that can't always be done. At first, we had the overseers' meetings at 11:30 and we found it caused disturbances in some departments by having overseers leave at that time just before noon. Everybody in the department knew that the overseer had gone out and wouldn't come back until after noon and that was the principle reason why we changed the time to 10:00 o'clock but our meetings are held in such places that the overseers would not have very far to go to get back to their departments. The plant is large

out in such a way that that can be done. Probably inside of one or two minutes they could all be back in their own departments.

CHAIRMAN ROBINSON: I imagine one thing in the mind of Mr. Rumsey was the slacking of production.

MR. RUMSEY: That partially.

CHAIRMAN ROBINSON: Of course, where you have piece workers that shouldn't affect them very much.

Any other discussion on these workmen's committees?

MR. STOWELL: This difference of opinion emphasizes what I said at first. An organization that is perfect for one plant may be of absolutely no use to another. This organization I have described—I have dared any one in the plant to improve it and there have been no changes whatever in it in a year and a half. Anything with any faults in it would be corrected within a short time and in Lawrence last year, the State Board of Education provided a course in safety engineering of which I was instructor. One of the problems I gave the class was to work up a safety organization for their own plants. In that class, I had assistant superintendents, master mechanics, and others of quite a number of the plants in Lawrence, and I had instructed them and given them my own organization as an example. They tried to draw up organizations for their own plants and there were none that could use that system at all. They found that they had to go on that general plan but make up their own plans from that. There was one plant in particular that tried to use this organization but they found they had to change it because of the layout of their own plant.

This is laid out to cover our own plant. There is no other plant at Lawrence built in the same way. I doubt if there is any other plant in the country built in the same way because our space is limited. When we increase, we must go a little distance away from the main part of the plant. This No. 10 mill in the worsted department that I speak of is one of the best plants in Lawrence. It employs about 1200.

A peculiar thing about the inspection committee in that plant is that they find it difficult to make any recommendations. Recently, instead of making recommendations they commended certain departments for being especially clean or for some particular reason of that kind. Some of the other parts of the plant are from sixty to seventy years old and of course the conditions are entirely different there and we try to make this organization cover our own plant.

MR. RENNIE: I would like to ask Mr. Stowell the rate of accidents in that particular plant.

MR. STOWELL: I have tried to make comparisons of the first year of the safety organization with the previous years but it is practically impossible to make any accurate comparison because during the preceding year it was during the war part of the time in which conditions were abnormal and accidents would occur and employees wouldn't report them and also nobody wanted all this information and the records were not kept in such a way that we could make an accurate comparison, but as near as I can figure, there was a reduction of the first year of organization of somewhere between twenty and twenty-five percent in the

### *Textile Section*

number of lost time accidents. The severity of the accidents was reduced something more than fifty per cent. Of course that was partly due to the fact that we put first-aid rooms in just about the time the safety organization started.

We watch the employees and they are obliged to go to the first-aid room for treatment no matter how slight the injury and we can take proper care of them and see that they don't go home unless it is necessary that they come back when they are ready to come back, and that is one of the principle causes why that reduction in severity of accidents has been made.

As near as I can figure, the rate of accidents at the present time including all lost time accidents, however slight, is about four to 100 employees per year.

MR. BEYER: I should say that is a very good record for a textile plant. We find the average is six or seven per hundred in textiles and on an average thirty or forty per cent.

CHAIRMAN ROBINSON: Now just before we leave the inspection committee, there is one thing I might tell you about my own case that may be interesting in regard to sanitation and cleanliness. We have, in our plant, a Sunday inspection, so called, where the heads of the various departments—there are about twelve of them all told—from the general manager down, the superintendent, assistant superintendents, chief engineer, superintendent of foundry, employment service man and each head of department makes an inspection of the plant on Sunday, so that it comes around about once in two or three months for each one, criticizing conditions, especially such items as oily waste left around and alleys were blocked and such things. We have got now, by those Sunday inspections, what we consider to be one of the cleanest looking plants in the city on a Sunday with the result that the habit is extended to week days. That is, the foremen in order not to have too much to do Saturdays cleaning, keep the place in better shape and it has resulted in better, cleaner, more sanitary conditions.

If nobody has more questions on safety committees, we will pass on.

MR. STOWELL: We used to give instructions orally to the members of the committee as to what they should do. We found it difficult to make them understand in some cases. This was quite an expensive thing to get up, but I found after we began to give it out we could almost make the changes in the committees. They understood what they were to do and they understood from this diagram where their committee fitted with the organization and if there is one thing that I would recommend more than any other, it is that the members of the committee have something of this kind. (Referring to the pamphlet of Information.) When a new member is elected, each overseer gives one of these to the new member and he knows what he is there for.

#### ACCIDENTS CAUSED BY SLIPPERY FLOORS

CHAIRMAN ROBINSON: One subject that has been brought up in my mind very distinctly by Mr. Clark's paper is slippery floors and I thi

that if anybody has any contribution to offer on the subject of accidents due to slippery floors, it would be welcome to the other members.

Mr. Beyer, what do you find in that line? Do you find many textile accidents caused by slippery floors or rolling bobbins or things like that?

MR. BEYER: We have found a number of accidents due to such cases. It is as hard to avoid entirely as accidents due to bare feet. I thought Mr. Clark had a very interesting paper and I am rather sorry he wasn't here personally to support some of the statements he made. It might have made a more interesting discussion had he been here.

There are two or three points that struck me as the paper was being read, in which it seems to me his deductions might be due to a misunderstanding of the conditions, as for example, in the rating schedule. He spoke about the use of machine ratios in the textile industry as compared with other industries.

I happen to have been a member of the committee that worked out those machine ratios and we found that there was a very much higher ratio of machines to operatives in the textile industry than in almost any other industrial division and we also found that the proportion of mechanical accidents in the textile industry was higher than almost any other industrial division so that we did not, as Mr. Clark seems to think, base our judgments merely on the fact that we found more machines there. That was only one thing considered and since we have the record of hundreds of plants over a period of years covering accidents and accident costs, we are in a much better position to form a judgment with all that data, than any one working in a plant whose vision is more or less limited to the accidents with which he comes in contact.

The matter was given very careful study. We had a very broad statistical basis back of it so it was not a snap judgment based on the appearance of the thing as one might infer that Mr. Clark thought it was.

He spoke about the accident reports being inaccurate or misleading, from the standpoint of the real cause of the accidents.

We do find that in many cases the immediate cause which leads to an accident may be, for example, a slippery floor which causes an employee to slip and make an unexpected motion and put his hand in a pair of gears, and yet, if the gears were guarded that slip would mean nothing. Employees slip many times and no accident occurs. So where an employee is injured in an unguarded gear, even though he put his hand in the gear in that way, I think it is fair to charge the accident to the gear, because the gear could be guarded to prevent the accident.

CHAIRMAN ROBINSON: On the other hand, if he hadn't slipped, he wouldn't have put his hand in the gear.

MR. BEYER: That is true, yet we know the management *could* guard the gears and could not always prevent the slipping, so I think it is perfectly logical to attribute such an accident to lack of mechanical protection.

Mr. Clark spoke also about the light, and about clean floors, both of which are very desirable, but he said the cost of maintaining such conditions is practically negligible. I think that is a rather questionable state-

### *Textile Section*

ment. In the newer mills we generally find lots of window area. . . of the older mills have large unlighted wall area and the building wide; to provide light in the middle of such buildings at all times is an inexpensive matter. The question of keeping the floors clean is only a matter of habit, and is more easily handled.

I think Mr. Clark's paper was very interesting and I only wish we were here to discuss it further.

CHAIRMAN ROBINSON: I think that is one thing the textile industry is up against, and perhaps in New England more than anywhere else that is that the mills were built a good many years ago, and they existing conditions which to change would mean a monetary outlay which is pretty hard to say is warranted, in order to reduce accident

The mills that are being built now-a-days, especially in the South where there are a large number of new mills being built, have taken consideration the lighting proposition, so that eventually all these mills will have to be replaced by newer buildings anyway, and at that time the lighting situation will naturally be improved.

MISS WILSON: I should like to ask a question for information there any one here who can tell whether or not there is value in putting whitening on twister-room floors to take up oil?

MR. C. E. PETTIBONE (American Mutual Liability Insurance Company, Boston): I cannot answer that directly, but I might say this, that I have found, on slippery, oily places that a great deal of the trouble could be avoided by sprinkling it with lime dust.

CHAIRMAN ROBINSON: Is that what you refer to as whitening?

MR. PETTIBONE: No, I imagine not, but the effect would be practically the same.

MISS WILSON: It is the same thing, practically a chalk.

CHAIRMAN ROBINSON: I found, in connection with wood-working establishments, our Providence Plant has used resin to some extent on floors, preventing slipping. I don't know whether that has been tried in textile mills or not.

MR. STOWELL: If there is any one thing we pay more attention to than any other, I think it is slippery floors. We tried various things. We tried powdered pumice-stone, possibly Miss Wilson refers to that. We tested various soap powders advertised to clean floors without making them slippery. The average scrubber isn't satisfied to clean the floor without a large amount of suds. We tested two or three of these powders and then the chemist analyzed them and found them simple. One was made up one of his own, and we use this powder made by him now. It is something like borax. I don't know what it is. It will clean the floor without suds, and ten minutes after the floor is washed it is dry and not slippery. The principal reason for slipping is a scum after it has been washed. In one part of our mill we use three women in washing floors, and there is no trouble at all there from slipping. The floors after washing are clean. After washing they mop them so that there is nothing left on the floor at all, and in a few minutes they are dry and not slippery. I think the principal cause of slippery floors is the wrong method of washing.

MR. R. G. STOWELL (Carter Bloxonend Flooring Company, Chicago): I represent a floor concern. I have been interested in the textile industry for the reason that a great many concerns have endeavored to produce a floor that would prevent slipping. Several are on the market, and all are good. In some textile institutions they are now considering the use of an end grain wearing surface which will prevent slipping. The question now up with these floor people is the very thing that you have up here now, as to how to clean them properly. There is no doubt that the end grain wearing surface on a wood-block floor will absorb a great many of the things which fall upon the floor, naturally, which could not be mopped up, but the dry-cleaning of an end grain floor is a thing that will make the end grain wearing surface the floor for textile mills, and we are hoping to produce that.

CHAIRMAN ROBINSON: That is an excellent suggestion for new mills. It is kind of an imposition to ask an old New England manufacturer to go through his plant and put in block pavement.

It is a mighty good thing not only for the non-slipping, but also for the quiet. In trucking over it you don't get the loud noise that you get on a smooth floor which is apt to disturb the operator.

MR. PETTIBONE: May I say something about the point Mr. Beyer brought up about the gears and slipping? A firm I was formerly with had analyses made of many accidents and we soon found that we would have something to do to determine to what to charge the accident. The question first came up as to who was responsible for accidents. You can follow that through and there is a certain responsibility to the president of the concern, possibly very remote; some to the foreman, and so on down the line, and we tried to find the man who by his action alone, the last man, could have prevented the accident. We found it was the man to whom we charged the accident, and on that same principle we took the last condition, which by changing, or protection (which in this case was the gears), would have prevented the accident, and blamed it on that.

I think you must have some rule along that line to determine how you are going to charge your accidents, and we have found that that worked out very satisfactorily.

CHAIRMAN ROBINSON: That is a good suggestion. Are there any other suggestions or questions, regarding slippery floors? How about material lying around on the floors: roving, bobbins, and so forth. how can you prevent that? I think myself that about the only thing is education.

MR. STOWELL: I think I have talked too much already, but that is another thing we do in sort of a systematic way in the weave room where you find most of that trouble. The weaver is held responsible for his section of the floor. The same thing holds good in other parts of the mill.

CHAIRMAN ROBINSON: Even though the bobbin may have come from a loom not in his section a section hand is held responsible for his section.

MR. STOWELL: Yes. The principal trouble is that some of the automatic looms don't drop their bobbins in the right place, but throw them on the floor.

## *Textile Section*

MR. RUMSEY: You come back to what I said before. If every foreman were a capable inspector, there would be no slippery floors.

CHAIRMAN ROBINSON: The foreman is the final man, and if you get the foreman with you, you will cut down accidents. I think you find that in most cases the foreman is the key man.

Are there any other suggestions?

We sent out a questionnaire here sometime ago, requesting that everyone consider any questions they would like discussed and send them in. We got a few questions, and one of them is on standard guage which we got from Mr. Rennie. I think, Mr. Rennie, that that will be taken care of in tomorrow's meeting.

The chief job of this section this year, will be to establish safe standards, and in that connection it might not be out of place to announce that the Textile Section have offered their services in joint sponsorship with the mutual casualty insurance companies, in drawing up a standard set of textile safety pamphlets, or a standard set of rules governing safety in textile plants.

There will be a meeting of this Section, together with the representatives of the mutual companies, tomorrow after the morning session to appoint a permanent committee to work on this for the Engineering Standards Committee, which is composed of the four engineering societies. The Engineering Standards Committee has volunteered to undertake standardization of all kinds of practices and work. The National Safety Council is very closely connected with them in safety standards. The Textile Section is the joint sponsor with the mutual casualty companies in drawing up the Textile Section Safe Practices.

MR. STOWELL: I would like to ask if anybody here can give me this information or not. I wanted to find a real up-to-date lunch room. Is there anybody who can tell me of such a place?

MR. CONRATH: I was down to the International Harvester Company at Milwaukee works and I saw a really elaborate lunch room there. One of their inspectors was here.

MR. RENNIE: I was through the Allis-Chalmers Company and saw an excellent lunch room there.

CHAIRMAN ROBINSON: We have not talked much about the jute and hemp industry but maybe Mr. Conrath will say a few words in regard to safety in this industry.

### THE JUTE AND HEMP INDUSTRY

MR. CONRATH: The only thing I can say about the jute and hemp industry is that we have had the same trouble with slippery floors, and have purchased electric machines for doing some of that work outside of working hours, Saturdays and Sundays, so they are all right. In certain places we have put matting or linoleum on the floors.

CHAIRMAN ROBINSON: Of course the wood-working industry recommends the use of rubber mats very largely around wood-working machinery. I am afraid if you attempt to do that around the looms in a textile mill it would be a very expensive proposition, but a corrugated rubber mat

is a good non-slipping surface. The only thing you have got to be careful about is not to have it projecting above the floor and thus make it a tripping hazard.

MR. A. E. CONRATH: The rubber and oil don't agree. The oil eats the rubber and softens it.

ADJOURNMENT.

### THURSDAY MORNING SESSION

THE meeting convened at 10 A. M., Chairman H. L. Robinson presiding.

#### REPORT OF NOMINATING COMMITTEE

MR. D. S. BEYER: The Nominating Committee has succeeded in making a unanimous report, with one exception, and that is for the chairman of the committee. We had one member that objected very strenuously to the name of Mr. Stowell, that member being Mr. Stowell himself, but the rest of the committee, combined, was able, by a majority vote, to put his name through as nominee for Chairman.

For Vice-Chairman the committee would like to appoint the name of A. E. Conrath, of the International Harvester Company, the present Vice-Chairman.

For secretary, Mr. B. G. Rumsey of the Standard Textile Products Company.

That would give representation on the committee of an Eastern mill, as Mr. Stowell represents the Pacific Mills; a Western mill, represented by Mr. Conrath; and a Southern mill, as some of the mills of Mr. Rumsey's company are located in the South. This will give a fairly good geographic division if the members decide to accept the recommendations of the Nominating Committee.

(The report of the Nominating Committee was accepted.)

(Mr. Bigelow, Asst. Chief Engineer, etc., then read a paper on "Accident Prevention in Cotton Mills", which with the discussion that followed will be embodied in a Safe Practices pamphlet to be published later. Accordingly this paper will not be included in the Proceedings.)

#### ORGANIZATION OF TEXTILE SECTION STANDARDIZATION COMMITTEE

CHAIRMAN ROBINSON: Now we have several casualty men with us, so I would suggest that we proceed to appoint a temporary secretary and a temporary chairman and get organized.

MR. BEYER: I think we have a very efficient secretary and chairman at present. I move they be nominated for permanent organization.

(Motion seconded and carried.)

CHAIRMAN ROBINSON: To explain a little further; the Textile Section, as some of you know, has had a standardization committee appointed for the purpose of getting up a safe practices pamphlet. As Miss Wilson

### *Textile Section*

stated yesterday, we had five or six meetings this year for drawing up pamphlet, and I would suggest, if I may be permitted to do so, that present committee be allowed to remain, representing the Textile Section of the National Safety Council. They are all big mill men, or the majority of them are, and have had considerable experience in textile work. I will read their names directly and you can add anybody to that committee that you want to. It is simply a representative committee of textile industries and manufacturers, and I would suggest also that new officers of this section serve on that committee.

The committee as it stands at present, is as follows:

|                |                 |
|----------------|-----------------|
| H. L. Robinson | Kenneth Moller  |
| A. E. Conrath  | David S. Beyer  |
| Ida M. Wilson  | A. Makepeace    |
| W. S. Ide      | Henry A. Owen   |
| Geo. Bigelow   | Robert Burgess  |
| James Strang   | C. E. Pettibone |

And the National Safety Council is to appoint one member. That member will probably be Mr. Williams, Chief Engineer, and Secretary at present time.

On that present committee we have got machine manufacturers, mill men, and we have also two insurance men, but that is incidental. I believe they will also be on the other committee.

Now for the Textile Section; I would recommend that you let this committee represent you, but I will also give you a chance to add any other that you think should be there, if you think of any men that are not ready on.

I would like to suggest, myself, that it might possibly be a good idea so long as so many textile mills are in Massachusetts and New England that the Associated Industries of Massachusetts have a representative on that committee. They are members, I presume, of the National Safety Council, but that may be something that your new committee will want to add, and perhaps shouldn't be added on to the Textile-Section committee.

Are there any other recommendations for nominations on that committee to represent the Textile Section for the American Engine Standards Committee on Textile Codes?

MR. CONRATH: Is Mr. Stowell on that committee?

CHAIRMAN ROBINSON: The new officers are on that committee. Stowell and Mr. Rumsey, the two new officers, belong ex-officio on that committee.

If there are no other names that you can suggest I will ask Mr. Beyer representing the casualty companies, if he has anything to say, but we go ahead on that new committee.

MR. BEYER: The National Association of Mutual Casualty Companies has been appointed as joint sponsor for the new code with the Textile Section. They had a meeting some days ago and appointed the following

ing members to represent them, and constitute the Mutual Casualty Companies' committee: Mr. Pettibone, of the American Mutual; Mr. Bessey, of the Employers' Mutual of New York (I am not certain of the detailed wording of these names, but you can get those later); Mr. Youmans, of the Employers' Mutual Liability Ins. Co., of Wausaw, Wis.; Mr. Tatum, of the Textile Employers' Mutual Liability Company, and myself, representing the Liberty Mutual.

It seems to me it might be well to have a joint meeting of the two joint sponsors and to elect officers to represent the joint committee. Unfortunately there doesn't seem to be many of these Mutual men here. They were all advised, and possibly they thought the meeting would last longer. Mr. Pettibone has just arrived, and some of the others may come in.

CHAIRMAN ROBINSON: Would it be better to hold off until 12 o'clock, or would you recommend appointing a Nominating Committee from these two lists and let them proceed with nominations, and call a meeting of the joint committees when they are ready?

MR. BEYER: I think it would be very desirable if we could get the permanent committee organized before we leave the Congress, because we have more representatives, undoubtedly, than we shall be able to get together for another year, since they are so scattered.

CHAIRMAN ROBINSON: Don't you think it would be well, before we have that meeting, to have the Nominating Committee ready to report something?

We can elect a Nominating Committee, it doesn't have to be appointed. The names can be suggested and somebody can make a motion that a certain number be appointed and names can be suggested as to who should be on that committee. Then, when you do have a joint meeting, you will have some business to transact. As it is now, if you have a joint meeting, the only business you will have will be the appointment of that Nominating Committee.

MR. BEYER: I think that is a good suggestion, particularly so, if we could have a meeting later on during the day.

CHAIRMAN ROBINSON: The chair is willing to accept a motion to that effect, that we elect a Nominating Committee.

MR. BEYER: Mr. Pettibone has just given a suggestion which I think is perhaps very good: that we appoint a Nominating Committee here and then take a mail vote of the members.

CHAIRMAN ROBINSON: That is a very good plan.

MR. BEYER: That would give everybody a chance to vote and save getting the people together again.

CHAIRMAN ROBINSON: Have you any suggestions as to who should serve? I think possibly you should have three men on that committee, or possibly five, who know the others and their connections.

MR. BEYER: I would suggest two from the Textile Section, two from the Mutual Casualty Companies, and one from the Council.

CHAIRMAN ROBINSON: I think that is a very good plan.

MR. BEYER: I move that the Chairman be empowered to appoint that committee.

CHAIRMAN ROBINSON: Have you the list of the Casualty Companies?

MR. BEYER: Yes, I can give you that.

CHAIRMAN BEYER: Then I will appoint Mr. Conrath and Mr. Runn as representing the Textile Committee, and Mr. Pettibone and Mr. Bessey representing the Casualty Companies.

Will somebody get in touch with Mr. Bessey? We will ask Mr. Williams, or somebody from the Council, to represent them.

Mr. Pettibone, will you serve as Chairman?

MR. PETTIBONE: Yes.

CHAIRMAN ROBINSON: Is there any special time you want to call the committee together?

MR. PETTIBONE: Are they all here?

CHAIRMAN ROBINSON: Mr. Bessey is not.

MR. BEYER: Perhaps if the committee would go in a body of the present four members and hunt Mr. Bessey, it might be safest.

MR. PETTIBONE: I will say that we will hold the meeting immediately after this meeting adjourns.

CHAIRMAN ROBINSON: Stepping out of the office as Chairman, I wish to present my sincere thanks for the aid of the committee and the Section during the past year.

I know that the new Chairman will be fully as well supported as I was. I am sure he has my hearty support, and I presume that everybody will be very glad to give any assistance.

In formulating this code you probably will be called upon to present your practices in your own plants, along these different lines, and anybody who has anything to suggest would do well to get in touch with the committee as finally appointed and make those suggestions.

I believe the intention is to have everybody that is interested in textile safety, from the manufacturers to the labor unions and the insurance companies and the operators, represented on that committee, so that everybody will have a chance to say something. But, if anybody who is a member of the Textile Section has anything to say or any suggestions to make to that committee, I know they will be only too glad to have their suggestions sent to them.

MR. STOWELL: There is one thing I would like to suggest before I forget it, and that is that there be some effort made to have this code, if it is issued, be agreed upon by all insurance companies, or any one else concerned. There are quite a number of books and pamphlets which have been issued on cotton mill safeguards, and other textile mill guarding, and they give different rules and cause a great deal of trouble.

Now in Massachusetts the insurance standards do not agree with the State Board of Labor, and we have a great deal of difficulty in that way.

I know that the Travellers' Insurance Company is getting up a cotton mill book now because they asked me for some pictures for their book, and it seems to me that somebody getting all these people together and getting uniform books would be of great help.

CHAIRMAN ROBINSON: Of course in getting up the pamphlet the insurance companies are only one of the entire committee appointed. The

was a chance to criticize it given to the textile mill owners and their representatives, and the manufacturers, so that it has had at least a partial examination by those interested, but it might be well if the various insurance companies should have a copy sent to them before it goes to press, and give them a chance to criticize it. That is something that your new committee can take up.

This will not be put on to the press before you have a meeting of your officers for the next year together with this Standardization Committee, and you can, at that time, if you desire, hold up the issuing of this copy until the joint committees have had a chance to decide whether they want to use any of it in their new code.

MR. G. D. BRAGDON (General Accident Company, Philadelphia): I have heard a good deal about the mutuals. Some five or six years ago I got up a set of safety standards for cotton mills and appeared before the Cotton Mill Owners' Association in Georgia. We tried very hard, at that time, to put over safety standards in that locality, but there do not seem to be any representatives of the Southern mills here.

CHAIRMAN ROBINSON: Mr. Rumsey is representing the Standard Textile Products. They have several mills in the South.

MR. BRAGDON: I know I was at about sixty per cent of the cotton mills about the Potomac River and at that time we had a set of standards drawn up, and while the cotton mill owners wouldn't adopt it, they gave us their assurance that they were heartily in favor of it. I haven't heard anything about it so I don't know whether anything has been done to put these standards before any of the Southern mill owners.

MR. BEYER: That is the intention of this committee that is being organized at the present time. At present it is just a steering committee which will assume the direct responsibility for getting together the final committee, which will pass on the standards. It is the intention to ask representatives of the stock insurance companies to serve, as well as all of the principal manufacturers' associations. There are two or three different manufacturers' associations in the East and some Southern cotton associations also. Every group of textile people who are organized and will be interested in this, will be asked to have a representative on the committee. We have included the machinery builders, and so forth. Ultimately the committees may have a hundred members.

It is the thought, that if it would be impossible to get them together every time, they would be sent copies of the data for criticism, and before the final work of the committee is undertaken, the entire personnel must be submitted to the American Engineering Standards Committee, and approved by them so that in each case they will go over the list and see for themselves that it is a broad, representative committee, before the ground is really cleared for any action.

The paper which was presented here, is merely a tentative, advance statement, worked up by the present committee but it will be the intention of the committee to get data such as you mentioned, to bring together, to start with, all of the different standards and publications that are available on the subject. This will be done in the case of each com-

mittee. Sometimes there may be half a dozen sets of standards prepared by different bodies along similar lines, and they will be tabulated and the best material taken from each, criticised, and new material added, and may be a couple of years before the final standards are issued.

CHAIRMAN ROBINSON: That is the idea of the Engineering Standards Committee.

MR. BRAGDON: My idea is that there shouldn't be several standards. The stock companies working in Southern States we would like to have a standard to work with.

CHAIRMAN ROBINSON: That is the idea of the Engineering Standards Committee. All these standards will eventually be standard when accepted and in order to have them national, when adopted, everybody that has any interest will be represented and have a chance to criticize them. Will this Nominating Committee also get in touch with Mr. Williams and tell him that he is the representative of the National Safety Council?

The committee is Mr. Conrath, Mr. Pettibone, Mr. Rumsey, Mr. Bess and Mr. Williams.

ADJOURNMENT.

---

#### TEXTILE SECTION STANDARDIZATION COMMITTEE

The personnel of the Textile Section Standardization Committee as constituted for the year ending with the Congress of 1921 is as follows:

C. H. Stowell, Pacific Mills, Lawrence, Mass.

A. Makepeace, American Printing Co., Fall River, Mass.

H. L. Robinson, Crompton & Knowles Loom Works, Worcester, Mass.

Ida M. Wilson, Lowell, Mass.

A. E. Conrath, International Harvester Co., St. Paul, Minn.

David S. Beyer, Liberty Mutual Insurance Co., Boston.

Kenneth Moller, Lockwood, Greene & Co., Boston.

W. S. Ide, S. Slater & Sons, Inc., Webster, Mass.

Henry A. Owen, Whitins Machine Works, Whitinsville, Mass.

Robert Burgess, Maverick Mills, Boston.

James Strang, Saco-Lowell Shops, Boston.

George Bigelow, Liberty Mutual Insurance Co., Boston.

S. J. Williams, Chief Engineer, National Safety Council.

B. G. Rumsey, The Standard Textile Products Co., New York City.

C. E. Pettibone, American Mutual Liability Insurance Co., Boston.

E. H. Coffin, Associated Industries of Massachusetts, Boston.

## Woodworking Section

September 29 and 30, 1920

---

J. E. RHODES, Chairman

Secretary-Treasurer, Southern Pine Association, New Orleans, La.

F. A. BARKER, Secretary

Resident Manager, Lumbermen's and Manufacturers' Insurance Agency,  
Milwaukee, Wisconsin

---

### WEDNESDAY MORNING SESSION

**T**HE meeting was called to order by the Chairman at 10 o'clock.  
CHAIRMAN RHODES: We will first have the report of the Secretary..

#### SECRETARY'S REPORT

I am sure the program for the Woodworking Section of our Congress which is now in session, will prove of interest to all of us. The Council and representatives of each section have been devoting considerable time since our last meeting in Cleveland to the preparation of a program that would cover the advanced work of safety in the lumber and woodworking industry, and the subjects selected must naturally be of interest.

I am advised by the executive office of the National Safety Council that there has been during the past year a very material increase in membership for the Woodworking Section. This is especially gratifying because of the apparent lack of interest heretofore in this hazardous industry.

Reports which we have received from various industries indicate that safety for small plants as well as large, is receiving careful attention from the owners.

The greatest problem brought to our attention is not the physical guarding as much as organization to promote the right spirit among employees, to secure their co-operation to think safety, eliminate carelessness and to co-operate to prevent accidents. This is more essential than physical protection in any industry. It appears that human nature just won't check itself on carelessness. The chance-taker and careless individual are endangering others just as much if not more than them.

selves and they must be educated that it is pure folly to be careless and to take chances.

During the last year the National Safety Council has received many favorable replies as regards its educational work through the medium of bulletins, plans for organization, and descriptive methods of physical guarding, and the Council desires to extend to you today upon request, any information or data that may be available in its files, and should the answer to your problem not be immediately available it will be obtained for you.

This is a service that the members of the National Safety Council should avail themselves of more frequently than they do. Don't merely pay your fees and accept what is given you without inquiring as to what more can be given you if you will make your wants known. I am wondering how many of you are aware that the Council has experienced safety engineers for your mechanical problems of safety, as well as experienced organizers for your problems of safety educational work.

I dare say a number of your problems will be brought to this Congress. We are mighty glad to have them brought here for discussion, but please remember lots of good assistance could have been secured by directing your inquiry prior to this time to the Council. We, therefore, urge you to take advantage of these facilities to which you as a member are entitled.

In conclusion please bear in mind that our section, although rapidly increasing in membership and prestige, wants your most sincere co-operation for the coming year on the following:

1. Our membership must increase. Each member should be able to secure at least one new member to the Council.
2. The Council, in order to make our section second to none, needs your assistance in furnishing material, data, etc., for safety in lumbering and woodworking plants. Keep in touch with the Council for new ideas, and be willing to furnish information as well as receive it. Suggestions and criticisms are always welcome.

CHAIRMAN RHODES: Mr. F. G. Lovett, of the Province of Ontario, which has taken a very great interest in safety work, is here prepared to discuss the need of improvement in the safeguarding of woodworking machines.

#### THE NEED OF IMPROVEMENT IN SAFEGUARDING WOODWORKING MACHINERY.

F. G. LOVETT, INDUSTRIAL ACCIDENT PREVENTION ASSOCIATIONS OF ONTARIO,  
TORONTO, ONT., CANADA

I think we are all agreed that the need of improvement in safeguarding woodworking machinery is a real one; in fact it is so self evident that it requires no emphasizing on my part. The real question is how best to meet that need.

Woodworking tools are perhaps the most hazardous of any one class of machines. The high rate of speed at which they run and the fact that in a large percentage of cases the material to be machined is held

the guards of the past have failed. When we can get co-operation along these lines, backed up by the employers, then the goal which we seek will be in sight.

There are many operations in a woodworking plant where standard guards cannot be used. Different plants having different methods and means of doing practically the same work. Managers and superintendents should design special guards for such work. This is a big field, and wonderful things might be accomplished if those in authority will only give the support so much needed. Many accidents are happening every day, and the employer blames the employees for being careless; no doubt in many cases they are careless, but they are not nearly so careless as the employer, whose fault lies in that he does not take a real interest in the welfare of his employees and does not consider the monotony under which the employees work day in and day out. The workman stands at the same machine doing the same work over and over again. We tell him to keep his mind on his work, but that is next to impossible. In a great many cases he has become so used to his surroundings, so accustomed to the various operations to be performed, that his mind is always wandering in other fields of thought, and it is under these conditions that most of the accidents happen. It is necessary, therefore, to have guards that will be real safeguards when the unforeseen happens.

#### SANITATION IN WOODWORKING INDUSTRIES

Another big need in the woodworking industries, at least in a large number of them, is improvement of the lighting systems, both natural and artificial. Windows are seldom, if ever, cleaned; walls are covered with dust and dirt which absorb instead of reflect light; and floors are littered with all kinds of waste material and shavings. Such conditions make a dismal place in which to work. Can we expect men to have clear minds under such conditions? I think not.

Many of our industries in this class, and this applies more particularly to the planing mills, are just where they were forty years ago. They have the same buildings with the same old equipment, and they are still using the same methods as were used by our forefathers when accident prevention was unknown and mutilated men were considered a necessary by-product of the industry. These are the plants that have the more serious types of accidents. These are the types of employers who will tell you that they have provided a guard when ordered by the inspector, and if the man doesn't use it, it is his own lookout. You know them, you have met them; they are in every town and city. This is where the first great improvement must begin, but we are not discouraged. They like other classes of employers will yield to treatment if it is wise and persistent, but in the meantime let us get together those who are alive to the needs of improvement in woodworking industries, let us invite their co-operation with the manufacturers of guards, and with the help of the National Safety Council this need of improvement in safeguarding wood-working machinery will be met.

CHAIRMAN RHODES: In his paper Mr. Lovett suggests one or two thoughts for discussion: whether or not wood-working machines ought to

be built with safeguards by the manufacturer as part of the machine or whether safeguards should be bought as extras after the machines are installed. There are some machines, of course, which are provided with them as an integral part of the machine, but there are many which are not.

#### DISCUSSION

MR. W. GRAHAM COLE (Director of Safety, Southern Pine Association): A year ago I was appointed as a representative of this section to the executive committee of the Engineering Section. That was composed of engineers interested in safety, their primary object being to secure information on engineering problems. I have been requested by this committee to mention that it is ready and willing to consider any problem presented to it by the Woodworking Section.

We have an engineering problem in safeguarding this machinery, and we have the opportunity to get the aid of the Engineering Section to solve it. The most important thing is a saw, and the Engineering Section has put on its program a paper on safeguarding the circular saw. That paper will be presented this afternoon and I think it is our duty to be there to help the engineers discuss the saw guard problems. It was put on primarily for our benefit.

CHAIRMAN RHODES: Mr. Schreiber, Deputy, Industrial Commission of Wisconsin, has prepared a paper on the "Essentials for Safety in a Woodworking Plant." We shall be glad to hear from Mr. Schreiber.

#### ESSENTIALS FOR SAFETY IN A WOODWORKING PLANT

HENRY SCHREIBER, DEPUTY, INDUSTRIAL COMMISSION OF WISCONSIN,  
OSHKOSH, WIS.

The Industrial Commission of Wisconsin, in the past year has been making a special effort to reduce saw accidents. All the deputies in the field have instructions to pay particular attention to saws, because accidents from this source keep coming in every day. For many years we have been familiar with woodworking machinery and have worked and lived among those who handle this kind of equipment. Nearly all the saw accidents occur on circular rip saws, hand feed. In the past year, of all the saw accidents I have investigated, only two occurred on a cross cut slasher saw. So, to strike an average, I will say that if you have fifty injuries on saws, forty-nine will happen on hand feed rip saws.

Now all the saws on which accidents have occurred, which I have seen in the shops in the past year, are guarded and equipped with a splitter and so forth. Some of these guards cover the saw entirely; others are attached to the splitter and cover the top of the saw; some are fastened to the ceiling and some to the saw table. I find saw guards of every kind and description, home made and patented devices costing anywhere from ten cents to fifty dollars. So, as I said, it is nearly impossible in this state to find any saw, on which an accident has happened, that is not guarded in some way. Still accidents are occurring

every day. Now, why do we have these accidents? How do they happen on the hand feed rip saw?

#### WHY AND HOW SAW ACCIDENTS OCCUR

We in the field during past years have not stopped at guarding. Guarding merely puts a device over the saw or covers it. This prevents a man from throwing his hand on top of the saw—that is about all any guard will do and possibly it is all it is good for. We have to take care of the saw itself, and there is all our trouble. Most of the saws on which these accidents occur have no set, are not hooked or hammered, have been filed or gummed or sharpened for weeks, and have practical teeth at all. Still they are in use, most of them, nine and ten hours a day. I have some samples here and I hope you will take a look at them. It won't do any harm, and it may help to prevent an accident.

I was in a shop recently where accidents were continually happening. They had in one department fifteen hand feed rip saws; all guards were asked the foreman how often he changed saws. I could hear the grunting like switch engines. "Well," he said, "I don't remember, I think they have been on for two weeks." These saws were in use ten hours a day. Well, they change twice a day now, and I don't remember their having an accident on these saws in the past two years. That is because a sharp saw will cut, clear itself, and will not kick back, turn, burn, or snake. As a rule, this is the story of the accident. The operator, being dull, Mr. Operator forces the timber in; the saw does not clear itself, and the board kicks back; the operator tries to catch the pieces and his fingers come in contact with the saw, with the result injury caused by the saw itself.

#### HOW SAWS SHOULD BE SHARPENED

When you get into a shop where they have saws, you need not ask whether they are sharp. You only need ask when they are changed. Sharp saws put on. You can tell whether they are dull or sharp by the way the operator has to push, and also by the sound. A sharp saw in operation will sing; a dull saw grunts, just as if a fellow is looking for a prescription and can't find it.

In large shops nearly every department has a rip saw or a cross saw that everybody uses and nobody takes care of. In the shop they call them man-killers. These saws are filed perhaps once in two years, they cause a good share of the accidents, because somebody has to make a box or a sewing table or a baking board, or to cut up pitch. There are a thousand and one other things cut up on these saws that the employee never sees and knows nothing about.

I know of some shops where saw accidents are at a premium. They have none, and have not had any for years, and they are woodworking establishments at that. I am referring to accidents on circular rip and cut-off saws. Their saws have a guard and are kept in shape. The operator is on the job, and knows his business. He gums them, gives them hammers them, etc. There is a whole lot in knowing how. Some

these filers don't belong in the filing room, for when they fix up a saw is as bad as if a shoemaker had tried to build a house. They are misplaced. The filer who knows his business hooks the saw right. hooking is meant this: the teeth should be filed so that the point strikes the wood first and clears itself. If the saw is not properly hooked, the bottom of the tooth strikes the lumber first. This causes the wood to kick back and then there is another accident. No matter how many guards you put on, the operator will get hurt, because the damn saw won't cut lumber.

#### PROPER OPERATION AND PLACING OF RESPONSIBILITY

In order to reduce the saw accidents, it will be necessary to place responsibility for the proper operation of saws and reform some filing rooms. Where one man can not take care of the work, he should have helpers. If one helper is not enough, get two, because one accident prevented might pay the wages of a half dozen helpers. Get enough men to do the work, and see to it that it is done right. Compel the foremen and superintendents to change the saws when they see that they are beginning to get dull, and you'll reduce the saw accidents at least 75 per cent and increase the production. I have been in some saw filing rooms when men have come in with saws and have asked for a sharp one. The filer has looked at the saw, and told him, "Why, that saw is all right. You put it back and I'll file it to-morrow. I've got something else to do." Well, that fellow instead of going to the superintendent or foreman, puts it back and bumps away on it. If, in this case, the superintendent and foreman were held responsible, this saw would never have been put back unfired, because, once the responsibility rests on these two men, they will not allow such chances to be taken.

#### POWER TO SEAL MACHINES

I can take you to any shop—the first one we come to perhaps—and you shall find in operation saws with teeth (sometimes three or four) broken off. Only last week, while inspecting in a Fox River Valley shop, the first saw I came to had four teeth gone. I didn't turn the saw all the way around because I was afraid there might not be any teeth on the other side at all. The places where the teeth had been broken out were worn smooth. This saw had been operating some time, to say the least, in this dangerous condition. Now, if I had had the authority to seal this machine so that it could not be operated until a sharp saw and one with teeth were in place, then my visit to this plant might have done some real good. You can readily see that if, as stated before, the responsibility was placed on the superintendent and foreman, placing a seal on this machine would have much better effect, because these men are responsible for production and it would not take them long to perceive that they can not get production from a machine which the law did not permit them to use. The saws would be kept sharp and in good condition after one such experience. You can bank on that.

OTHER WOODWORKING MACHINES SAFER BECAUSE THEY TURN OUT  
FINISHED PRODUCT

As to accidents on other woodworking machines, these are very few. Shaper accidents are practically eliminated because the shaper knife heads are guarded and you can't do a job with dull knives. The shaper produces a finished product. If a man were running dovetail, bending rails or running panels, etc., so that a half dozen men had to sand and scrape in order to have them right, somebody would bother, and it would not happen again. The same thing applies to stickers, moulding stickers, door, sash, blind, and core stickers. If the finished pieces are not smooth, some one will talk Sunday School to somebody, and it won't happen again.

The same applies to tenon machines, boring machines, and all others which turn out a finished product. Saws do not turn out a finished product, and therefore are not properly taken care of. Hence the accidents. Machines which turn out a finished product are cared for, and the accidents are practically eliminated. It can't be any other way, because you can't do a good piece of work with dull knives or saws.

Self feed rip saws, the modern up to date self feed rip saws are getting to be regular automatic machines. The construction is practically fool proof for the operator. Band resaws, band rip saws, jig saws and other band saws are kept in proper working condition because otherwise they spoil the lumber. No mill superintendent or foreman will stand for this waste of material very long. Therefore, the scarcity of accidents on these saws.

PLACING THE RESPONSIBILITY FOR ACCIDENTS

Now, I don't blame the employer for these accidents entirely. He doesn't know anything about the condition of each saw and hasn't time to pay attention to it. He leaves this to his superintendent, foremen and other men, and he should hold these men personally responsible. The employer furnishes the saws, the knives, and everything else that is needed, and it is up to the men in the shop to use them right, get the work done, and avoid accidents.

The present condition can only be attributed to the lack of proper supervision or regulation. I wish to leave with each one of you these three main thoughts. They form together a means by which accidents on saws can be effectively decreased. These three governing features are:

1. Proper maintenance, repairs and upkeep of saws. Sharp saws.
2. Placing responsibility on the superintendent and foremen—the only men who can get real action.
3. The State officials should have the authority to seal machines the condition of which are such as to be a real danger.

(Mr. Schreiber then presented exhibits of saws and samples of work finished on various machines and demonstrated how tools in proper condition make for safety as well as efficiency and the highest grade of product.)

CHAIRMAN RHODES: The next paper will be by Mr. James C. Wilson further continuing the need of safety in woodworking machinery.

MR. WILSON: I am a claim adjuster, and not a manufacturer. I am here today undoubtedly for the same reason that a great many others are to get a further incentive for safety work. The death rate over the last fifty to one hundred and fifty accidents, and most of them are in the woodworking industries, because that is the class of business that our company insures exclusively.

It seems that every time we have a slump in business our accident frequency goes up. The number of accidents per hundred men employed today is greater than it was six months ago. Not only that, but the accidents are more severe.

In analyzing the accident reports for the past two years we find they are increasing all the time. More employees are hurt today than before, costs more to take care of them. Something has to be done.

One of our representatives was in San Francisco at the meeting of the International Association of Industrial Accident Boards and Commissions. They are pushing rehabilitation work, something that comes after a man is hurt. I believe they have got the cart before the horse. They ought to do something to prevent the accidents; take care of the fellow before he is hurt instead of after he is hurt.

Mr. Schreiber gave me a big idea in accident prevention. It never struck me as forcibly as it did this morning, that dull tools are so oft the cause of an accident. But it is just as plain as day that these r-saws won't cut the wood unless they are perfectly sharp.

## THE NEED OF IMPROVEMENT IN THE SAFEGUARDING OF WOODWORKING MACHINERY

JAMES C. WILSON, ASSISTANT SECRETARY, LUMBERMEN'S MUTUAL CASUALTY COMPANY, CHICAGO

The almost universal application of workmen's compensation laws has drawn men from all industries in practically all states in the union in safety work and everyone here is vitally interested in anything which will eliminate the preventable accident.

As nearly as I can determine, approximately 80 per cent of all accidents are preventable, and I am sure the percentage of industrial accidents is at least so high if not higher.

In our efforts to analyze the causes of preventable accidents we have studied the time of day; the day of the week; the nationality of the injured; whether married or single; his age; his experience and whether injured previously or not, because a long time ago it was forcibly brought to our attention that the human element is the greatest factor in all cases and that the injured man himself contributed to his accident in practically all cases.

### BLUE MONDAY

We found that accidents were—in the good old days—and still are, in spite of prohibition, more frequent in the first three hours of the day.

following a holiday or Sunday. The next highest time is the last hour of the same day. This proves that the laborer does not rest on Sunday. Instead he will do some unaccustomed work, take a trip or do something else which brings him back to his machine on Monday far below standard, so that it requires at least two days to speed up again.

Manufacturers on a piece work basis report the same facts—their low point is on Monday and their peak on Wednesday. Following Monday or the day after a holiday in accident frequency comes Saturday, and for this we blame fatigue and carelessness, because a man gets careless after running a machine or saw eight hours a day without mishap for five or six days. But a "hang-over" and a tired arm or strained eyes are not all the controlling causes. Many men, especially during the past few years of unsettled conditions and high wages, have attempted to handle jobs for which they are not fitted, either by experience or ability. This is particularly true in trades where boys under 21 years are employed.

Since we must admit that such a large percentage of accidents can be prevented, we must seek the remedy, and human nature always turns to the nearest remedy which in our case is "Safeguarding." This, of course, is a simple solution to a part of our troubles, and to me it cures the smallest ailment and is only a fair start on the road to safety. For the figures I'll give you shortly show we have almost as many accidents on guarded machines as on the un-guarded ones.

#### COMPEL THE WORKMAN TO USE THE GUARDS

Many accident reports state that the guard was provided but was not in use, and we find this true of practically every inspection we make. This condition is bound to exist as long as the worker is permitted to do as he pleases about guards. In spite of the safety campaign which has been waged for years by this admirable organization, "The National Safety Council," by state commissions and innumerable firms, corporations, and insurance companies, the workman is not in sympathy—he is not properly digesting his education. Whether he is being given the proper diet is a question.

If all states penalized the workman for removing a guard, much good would result. Of course, the employer must be made to provide the required protection. The State of Wisconsin without doubt is leading the other states in the question of safeguarding, but the figures just published for 1919 by the Wisconsin Industrial Commission clearly indicate the need of improvements in all guarding.

#### ECONOMIC LOSS OF INDUSTRIAL ACCIDENTS

They report 14,995 accidents causing a total loss to the workman of 2,875,875 days or in round numbers three million. This means the labor of 1,000 men for 3 years. There are approximately 75 counties in this state, and this lost time would give each county 40 men for 3 years to build roads—surely a terrible economic loss. The Commission further reported 226 deaths and 21 cases of total permanent disability.

In compiling our loss experience on guarding, our company finds the following information:

On saws of all types, guarded, we find 757 accidents costing in compensation an average of \$41.50. Seven hundred and sixty-five claims on unguarded saws cost an average of \$67.35; of these 548 are rip saw cases, both guarded and unguarded, which averaged \$88.10, clearly indicating that a rip saw is a dangerous plaything.

On guarded knife cutting machines we found 509 accidents with an average cost of \$25.50; and 593 unguarded ones average \$52.50, almost twice as much. In this class we put square head jointers, prohibited here in Wisconsin, and find the average cost per case is \$187.79, while accidents on cylinder head jointers average \$53.10 each.

#### GUARDS FOR THE POINT OF OPERATION

It is our experience, dealing exclusively with the lumber and woodworking industry, that the machinery and equipment used in these industries are more difficult to guard *at operating points* than any other machines as a class. It is true that there has been some permanent safeguarding, such as the safety cylinder head in jointers, but in a majority of cases the guard is devised on the machine in accordance with the work for which same is being used, which has meant, in a large percentage of cases, guards that are more or less impractical; at least the operator, because of the non-permanency of the guard, is prejudiced against it and does not use it. To illustrate, we may take a common circular saw and we immediately observe a hundred or more guards manufactured. Each carries a different thought of protection, which indicates that not one is as yet properly designed for universal work. It would also be possible to enumerate a dozen other ordinary woodworking machines which present a like condition. Therefore, it is obvious that the need of improvement in the safeguarding of woodworking machinery must largely come from a source other than standardized guards.

#### GUARDS SHOULD BE MADE FOR PERMANENCY

It has been our practice in recommending protection for this class of machines, to devise a guard which would be practical for the majority of the work being done, as well as for a considerable degree of permanency. In other words, we are having a large percentage of our accidents occur by reason of the operator removing the guard which has been provided, and he will continue to do so if that guard does not impress him as a permanent and necessary part of the machine. A machine properly equipped with a guard for a certain type of work is used without it by the operator on the least excuse or the slightest pretext that the work he is about to do makes a guard impractical, and we find he deliberately leaves the guard off the machine when he returns to the standard work for which it originally was installed. Oftentimes guards can be so designed to serve the purpose of convenience in work, as well as safety. To illus-

trate, we have frequently recommended, and it has been tried out with considerable success, a pattern or form guard for shaper work. In a good many cases this pattern or form, which is necessary in shaper work, can be designed to give the essential protection at the point of operation. This means permanency in construction of a guard because it is a part of the machine and is necessary to do good work.

One of the most substantial and most needed permanent guards recommended for woodworking plants is the complete exhaust system. We find repeatedly our most serious accidents on knife cutting machines follow the removal of the exhaust hood, or that they have occurred because the machines are not equipped with such devices.

#### SUGGESTIONS AND RECOMMENDATIONS

This condition has been brought to the point where serious thought must be given by the manufacturers, the State Departments and the employers, as well as the safety organizations, to the improvement of all forms of woodworking safeguards with particular emphasis on the point of operation. The attitude of labor toward education, or toward the use of guards provided by the employers, clearly indicates to us that some radical and drastic action must be taken in the way of State legislation, and we believe that such legislation should, first, make certain requirements of the manufacturer of new machinery; second, compel the employer, to use only properly safeguarded machines, and lastly, penalize the workmen for not using or for removing guards which were built in the machine or attached after it has been installed.

We recommend that improvement in safeguarding be carried out on the following essential basis:

(1) The purchasing department must insist that the manufacturer provide, as far as possible, permanent guards for all hazards of the machine which he is selling.

(2) The safety engineer of the plant should immediately inspect every new machine and, if it is not equipped with a proper safety appliance, design one which will be permanent and which, if possible, will facilitate operation of the machine.

(3) The employer through his supervisor should insist that the employee operate the machine with guards in place at all times.

(4) The State should check up the employer and employee to insure compliance with the laws pertaining to installation and use of safety appliances.

(5) The insurance companies, should there be such, carrying the insurance on the risk, should familiarize themselves with safety requirements and State laws, check up at proper intervals through their inspection department industries which they insure, and assist the employer by suggestion and education to make his plant perfectly safe for the workers.

CHAIRMAN RHODES: Is there any discussion?

## DISCUSSION

MR. H. W. BEAGLE (Surtz Guard Company, Chicago): How are the accidents classified when the guards are hung up on so-called guarded machines?

MR. WILSON: If it is guarded, it is guarded. We only classify guarded accidents as accidents on a machine that is properly guarded at the time of the accident. The unguarded ones occur on the machines that are not guarded, whether the guard is hung up on a nail or not.

I want to ask Mr. Schreiber if he has seen a good, efficient guard for a dado head.

MR. SCHREIBER: I have not seen any.

MR. LEVY: I will venture to say in 90 per cent of the plants, anywhere from 8-inch to 16-inch saws are used on one machine, and we have to use the same guard for every saw. The men cannot put new guards on every few minutes. We must have a guard as efficient as possible for all types of saws. We can't have a variety of saws in a small industry. One saw must do all classes of work. It must be a rip saw, trim saw, dado head, groover, all combined. The guard must not interfere with the different classes of work. A man has to hold his work at various angles and hold it to the form by hand. The guard must not strike the work. The operator wants to watch the work and the guard that completely covers the saw interferes. Oftentimes he does not cut to a form, but to a pencil line or a scratch line. What we want is a saw guard that will meet the requirements for special kinds of work. For the rip saw, where no attention is paid to knots, checks, and such things, the guard that covers the saw is the ideal thing, but not for special work.

There is another machine which I would like to refer to, that is, the shaper. We have that pretty well protected, but I find that many industries are using the guard just as they receive it from the manufacturer. The general type of guard today is the spring with the wooden shoe. The operator tries to use that shoe for all classes of work, instead of using the various types of shoes having various sets of springs, for different classes of work.

That is a case for the superintendent and the foreman. I don't think the fault lies so much with the man on the job. It lies with the manager and superintendent. If we at this Congress could do anything to arouse an interest among the manufacturers of woodworking machinery so they will devise guards to take care of certain classes of work, then I think we shall get somewhere. The standard guards provided can only be used on a small proportion of the work.

CHAIRMAN RHODES: Are there any representatives of machinery manufacturers who wish to offer anything on this subject?

MR. E. E. JONES (President, Surtz Guard Co., Chicago): There are three points that I consider important; the size of the saw, sawing to the line, and edging. Edging is what I call straightening the board. In the exhibit of saw guards in the basement you will notice the front of the hood is toward the operator, so that he can saw to a line and straighten the lumber. Originally those guards were made entirely open, and that is

where the point comes in. of putting a 12-inch guard on a 16-inch saw. There is nothing to prevent it. Now you have to provide a guard for the several saws, or have several guards for the machine. The latter is the better way for actual efficiency, regardless of the little time it takes to change the guard. The large factories all have machines that will not have a variance of over an inch in saws. I worked for several years in a woodworking plant, and when a 14-inch saw had worn down to twelve inches it was put on another machine, and never used on the first machine again. This I consider the ideal condition.

MR. E. ROSS FARRA (American Car & Foundry Co., Wilmington, Delaware): I would like to know how you are going to guard a saw for edging. We have no laws in Delaware in this subject. We can't make a man keep a guard on his machine, and we have had more than one accident.

MEMBER: We leave it to the men themselves. We make a direct appeal to the men in our plants to make a special effort to avoid accidents. We ask them to make suggestions for safeguarding dangerous places, and if they make suggestions and we adopt them, we pay for them. We have eliminated 43 per cent of the accidents.

MR. SCHREIBER: I see there are two expert manufacturers here from my territory. I would like to hear from them, Mr. Thalheim and Mr. Balthaser.

MR. JOHN THALHEIM (Gurney Refrigerator Co., Fond du Lac, Wis.): I am the first mentioned gentleman. I came here to learn. I have learned quite a bit since I have been sitting here. I will leave it to Mr. Balthaser to do the talking.

MR. LEO BALTHASER (Sanitary Refrigerator Co., Fond du Lac, Wis.): I think some one with more experience will be able to tell you more about it. I made it compulsory to use the guard. Any man who does not is discharged. We insist that guards are put on for a purpose, and they must be used, and the first man we catch not using them will be discharged. We get very good results.

We do edging on a self-feed rip saw, and the guards are arranged so it is not necessary to remove them. But there are different types of guards, and it is possible some of them might have to be removed.

CHAIRMAN RHODES: You discharge the employee if he takes off a guard?

MR. BALTHASER: Yes.

MEMBER: We can't fire good sawyers. They are too scarce. Many of our men are sixty-three years old and have been sawyers for thirty years. They don't want to change.

We have an old-style boring machine and mortiser. I understand they are not combined any more. I got a guard for the boring bit and found that the machine then became more dangerous than ever. The boring bit goes down through the material, and when the mortiser is used the tables moves up to the knife. The tendency is to catch a fellow between the table and the guard. It seems to be impossible to get the belts adjusted so they would stop instantly. The boring bits will make any-

where from 25 to 100 revolutions after the power is off. I would like to know how to guard the boring bit so it won't be an additional hazard.

MEMBER: The Fairbanks-Morse Company has dozens of boring machines that are guarded, whether idle or boring, combination or boring machines.

CHAIRMAN RHODES: I find a great deal depends on the employee and his training. Mr. F. C. Dana will discuss this subject.

MR. DANA: First of all I would like to answer the question the gentleman just raised about men who have been in his employ for thirty or forty years, and whom he was afraid he would not be able to replace if he discharged them. My answer is that he can discharge one man and eliminate that trouble, and the man to discharge in that case is the foreman. He is absolutely not on the job if he tolerates any practice like that. If he is the right kind of foreman he can take the matter up with those men in a manner in which they will be very willing to agree with him. You have got to have a foreman who is a leader of men, and if he has the necessary qualifications to be a leader of men, nine times out of ten he can get the fellows to keep the guards on the machines. We have very seldom had trouble in getting a man to keep a guard on a machine. In fact it is the new men we have the most trouble with.

When we put new guards on the machines we get the suggestions from the operators, who often make very valuable suggestions. In two cases within the past two years the operators have practically designed the guards themselves, and I believe they proved to be just as efficient guards as you could buy for the machine. This is an incentive for the man to be a booster. The other men that work around him will want to put something on their machines. It has started a safety movement through the department, and every man is working for safety.

We have a ruling that no man can take a guard from a machine without the consent of the foreman. If he does, he is discharged. We have discharged a man in eight months for taking a guard off a machine without permission.

The new man that comes into the shop, if he has had no experience at all, is nervous, and looking around instead of watching his machine. We employ about 140 woodworking machine hands, and we have eight men in that department who are old hands. When a new employee is brought in the department he is turned over to the foreman. The foreman has a record of his past experience on his employment card, and he decides which one of the eight old hands can best instruct the new man. He remains directly under the supervision of the old hand for a period varying from two weeks to a month, and in no case is he ever released from the supervision of that man in less than two weeks' time. The first thing he is taught is how to run that machine without accidents.

In the past year we have had only one accident of any consequence in our woodworking machine shop. One man lost his fingers. That is the only accident where there has been any compensation paid. I attribute that record principally to that foreman and the eight men he has for the instruction, because those are the men that are certainly getting the results. It means a great deal not to have any time lost from accidents.

**TRAINING MACHINE OPERATORS IN SAFE METHODS**

**F. C. DANA, DIRECTOR OF PERSONNEL, KISSEL MOTOR CAR COMPANY,  
HARTFORD, WIS.**

This is a subject that was given very little consideration by the majority of manufacturers until recent years. The idea formerly was that if you hired an experienced woodworking machine hand, he was supposed to be thoroughly familiar with the operation of his particular machine and, therefore, should be able to operate the same without danger of injury. In theory this idea might seem flawless, but it was far from practical, as was shown by the vast amount of lost time due to accidents.

I find that injuries caused by woodworking machinery usually result in a greater loss of time than injuries occurring in other departments and should be given serious consideration, because they often cause the operators to become less efficient, due to the loss of fingers and hands.

Bearing me out in this statement is the report of the Wisconsin Industrial Commission regarding industrial accidents in the woodworking industry. This report for the years 1915-16-17 shows that there were 2,365 accidents during this period, 50 per cent of which occurred on saws. The injuries on saws alone were responsible for four deaths, two arms cut off at elbow, three loss of hand, 76 loss of one finger, 36 loss of two fingers, 13 loss of three fingers, five loss of four fingers, one loss of foot, three loss of eye, and one facial disfigurement. This shows the great need of maximum safety work in this industry.

What were the causes of these accidents and how could they be reduced if not entirely eliminated? The causes usually were due to lack of guards, carelessness on the part of the operator, inadequately lighted shops, and the lack of proper instruction in the methods of operating the machine in order to avoid injury.

Adequate guards can be made to protect practically every machine and if you equip your machines with practical guards, you will find in the majority of cases you have won the operator of that machine for the safety movement. See that your guards amply protect the point of operation. This is of vital importance, as all of your serious accidents occur on this part of the machine. Obtain proper lighting facilities. After this has been done, great care should be taken in selecting competent men. A careful workman is one of your greatest assets and it is necessary that he be educated along lines of safety. This education should begin the moment the man enters the department. Who is going to see that the new employee gets the proper start?—the foreman. Remember he is your key man, and the responsibility for the newcomer's safety rests in a large degree upon his shoulders.

**FOREMAN MUST INSTRUCT NEW EMPLOYEE**

Statistics show that accidents occur to new men in a ratio of six to one. Who is going to aid you most in reducing this? Your foreman. The foreman who today does not instruct every new employee, or dele-

gate the duty to some one else who is trustworthy—the foreman who fails to instruct every new employee regarding the hazards of his work is no longer fit to be a foreman. Foremen today are of a different type from that of several years ago. We all realize that. At that time a foreman's ability to a great extent was based on the number of men he hired and fired. He was not considered to be as important as he is today. Today he is one of the dominating factors in your plant, and he must have the qualifications to be a leader of men. If your foremen are possessed with these necessary qualifications, they will aid materially in bringing the safety work to a high degree of efficiency.

If you were to have a graphical analysis of the accidents occurring in our industrial plants showing the causes of injury and the terms of service of the men involved, you would find that your line representative men in the employ for one month would be the longest. This is perfectly natural, the average new man is not at ease when he enters the shop.

After all, safety is a matter of education, and if your key men have been taught the lesson and are vitally interested in their work, they will carry the message on to the men. Some organizations are large enough, so that they can have schools in safety, and where this can be done it is an excellent idea.

CHAIRMAN RHODES: Has any one anything to offer in regard to their efforts to train employees?

#### DISCUSSION

MR. COLE: I would like to answer the gentleman's question as to how to keep the guard in place. That is a little bit of what is being termed today "human engineering." The greatest thing in the world, in any industrial work, is obtaining the safety interest of the men. I have ceased to preach safety. I believe in working safety. If we can get the men in the shop to feel they have an incentive to work for safety, we will probably have more guards kept on the machines. I have in mind a logging company and a saw-mill company. A large flag is flown over the mill that shows the smallest percentage of accidents for a given period. The two mills are about the same size, and their hazards are identical. It is a game with those men, they want to get the flag from the other mill. One mill had the flag for three months, when a sawyer had his leg broken. While he was in the hospital one of his friends asked him if his leg hurt him. He replied, "Yes, a little, but what hurts me most is that I kept the flag away from my mill." If we can encourage that spirit among the men, they are going to work for safety. They are working for a purpose, and they know they will get some credit. They are going to see that the guards are kept on, because they know that an accident will discredit their mill. I have here a chart from which I wish to read some figures. These figures were obtained from the accident reports received from the subscribers of the Southern Pine Association for the first three months of this year. Twenty per cent of these accidents were to men who had been in the employ of their company less than one

month, 38 per cent to men who had been in the employ of their company less than three months, 54 per cent to men who had been in the employ of their company less than six months, and 72 per cent to men who had been in the employ of their company less than one year. Considering severity, 25 per cent of the resulting time lost was incurred by men who had been employed less than one month, 59 per cent by men who had been employed less than three months, 63 per cent by men who had been employed less than six months, and 80 per cent by men who had been employed less than one year. I think that emphasizes Mr. Dana's idea of the need of training the employees.

A MEMBER: Our company at present has a committee composed of men from each department, who inspect the shops, make note of unsafe conditions and encourage the laborer to work for the interests of safety. This company also pays \$50 a month, divided into three prizes, which are awarded to any one, laborer, office man, or superintendent, for the best suggestions each month.

My instructions are to see that the men live up to the rules of the company, and if a man does not live up to the rules of the company, to discharge him. It is just as easy to hire a man to take his place, no matter if he has been there for fifty years, after he is discharged, as it is after he is killed or injured permanently. Then you have to find a man anyway to take his place, and, in addition, you have benefits to pay. It is sometimes hard to find some one to take a particular position, but our orders are to discharge any one who fails to live up to the rules.

CHAIRMAN RHODES: The human element is the largest factor in the prevention of accidents. With the large turnover of labor during the last two or three years, probably every plant has had a greater number of new men on its pay roll than ever before. There are probably different conditions in every plant that have to be handled according to the peculiar situation found.

The subjects assigned to the Wood-Working Section of the National Safety Council naturally fall into two general divisions: wood-working operations, and logging and lumbering. I feel we have had a very splendid morning's session with the discussion of subjects of interest to wood-working men, the factory men, and the manufacturers. Tomorrow our program will deal a little more largely with matters of interest to loggers and lumber men, but it will also cover a great deal of the human element factor, which is of direct interest to factory employees and employers.

MR. BYRON: I would like to ask if any one present knows anything about the depths of throats on round head jointers.

MR. D. D. EVANS (Deputy, Industrial Commission of Wisconsin): Less than a year ago the Industrial Commission of Wisconsin asked committees to make investigations on round head jointers, where accidents have occurred. When the ruling was first put into effect that round heads should be used, there was no specific depth mentioned, and the first ones had a  $\frac{3}{8}$ -inch throat with a  $\frac{1}{2}$ -inch bolt. By the use of the shallow throat, it was possible to cut out the sanding operation on a great deal

of the machine work. But we find, since lumber is becoming poorer : the greed for products is getting greater, wood-working men begin order the throats larger, so they can take a bigger cut. When the round heads first came into use, you would not find any that were cutting more than about 3/16 of an inch. Today we find them using a 3/8-inch cut. It is a different kind of lumber they are working on now. On investigation of accidents, I found the shallowest throat was 5/16-inch deep and 1/2-inch wide. The largest was 3/8-inch wide and 5/8-inch deep. I found a great majority of accidents on round heads occurred with the wide and deep throat cutters.

CHAIRMAN RHODES: Is there anything further? This is a big and interesting subject, Gentlemen. It is not a matter of theory. I have become very much convinced of that since I have attended these meetings for the last two years. The three thousand or more delegates who gathered here, representing all of the principal industries of the country, cannot but have a good time, but, if you will attend the sections about this building this morning, you will find they are all as fully and sincerely interested, possibly some more so, than we have been here this morning. Many industries are getting more out of these conferences than we are. The industrial casualties in the United States have been appalling, and the National Safety Council has become so great and strong as it is because of the realization by business men and large employers of the necessity of doing something in a practical way to reduce the drain on our humanity and our national efficiency.

Representing the industries that we do, working in lumber, it seems to me to be nothing more than proper, in fact, an obligation and a duty, to take advantage of the opportunity that is given us to become a part of this great organization, and do what we can to spread the gospel of safety through the industry.

ADJOURNMENT.

## THURSDAY MORNING SESSION

THE meeting was called to order by the chairman at 10 o'clock.

CHAIRMAN RHODES: We have done what we can to create interest in the Wood-working Section of the National Safety Council. We have written personal letters to everybody whom we thought might be able to attend these meetings and we were much gratified with the attendance yesterday. The attendance yesterday consisted principally of mill-work and factory men. The program this morning will consist of papers of interest to lumbermen and loggers.

The small attendance does not indicate lack of interest on the part of lumbermen in this work. However, I hope very much that we can interest them to co-operate with the Council a great deal more during the next year. The lumbermen are taking increasing interest in safety measures of all kinds.

The Southern Pine Association, consisting of two hundred and forty

members, organized a Safety First Department about two years ago for the express purpose of assisting its members in the reduction of accidents and hazards among their employees. I am taking the liberty of referring to this, for which you will pardon me, because it is a matter very close to me, and I know that the description of that work will be of interest to you. Mr. W. Graham Cole, Director of Safety and Industrial Relations of the Southern Pine Association, is in charge of this work among the Southern saw mills and logging camps. He has achieved a record that is very satisfactory to us.

In the first place we had difficulty in interesting the rank and file of the employees in work of this character as they are usually more or less suspicious, but they have come to see pretty generally that the work is being conducted for their benefit and is prompted by a sincere interest in their welfare.

I will ask Mr. Cole to explain to you some of the details of the work, the problems he has tackled, and what he has been able to accomplish.

### SAFETY WORK OF THE SOUTHERN PINE ASSOCIATION

W. GRAHAM COLE, DIRECTOR OF SAFETY AND INDUSTRIAL RELATIONS, SOUTHERN PINE ASSOCIATION, NEW ORLEANS, LA.

In response to the request of your Chairman, I will endeavor to explain what we are trying to accomplish for safety in the Southern saw-mills and lumber camps. Previous to the time that the Safety Department of the Southern Pine Association was organized, a few of the insurance companies in the South had started to work along definite safety lines, but it was a new problem for an association of lumbermen to undertake such activities.

To interest the manufacturers, in this plan was a difficult problem. We felt that the first thing to do was to carry on an advertising and publicity campaign. We believe a great deal in personal work, but from the standpoint of an association which has over three hundred members (employing nearly one hundred thousand men) this was impractical. Our idea was to sell the plan to the big boss and assist him in passing it on down. Safety work has to emanate from the man at the top, not from the man at the bottom. We realized that if we could get the general managers sold on the idea, they in turn would not have much trouble in selling it to their employees.

We found out that a great many safety men in the North who had put the safety idea across in their shops and factories, were skeptical as to whether it could be put across in the logging camps and saw mills of the South with the same success.

The Southern logging man is pretty far away from many of the human interests which are to be found in the larger cities, such as theatres, etc.; therefore, when you give him this idea, it is something to absorb his attention which is not otherwise absorbed, and he is pretty quick to take to it.

## *Woodworking Section*

### GETTING AT THE CAUSES OF ACCIDENTS

The problem, as I said before, was to sell safety to the owner of business, and through him to his employees. In starting out, we decided to begin with an advertising and publicity safety campaign. In or however, to make our bulletins practical and applicable to the work, felt it necessary to get some history of the accidents which were occurring in the lumber industry. There were plenty of statistics on steel and chemical industries, on railroad operations, etc., but the previous accident statistics of the saw mill and logging industry were few. We undertook, therefore, to obtain accident reports from the operations of all of our subscribers, and for this purpose we prepared and furnished an accident report form, but advised our people that a copy of the insurance report was equally acceptable.

Last January we issued a report of the activities of our department for a year. This report was prepared and published for the benefit of the foremen, each one being supplied with a copy. I feel that the foremen are the chief aids in all safety work; after obtaining the interest of management in safety it is necessary to impress the foreman with the fact that safety is a part of his daily work. Some of the charts which we had prepared from the accident records were included in this report. These charts were based upon both frequency and severity, in order to show not only how often accidents occurred, but how serious were the results. The more vital question, of course, is that of seriousness. We have used the figure of days lost per month per man employed. From this information, we were soon able to discover the causes which were producing the most serious accidents.

We issue two bulletins every month, and have them illustrated wherever possible. I consider a camera as an essential part of my traveling equipment, and when I see anything that may be useful, I take a picture of it. These bulletins are posted throughout the logging camps and saw mills.

In addition, we have prepared a card illustrating the "V Bed" method of felling timber. These cards are placed in the hands of our log sawyers. Just a word in passing concerning this method which is clearly illustrated by this stump. In order to cut the "V Bed," each sawyer must be provided with an axe. Then, by one man working from each side, a deep V-shaped notch is cut. The saw is then started from the opposite side of the tree, so that it will meet the upper points of the V. If the notch has been cut deep enough, the falling tree will break clean, pulling no splinters from the butt. The V-shaped wedge on the end of the log prevents it from kicking back over the stump.

### THE V-BED METHOD OF FELLING

In connection with our work, we have organized safety committees. We feel, as I mentioned yesterday morning, that if we can give the men definite safety work to perform instead of simply preaching safety, our work will be much more effective. One of these committees in con-

sidering ways and means for preventing accidents, found that a great many of them were due to trees kicking back over the stump. They went out into the woods in a practical way and endeavored to find out whether this could be prevented. Their efforts resulted in the idea represented by this stump. Feeling that the "V Bed" will prevent many accidents throughout the industry, the Southern Pine Association has decided to advertise it to the fullest extent.

We have developed the following sales points in trying to place the method before our manufacturers. In the first place, considering safety, this V-shaped wedge on the log prevents it from jumping back over the stump; second, by being chopped and sawed, the only points of fracture of the falling timber are near the heart—this prevents splinter-draw; third, the bed is cut out of the stump, not out of the log, thus saving considerable lumber; fourth, by pairing off, one man chopping left-handed and the other right-handed, the two sides can be chopped at the same time, thus allowing more logs to be cut per hour than by the old method.

In addition to our bulletins, we issued a small pamphlet to take the place of the old rule book. We endeavored to write it in a more suggestive manner, however, in order to make a stronger appeal to the men. This pamphlet has been distributed so that it can be placed in the hands of all the men whom the management feels will benefit by it. We have distributed over fifty thousand of these pamphlets during the last six months.

Now, just a word for the charts which give an idea of how we tackled the work of getting some benefit out of dry statistics. I feel that these charts are particularly important as a means of proving our facts to our members. During the last year we found that of all the accidents reported in the industry, 65 per cent were in the logging operations rather than in the mills. Furthermore, of the 35 per cent which were in the mills, we found that only one-sixth of the time lost from those accidents was due to what were considered as mechanically preventable accidents. In other words, only about six per cent of the total lost time in the entire operations from log to car was due to mechanically preventable accidents. We used this fact as a strong argument that although safeguards are necessary, it is even more essential that we consider the human element.

The accidents were often found to be directly chargeable to foremen, due to the fact that they have not properly instructed their men in safety work. In my estimation this indicates in the strongest manner possible the need for good safety educational work among the foremen as well as among the men.

#### ACCIDENT FREQUENCY AND SEVERITY

This chart (exhibiting chart) shows by a line the monthly frequency rates, i. e., the number of accidents per thousand men per month, from July, 1919 to June, 1920. You will notice that there is a considerable increase for 1920. I consider that as a very good indication. The actual

number of accidents has not increased, but more attention is being given to all injuries and more reports are being made out for minor accidents which explains the increased rate.

The lower half of this chart shows, for the same period, the severity, i. e., the number of days lost per man per month. It shows a decrease of one-quarter of a day per man per month, which, when multiplied by three hundred days in a working year and fifty or sixty thousand men which the association represents, becomes quite an enormous figure. Although more reports are being sent in, the results are decreasing in seriousness. We feel that this is an excellent showing.

The next chart (exhibiting chart) shows the percentage of accident and gives our men, right out in the field, an idea of what particular work they are doing that is causing serious accidents. For instance, falls on trees, logs, and lumber caused 13 per cent of the accidents, but 28 per cent of the time lost, and was our most serious cause.

This next chart (exhibiting chart) shows the same accidents classified by departments. This last chart simply represents the time of the day in which most of the accidents occur. We find that there is a peak in the morning about eleven o'clock, just a little while before the noon hour, and another in the afternoon about four o'clock, the four o'clock peak being a little higher than the one in the morning. These results are similar to those obtained in other industries.

I just wanted to show how we have undertaken this work, and if I can answer any questions regarding it, I shall be very glad to do so.

**CHAIRMAN RHODES:** Mr. Cole's work has inspired a great deal of interest among the employees in the Southern mills and plant committees are being organized in quite a number of saw mill operations. His work including the extensive line of bulletins which he has issued have had pretty wide circulation throughout the entire country.

The Chairman cannot conceal his disappointment at the lack of interest among the lumbermen in this meeting. Efforts were made to secure a large attendance, but the gentlemen evidently have not arrived, and I am particularly disappointed because we have a speaker who has come more than a thousand miles to attend this meeting, and who has a very interesting message to convey.

The second paper on the morning program was scheduled to be delivered by Mr. V. A. Griffith, but I am pleased to say to you that since the program was printed he has been elected District Judge.

He is very much interested in safety work in the South and his subject, "Results Obtained in the Manufacture of Lumber by the Adoption of a Plan of Safety Organization," will be of interest to you and it will be of interest to lumbermen generally. I am sorry there are not more present to greet Judge Griffith, whom I have the pleasure to introduce.

## RESULTS OBTAINED IN THE MANUFACTURE OF LUMBER BY THE ADOPTION OF A PLAN OF SAFETY ORGANIZATION

V. A. GRIFFITH, GRIFFITH AND WALLACE, ATTORNEYS, EDWARD HINES YELLOW PINE TRUSTEES, GULFPORT, MISS.

There is scarcely any doubt that there are more real obstacles to be surmounted and more discouragements to be overcome in organizing a lumber manufacturing plant for safety and in keeping it organized than in any other substantial industrial enterprise. And foremost of these difficulties is the indifferent mental attitude towards it of those who chiefly benefit by safety, that is, the workers themselves—an attitude growing out of the long pioneer history of the lumber business, and its heretofore chronic practices of very frankly disregarding the matter of mere personal safety. It has not been so long ago that the typical saw mill was an affair in which two men did all the logging from the tree to the mill, and two more did all the remainder of the work, unless the outfit happened to be steam propelled, in which case there was an additional man. The machinery was usually crude and crudely arranged, but there was plenty of room and plenty of time, and the few operatives frequently regarded it as adding zest and flavor to the employment that it was so manifestly an adventure with danger. And even yet a very substantial portion of the lumber of the country comes from such outfits, and by far the larger number of saw mill operatives now in the service have received their original training in small plants and under more or less primitive surroundings. They are as a rule brawny men of self-reliant character and are much inclined to regard special effort towards the promotion of safety as somewhat a reflection upon their sturdy ability to take care of themselves and also as an effeminate turn taken in what to them is a very masculine business. Many of them regard accidents as belonging to the industry, and strange to say, some firmly believe that when the time shall arrive for any one of them to be hurt he will be, regardless of any mere human effort to the contrary.

### HIGH TURNOVER A DISADVANTAGE

There is also perhaps a larger proportion of turnover among saw mill employees than in any other substantial industry, a fact that very strongly militates against a safety organization, and in conjunction with this there yet lingers even in the larger plant the old ever present idea that the particular operation is only a temporary one, and that in a while it will be cut out and gone. The best and most satisfactory of safety organizations must have had, as foundations upon which to build, the three requisites of permanency of plant, permanency of operating crew, and at least a fair tradition of past community interest. Other difficulties may be stated, but from the above alone it is apparent that the average saw

mill promises but little for safety organization except upon extraordinary and very sincere and earnest effort.

It is not surprising therefore that but few attempts in a thorough organized, systematic, and well sustained way have been made for safety in the lumber industry. Nevertheless, the owners and managers, especially of the larger plants and operations, in the lumber manufacturing business are as well informed as to what advancements are being made in the industrial world, and are as truly anxious to keep abreast of these advancements and to take part in patriotic and humanitarian work as those of any other industry.

#### BASIS OF SAFETY ORGANIZATION

Having observed the satisfactory results of systematic safety organization in other lines of endeavor, and having the faith that by sustained effort the difficulties in the way could be finally obviated, it was determined toward the end of last year (1919) by the Edward Hines management in Mississippi to adopt such a plan for their lumbering operation in that State, and to do so upon a thorough and comprehensive basis just as if their plants had existed for years and expected to continue in operation for all future time to come. And while, to make it reasonably certain of success, it was determined to place it upon a compulsory basis throughout, it was appreciated in the very beginning that, unless the interest of the men could be enlisted upon some other than a compulsory basis, the plan could not attain that measure of success which would make it really worth while. So an organization was worked out and put in operation wherein the voluntary co-operation of the men was sought for and emphasized to the highest practicable degree. To overcome so far as possible the difficulties first herein mentioned and to get the men so far as could be, into a receptive mental attitude, it was in meetings and by distributed literature impressed upon them that by far the larger percentage of accidents in saw mills and lumber camps was preventable in the first place, and, in the second place, that it was an entirely erroneous impression that accidents as a rule resulted from defects in machinery, appliances, and ways, that, contrary to the common impressions, more than 70 per cent of all accidents resulted from carelessness, thoughtlessness, or inattention on the part of the men themselves, and that therefore the success of the plan depended upon the workmen themselves and only in a small part upon the plant equipment and upon the management. It was especially promised them that so far as the percentage was due to defects or want of safe guards in machinery, appliances, and ways, the management would set about forthwith to correct all that and would be diligent to install safety devices and guards not only in all places where such a device had been originally intended, but that all possible efforts would be made to invent and install other and further safeguards and safety appliances, and, as a further assurance or guaranty of this, the position of general inspector for safety was created and a special crew of men were put to work under his direction to install the guards and safety devices mentioned.

## EMPLOYEES MAKE VALUABLE SUGGESTIONS

This work was faithfully carried on throughout the plants in a way that the men in their daily work were as constantly as practicable made aware of it as redeeming the promises made to them in that connection and at the same time impressing them with the fixed purpose of the management to make safety a real and genuine part of the operations. Moreover, the men themselves were encouraged to co-operate in this matter of installing and devising safeguards, one of the means adopted to the end being a standing invitation to them to make suggestions in writing to be placed in a box called the Suggestion Box, it being guaranteed that every suggestion would receive respectful consideration and those worthy of adoption would be adopted and credit given to the person making the good suggestion, and a system of cash prizes for valuable suggestions was instituted, so that not only the sense of pride in the men was appealed to in their being called upon thus to join in a creative work of value, but also the incentive of immediate pecuniary gain was offered in the competition for these prizes. The result has been that not only have many valuable suggestions for safety been received but also suggestions beyond the scope of safety, it being estimated that the value of the suggestions so received which were outside of the scope of safety has been equal to or in excess of the total cost of everything done or spent in the safety work. For instance, a negro made a suggestion which was found to have nothing to do with safety but which was so valuable as an operative matter that he was awarded a prize of \$10 for it. The improvement was made at a cost of \$40 and has been found to save \$200 per month in the expense of operation. A white man made a suggestion by which 300 feet of trestle costing \$5.00 per foot was saved, and many like illustrations could be given. The spirit of co-operation and good will on the part of the men appealed to by these various features has reduced the labor turnover with the result that with a somewhat smaller total force the aggregate output has been increased 10 per cent. We come, therefore, immediately to the showing that even if such an organization as was adopted saved nothing in accidents and in preventing injuries and suffering, it has more than paid for all its costs in money, time, and effort by the reduction of operating expenses, in lowering the rate of turn over, and in increasing the output on a decreased force.

## SAFETY ORGANIZATION COMPRISES SIX UNITS

But the results in prevention of injury have been equally satisfactory, considering all the untoward obstacles which had to be overcome. As stated, the plan of safety organization adopted was one which involved an appeal to the interest and best human qualities of the men themselves, from the lowest grade in the ranks up to the general manager. The organization embraced two saw mill plants and two logging operations, extending over an area of some fifty miles north and south, and an operative force of about 1200 men. Over each plant and logging operation there was constituted a General Committee consisting of a Chairman, the

### *Woodworking Section*

general inspector, the superintendent, the auditor, and the saw mill man. The second element of the organization is the general inspector whose duty it is to keep all the units in action and to assist and guide in the work in general, and to form the main coordinating link between them all. The third unit is the foreman's safety committee, consisting of five foremen at each plant or logging operation. Working in close conjunction with them is the fourth unit, the workmen's safety committee, consisting of five white workmen and a separate colored workmen's safety committee consisting of three colored workmen. The fifth and sixth units are, respectively, the foreman of each department and the weekly safety overseer in each department. In this organization it is understood that the foreman is the most important unit and that his attitude toward safety determines very largely that of the men under him. The foreman is by every possible means impressed with his position of leadership and with the necessity of his sincerely maintaining the same in all good faith and perseverance if the work is to succeed and if he expects to rank well in the esteem of his superiors. The foreman is further impressed with the added opportunity which the safety work affords him to get on terms of close human touch with his men, where the men may be made to feel more than ever that the foreman (if he is the right kind of a foreman) is their friend and helper and well-wisher and that his chief concern is, as it ought to be, their welfare and success in their work in all respects, not alone in safety.

To further arouse the interest and enthusiasm of the foremen they are rotated in committees, each committee serving three months, and are given rather broad privileges as to inspection, reports and recommendations. They also visit at the employer's expense the other plants of the employers and also distant plants on occasion, and they receive the full time and expenses when thus engaged. The same general duties and privileges are allowed the workmen's committee, which committees are elected by the men themselves for three months and are rotated personnel.

#### ACCIDENT RATES ARE REDUCED

It was said that this plan of organization was too elaborate for a lumber operation, too complicated for the comprehension of, and handling by, the type of men found as employees in such works. And so it would have been without the presence of the co-ordinating agency of the general inspector, but with his aid and constant attention it has been made to work and work well.

Every accident however trivial is required to be formally reported and every one must receive immediate medical attention, which is at the cost of the employer. Thus the suffering and loss which formerly resulted from infection from apparently trivial hurts have now been reduced to a fair minimum. First aid kits and first aid stations have been installed throughout all the works, and workmen's safety committees are trained by the surgeons in their use. The frequency rate of accident (and these figures include every kind of accident down to the most trivial) has been reduced in the plants from 70 per 1000 men per month to 40, and in the

woods operations, while the frequency rate has not been substantially reduced, there has been a striking reduction in the severity rate. As a matter of fact, the frequency rate has improved considerably more than the above statements would indicate, because of the fact that practically all accidents are now being recorded. Foremen are being trained to report every injury, however slight, and accidents are now being reported which formerly were not noted at all.

#### SAFETY WORK MAKES BIG SAVING

As to the cost, as against the former practice of carrying liability insurance, a substantial saving of expense has already resulted. Although there is no workmen's compensation law in the State, half time is being paid for all time lost on account of injuries received; physician's attendance, drugs, and hospital bills are paid by the employer; all this without regard to the question of legal liability, that is to say, without regard to whether the injury was the fault of the employer or of the employee. And in spite of this extra-legal and far more liberal policy of compensation, the total cost to the employer has been less by approximately 30 per cent than the premiums formerly paid to liability insurance companies. It is to be noted that in the present estimate of cost everything that is spent for the maintenance of the safety organizations, such as salary of general inspector, and of all other agents and employees so far as apportionable to the safety work and to the casualty department are charged into this cost.

The results in the short time of six months may, therefore, be stated as equalling every reasonable expectation, and in some respects to have been more than was really anticipated. Of course, there have been foremen, even in the more important departments, who have taken to the work slowly and with ill-concealed indifference. They have croaked around about its not having been done at So and So where they came from and had their training, and that "they didn't kill so many there" and that "it is a lot of extra trouble and humbug for nothing." There are still men in the ranks who continue to regard the whole program with a smiling tolerance to be endured until, as they think, the enthusiasm presently aroused shall have time to die down, and it is not to be doubted that there are yet a few who even look hopefully to a day when, as they expect, the same old system of carelessness and indifference to results may have sway as in the past. But over against these are foremen and men who have taken and are taking a genuine and sincere interest in the work and are determining to make it a lasting success.

#### VALUE OF EMPLOYEE DETERMINED BY HIS INTEREST IN SAFETY

It has now arrived at the time when the management is beginning to take definite note of the fact that the efficiency of both foremen and men is fairly accurately gauged by the direct interest taken by them in the safety work. Or to state this proposition in other words, and this seems to me is the highest and most comprehensive tribute that could be paid

to the general efficacy of safety work: The management is now finding that the value of the individual employee as a producer, whether he be foreman or workman, is very nearly in direct proportion to the interest which that employee is taking in the matter of aiding and encouraging the advancement of the safety work. Therefore, the progress of the plan is just now about to reach the stage when it will be up to the management to make absolutely secure the continued increasing success of the plan by beginning to let out of the works as judiciously as can be done all those who will not genuinely take part and aid sincerely in the progress of the plan and its purposes from beginning to end, and more especially will this be the test as to retaining in their employ indifferent foremen. It is inconceivable that any intelligent management with the result before it which has been accomplished in so short a time will not take the requisite steps in this connection, unpleasant as it may be to any management to sever relations with some employees who have been long in the service.

#### SUMMARY OF RESULTS OBTAINED

To sum up the results: There has been created a feeling of closer personal relations between employer and employee, a stronger sense of loyalty and good will. The rate of turnover has been reduced, and with a smaller force there has been a 10 per cent increase of output. The cost of operations has been reduced by an amount more than equaling all that has been spent for safety and for the maintenance of the safety organization, through the installation of suggestions made by the men. The frequency rate of accidents has been reduced 40 per cent and the severity rate nearly as much. The total cost of the safety and casualty departments, on a much more liberal basis than ever before as to allowances, has been reduced 30 per cent below the old premium cost for accident insurance. And with it all there is the greater and more genuine satisfaction that there has been put into the work the spirit of humanity, of kindness, and of patriotism, which to every good man outweighs mere dollars and cents beyond any thought of comparison.

CHAIRMAN RHODES: Judge Griffith, I want to thank you in behalf of the Woodworking Section for the splendid paper you have submitted to us.

I want to say to those present, who may not be so familiar with the lumber business, that Judge Griffith has spoken for one of the largest lumber companies in the United States. There is so much information in this paper that I know will be of interest to the lumbermen that I am going to see that it is printed in a special separate pamphlet and distributed to them as widely as possible throughout the country in addition to its publication by the National Safety Council.

I want to introduce the man who has been actively and closely identified with that work, who has charge of it directly for the Edward Hines Yellow Pine Trustees, at Gulfport, Mississippi, Mr. C. L. Skatvold.

MR. SKATVOLD: The direct application of Safety First brings about efficiency on the part of the employees. Efficiency goes with Safety.

(A Nominating Committee was appointed by the Chairman.)

CHAIRMAN RHODES: The next subject on the program is "Safety and Sanitary Accomplishments of the Loyal Legion of Loggers and Lumbermen", by Dr. S. T. Tharaldsen, sanitary officer of this organization, from Portland, Oregon.

It may be of interest to you to know what the Loyal Legion of Loggers and Lumbermen is. During the war the I. W. W.'s, operating largely through the logging camps in the States of Washington and Oregon, at that time did what they could to prevent the production of lumber for war purposes, chiefly aeroplane stock from spruce.

The situation became so difficult that the War Department was finally obliged to undertake the production of aeroplane spruce in that section of the country and—as a result, I believe, of the efforts to increase production and to enable the employers to get more closely in contact with the men—there was organized the Loyal Legion of Loggers and Lumbermen, in which the employers and employees have equal participation. Many of the manufacturers of lumber in the Northwest informed me that the results have been very satisfactory; others feel that they have not been so satisfactory.

I have a letter from Dr. Tharaldsen, in which he states that he has been delayed, and is unable to come from Portland, and submits his paper, which will now be read.

### SAFETY AND SANITARY ACCOMPLISHMENTS OF THE LOYAL LEGION OF LOGGERS AND LUMBERMEN

DR. T. THARALDSEN. SANITARY OFFICER. LOYAL LEGION OF LOGGERS AND  
LUMBERMEN, PORTLAND, OREGON

The chief objects of the National Safety Council as I understand them are, first, to insure to the worker a safe place to work; secondly, to educate the worker to protect himself and his fellow worker. The result will be the elimination of preventable accidents and the consequent loss of life, limb, time and money.

The Loyal Legion of Loggers and Lumbermen, commonly known as the 4-L's, is solidly back of this movement in the territory in which we operate. I wish to lay particular stress on two of the results which we hope to obtain and describe briefly to you the methods we have used and the progress made to date. We are endeavoring to obtain for our members a safe place to work and a safe place to live. We recognize that while the time loss due to accident is of great importance, it is but of relatively small importance when compared to the time loss due to sickness. So in the matter of providing a safe place in which to work, in addition to safety devices of all kinds, we stress the importance of sanitary drinking fountains, sanitary toilets, rest rooms, and comfort stations. Then, when the whistle blows, we follow our members to their living quarters. The nature of the lumbering and logging industry is such that a very large percentage of our members live in camps which are usually of a more or less temporary nature.

## IMPORTANCE OF HOUSING

Prior to the organization of the 4-L's very little attention was paid to the housing of men in camps. Some few of the larger operations had begun to realize the importance of this work, but on the whole, living conditions were bad except for one feature. The mess in the lumbering industry of the Pacific Northwest was superior to that in any other industry in the world, and the waste was terrific. A logger philosopher described the situation very aptly by the phrase, "They feed us like kings, and sleep us like hogs." Bunk-houses were poorly constructed, inadequately lighted and ventilated, and in most instances seldom swept, and never scrubbed. They were greatly overcrowded, and no one paid the least attention to such important matters as ventilation, air space, or floor space. Bathing facilities, dry rooms, and recreation rooms were almost wholly lacking. The toilets and the hog pens were the two most constant and conspicuous features of the camp.

A careful survey of living conditions in camps was made, and the results were laid before the operators.

This survey demonstrated one very interesting fact. Over 90 per cent of the operators were willing and anxious to correct these conditions, once their attention had been directed to the necessity of doing so. In other words, the average operator had so concentrated his efforts on production that it had never occurred to him that his employees were not properly cared for outside of working hours. Camp to him meant but one thing—food. In response to a question regarding his camp the typical answer was, "I've got the best cook in the State, and I buy the best of everything. I lose hundreds of dollars every month on my dining room." A Sanitary Department has been created; a sanitary pamphlet published, containing sanitary regulations and detailed specifications for camp construction; local sanitary committees formed; sanitary inspections of camps are made and reported at definite intervals. The closest co-operation with State Boards of Health and the U. S. Public Health service is maintained.

## BRIGHTENING UP THE LOGGING CAMP

The results to date really are remarkable. Practically all camps now provide shower baths. The minimum of 400 cubic feet of air space per man in bunk houses is seldom violated. In the rainy districts, dry rooms are a common feature. Hog pens have been moved from the immediate vicinity of the camp. Kitchens, mess halls, and toilets are fly-proofed. The common drinking cup and the water bucket have been replaced by the sanitary drinking fountain. Electric lights are replacing the smoky and expensive oil lamp. Stationary wash tubs, with hot and cold water under shelter, have superseded the half barrel and butter firkin formerly used. The double deck bunk is slowly but surely disappearing from the bunk house. The company owned blankets, sheets, and pillow cases are gradually replacing the old unsanitary blanket roll. Practically all camps except the very small or very temporary ones are provided with a recrea-

tion hall or reading room. In many of the larger and more permanent camps some very pretentious halls are provided, with pool and billiard tables, reading rooms, bowling alleys, moving picture machines, boxing gloves and similar equipment.

By directing the attention of our affiliated operators to camp conditions, and taken as a whole they proved to be very willing listeners, they were soon convinced that industrial sanitation is not a fad, but on the contrary is a necessity which can no longer be ignored. They were convinced that a sanitary and livable camp is an essential to the company, and one which pays well by preventing depletion of its working force by disease, which reduces the labor turnover and increases the efficiency of the crew, due to the fact that they are contented. That there has been a very appreciable decrease in the labor turnover is illustrated by the remark of the manager of a well known employment office, who is quoted as saying, "There won't be much need for an employment office pretty soon if the 4-L's keep on cleaning up the camps."

#### TEACHING THE LUMBERJACK TO APPRECIATE THE VALUE OF HYGIENE

The second phase of this work, and the phase which has presented the most obstacles, has been the effort to obtain the complete co-operation of the crew. This is by far the most important part of our health program and will ultimately produce the best results in our campaign for prevention of disease. All improvements in camps will prove of little avail if we fail to inculcate into the individuals who live therein, a better understanding of how diseases are spread. We must bring home to each individual the fact that the presence of a disease carrier in a camp is more of a menace to the health of the crew than is an overcrowded bunk house; that unclean hands are a greater menace than an odoriferous and unsightly garbage pile; that the sanitary toilets, kitchens, and mess halls simply close avenues for the transmission of diseases and are safeguards in the presence of a disease carrier. In short, the lesson we endeavor to teach is this: a bunk house is as clean as its filthiest occupant, and the health of no camp is safe if it harbors an individual who is suffering from or is the innocent carrier of a transmittable disease.

In many instances, with very little effort, we have succeeded in obtaining the most complete co-operation, and in these instances the progress made has been remarkable, but unfortunately in many instances we find that the best appointed camps are allowed to run down, due to the fact that the individual members take no personal interest in the matter. At times this has proved to be very discouraging both to this department and to the operator. However, I believe that the morale of the men has improved markedly within the past two years and has about kept pace with the sanitary improvements. To assist in building up this morale we have instituted what we term a "personal service". Under this head are grouped all our various endeavors to be of assistance in individual cases. The U. S. Public Health Service and the Department of Agriculture have very kindly furnished us with a supply of the various pamphlets

dealing with such vital questions as flies, bed-bugs, and cockroaches. These are furnished to all camps and have been of inestimable value to us in combating these germ carriers. Through the U. S. Public Health Service, we also obtained what I believe to be the most rational "doctor book" for lay readers. This is known as "Miscellaneous Publication No. 1 Care of the Sick and First Aid to the Injured." A copy of this book has been placed in each of our 400 locals.

#### PLANS FOR CONTROL OF VENEREAL DISEASES

In conjunction with the U. S. Public Health Service and the State health authorities, we are about to institute a very active campaign for the control of venereal diseases. In this connection lectures will be given in the camps and the various phases of the diseases will be illustrated by moving pictures and lantern slides. Free clinics will be established at various central points, where our membership will be enabled to obtain advice, and if necessary, free treatment for these diseases. Health talks dealing with other diseases will also be made. In fact, we hope by improving sanitary conditions, installing safety devices, and educating our membership along these lines eventually to make the lumbering industry the most attractive industry to the worker. Too much attention cannot be given the subject of sanitation and living conditions. Statistics prove that the time loss due to preventable accidents is about one-eighth of that due to preventable diseases.

The L. L. L. L. is squarely facing both problems and is slowly but surely progressing. That our efforts are being rewarded is very apparent to anyone who has followed the history of the lumbering industry in the Pacific Northwest. The data collected to date from affiliated 4-L operators indicate that 382 operators employing more than 61,000 men scattered in small groups over the states of Washington, Oregon, and Idaho, have in the past year expended more than one million dollars for improvements which affect the living conditions of their employees. I believe that it can safely be asserted that the past year has shown a greater degree of improvement in living conditions in camps and mills than any like period in the entire history of the industry. The effect of our work upon the morale of the employee is of course less tangible and more difficult to demonstrate in cold figures, but nevertheless, it is equally as apparent to the close observer who is in touch with the situation. Speed the day when periodical physical examinations for all persons in the industry will make it possible for us to demonstrate by reliable statistics the economic value of modern public health activities.

To sum up our endeavors I will repeat a statement which I have often made in talks to the men in the camps. "We are trying to eliminate all preventable diseases from our midst. When this is accomplished the most common cause of death will be old age."

CHAIRMAN RHODES: We in the South have followed rather closely the work of the four L's, and have not known exactly what its practical results would be, but with evidence like this given by the operators there

selves, I am sure it will be of great interest to the Southern lumbermen.

(The Nominating Committee reported the following nominations: For chairman, Mr. E. Ross Farra, American Car and Foundry Company, Wilmington, Delaware; for vice-chairman, Mr. F. G. Lovett, Industrial Accident Prevention Associations of Ontario, Toronto, Ontario, Canada; for secretary, Mr. F. A. Barker, Lumbermen's and Manufacturers' Insurance Agency, Milwaukee, Wisconsin. On motion duly made and seconded, the nominees were elected.)

CHAIRMAN RHODES: This concludes our program for the morning, and the Chairman is in a little doubt as to the advisability of adjourning the section finally because of the fact that the three papers scheduled for tomorrow include two men who are not here—Mr. Weathersby, of Silsbee, Texas, and Mr. Horn, of Nashville, Tenn.

Would it be your pleasure that we have these two papers scheduled for tomorrow presented at this time, and conclude the session, or hold the other session tomorrow morning?

(On motion it was voted to read the papers and conclude the meeting of the section.)

## SAFETY AS APPLIED TO SOUTHERN LOGGING OPERATIONS

R. L. WEATHERSBY, LOGGING SUPERINTENDENT, KIRBY LUMBER COMPANY,  
SILSBEE, TEXAS

Down South, there is growing, large-bodied, tall, straight, free from knots and shakes, what is known to the world's lumber trade as Southern pine. Within the shades of these forests dwell the loggers who fell the trees and start them on their way to serve man's purpose. These men, whose activities are in the great out of doors, are exposed to falling temperatures of winter and heat's penetrating rays of summer. They must adjust themselves to the varying conditions of a country which, it had long been thought, could not be benefited by any set rules of safety, and which, therefore, was a place where every man was for himself and the devil CARELESSNESS for them all. With the advent of safety organization, this state of affairs has changed and it is not necessary for me to tell this body of the benefits derived and that will be further derived from its continued development.

The simple fact is that the woodsman through the mental teachings of safety has begun to think, and through this factor, the strongest of safeguards, has in addition created and put into effect mechanical devices whereby the necessity for taking dangerous chances has been largely eliminated. All accidents can be prevented, but man has not yet and never will reach the foresight of caution which will bring this about. Accidents will occur when we have concluded that every preventative has been applied; fool-proofing is yet an undeveloped science, and it all demonstrates that it should be the duty of the individual and industry to continue to lower the minimum.

Essentially first is the inspection of tools and equipment and the direction of the handling and doing things in the safe way. It is useless to put down one-hundred-pound steel and not properly spike it; to purchase safe equipment to be handled by a careless man; or to subscribe for safety first bulletins for bung fodder.

#### HAND TOOLS

Tools, especially double-bit axes and cross-cut saws, should not be carried in the caboose conveying workmen to and from the woods, unless confined in a box or locker provided for that purpose. Upon reaching the woods cross-cut saws should be carried upon the shoulder with teeth projecting outward, while axes should be carried in hand, never upon the shoulder. Sawyers should protect themselves against any underbrush that might foul the axe when dapping a tree preparatory to its felling. When the tree begins to fall they should step back a safe distance, avoiding the danger of a kickback, watching its top to prevent injury from falling limbs; and before approaching the fallen tree, observe surrounding timber and protect themselves against hanging limbs or other timber that might have been disturbed or broken in the fall of tree. In trimming tops of fallen timber the same precaution is necessary as in dapping in so far as fouling of axe by underbrush is concerned and possible injury to workman associate or both.

#### SKIDDING

These are hazardous operations and every man engaged therein should be his brother's keeper. Drum pullers should never pull slack out of line until signaled by flagman, who should never give signal until log is securely hooked and until he has stepped to opposite side of log from direction it will be pulled. Drum pullers coming into yard with log should use necessary precaution to prevent it hanging against any obstruction that would cause tongs to release, injuring flagger or decker, a frequent accident. Log should not be decked when rider is between deck and track as it might roll entirely over car, injuring rider or horse. Slack should be taken out of lines slowly by drum pullers until line has tightened to prevent throwing limbs or other obstructions, which are frequently thrown a long distance by a sudden jerk of the line. Logs being skidded should be watched closely by ground men so that they may protect themselves against small trees that might be uprooted if hit, or rotten limbs that might be thrown upon workmen. Skidder and drum men should know that sheaves on their booms are in safe condition to prevent falling upon them underneath.

#### LOADING

Loadermen should be cautious in removing logs from deck to prevent disturbing them before tong hooker can get into clear and to prevent its breaking, which invariably happens from rough and clumsy handling. Ground men should know condition of bunk load before attempting to

fasten toggle chain. Loadermen should never pull log before tong setters have set their tongs and stepped aside to guard against injury from a skidding log. After completing load, loadermen should deadman same when in a hilly country to prevent run away of cars, which results in serious loss both to life and property.

#### TRACK WORK

Steel gang foreman should not permit men to ride steel cars. This is the most dangerous car operated, due to the fact that necessity demands its operation over tracks which are in course of construction and otherwise weak and which, therefore, make the car more susceptible to derailment and wrecking. Men engaged in spiking, handling ties, or other materials should be experienced. Gangs should be filled out with this thought in mind and perfected as nearly as possible; their supervision by green foremen should never be tolerated. Handling the materials just mentioned is the greatest source of the promiscuous minor and serious injuries, which are often due to ignorance of men supervised by a careless foreman who does not regard the safety of his crew. He might lie to you in explaining how he broke some tool to prevent your reprimand for carelessness; but if you give no thought for the safety of your men and he gives none for his crew, a broken limb is sent back to the camp dangling to a workman with the simple explanation that "he got hurt; how? I do not know." A careless foreman lets the calamity go at that and you stand for it. These occurrences can and should be prevented by more careful and intelligent handling, and the industry that regards not the safety of its men has yet to learn it is shirking a responsibility.

The safety of your train crews is largely within the hands of your track forces. Removal of a tie or a spike, or making repairs without the forethought of the necessary signal to permit approaching trains to protect themselves, are all within the hands of your track men. You should at least know whether you have a careful foreman who realizes his responsibility. Have you foremen on the section who will display the danger flag to warn the engineer, who is running for the hill, that he may get his train under control before reaching the point of danger? Think this over; and if you have not, then you, yourself, are asleep at the switch.

#### TRAIN CREWS

Engine men should carefully go over their engines before leaving the roundhouse. Those little things, a nut here and a bolt there, develop into big and dangerous things unless continuous attention is given. It should be known that gauge cocks and water columns are in good condition with sufficient water in boiler. It should be the duty of some individual in the train crew to examine all hand holds, steps, pilots, and footboards with brake rigging on caboose. Do not take chances which can be lessened by the suggested caution and care. Firemen should know whether the king pin between engine and tank is in safe condition, as a

break here invariably results in a fatal accident. Care should be used in coupling together loaded cars when making up trains or otherwise and where logs are found projecting that will not permit clearance for brakeman in making coupling, he should deadman his car and with connecting load shove projecting logs far enough back to provide sufficient clearance. In such procedures the engine man should exercise such caution in handling his engine as will prevent disturbing the entire load. Trainmen should never walk on moving cars, which as a rule are covered with bark, which further adds to the danger of such practice. Cars generally in use are of skeleton type and a man falling suddenly always goes underneath, which results in the loss of limb or death. The engine man, before going under his engine, should know that throttle is shut off, the reverse lever on center, and the engine well chocked. Care should be exercised to avoid hitting a valve, especially blow-off cock which only requires a slight vibration to release when under pressure. The engine man should further know that the headlights are in good condition, as there are many unexpected delays which compel running after dark where the right of way is not fenced and where other standards of protection are not provided in the form of signals that would warn him of danger. The fireman should never clean the ash pan or fill rod cups without cautioning the engineer, as a slight movement of engine when he is so engaged may result seriously.

That which I have said concerning the necessity of carefulness in handling train equipment applies to all equipment, skidders, loaders, and all appurtenances necessary in logging. The employment of careless men to handle your equipment or to operate your trains should be criminal. It will not perhaps be possible to secure men who are 100 per cent efficient in rules governing the operation of trains over our great trunk lines, nor is such perfection absolutely essential; but we do need careful common-sense men who know and observe the signals and rules governing the operation of logging trains, which have their individual and peculiar dangers that cannot be guarded against other than by absolute carefulness.

#### ROLLWAYS

**FIRST:** See that there are no loaded cars which will not clear the rollway.

**SECOND:** Know that man hole is clear and not filled with bark or other debris which will prevent your getting into same with safety.

**THIRD:** Observe the load; and before knocking the toggle, determine in what manner it is going to break, and be sure that you are in position to get in the clear.

**FOURTH:** Do not attempt to unload lapped loads before they have been separated.

**FIFTH:** In the beginning make sure that there are no men at foot of rollway picking up sinkers, or otherwise engaged, upon whom logs might roll.

**SIXTH:** And lastly, if you have been careless and observed none of these precautions, resulting in your being caught upon the rollway,

blocked by falling logs from the man hole, run like h--l: it's up to you and your Maker.

This is a long and to some of you perhaps a dry subject; there is absolutely nothing new in what I have said. It is all known to every experienced logger and I have simply and as briefly as possible gone over what constitutes common-sense safety as it is applicable to general woods operations that require no scientific or perplexing thought to interpret. Safety first, self protection, is born in a man of normal mind, but in the great race we are making, we forget and confuse the gift of proper thinking. The problem before this body and its universal teaching to the individual should be to exercise his power of concentration on those things in which he is NOT TO FORGET. This is what you are undertaking both for the individual and industry. The man or industry who will not accept his part in this great work by unselfish co-operation should be outlawed. The fruit from safety training means a clear and active mind whose possessor may without danger govern the demon of fire, control the deadly currents of electricity and ride upon the bosom of unknown seas.

#### THE TRADE JOURNAL AS A VALUABLE AID TO SAFETY

S. F. HORN, EDITOR, "SOUTHERN LUMBERMAN," NASHVILLE, TENN.

It is perhaps restating an obvious fact to say that the trade paper possesses unusual possibilities for educational work in the furtherance of the safety movement. The very primary function of the trade paper is the dissemination of practical information which will be of real and positive value to those engaged in the line of industry to which it is devoted; and surely no information is of greater value than that which tends to promote safety. An idea of the possibilities for good work in the direction of safety possessed by the trade papers may be gathered from the assertion of the National Safety Council that three-fourths of all deaths and serious injuries in industry can be eliminated, and that not more than half of this reduction can be accomplished by mechanical means, leaving one-half to two-thirds of it to be done through the medium of organization and education.

In my opinion, however, the trade papers as a class have not yet fully recognized the vast field for good work in this direction, and it is my earnest hope that the work they do along this line in the future will far over-shadow what has been done in the past—and that is not minimizing the value of past performances. As a matter of fact, the work which the trade papers have done to speed the safety movement has already been attended by conspicuous success, not only in the lumber and wood-working trades, but in various other industries. A few instances may be interesting.

For example, one of the leading trade journals devoted to the coal trade early recognized the great importance of safety work in coal mining. In recognition of the importance of the subject they ran a great

deal of material relative to first aid meets. This grew to such proportions as to occupy much of the space in the paper, and it was necessary to reduce the volume of the material. Reports from the mines show that there was an immediately noticeable decline in interest in the first aid movement coincident with the restriction of publicity on the subject. This particular paper also runs an annual safety and welfare number and it is stated that these special issues have had the visible effect of stimulating the safety sentiment and creating a desire to purchase safety equipment.

#### TRADE PAPERS PUBLISH SAFETY INFORMATION

The trade papers devoted to the railroad business have been notably active in this work. One of them, for instance, devoted much time and work to an investigation of the use of motor cars used by maintenance gangs in going to and from their work. An undue proportion of accidents occurring in the earlier years on some roads where these cars were used had led to their absolute prohibition by certain railways. This trade paper, however, through the publication of rules for best practice in operation of these cars and an insistent stressing of the fact that operation of such cars could be made safe by following proper rules helped to remove the restrictions on the use of this valuable time and money saving utility in maintenance work.

In the iron and steel trades the trade journals have not lagged. The subject of safety has attracted their deepest interest and has been treated not only from the viewpoint of humanitarianism but from that of conservation of workmanship and skill, looking towards the advancement of efficiency. They have published from time to time the safety codes proposed or adopted by the various states with reference to the iron and steel works, foundry, and machine shop operations; and have given much publicity to the elaborate safety and welfare work which the various steel companies have been carrying forward on their own individual account.

#### SAFETY INSTRUCTIONS MADE INTERESTING

Innumerable instances could be recounted of the work of trade papers in advancing the safety movement in other industries, but we are interested primarily in the lumber and woodworking trades. It is a source of great gratification to me to be able to say that the work which has been done for safety by the lumber trade papers has been persistent, energetic and, I believe, productive of very beneficial results. The lumber trade is a particularly prolific source of accidents, not only on account of the hazardous nature of the work but also due to the type of common labor so frequently employed in the woods and about the mills. Carelessness seems to be an inherent trait of the labor employed in sawmill and logging operations—and carelessness has no place where powerful saws are tearing their way through logs or where giant trees are crashing to the ground.

It is remarkable, for instance, how many accidents occur in the lumber trade through sheer carelessness in the method of carrying axes and

cross-cut saws. Carrying an axe might appear to the layman to be an extremely simple matter, but in this as in other things there is a right way and a wrong way; and one of the most interesting articles on safety which we ever published was on this particular phase of the question, illustrated with drawings showing the safe way and the dangerous way. This article pointed out that if a man carries his axe in his hand with the head under or in front of the arm, he is likely to be seriously injured should he happen to stumble and fall—and it is an easy matter to stumble when pushing one's way through the woods. If the axe is carried over the shoulder, with the head of the axe back of the shoulder the probability of accident is materially lessened. The only safe way to carry a saw, it was pointed out, is to put it on the shoulder with the teeth pointed outward and the hand on one end. If the saw is carried under the arm, as is frequently done, the man is almost certain to be seriously injured or lacerated in case of a fall. It is pleasing to think that through the publication of this one little article we may have been the means of helping the prevention of many accidents. The real importance of this apparently trifling matter is emphasized by the fact that over 19 per cent of all the accidents in logging operations originate in the handling of saws, axes, and other hand tools.

#### CO-OPERATION WITH SOUTHERN PINE ASSOCIATION

One of the most potent forces for good in advancing the safety movement in the lumber industry has been the Department of Safety and Industrial Relations of the Southern Pine Association, whose work under the direction of Mr. W. Graham Cole is well known throughout the industry. Through co-operation with this department, the lumber trade journals have been able to render the results of its good work available to those lumber manufacturers who are not affiliated with the association. One of the best mediums of publicity adopted by the association is a series of large posters, most of them graphically illustrated, cautioning the workers to be careful and pointing out specific dangers. By an arrangement with the trade papers, advance copies of these posters are available to the lumber trade press for reproduction in their columns simultaneous with their distribution by the association.

These posters are models of their kind. Posted in a conspicuous place, the worker can not escape their lesson. A typical example, devoted to the dangers incident to skidding logs, is headed "Get on the Safe Side Before Giving Signal" and goes on to recount the case of a mythical Jim Smith who stood between the log and the skidder while fastening the chocker and who was thrown under the log when the drum puller took up too soon. The poster is illustrated with two skillfully posed photographs showing just how the unfortunate Jim was injured. The poster, incidentally, does not place all the blame on Jim but closes with an emphatic admonition to skidder drum pullers to be sure they receive the proper signal before pulling a log.

Mr. Cole, above referred to, is not only an unusually efficient safety engineer, but recognizes the value of the trade papers in his work and is

kind enough to oblige with specially written articles on the subject of safety. One of the most attractive articles in the 1919 Christmas Edition of the *Southern Lumberman*, and one which attracted much favorable comment, was from his pen. It was copiously illustrated with reproductions of some of the posters of the Southern Pine Association, and if the testimony of the papers' readers is to be believed, was a strong link in the chain of education for safety in the lumber trade. Another activity in this connection undertaken by the *Southern Lumberman* was the publication of a series of safety lectures made available through the National Safety Council which, we are pleased to believe, had a beneficial effect.

#### EDITORIALS ON SAFETY

The *Southern Lumberman*, and the same is true of other lumber trade papers; has also given considerable editorial attention to this all-important subject. We recall a recent editorial we had in this connection based on a sad incident at a Southern sawmill. The owner of this mill converted to the safety movement, undertook to install a guard on the sawyer's box. The sawyer strenuously objected to the installation of the guard, however, and, being an old and valued employee, his wishes were regarded and the guard left off. Shortly thereafter he was struck by a wild log and almost instantly killed. Incidentally, his family sued for and recovered a large sum of money in damages. This incident is a graphic illustration of the fact that it is necessary not only to educate the mill owner, but the employee as well. It also demonstrates the owner's folly in being deterred from doing what he knew was right on account of the whim of an individual.

I have perhaps devoted too much attention to what my own paper has done in the safety movement, but my experience has naturally rendered me more familiar with its accomplishments than any other. I wish to emphasize the point, however, that the other lumber papers have shown a most commendable energy and enterprise in this movement. This has been particularly apparent in the Pacific Northwest.

Several months ago the Safety Board of the State of Washington prescribed rather elaborate safety regulations for the sawmills and logging railroads in the state, covering the construction and operation of log hauls, log decks, band and circular saws, edgers, slashers, jointers, shapers, stickers, etc. The promulgation of these regulations was materially assisted by the western lumber trade papers, which printed the regulations in detail accompanied by photographs of the various safeguards in actual operation. When such safeguards are first proposed, many of the sawmill operators are likely to regard them as unduly onerous, but their explanation and illustration by the trade papers goes a long way toward demonstrating their practicability and their value to the employer as well as the employee. And it is obvious that the proportion of accidents will be materially reduced if the employee is provided with a safe place to work.

## TRADE PAPERS STIMULATE SAFETY EDUCATION

The Northwestern lumber papers were also active in giving wide publicity to the fire rules for logging camps recommended by the fire prevention committee of the Pacific Logging Congress. When we remember the tremendous damage to property and loss of life—not to mention the destruction of growing timber—incident to the great forest fires of the West, it is hard to overestimate the importance of the work which the lumber trade papers can do in the work of building up respect for these fire rules.

One movement which is now gaining in favor among the sawmills of the South is the formation of employees' safety organizations, interest in which was to a great extent stimulated by the educational work in this direction conducted by the lumber trade papers. Several of the lumber trade papers published articles regarding the first of these organizations which was formed and which proved to be a model of its kind. Commenting on the causes which led up to its organization, the general manager of the operation stated: "We have been attempting to carry on a certain amount of Safety First work for a number of years, but have met with indifferent success. After numerous conferences, we finally decided that an organized Safety First program was necessary, both from a humane and business standpoint, and that this work should be compulsory. In order to carry out this idea, however, we felt that it was necessary to enlist the interest of the men themselves. From a close study of our accident reports we found that the majority of them were unnecessary; they caused an unnecessary expense and reduced the efficiency of our employees. Our work up to the present time has convinced us that Safety First work will do many things among the men, will insure a better class of employees, and will save considerable in labor. To sum up, we will have a better class of employees, more loyalty from our men, and a greater degree of efficiency. We have had the plan of safety organization installed only thirty days, but our accident list is already decreasing rapidly, our men are becoming very much interested, and we are keeping up their interest."

Can there be any question that the publication in the trade papers of such eloquent testimony of the real value of safety work, emanating from one of the recognized leaders in the industry, can fail to arouse other lumber manufacturers to the practical benefits to be derived from the undertaking of similar movements at their own plants?

## PUBLICITY FOR SAFETY THROUGH ADVERTISING

Although the principal function of the trade paper in safety work lies along the lines of education, I feel that I may take the liberty of referring to another service which it can perform and which has never been developed to its fullest degree of usefulness. While not deprecating the immense effectiveness of educational work in the safety movement, there is no gainsaying the value of mechanical appliances for the protection of saws, belting, emery wheels, and similar sources of danger. The

probability of accidents originating in a rip saw, for instance, are visibly diminished if that rip saw be protected with a guard. Effective guards are manufactured, yet how few of them are seen in sawmills and wood working plants. Such mechanical safety appliances are frequently referred to in the reading columns of the trade papers, but even if a sawmill operator becomes convinced of the advisability of using them he is not informed as to where he can buy them and does not know where to look for them. This is due to the unaccountable fact that the manufacturers of such contrivances have for some strange reason never seen fit to advertise their wares in the lumber trade papers. I do not mention this because of the profit which my paper or the other lumber paper might derive from such advertising—it would be comparatively insignificant in proportion to the volume of other advertising—but it has long been a source of surprise and regret to me that the manufacturers of saw guards, etc., did not recognize the benefits to be derived from advertising to the lumber manufacturers. I believe that the comparative scarcity of such safety appliances in the sawmill trade may be directly traced to this source.

There are other more capable and more interesting speakers on the program, and I shall not burden you further with a recountal of the work which the trade paper has done, is doing, and can do in the safety program. Too much of this sort of thing is destructive to any sense of modesty which one may have. But, in closing, I take the liberty of speaking for the entire lumber trade press when I say that the lumber trade paper can always be counted on in the future to bend their every energy to the preaching of the gospel of safety—and they reach a large and open-minded audience.

## LOGGING ACCIDENTS ON THE PACIFIC COAST

WILLIAM A. MARSHALL, CHAIRMAN, OREGON INDUSTRIAL ACCIDENT COMMISSION, SALEM, OREGON

The purpose of this brief paper is (1) to show the great need and value of accident prevention in logging operations on the Pacific Coast by presenting facts showing the severity of disabilities resulting from accidents in this industry as compared with other industries, and (2) by offering additional statistics as to causes of these accidents, perhaps aid in determining the particular causes toward which preventive measures should first be directed. Accident experience of the logging industry in the State of Oregon is used on the assumption that conditions in this industry do not differ materially in the coast states and our neighboring Province of British Columbia.

### FREQUENCY AND SEVERITY

A study of the comparative severity of logging accidents and accidents occurring in all other industries in Oregon during a period of three years shows clearly that logging is by far the most hazardous of any

Logging Accidents in the State of Oregon, for the period July 1, 1918, to June 30, 1920—By cause.

important operation in the State. Using the method of weighting or measuring the severity of accidents in term of days lost, it was found that all occupations of the State other than logging showed an average loss per full time worker of 18.8 days, while logging operations developed an average of 44.2 days. Segregating the construction, maintenance and operation of logging railroads from other logging operations, the former showed an average loss per full time worker of 34.8 days, while the average for the latter was 46.9 days.

The experience for the same period revealed a similar condition relative to frequency of accidents in logging operations and all other industries. All logging operations developed a frequency of .213 accidents per full time worker, while the average for all other occupations in the State was but .206. Here, too, it was found that all work in connection with the movement of logs by railroad resulted in an average frequency of but .116, while for other work in logging the average was .241.

#### A COMPARISON OF INJURIES

The following table, based upon the same three year experience, affords a comparison of severity by type of injury. It should be understood that figures here given for logging include construction, maintenance, and operation of logging railroads:

|                                    | Logging      | All Industries |
|------------------------------------|--------------|----------------|
| Fatal ..... (per cent)             | 3.37         | .90            |
| Permanent Total ..... (per cent)   | .24          | .07            |
| Permanent Partial ..... (per cent) | 6.52         | 4.76           |
| Temporary Total ..... (per cent)   | 89.87        | 94.27          |
|                                    | <hr/> 100.00 | <hr/> 100.00   |

When it is understood that the above figures include all accidents involving loss of time, even for as short a period as one day, and that, on the average, of every 100 accidents in logging operations 3.61 will result fatally or in permanent total disability, 6.52 in permanent partial disability, and that the remaining accidents cause an average period of disability greater than any other important industry, in the state, then the need of preventive measures is obvious.

#### CAUSES OF LOGGING ACCIDENTS

The tables on pages 1366 and 1367 show the causes of accidents in all cases disposed of by the Oregon Industrial Accident Commission during a period of two years ending June 30, 1920. To the summary is added a column showing the amounts of compensation paid out on account of these accidents:

By referring to the number of accidents and the total paid for compensation, it will be noted that the average compensation per case was \$215.65. This does not include the cost of administration or medical aid. It should also be noted that the average estimated loss of actual or potential working days per accident was 310. These figures as to average cost

and average days lost per case were found to be more than double the averages for all industries in the State combined.

As in all our former studies, these tables show the serious accidents in logging occur more frequently in (1) felling and bucking, (2) pulling logs by power to point of loading, and (3) the operation of logging trains.

**STATUS OF ACCIDENT PREVENTION**

Reviewing the various tests applied to show the great waste resulting from accidents in this industry, it is clear that coöperation of employers and workmen in organized educational safety work will pay handsomely. During the past several years there has been increased interest by logging operators of the Pacific Coast in this work. The activities in the states of Washington, California, and Oregon, and in British Columbia, particularly during the past year, include additional legislation, district organization of employers, safety committee and educational work, and establishment of safety standards.

In conclusion, I am pleased to be able to say that in the improvement obtained along safety lines on the Pacific Coast the National Safety Council has been an important factor.

**CHAIRMAN RHODES:** The National Safety Council is eager to have all the memberships that we can secure, and a good many of the lumber companies on the Pacific Coast are now members of the Council. We are all expected to boost the Council and urge membership wherever possible.

I want to pledge to Mr. E. Ross Farra, the incoming chairman, my personal co-operation in his work during the coming year in making the section as successful as possible and in getting out as good an attendance as we can at the next Congress.

**ADJOURNMENT.**

1. The first step in the process of the investigation is the identification of the problem. This is done by the investigator who is responsible for the study. The next step is to collect data. This is done by the investigator who is responsible for the study. The next step is to analyze the data. This is done by the investigator who is responsible for the study. The next step is to interpret the results. This is done by the investigator who is responsible for the study. The next step is to draw conclusions. This is done by the investigator who is responsible for the study. The next step is to report the findings. This is done by the investigator who is responsible for the study. The next step is to discuss the implications. This is done by the investigator who is responsible for the study. The next step is to recommend further research. This is done by the investigator who is responsible for the study. The next step is to conclude the study. This is done by the investigator who is responsible for the study.

1. The first of these is the fact that the United States has a large and growing population of people who are not citizens of the United States. This is a result of the large number of immigrants who have come to the United States in recent years, and the fact that many of these immigrants are not naturalized citizens.

2. The second of these is the fact that the United States has a large and growing population of people who are not citizens of the United States. This is a result of the large number of immigrants who have come to the United States in recent years, and the fact that many of these immigrants are not naturalized citizens.

3. The third of these is the fact that the United States has a large and growing population of people who are not citizens of the United States. This is a result of the large number of immigrants who have come to the United States in recent years, and the fact that many of these immigrants are not naturalized citizens.

4. The fourth of these is the fact that the United States has a large and growing population of people who are not citizens of the United States. This is a result of the large number of immigrants who have come to the United States in recent years, and the fact that many of these immigrants are not naturalized citizens.

5. The fifth of these is the fact that the United States has a large and growing population of people who are not citizens of the United States. This is a result of the large number of immigrants who have come to the United States in recent years, and the fact that many of these immigrants are not naturalized citizens.

6. The sixth of these is the fact that the United States has a large and growing population of people who are not citizens of the United States. This is a result of the large number of immigrants who have come to the United States in recent years, and the fact that many of these immigrants are not naturalized citizens.

7. The seventh of these is the fact that the United States has a large and growing population of people who are not citizens of the United States. This is a result of the large number of immigrants who have come to the United States in recent years, and the fact that many of these immigrants are not naturalized citizens.

8. The eighth of these is the fact that the United States has a large and growing population of people who are not citizens of the United States. This is a result of the large number of immigrants who have come to the United States in recent years, and the fact that many of these immigrants are not naturalized citizens.

9. The ninth of these is the fact that the United States has a large and growing population of people who are not citizens of the United States. This is a result of the large number of immigrants who have come to the United States in recent years, and the fact that many of these immigrants are not naturalized citizens.

10. The tenth of these is the fact that the United States has a large and growing population of people who are not citizens of the United States. This is a result of the large number of immigrants who have come to the United States in recent years, and the fact that many of these immigrants are not naturalized citizens.
