The second session was called to order at nine-forty-five o'clock by the chairman, S. E. Whiting.

CHAIRMAN WHITING: We have a little routine work to do before we get at the technical papers. The election of officers for the next year comes first, and I will call for a report from the Nominating Committee.

Report of the Nominating Committee

We, the Nominating Committee, appointed by you to select a suitable personnel of officers to serve the Chemical Section for the next fiscal year, have attended to that duty, and after careful consideration submit the following names in nomination:

Chairman: Dr. Leonard Greensburgh, U. S. Public Health Service, School of Medicine, Yale University, New Haven, Conn.

Vice-Chairman: C. F. Whittemore, Western Electric Co., Chicago, Ill.

Vice-Chairman: E. C. Rogers, The Grasselli Chemical Co., Cleveland, Ohio.

Vice-Chairman: C. E. Rice, The Dow Chemical Co., Midland, Mich.

Secretary: Wm. A. Baxter, The Newport Co., Milwaukee, Wis.

Chairman, Posters, Lantern Slides and Safety Kinks Committee: H. L. Miner, E. I. du Pont de Nemours & Co., Wilmington, Del.

Chairman, Membership Committee: E. C. Rogers, The Grasselli Chemical Co., Cleveland, Ohio.

Chairman, Industrial Poison Committee: S. E. Whiting, Liberty Mutual Insurance Co., Boston, Mass.

Chairman, Program Committee: C. F. Whittemore, Western Electric Co., Chicago, Illinois.

Chairman, Statistics Committee: C. E. Rice, The Dow Chemical Co., Midland, Michigan.

News Letter Editor: Chairman, Vice-Chairmen and Committee Chairmen.

Engineering Representative: L. A. DeBlois, National Bureau of Casualty & Surety Underwriters, New York City.

Chairman, Publicity Committee: Dr. H. E. Howe, American Chemical Society, Washington, D. C.

Executive Committee:

The officers and

S. H. Kershaw, National Safety Council, Chicago, Ill.

Ira V. Kepner, Pennsylvania Salt Mfg. Co., Philadelphia, Pa.

J. S. Shaw, Hercules Powder Co., Wilmington, Del.

Dr. C. L. Reese, American Institute of Chemical Engineers, Brooklyn, N. Y.

Prof. C. E. A. Winslow, School of Medicine, Yale University, New Haven, Conn.

John Roach, Deputy Commissioner of Labor, State of New Jersey, Trenton, N. J.

H. C. Parmelee, Editor, Chemical and Metallurgical Engineering, McGraw-Hill Co., Inc., 10th Ave. and 36th St., New York City.

A. L. Watson, Koppers Company, Pittsburgh, Pa.

CHAIRMAN WHITING: Are there any other nominations for officers.

(A motion was made, seconded, put to a vote and carried.)

MEMBER: I move that the secretary be instructed to cast one ballot.

(The motion was seconded, put to a vote and was carried.)

CHAIRMAN WHITING: We are now ready to go on with any other committee reports. There is one committee that has certainly worked hard and that is the Membership Committee. This is the committee that must keep our section alive by getting new names. That is a difficult job and it isn't altogether appreciated as much as it should be. I would like to have a report from the man who has been the chairman of the Membership Committee for ten years. He deserves a great deal of credit and appreciation for retaining that burden under protest for all this period. I would like to have Mr. Kepner, who has been doing that work, tell us about the present status of our membership.

Report of Membership Committee

As chairman of the Membership Committee of the Chemical Section, National Safety Council, and because I happened to have been one of those concerned with the formation of the Section, it gives me great pleasure to report the progress which has been made in the growth of our memberships.

From a membership of four in 1915 the growth of the Chemical Section has been most encouraging, and although our cancellations a few years ago kept pace with our new memberships, at the close of the last Annual Congress, held in the City of Detroit, Mich., the Chemical Section had 195 members. However, during the past year we lost five members by cancellation; but, to make up for this an extensive membership campaign was inaugurated and our memberships were increased by 143, making a total membership, as of September 1, 1927, of 333.

As I am now retiring from the Membership Committee, after being its chairman for the past ten years, I want to take this opportunity to express my thanks and appreciation to the Chicago Staff Officers, and to the members of the Section who have served with me on the various Membership Committees, for their help, for without their efforts the Chemical Section would not be what it is today—one of the most active sections of the National Safety Council.

IRA V. KEPNER, Chairman, Membership Committee.

CHAIRMAN WHITING: Gentlemen, you have heard the report of Mr. Kepner's work, and it is Mr. Kepner's work largely because he could never get anybody else to help him very much.

C. L. YORK (General Electric Company, Schenectady, N. Y.): I move that we give Mr. Kepner a rising vote of thanks.

CHAIRMAN WHITING: It is moved that we give Mr. Kepner a rising vote of appreciation for his work for all those years. If you are in favor of that motion please rise.

(The members all arose.)

CHAIRMAN WHITING: Our next paper was assigned to Mr. J. M. Rowland, who prepared a portion of this report and was then called away for about a month, so that he could neither finish the report nor attend this meeting. Fortunately, however, Mr. John Shaw, assistant general manager of Hercules Powder Company, has consented under a ten-minute notice to read Mr. Rowland's report.

The Safe Preparation of Tanks and Other Chemical Apparatus for Repairs and Inspection

J. M. Rowland, Chief Engineer, Hooker Electro-Chemical Company,
Niagara Falls, N. Y.

We are all familiar with the old saying, "It is the unloaded gun that fires and kills." Like the unloaded gun is the "empty tank." A tank may be filled with a liquid which when drawn off will leave the tank filled with a gas which the liquid

has evolved. The tank may seem to be empty, while its gas contents are far more dangerous than the liquid.

In 1917 a tank car of benzene was being unloaded at one of the chemical plants manufacturing war munitions. The unloading had just started when the car was struck by lightning and the contents ignited. The dome was open to permit the insertion of the suction pipe and the tank was full. It burned furiously for a few minutes, shooting a column of fire and black smoke, and then went out. The moment the fire stopped the tank appeared to breathe, draw in fresh oxygen, and the fire started again. This was repeated several times, each time the fire diminishing, until finally it failed to re-ignite. Had the tank been nearly empty when struck by lightning, it would have contained such a large volume of gas that there is little doubt but what it would have exploded, doing serious damage. As it was, measurements made after the fire showed but slight loss of the benzene.

In preparing a tank for inspection or repairs, our first thought should be for its gaseous condition, the invisible, intangible substance that may travel a long distance to flash back a stream of fire from a riveter's forge or locomotive and blow our tank to pieces. On the other hand, this same invisible substance may be of such a nature that it lurks within the walls and it is not until a man has entered through a small opening that he finds himself in an atmosphere of suffocation or poison. Having unloaded the tank and drained the last dregs of what it was presumably carrying, we now stop and think about its internal atmosphere. If we know the nature of the liquid that was drained from it we may know that the gas given from that liquid is flammable, and undoubtedly the tank was vented when it was drained and probably sucked in some air, and the mixture of this air with the gas might make a highly explosive compound. On the other hand, we may not know what the liquid was, whether or not it would evolve a gas, and are totally in the dark. What are we to do? Just one thing. Consider it a loaded gun until we have swabbed the barrel and know the gun is clean.

The Most Important Natural Supply Is Water

Man's supplies were created before he was put on this earth to live and work for chemical plants and railroads and the most important of nature's supplies is water. We find it particularly useful for our present problem in its liquid state and as steam. We may have to modify it somewhat in special cases to prevent injury to our particular tank, but in most cases we can use it as it comes from the pipe line. Our problem now is to make sure that no dangerous gas known or unknown exists in the tank. We might wash the inside of the tank with a hose, but cannot be sure that this would do the work thoroughly; so instead we flood the tank and in so doing the water occupies all the space and drives the gas out. When we do this we must be careful about the gas we are driving out, it may be flammable, flash back and explode the tank when it is only partially filled, or if the tank is in a building, it may spread dangerous fumes. We should close the tank and pipe the gases to a safe place outside the building, or if it happens to be a tank car move it to a safe location to do the flooding.

When the tank is flooded the gas has gone and we have now a tank to deal with filled with water plus gas as the water has absorbed and which the water may give up when it is drawn off, so we must use care in sending this water to waste. When the water is all gone the tank is empty again, but the gun barrel may not yet be swabbed clean. However, we can more safely squint through to see the dirty spots. We may find our tank contains a slime or sludge that will not mix with water and, now exposed, continues to give off more gas. We can give it one, two, three or more floodings if we wish, but yet the sludge remains and fumes continue. Now we resort to steam, draw off the water to expose the slime and sludge and introduce live steam into the tank giving it a free outlet through our vent pipe. Many sub-

stances that will not mix with water cannot withstand the seductive heat of live steam and merrily change into a gaseous state and go out the vent pipe with it. In most cases these simple home remedies will suffice, but if the patient does not respond then call the doctor, this time a doctor of chemistry, to diagnose our particular tank and prescribe the treatment, because a remedy in one case might mean injury in another.

In cleaning our tanks and chemical apparatus we must not lose sight of the materials of construction and must be guarded in the cleaning treatment that we do not injure them. If it is stoneware, we must be careful with steam because sudden temperature changes will cause internal strains that may break it. If it is steel, carrying strong sulphuric or mixed acid, the chemist will rightly tell us that the diluted acid will quickly attack and injure the steel, therefore, we must clean it so quick and thoroughly that the weak acid does not have time to do its destructive work or, better still, neutralize it early in the process of cleaning. If it is rubber lined equipment, we must not use steam and if we use hot water it should not be hotter than 150 degrees F. because the rubber lining may be softened or injured. So it goes for the special materials and special uses, each one having its own characteristics.

Use of Tankage for Liquified Gases

There is one use of tankage and chemical equipment quite different from the rest and that is for the liquefied gases, such as ammonia, carbon dioxide, chlorine, sulphur dioxide and others. These gases are handled in steel and shipped sometimes in tank cars and at other times in smaller containers and handled in plants in pipe lines and tankage. These gases, due to the temperature and pressure to which they are subjected, are condensed into a liquid and handled as such. When the gas is discharged from such a tank or container the pressure is reduced and the liquid boils to evolve more gas. In order to boil, the liquid must absorb heat and if the boiling is rapid it cannot always get heat fast enough through the steel shell to satisfy it, with the result that it freezes into an ice inside the container and then evaporates more slowly, with a reduction in pressure to practically atmosphere. This is generally evidenced by the sweating or formation of snow on the outside below the liquor level. One might judge from the gas pressure that the container was empty, actually, it may be half or three-quarters full. Under such conditions the container should be closed and allowed to stand and when, after standing, it does not build up any pressure all the liquid has evaporated.

The tunnels and sewers of the chemical plant sometimes offer the most difficult conditions because of the impossibility of stopping the flow through them and the unknown nature of the gases formed by the combining effluents from different departments. Such conditions should be met by forced draft ventilation and the precaution exercised by the Bureau of Mines.

It would require a book filled with chemical formulae, reactions and instructions to adequately cover all the conditions encountered in this field. It has been the object of this paper to touch the high spots in a general way to introduce the subject for discussion and in the preparation of tanks and chemical apparatus for inspection and repairs to use caution and to urge that we do not forget the "Unloaded Tank."

CHAIRMAN WHITING: Mr. Shaw, do you wish to add any personal discussion at this time?

MR. SHAW: We have been very much interested in the danger arising under just the conditions which are outlined by Mr. Rowland in his paper. A partially filled or an empty tank, especially in the handling of solvents of the petroleum type, is dangerous. The railroad switchmen have told me in our yards that they are more afraid

of an empty tank car than they are of a car that is full. I saw a brakeman with his lantern one night running along the top of a train of tank cars, and when he came to a certain one, he stopped. He got down and ran along the road bed past several more tanks and then climbed up again on the train. I wanted to know, of course, why it was he did that. He said the reason he got off the train instead of running over all the tanks was because he was afraid. He said they had some terrific explosions from empty tanks at some time or other.

In regard to the cleaning out of steel tanks which have contained acid, of course we wouldn't use steam. Ionization would be so rapid from the weak acid formed that it would attack the steel so quickly it would destroy the tank. It has been our custom to drain the acid tank and, depending on its size, a certain quantity of soda ash would be dumped into the tank and then a large stream of water would be run into it with which to dissolve and mix it. We fill the tank to overflowing so that the top steel sheet of tank, caulking and seams and so forth will be neutralized as well as the sides and the bottom. After that we let the tank stand full of weak soda water for a few hours. We then drain it and get in it with a large stream of water, usually a fire hose, and wash it very quickly. If there is any sludge, we generally manage to break that up with a stiff high pressure stream of water. If there is any doubt about leaving sour water in the tank afterwards, we again go over it adding a little more soda ash, etc. Of course these last remarks are not so much for safety as for saving the tank.

Work Carried on in Too Routine a Manner

CHAIRMAN WHITING: Looking at this tank problem from the standpoint of an insurance company, we get the distinct impression that everything goes on happily for years and then some combination comes up with a tank, whether a railroad tank car or a fixed tank in the plant, when some extraordinary operation is under way, such as repairs of leaks or cleaning of any form. The impression we get from that work is that there is not sufficient technical supervision given to it to make it absolutely sure that you will not get into trouble.

You go through that work in too much of a routine way. There have been a number of very serious tank accidents, and by that I mean involving the lives of two or three men and perhaps considerable property damage, where some little element of safety has been overlooked. For example, I don't know that every operating chemical company has a rule requiring the putting of a life rope around a man when they put him into a tank. If you do not put the life rope on and if by chance there is some asphyxiating gas released from the sludge or residue a very serious situation develops right there with that unconscious man in the tank. Another man almost instinctively goes into the tank after him just as a man would dive into water to rescue a drowning man. This second man may be overcome. Finally a lot of men arrive and realize that something intelligent ought to be done but they don't have time to work out a safe method of handling the situation. They are in a serious jam.

It certainly is a very wise practice to have a procedure carefully outlined and supervised for every such operation whether you know the tank is empty or not, because as Mr. Rowland has said, an empty tank is the most dangerous of all, and he is right. I should like to hear from the operating men as to what precautions should be taken. There is a man with whom I have just spoken who said he never had a tank accident. I would like Mr. Rogers to tell us why he never had or never will have this trouble and what precautions he takes to prevent it.

E. C. ROGERS (Grasselli Chemical Company, Cleveland, O.): Mr. Chairman, I think we have hit upon a solution of the question of preparing tanks for repair work, a question that is about as interesting and perplexing as any question ever brought up and with far more than the average operating hazards.

In cleaning a sulphuric storage tank the first thing we do is to put the work in charge of a man who knows his job—a foreman. We don't leave it to any workman. We insist upon proper supervision. First. The tank is then drained. We open the manhole, allow the tank to stand for a while, remove the clean-out patch, rig up a V-shaped trough up to the clean-out hole which is run to a pit or a lead-lined tank on the wagon. The men work from the outside through that clean-out hole with a long-handled hose, drag all the mud they can into the trough which will suffice ordinarily where you just want to get rid of your mud. That is just a question of taking the sediment out.

If you have to repair the tank you have to go farther. After we get what mud we can scrape out we turn on a fire hose and stir up all the mud we can around the corners and then we drain that off, then we let the tank stand. After that we go in there with sponges and sponge it out, prepare it for the repairman and he repairs it. The danger of course is in the sediment which might accumulate around the edges or in the corners. When a man goes in there with a hoe he stirs that up and thus makes it dangerous. We also provide our men with ammonium carbonate and even with bottles of ammonia and we have very little trouble from it.

CHAIRMAN WHITING: Eastman Kodak has a good number of tanks, I believe. Mr. Armstrong might tell us about their practices.

Teaching the New Man to Be Extra Careful

A. L. ARMSTRONG (Eastman Kodak Company, Rochester, N. Y.): Our practice in cleaning acid tank cars and acid steel tanks is practically the same as outlined here. We go a little farther than the supervision in regard to having the men appreciate what will happen in empty tanks unless care is taken. We put these men into a class and education is given to them practically all the time.

When a new man comes into a job he can't go into the plant until he has a thorough knowledge of what will happen under certain conditions. We find in our plant when we have trouble that the only thing we have to do is to find out who has been doing something that is contrary to general practice, and I think that holds good pretty well along the entire line. These men know before they go to work exactly what will happen, in a general way of course, when different chemicals are mixed—when water is turned into the acid or the acid into the water. They have a full appreciation of it, and that is gotten over to them in a laboratory by giving them actual demonstrations.

For emergency cases such as have been spoken of, we have installed at every point where the tank cars are handled, where chlorine cylinders are handled or where inflammable vapors are handled, the All Service type masks. These masks are in glass cases and are never used for anything but emergency work. If they are ever used once they are never put back into that case. There are nothing but absolutely new masks in there and then we know that a man isn't going to a tank car unless he has a new mask on. In our 25 years of handling acids we have never had an accident. I believe, due entirely to the fact that the man on the job really appreciates the dangers attendant upon this sort of thing. I think that is the real answer. If a man knows what he is doing he won't go into the tank and do the wrong thing.

A. L. THOMAS (E. I. du Pont de Nemours & Company, Gibbstown, N. J.): The gentleman spoke there about using the masks in the glass cases. When your men go down into those tanks, do you furnish them with a gas mask then?

MR. ARMSTRONG: Our men all have life lines on them when they go in and there are two men on the job at all times. We have used them for the last twelve years, and the masks in the glass cases are more for emergency work than anything else. The men are all furnished with regular masks and they can have a new one when-

ever they want it. These masks are checked up once each week so that we are sure they have a new one when they should have a new one.

The emergency masks are only for emergency purposes. For example, a man might disobey orders sometimes, as we all know they do at times, and he might go into a benzol tank or into an acid tank and be overcome and then we would use one of these masks. We have them four and five in a glass case, depending upon the amount of work we do at that particular point and so the men can grab these masks and go in and take care of a situation of that kind should one arise.

MR. THOMAS: I thought that was what you meant but I thought somebody might misunderstand it and that was why I asked you about it.

CHAIRMAN WHITING: Don't either of you gentlemen use the fresh air hose masks.

MR. ARMSTRONG: No. We don't use fresh air hose masks and I am not very keen on them.

CHAIRMAN WHITING: Doesn't du Pont use them?

MR. THOMAS: Very seldom. We have discontinued the use of them.

Discussion About Types of Masks

MR. ARMSTRONG: There is a new type of mask put out by a well known concern. It is the French type of mouthpiece which does not cover the eyes, it just fits over the nose and mouth. They make a harness for that mask and it is very light. Our men like it quite a bit because they can see what they are doing and also see where they are going. I think it is far superior to the mask which fits over the entire face. That one is so disagreeable to use.

I would like to say a word in regard to the fresh air hose type which you speak about. They are about the hardest proposition to keep in repair and it is difficult to know they are going to work properly, when you need them quickly. We have practically discarded all of them.

CHAIRMAN WHITING: I am surprised at that because of course the chemical mask has to be maintained and you can't tell by a physical inspection whether it is in workable condition or not. The fresh air hose masks can be inspected and it is visible whether they are workable or not.

MR. THOMAS: There was an air mask made in New Jersey a few years ago which was a very good one, but they didn't seem to get enough money to finance the thing.

CHAIRMAN WHITING: Do any of you use a life line around the man?

MR. ARMSTRONG: We use a life line in every case. We never allow a man to go into a tank without one regardless of the fact that it has been cleaned out and inspected. Our repair men always work with a life line on.

CHAIRMAN WHITING: Is that your practice, Du Pont?

F. J. O'CONNOR (E. I. du Pont de Nemours & Company, Wilmington, Del.): Yes; our men always do.

CHAIRMAN WHITING: Could you give us any more information, Mr. O'Connor?

MR. O'CONNOR: I would like to ask a question. On a tank car which has had solvent in it and which has been subjected to one, two or three washings, what is the final determination for allowing a man to enter the car for repair purposes? I mean what test of the inside of the tank is made to show whether there is any more gas in it or not. I would like to know whether one washing is sufficient or are three washings necessary?

CHAIRMAN WHITING: That is a very good point. Mr. Shaw, what have you to say on that?

MR. SHAW: We are very much interested in that too. I understand that U. G. I.

of Philadelphia have an instrument which makes a very accurate and delicate determination. Up to this time, so far as I know, we have depended on the time element after several floodings. We would wait to make sure it was safe. I would like to call on Mr. Voke, who has charge of one of our ships of the naval stores plant. He is ship's supervisor.

F. W. VOLK (Hercules Powder Co., Brunswick, Ga.): It has been our experience that it is not necessary to flood every tank. I have in mind solvent tanks in which petroleum solvents have been carried. Flooding might be necessary, but usually we steam them from 16 to 24 hours, using live steam and we find that is sufficient. We have never had a case of a man being overcome yet. I want to point out to you gentlemen that if a man is overcome in a tank with only a manhole for egress, he becomes an octopus. It is a very difficult proposition to get him out of that tank. The best way to do it is to put a mask on a man and put him in there and then hoist the man out.

I would like to ask information from anyone. Do you consider it is dangerous practice to caulk a tank, from the outside?

CHAIRMAN WHITING: Who is ready to answer that question?

Caulking Tanks Filled with Solvents

F. W. LAW (Standard Oil Company, Whiting, Ind.): We have caulked our tanks when they were full of solvents; that is, where there are leaks present. We have found that there was no danger; that is, we haven't run into any danger yet from this caulking of tanks.

CHAIRMAN WHITING: Have you ever had any ignition started at the leak due to friction sparks?

MR. LAW: No, we haven't.

CHAIRMAN WHITING: Would you consider it serious if it did ignite? I mean, if it were a very small leak.

MR. LAW: We do not. Our caulkers use a wet sack over the tools which is an extra precaution. In our can house many times we have leaking gasoline cans,—the five-gallon cans. They solder these cans while they are filled with gasoline. We have never had any trouble yet from this source that we are aware of. Everybody has the idea that gasoline is very dangerous. Of course it is dangerous, but the real danger is not when the tanks are full but when the tanks are empty.

When we have repairs inside tanks to be done by our boiler makers, we use the test lamp, but we have found that even though we use test lamps there is still a danger in the tanks due to the fact that we may have wooden supports to our roof which after the tanks are flooded or steamed and it may be a relatively hot day with the sun beating down on the tank roof, the oil or gas show up in the timbers above. It may vaporize after you make the test with your lamp. The gas collects at the top and we have had several explosions even after the test lamp has been used. Even vent pipes do not always take away this gas fast enough.

CHAIRMAN WHITING: If you have had a leaky tank, you would caulk it? Would you also braze it or solder it if necessary?

MR. LAW: No, sir; but it is not our usual practice to empty the tank for caulking only.

CHAIRMAN WHITING: What is your practice on the empty tank, if you have to put a man into it?

MR. LAW: We steam it, fill it with water, steam it again and let it stand for twenty-four hours.

CHAIRMAN WHITING: In that steaming, have you a ventilating opening at the bottom as well as the top or only at the top?

MR. LAW: If there is an opening at the top we open the top as well as the bottom in order to get complete circulation.

CHAIRMAN WHITING: Do you use a power drive ventilation or blower of any kind?

MR. LAW: No. I would like to ask a question about a lead-lined tank. We have agitators which are lead-lined. The lead lining lies against the shell of the tank. Oftentimes the lead-lining cracks and some of the gas or oil gets in back of this lead lining. We have been wondering how we could get this out. We have drain lines underneath which are supposed to drain this stuff out, but oftentimes our lead is so tight against our outer shell that it pockets the stuff in between the lead lining and the shell with the result that we are taking a chance when our lead burner goes in there to repair it. You see, he might run into one of those pockets and probably cause a serious explosion.

CHAIRMAN WHITING: That is a very interesting question to get an answer for. Before you quit, what is your practice with regard to protecting a man when he does go into a tank after it is cleaned and tested? I am referring to the rope or mask.

MR. LAW: We have a rope which we use. We are not using masks.

CHAIRMAN WHITING: Do you have a second man outside?

MR. LAW: We have a man up on top with a harness at all times.

Making a Test of the Tank Air

CHAIRMAN WHITING: Who can answer that question on a lead-lined tank which has become cracked slightly allowing some of the solvent to get in back of it? What would you do then; I mean, before you would send a man to weld the crack together?

J. S. SPICER (Pennsylvania Department of Labor and Industry, Harrisburg, Pa.): I would like to ask that gentleman what he meant by the test light. Does he mean a light that is put into the tank or do they take a sample of the gas to the laboratory and test it there?

MR. ARMSTRONG: That test lamp is nothing more nor less than taking a sample of the tank air and going to the laboratory and firing it. A better test for your tank car, however, I believe, is the Orsat test. You can take an Orsat reading of your vapor in the tank and you can get the actual concentration providing you run a blank first. There isn't any question about it. I think it is superior to the test lamp or anything else that you can use.

I would also like to say that we would not consider it a very good practice to caulk any tank from the outside if it contained any flammable liquids of any kind. The gentleman said they never had any trouble, but personally I wouldn't do that from what I know, and I wouldn't want to ask anyone else to do it.

CHAIRMAN WHITING: I presume Mr. Law refers to very minor leaks, and wouldn't attempt it with a bad leak.

MR. ARMSTRONG: Not with leaks of any kind.

MR. CHASE: I agree with Mr. Armstrong. I wouldn't caulk a tank containing a flammable liquid. Empty it and flood it with water, steam it and fill it full of water again, then you are safe. Why not go the whole way? You might say that you have no tank into which to transfer the contents of the leaky tank. Well, you should have ample equipment; pump the solvent out of the one tank into another. That is the safe way.

CHAIRMAN WHITING: That is a very interesting difference of opinion. Of course Standard Oil has had a vast experience in handling of solvents. Would you like to come back at him on that, Mr. Law? Is it the regular practice at all Standard Oil locations?

MR. LAW: It is in the Standard Oil of Indiana.

W. C. REIBLING (American Tar Products Company, Cicero, Ill.): I would like to offer a suggestion for that lead-lined tank. You might be able perhaps to get rid of the liquid by heating it from the outside. I wish Mr. Armstrong would state here what he said yesterday about the full tank catching fire. We don't want to have the idea that the only tanks to be considered dangerous are the empty tanks.

CHAIRMAN WHITING: Before Mr. Armstrong answers that, I would like to call your attention to the bulletins of the Interstate Commerce Commission. It was suggested at our meeting last year that every one of you men subscribe to this service and distribute the I. C. C. bulletins to your practical operating men. You will find in them repeated stories about full tanks and empty tanks getting into trouble. If a full tank gets afire it may not always blow up, but it will burn up and boil up and will extend its trouble over a wide area.

Experimenting With an Explosive Condition

MR. ARMSTRONG: Yesterday in the discussion on static electricity in the Engineering Section, the point was brought up that probably it would not fire a full tank if the tank did get afire; that is, that the fire wouldn't be very dangerous due to the fact that you could put it out. I think there are a great many firms all over the country who operate these cars and feel that they are not in danger due to the fact that they have too rich a mixture in the tank if it is at least three-quarters full. They think it is too full to cause an explosion.

I can speak from experience and tell you that we felt very much the same and we had felt so for a good many years. We had a flash in the mouth of a tank which was within ten or twelve inches of being full. Afterward we ran experiments to prove it. We found that with a tank partly filled and under the right conditions we could get a flash down into the tank. Immediately after the flash we would get a cooling and partial vacuum which draws fresh air into the tank and this gives a good explosive mixture and you then get a terrific explosion. We had one.

CHAIRMAN WHITING: Enough to wreck the tank?

MR. ARMSTRONG: You bet your life. We got enough to wreck the tank.

MR. COOK: Mr. Chairman, in regard to the test lamps, I happen to have on file the names of two men who put that information out. I would be glad to send that out to anyone who would be interested. I believe the device tests the concentration vapors in the atmosphere. As I understand it, you can see a visible flash inside the test lamp if there is such an atmosphere. I would be interested to know how reliable such a test is supposed to be. Of course, it is much more simple than using an Orsat or other determination. I have no experience on the reliability of such a test lamp.

The Test Lamp Not Dependable

MR. ARMSTRONG: I would say in answer that I have known a test being run over a number of years which was similar to the test lamp, and it has been proven that it was not reliable. I have information which you wish to get with regard to knowing whether or not you have an explosive mixture or whether you have a mixture which will burn, whereas the Orsat apparatus is on the same principle as the apparatus used for determining the amount of benzol and other industrial poisons in the air. If you run a blank on your air before taking your test you can read it; the whole performance doesn't take over three minutes. An Orsat can be carried around any place in the field and the work can be done very handily.

On this question again of caulking a full tank car, it would be mighty interesting if some of you gentlemen would get the latest report on the propagation of flame put out by the Underwriters' Laboratories. They have spent a great many years run-

ning these tests and they will give you data which I think will prove to any one that it is dangerous to caulk a full tank car.

MR. LAW: I don't want you to get me wrong. I don't mean tank cars at all. I am referring to storage tanks.

CHAIRMAN WHITING: Why do you make that distinction between caulking a stationary tank and a tank car from the safety standpoint? You are referring to a field tank, for example?

MR. LAW: Yes, field tanks.

MR. RIEDERER: As far as acid tank cars are concerned on the railroad tracks, I believe that matter is taken care of by the Interstate Commerce Commission ruling. Either Tariff Number 1 or B 9 explains that. If a tank containing acid leaks, and it is marked defective, it must be followed by actual repairs. It is up to the owner of the tank car to thoroughly clean that as a rule because the concern repairing the tank car is not in a position to do so. At the same time I would like to mention the fact that almost everybody is familiar with the Interstate Commerce Commission's ruling that the tank car should receive not only the sixty-pound test but should always have a thorough inspection after twenty years' service, and that must be done every year.

Interstate Commerce Commission May Act

In the future, undoubtedly there will be more of that kind of work going on than in the past. A tank car will be ruled out by the Interstate Commerce Commission if it is not tested every year. I am mentioning this at this point because the majority of tank cars built since 1910 are getting near the twenty-year period.

CHAIRMAN WHITING: It is very well to call attention to the new ruling.

MR. ROGERS: I would like to ask how the sulphuric tank cars are cleaned out.

MR. SHAW: In the same way you would a storage tank in your plant. Put some soda ash into it and fill it up with water. If it has much sludge in it you will have a job on your hands. You will have to use a very quick stream of water and lots of it and you will have to wash it out quickly, you don't want any weak acid to lurk there. Then fill it up with water and let it stand.

MR. ROGERS: We have started on a new method. We have a drum and fill that up with lime and we have a pump attached to the water and we run the lime into the water and when we get the tank partly filled we turn air through the same line which agitates the mud. We then blow the whole thing out and this method cleans it quite thoroughly and it avoids a whole lot of trouble. This method also prevents deterioration of the steel.

MR. SHAW: We have done this where we have had much sludge in the tank car or in the storage tank. We pump in the soda ash and water fill it up with mixed acid or sulphuric acid which the tank contained and we agitate this with the air pump. We then pump it out to a settling tank and separate it later. After that we go after the tank in the usual way of water and soda ash. I don't like lime for the reason that it is not so easy to get out of the tank as the soda ash is. It is a little harder to get rid of.

A Satisfactory Way of Getting Mud Out

A. B. NIXON (Hercules Powder Company, Parlin, N. J.): We have found a very successful scheme of getting the mud out and also getting agitation at the same time. We do it by taking a fire hose without a nozzle on it and letting about six feet of it almost touch the bottom and then tie it at the top and turn on a full blast of water. That causes the hose to swish around the inside of the tank and it cleans it out in very good shape, and the weak acid is drawn off.

CHAIRMAN WHITING: That is a good practical way. Nobody has said anything about an electrical hazard in connection with such work. I assume you must have to see what you do inside of a tank and therefore you need a light. What is the safe answer to a light inside of a tank? I will tell you right now that you can kill a man with 110 volts if you use in a tank an electrical extension lamp that isn't properly designed. Of course you have the flash hazard as well as the shock hazard. What are you doing about that? How are you going to light the interior of any tank?

Lighting the Interior of the Tank

MR. RIEDERER: Mr. Chairman, we use a cable which is placed inside of a half-inch rubber hose. The lamp connection is absolutely gas tight and it has the wire cage over it. We use a standard safety extension cord; it is so heavy that the fellow wouldn't take it and stick it anywhere because it can't be handled that way. It is purposely made so that he will not use it indiscriminately. It can be run over with a wagon and not be harmed on the inside. I agree with you that it is possible to kill a man with 110 volts. We killed a man with 85 volts. We had to go to that extreme and we have to use cable that will fit through a half-inch rubber hose.

CHAIRMAN WHITING: I think you all know that the modern type of extension cord has no braiding on it any more than tires of automobiles have braiding on the outside, but they do have a high grade of mechanical rubber which will stand the abuse which Mr. Riederer mentions. That will give you safety from spark or shock from the cord itself and then the lighting device can be a vapor-proof lamp in a good substantial holder.

MR. NIXON: Wherever our tanks permit and where it usually takes a large opening or two openings from the tank, we use a flood light from above to light the interior of the tank and it doesn't go into the tank at all.

MR. LAW: We have now adopted a thirty-two volt transformer for feeding lights that go into tanks or tank cars.

CHAIRMAN WHITING: That is very good practice. There is no question but that there are plenty of 110 volt death cases on record in places where the man's body was very well grounded, as it is in a tank.

MR. NIXON: Does 32 volts remove the danger absolutely?

CHAIRMAN WHITING: I don't think anybody can answer that question. Theoretically it doesn't remove the hazard because it is the current flowing through the body rather than the voltage that kills a man. You might get a fatal current even at 32 volts but I should think that it is highly improbable. However, you will certainly get a milder shock under the identical conditions than you would get from 110 volts. But it is not positively known whether you can kill a man at 32 volts or not.

Problem in Cleaning Varnish Tanks

MR. SMITH (Pittsburgh Plate Glass Company, Pittsburgh, Pa.): We have a problem in cleaning the varnish tanks. The varnish skins collect on the side of the tank and in feeding the varnish skins and these skins collect on the side of the tank and in collecting there become quite a thick layer. Of course we have to go inside and clean these tanks. I was wondering, however, as to the efficiency of a forced draft on the tank because when a man scrapes down this skin the solvent is underneath and the tank is filled with toxic fumes. Would a forced draft be efficient in a tank of that type?

CHAIRMAN WHITING: Has anybody had any practical experience in that respect? You know that electric light companies in working in street man-holes very gen-

erally use forced ventilation for protection. Of course that is only a small volume to ventilate. Again, you can have your forced ventilation on the masks if you use masks. In that way you can pump air to the man and not merely to the tank.

MR. SMITH: In that case you will have the trouble of getting your air hose smeared with varnish, and this could prove a serious difficulty.

CHAIRMAN WHITING: Have you tried steam?

MR. SMITH: Well, steam would cause water to get mixed up with the varnish at the bottom of the tank.

A Mask Should Certainly Be Provided

MR. ARMSTRONG: I think it is a pretty general practice to use a fresh air hose in all tanks. I think that ninety per cent of the firms that have this problem stick a three-quarter inch compressed hose in and in addition to that a man should certainly be equipped with a mask.

MR. SMITH: We do equip them with a mask but it becomes inefficient after a man is in there an hour. We have to change our feed to the mask and we have to have a second man on the outside of the tank to take care of any trouble that might arise. But if we can get away from the mask the man is allowed to work freer.

MR. ARMSTRONG: I don't believe you can.

CHAIRMAN WHITING: What is the size of those tanks?

MR. SMITH: About 1,700 gallons.

CHAIRMAN WHITING: I should think you could ventilate a tank of that size with power enough back of the blower.

MR. ARMSTRONG: I would suggest that he use an All Service type mask which records the amount left in the mask and the man inside can always tell whether he is safe or whether he is in danger by simply glancing down at the canister, and he could then put a new one on. They now have a canister with two tanks. That is the simplest way, I should think.

CHAIRMAN WHITING: But what about starting an explosion after scraping down the tank, by a friction spark, if you don't keep that vapor down?

MR. ARMSTRONG: If it is as he says, that there is wet varnish back of the skin and he pulls it off, I don't believe that it would be possible to introduce sufficient air to keep portions of that tank below an explosive mixture.

Tanks Uniform in Size and Well Ventilated

B. G. EDGECOMB (Mountain Varnish & Color Works, Inc., Toledo, O.): We have had considerable experience in the cleaning of varnish tanks. We built a plant about eight years ago and have been cleaning of tanks a great deal since. We had used tanks which ran as high as twelve to fourteen feet deep and this is rather a hazardous thing to clean out by getting into them. In working out a new scheme we made all of our tanks of the same volume or capacity and all of the hole and at the bottom we have an eight by ten manhole plate at the front. In cleaning those tanks we don't have any terrible difficulty. We run an air hose in at the bottom manhole plate and let that contribute all the time they are cleaning the tank. It is about a three-quarter compressed air hose.

CHAIRMAN WHITING: Regarding this question of any possible difference from a safety point of view between solvent tank cars and field storage tanks, both Mr. Shaw and Mr. Armstrong want to be on record that they do not recognize any difference from the safety standpoint and that both types should be handled by the same safety methods.

Has anyone used the following method for cleaning the film from the sides of a tank in the case of any hydro-carbon oil? It was told to me by a man who used to work for the Barrett Manufacturing Company. He said that they would put in a mixture of some chemical like cresol and that would saponify the film of oil so it could be rinsed off. That was the principal way they depended upon in getting the sides of the tank really clean. Has anyone had experience in that method?

MR. ROGERS: I would like to ask someone what method they have used in regard to sulphuric chamber systems. I refer to the procedure of unpacking a hot or a cold tower. It is a dirty, rotten job and it can be dangerous. I would like to ask what is the best method to use.

CHAIRMAN WHITING: That is up to you, Mr. Shaw.

Fatal Accident While Gaging a Field Tank

MR. SHAW: I haven't had any experience in chamber plants, in cleaning a tower. There might be a volunteer in the room who might offer something.

CHAIRMAN WHITING: Can anyone answer Mr. Rogers' question? It looks as though you will have to work that out yourself and give us your answer next year.

MR. ROGERS: We haven't any difficulty with it whatever but I just wondered if there wasn't a better method in use than the one we are using. We are always looking for a chance to improve our methods.

CHAIRMAN WHITING: I want to put the following into the records: Two men were outdoors gaging a field tank of a crude oil refining plant. The two men were both asphyxiated right on the top of the tank while they were gauging that tank. I couldn't get the technical details of the case, but I was told that it was caused through hydrogen sulphide poisoning, which, as we know, is very quick in its action. One of the men was gauging and was overcome. His companion went for help and the man who came back to help him was also caught. They were both killed, possibly by hydrogen sulphide. This was while working at an outdoor job where you would ordinarily think a man was entirely safe.

MR. COOK: I happened to investigate that accident shortly after it happened and it was pretty definitely determined that the hydro carbon vapors themselves were the cause of the fatal asphyxiations, rather than the presence of any hydrogen sulphide. Down in certain regions in the oil fields of northern Texas there have been about half a dozen such fatalities which were largely due to hydrogen sulphide poisoning. In these tanks crude petroleum was stored. In the case that you have reference to, the first distillate from the tanks themselves is what caused the asphyxiations. It has been fairly definitely determined that it was the hydro-carbons themselves.

CHAIRMAN WHITING: Why were the fumes so concentrated that the men couldn't get away from them?

Atmospheric Conditions May Have Played a Part

MR. COOK: The atmospheric conditions on that night were particularly adapted for such an accident. There wasn't a breath of air stirring. Apparently the first man who died remained on the top of the tank longer than he should have. He perhaps put his nose rather close to the gauging pipe, and the second man who died went up to help him and exerted himself in helping the man who originally keeled over. The thought was that it was very likely that as much as three- or four-tenths of a per cent of hydrocarbon vapor was present at the top of the

tank. I think that it is not generally realized that a low concentration of hydrocarbon vapors will cause asphyxiation.

CHAIRMAN WHITING: It will cause unconsciousness and then if a man remains there he dies. It doesn't kill him instantly, of course.

MR. COOK: It is merely asphyxiation and not a poisoning.

MR. NIXON: In connection with the danger of asphyxiation or of similar phenomena on outside tanks and outside exposure, I might mention that in 1916 in San Diego the Hercules Powder Company were working with kelp. We had a battery of probably seventy tanks in which fermentation was carried on with kelp as the first step. It was recognized that there was danger to a man on the top of the tanks who might be taking samples and in doing so might lean directly over the opening. However, no man ever went up on the tanks alone.

Fumes Overcome Men Outside the Tank

The laboratory was 200 feet away from those tanks and one night a man started from the end of the laboratory for the tanks and fell over. A man saw him fall and when he saw the man didn't get up he thought the man had injured himself when he fell. He went out to help pick the man up. This man also went over. It was fortunate that when the next man arrived there, the wind had changed and the third man was not overcome. This will show what can happen even in the outside atmosphere. I don't know what gas it was. We have tried to find out since then. There was some carbon monoxide given off, as well as some hydrogen sulphide. I never knew exactly what caused it.

C. E. RICE (Dow Chemical Company, Midland, Mich.): Mr. Chairman, much has been said about tank cleaning and when it is safe to work. Personally, I think a tank is never clean. The best answer to the question as to when a tank is clean is when a superintendent of a plant is willing to go in himself. I think many times when we send a workman to work in a tank we ourselves are found standing back beyond the death line. As I say, a tank is clean and safe for a workman to go into whenever the safety man and the plant manager are willing to go in with him. That is a thought worth thinking about.

MR. SHAW: How are we going to tell?

MR. RICE: You ought to know. That is the job of the plant manager and the safety men. Nothing so far has been said this morning in regard to steel, lead and copper metals absorbing vapors. I have had one or two instances where carbon bisulphide, anilin oil, chloroform and carbon tetrachloride were carried in tanks and which rendered them unclean and they can't be cleaned. A steel tank will absorb these. I don't know of any way to clean these tanks and to my mind a used tank is never clean.

Tank Valves Are Not Always Reliable

A. W. SKERRY (E. I. du Pont de Nemours & Company, Barksdale, Wis.): There was one question which I don't think has been touched on in this morning's meeting. We have been discussing the cleanliness of the tank. We will now take it for granted that the tanks are cleaned, but we don't know whether all the connections to those tanks and from those tanks have been thoroughly closed that no material might enter.

We have found out through experience that you cannot depend on the valves to stop off liquids from going into our tanks. We have found that we must blank off with a solid blank all the connections to and from the tanks. This does not mean only incoming the acid or liquid valves which may have been handled, but

it also means the discharge valves from the tanks which may allow drippings to back up into the tank. Another thing I would like to call to your attention is that if you have air agitation piped to the tank that air line must also be blocked off because there is a chance of a small amount of acid or some foreign material being in the air pipes and a gush of air coming back might do some damage. So in summing up this question, it appears to me from the experience I have had, that the only way in which you can insure a tank being clean after you have had it cleaned is to break off all connections from that tank and be sure not to trust the valves.

CHAIRMAN WHITING: Is there any further discussion? We will have to close very shortly. Incidentally this is our round table as well as our first paper. I can assure you that from what I have heard; as an ordinary insurance man I will never go into a tank or anywhere near it.

At the last Congress you may recall we had a very excellent paper on the treatment of chemical burns based on research at the Henry Ford Hospital. Dr. Davidson told us then that he had not gone into the question of chemical burns in the eye, but only of chemical burns on the body. We are very fortunate indeed to have now the report of further investigations which have been made at the Henry Ford Hospital on the particular question of chemical eye burns, by Dr. K. W. Cosgrove.

The First Aid Treatment of Chemical Burns of the Eye

K. W. Cosgrove, M. D., and W. B. Hubbard, M. D., Henry Ford Hospital,
Detroit, Mich.

The important chemical burns of the eye, like those of the skin, are mainly due to acid or alkali. It has generally been taught that the best method of treatment of such injuries is the use of some neutralizing agent, either alone,¹ or following irrigation of the eye with water.²⁻³ A year ago, Davidson⁴ showed conclusively that the intensity of an acid or alkali burn of the skin is increased by the use of a neutralizing agent and demonstrated that dilution is more effective than neutralization as a first aid method.

The experiments on which this report is based follow closely the work of Davidson on chemical burns of the skin. The eye differs from the skin in presenting a continually moist surface. When an irritant is applied to the eye, there is rapid outpouring of tears which tends to dilute and mechanically remove the offending material. Also the eye has no horny layer to protect it.

In any attempt to save sight after a chemical burn, the cornea of the eye is the important area. The cornea is the clear window in front of the eye. Any opacity of this area causes loss of vision. The cornea is made up of several transparent layers. On the outer surface is a layer of epithelium limited below by Bowman's capsule. Beneath this are stroma cells which are limited on the inner surface by Descemet's membrane. To cause an opacity of the cornea, the injury must penetrate through Bowman's capsule. If the injury penetrates entirely through the coats of the eye, collapse of the eye results. Therefore, the extent of permanent damage in the eye resulting from a chemical burn is directly related to the depth to which the burn is allowed to penetrate. There are three things which control this: (1) The strength and character of the chemical. (2) The length of time before initial treatment. (3) The type of the initial treatment.

There is considerable confusion in the literature about the best method of treatment. This fact and the fact that there has been no controlled work done, made it seem desirable to study the effects of various treatments in the labora-

tory where conditions could be controlled. Rats and rabbits were anaesthetized and the irritant instilled into the eye. At a set time by stop watch, the initial treatment was given. This treatment consisted of irrigation from a rubber syringe with water or other solutions. The eyes were observed at 12 hours and every day for at least two weeks. Some of the eyes were examined microscopically. Control eyes without treatment were also observed. The time before treatment was varied to determine the length of time a given chemical could be left in the eye without causing a permanent opacity of the cornea after various treatments. It must be borne in mind that the rat's eye differs from the human eye, not only in thickness of the cornea, but in having a smaller amount of tears. So that the severe results noted in the rat would not be seen in the human. A drop of a chemical in the human eye would within a second be diluted at least 10 times by the tears. Also the human eye is larger and a drop would not necessarily strike the cornea and interfere with vision before it had been diluted. The time increment, therefore, must be considered as only relative for clinical purposes.

Sulphuric Acid

The action of concentrated solutions of sulphuric acid on the cell is the splitting off of the O and OH ions with resultant carbonization. Acid albumens are also formed.

Concentrated or 95 per cent sulphuric acid in the eye without treatment completely destroyed the eyeball. The rat died in 48 hours, the destruction having penetrated to the brain, carrying infection with it. When the acid was neutralized with 2 per cent sodium bicarbonate after 10 seconds of burn, a similar destruction occurred, death coming in two or three days. The eyes treated by vigorous washing with water after a similar length of time were not collapsed, but resulted in very marked scarring of the cornea. None of the rats died.

Using 50 per cent sulphuric acid, the control eye showed very marked scarring of the cornea. Seven out of eight eyes treated with sodium bicarbonate in 10 to 15 seconds were similarly scarred. Of the eight eyes irrigated with water, seven had normal eyes in two or three days, one only showing some opacity of the cornea. Using 30, 20, and 10 per cent solutions similar results were obtained.

A graph was made of the relative time a solution can be left in a rat's eye with two treatments before causing a permanent opacity. This shows that the period of safety is lengthened 10 to 25 seconds by treatment. These added seconds give us a greater possibility of saving sight. It further shows that at any length of time after a burn water is better than neutralization, of course, excepting a period of burn sufficient to cause complete destruction, after which neither treatment is of any benefit in saving sight.

Nitric Acid

When nitric acid comes in contact with the skin it gives a characteristic yellow xanthoproteic reaction. The removal of nitric acid before serious damage has been done is more difficult than sulphuric acid. Using a 68 per cent nitric acid, the untreated and the eyes treated with two per cent sodium bicarbonate all were completely destroyed. The eyes treated with water irrigations showed marked scarring of the cornea, but none were destroyed. After a burn of 15 seconds, or longer, the eyes were destroyed despite the treatment. Similar results were obtained using a 30 per cent solution of nitric acid to produce the burn.

With 20 per cent nitric acid, the control rats showed very marked scarring of the cornea. After a burn of from 5 to 20 seconds, 60 per cent of the eyes treated with either water or sodium bicarbonate solutions resulted in transparent corneas. However, the water treated eyes cleared up two to three days before those in which sodium bicarbonate was used. The eyes irrigated with water showed some slight permanent opacity.

Ten per cent nitric acid can remain in a rat's eye five minutes and result in a clear cornea if treated with water irrigation. If the acid is neutralized after a similar time, a permanent opacity results.

Phenol

The problem here is somewhat different than in the two preceding groups. Although commonly spoken of as an acid, carbolic is only very slight acid to litmus. It is, however, a protoplasmic poison. It precipitates the cell proteins loosely, allowing the poison to penetrate deeply, causing death of the cells. The question is not one between neutralization and irrigation, but between various irrigating solutions. Water, alcohol 25 per cent, sodium sulphate and glycerine solutions, were used as treatments. As carbolic is not soluble in water in suitable strengths, the fractional solutions used to produce a burn were dissolved in glycerine.

Using 87 per cent carbolic, the untreated eye was completely destroyed. Eyes treated immediately after the burn resulted in clear corneas when water or sodium sulphate four per cent were used. Using Alcohol 25 per cent, the cornea showed some slight permanent opacity. When the acid was left 10 seconds or longer before treatment, 60 per cent of the eyes treated with water resulted in transparent corneas, only 25 per cent after alcohol irrigation and 10 per cent after sodium sulphate treatment.

A 50 per cent solution of carbolic in glycerine left in the eye without treatment, caused a very opaque cornea as an end result. After a burn of 10 seconds or longer, 30 per cent of the eyes with any treatment had transparent corneas in three to five days. The treatments used were water, alcohol, sodium sulphate and glycerine; 20 and 10 per cent solutions gave similar results.

Sodium Hydroxide

The caustic alkali combines with the cell proteins to form alkali albuminates and with fats to form soaps.² The action is rapid on the unprotected cell as found in the cornea. The rapidity of action makes it difficult to obtain an eye useful for vision with any treatment.

The eyes not treated were destroyed after a burn with 40, 20, and 10 per cent solutions. The eyes neutralized with two per cent acetic acid followed a similar course. Only 60 per cent of the eyes washed after a similar time were lost, the remainder having permanent opacities.

Lye

Commercial lye (impure potassium hydroxide) often accidentally gets into the eye and causes quite severe burns. Its action is similar to sodium hydroxide only less penetrating. Powdered lye was placed in the eye and when no treatment was given, resulted in destruction of the eye. When irrigated with water immediately, a very slightly cloudy cornea resulted, whereas, with acetic acid two per cent treatment, a very cloudy cornea followed. After 10 seconds of burn with any treatment there was marked scarring of the cornea.

Ammonium Hydroxide

The action of ammonia according to Sollman¹ is a penetration through the outer layers of the epithelium to form fluid in the lower layers with death of the cells. A 28 per cent solution was used in the laboratory to produce burns. Acetic acid two per cent and water were used as treatment. The cornea was destroyed when no treatment was given. When the alkali was neutralized with acetic acid two per cent even after one minute of burn, a cloudy cornea resulted. However, when the eyes were irrigated with water any burn up to four minutes duration resulted in transparent cornea. After five minutes sufficient damage had already been caused to result in permanent scarring.

Lime

The use of lime, plaster and allied material, is widespread and often results in considerable loss of vision when it comes in contact with the cornea. If quick lime gets into the eye, the process of slacking produces considerable heat which in itself produces a severe burn. In addition to that, insoluble calcium carbonate is laid down in the cell, causing marked loss of vision. Barkan, Barkan² and Wolff³ advise the removal of the lime through irrigation with water and later dissolving the calcium carbonate with neutral 10 per cent ammonium tartrate.

Metallic Salts

The most frequent burns seen from metallic salts are from silver nitrate, copper sulphate, zinc chloride or arsenic. Metallic salts combine with proteins to form metallic albuminates and an acid.⁴ The free acid exerts its own action on the cells, giving us a double local effect. The salts of mercury, zinc, copper and silver form soluble compounds allowing the effect to penetrate deeply.

Silver nitrate and copper sulphate may be controlled with sodium chloride irrigation using one to two per cent solution. This forms harmless chlorides.

¹Refer to Bibliography following the paper.

Arsenic acts as a corrosive very slowly so that a considerable period of time elapses before permanent damage is done. Mechanical removal with water readily prevents loss of sight.

McCord and Kilker⁵ have advised the use of sodium bicarbonate as a treatment for zinc chloride burns of the skin. Innocuous zinc carbonate is said to be formed. This treatment would also be applicable in the eye.

Discussion

It has been demonstrated by the experiments that neutralization of the caustic acids and alkali cause increased damage to the cornea. This added damage may be the result of heat produced locally by the chemical reaction. Also there is the theory that water supplies the hygroscopic caustics with the necessary H. and O.H. ions, thus preventing their withdrawal from the cell. Free O. and O.H. ions in the cell are incompatible with cell life.

Subsequent Treatment

The method in common practice today is the application of a bland ointment in the eye, three or four times daily. Unless the discharge and slough is extensive, no irrigation of the eye is necessary. The bland ointment prevents roughened lids from doing damage to the cornea and promotes rapid healing. Atropine is used to place the ciliary body at rest. Cold compresses and salicylates are used to decrease pain.

Conclusions

(1) It has been shown that, regardless of the concentration of a chemical, or of the time interval, the best result is obtained with irrigation and that neutralization definitely causes damage.

(2) Experiments show that neutralization is not of added benefit after thorough irrigation and causes more damage when done before washing than washing alone.

(3) The mechanical removal of the chemical is the most important factor. This is shown in the experiments with carbolic which substance is not soluble in water.

(4) The tremendous importance of time before first aid is given has been demonstrated.

(5) It has been further shown that after a certain time of exposure for any concentration irreparable damage has been done.

Practical points are suggested by the experiments as to the best first aid methods. Numerous drinking fountains placed so that no time would be lost would be advisable. Time before initial treatment is a big factor in saving sight and if every man could be taught to run as fast as possible to a drinking fountain and open the eye in the running water when a chemical has gotten in his eye, we feel that both the loss of sight and time would be very greatly decreased.

Tears Would Assist In Cleansing the Human Eye

A number of lantern slides were exhibited by Dr. Cosgrove who pointed out in detail the relative damage to the cornea and other parts of the eye that result from the chemical burns under the two methods of treatment.

CHAIRMAN WHITING: These were not human eyes, but animal eyes. How would the result be with the human eye?

DR. COSGROVE: I have never been able to determine the human eye because the tears would neutralize the material and it would be diluted by the tears, and it would be impossible to say accurately. Of course you might do it if you took out the tear glands or something like that, but we haven't any human being who would want to be practiced on the eye. The interval of exposure would probably be more like minutes than seconds.

In closing let me impress upon every one of you and let every man in every factory who has anything to do with chemicals know that it isn't the treatment that is given but it is the length of time before the treatment is given that is important. Of course I have shown that neutralization is not as beneficial as water. but water, if it is not present can't be used. If you have a neutralizing substance present it would be better to use it immediately rather than wait any length of time for water.

CHAIRMAN WHITING: That is certainly a splendid contribution to our knowledge on the subject of eye burns, and it has the same practical application which we have from Dr. Davidson's work that water which we have most everywhere in the plant is sufficient and preferable to any neutralizing solution. We are fortunate in having some discussion on this subject by Dr. Hubbard.

Initial Treatment of Chemical Burns of the Eye

Discussion by W. B. Hubbard, M. D., Henry Ford Hospital, Detroit, Mich.

The time factor in treating chemical burns cannot be too strongly emphasized. A slight delay before first aid treatment may mean the difference between a useful and a blind eye. Keeping this in mind, the first aid treatment must be the most convenient method. Water is the most convenient and, as has been shown, actually lengthens the time interval of safety.

The effect of the solutions used in treatment was noted on control rats. No damage was done to the control eyes. As alcohol burns of the eye might occur by accident, or by treating injured eyes, experiments were done to note the strength and time necessary to produce burns. Various dilutions of grain alcohol were placed in the eyes and observed as in the other experiments. It was found that dilutions up to 75 per cent caused no permanent destruction of the epithelium of the cornea.

The benefit of neutralization before or after washing was considered. Experiments were done on rat eyes in groups of 13 with nitric acid, 20 per cent, and with sulphuric acid, 50 per cent. The first group was neutralized and immediately washed with water. The second group was washed and neutralized immediately afterward. The third group was washed, and the fourth group was neutralized. Neutralization followed by washing resulted in more serious damage than with washing alone. The results were very similar to those obtained by neutralization alone. Neutralization immediately after a thorough irrigation gave the same results as obtained with irrigation only. We concluded that neutralization before irrigation was harmful, and that it was of no benefit afterward.

Occasionally iodine eye burns are seen. Experiment with this drug showed that irrigation was a better treatment than neutralization. There was practically no difference in the results obtained by removal with alcohol, 25 per cent, and with water. Neutralization with starch solution resulted in severe destruction.

A Drinking Fountain Within Ten Seconds

In advising the use of drinking fountains in the first aid treatment, it must be considered that in burns of both eyes a man may not be able to run. In that emergency, the man should be helped to a fountain, or water should be dashed into his eyes. In placing drinking fountains the ideal would be one within ten seconds reach of every workman. Each fountain should be placarded directing the workmen to use the fountain in case of chemical eye burn.

After our experiments were practically completed and our opinions formed, we discovered that water alone was being used in a Detroit Willard Battery Service Station, where a water hose is turned on a man's eye immediately after an acid burn. They report very good results from this treatment. Few cases, however, receive proper treatment, as the following typical case shows: Mr. B. D. was employed by the B. M. Co. He was struck in both eyes by a flying spray of hydrochloric acid. He was treated 15 minutes later at the First Aid station with a few drops of some solution, probably a weak alkali. From the time of the accident, vision in both eyes was blurred, and at the end of one month, he presented himself at the hospital. At that time vision in each eye was only 0.1, and small, fairly superficial permanent opacities were present on the cornea of both eyes. From our experiments we feel that washing with water in 10 to 15 seconds would have prevented any loss of vision.

An Example of the Proper Treatment

An example of proper treatment is the case of Mr. S. K.: boric acid solution was being instilled into his eye for a mild infection. By mistake, phenol drops were used. Realizing some mistake, he rushed immediately to a tap and thoroughly irrigated the eye with water. Examination of the eye after several weeks showed only a small opacity, and vision was only slightly impaired. Had the acid been allowed to remain in the eye until removed by tears or until neutralization was possible, complete loss of vision may have resulted.

Delay in first aid treatment of chemical burns of the eye must be avoided. Any available solution, which is not harmful in itself, is of more value immediately, than any other treatment in five minutes.

CHAIRMAN WHITING: Thank you very much, Doctor. There are several questions which I should like to ask, and undoubtedly others would like to ask a question. Before our speakers reply, we shall be very glad to hear from Dr. Smyth of the University of Pennsylvania.

DR. SMYTH: I don't know that I have anything further to add. I think this is a splendid contribution and I listened to Dr. Davidson's paper last year and was glad to see the follow-up work on chemical burns of the eye. I felt they would get the same results with the eye as with the skin. I think they deserve a great deal of credit for bringing out these points which cannot be emphasized too strongly—immediate and thorough washing with water. If you don't have water handy then use the next best thing you have.

CHAIRMAN WHITING: The Chemical Section certainly appreciates very greatly having such research presented directly to us in their initial stages, and I think that undoubtedly the papers will be reprinted and made available for distribution later. Is there anyone else who would like to begin by asking a question?

CAPTAIN G. R. G. FISHER (Illinois Manufacturers' Association, Chicago, Ill.): I would like to ask Dr. Cosgrove if, in treating an eye burn such as has been described and which has been thoroughly irrigated, would it be of any avail or would anything be gained by putting in a drop or two of castor oil before sending for the doctor.

Castor Oil Would Probably Be of Benefit

DR. COSGROVE: Of course oil in the treatment of burns has always been recognized, and as I say, we have used a bland ointment in the Ford Motor Company that was placed in the eye of the person at the first aid station before he was sent to the main hospital. Castor oil wouldn't be of any damage and it would probably be of benefit.

H. JACOBSEN (E. I. du Pont de Nemours & Company, Newark, N. J.): I would like to ask Dr. Cosgrove something in reference to barium in the eye.

MR. SMITH: Hot barium brings several other chemicals to my mind with which we have had trouble and have had to combat and I should like to know from Dr. Cosgrove whether he has any knowledge of sodium sulphite, sodium sulphate, barium sulphite, barium sulphate, hot sulphuric acid solutions, and those last solutions were hot—boiling.

MR. ARMSTRONG: Silver nitrate?

CHAIRMAN WHITING: I would like to ask how long the washing should be continued. I would also like to ask this question: What do you do if the man closes his eyelids so vigorously that you have difficulty in getting any irrigation into the eye? If he is helpless in your hands, what are you going to do to get that irrigation in if the eyelids are tightly closed?

Various Additional Questions on the Subject

Here is another question: The first-aid kits which are available in most first-aid stations have either castor oil, argyrol or the ordinary eye-wash. Should any of those be given after the thorough irrigation and before sending the case to the eye specialist?

MR. COOK: Was potassium iodide solution tried out in washing cases of iodine burn, and is it a much better solvent of iodine than water?

CHAIRMAN WHITING: Any other questions?

G. R. STEARS (Western Electric Company, Cicero, Ill.): I would like to know what the best first aid treatment is for hydrated lime dust and sulphur dust in the eye.

CHAIRMAN WHITING: Any more questions? Doctor, you might begin to answer them now, if you will.

DR. COSGROVE: Mr. Jacobsen asked about hot barium. Of course anything hot is going to cause a burn and I don't know anything personally about barium, but I think the general rule which applies to most everything is the removal with irrigation of water preferably or with anything handy. That would be the best thing of course in a heat burn. In a heat burn we have a different thing to contend with and yet it is not such a serious thing. Heat will only penetrate a certain depth, depending upon the amount of heat, and it doesn't have to be stopped. It stops itself. I don't know anything about what the effects of barium would be on the eye, but irrigation would be of benefit.

F. A. SMITH, JR. (Titanium Pigment Company, Inc.): I asked about sodium sulphite and sodium sulphate.

DR. COSGROVE: Sodium sulphate in solutions up to ten per cent were used in the laboratory and caused no damage. I couldn't say as to anything stronger than that. I know nothing about sodium sulphite.

Of course when you come to hot sulphuric acids you have the heat again and you can only deal with it by irrigation. The solution with irrigation will cool the heat and prevent some of the burn, but when the heat strikes you the burn is there and you can't do anything except to treat it with the ointment or oil, whichever you prefer.

How Long Should the Eye Be Washed?

The next question was: How long should an eye be washed? As a rule, a syringe full of water was what we used. A syringe would contain probably about four or six ounces. I should say that it wouldn't take more than ten to fifteen seconds of washing in a drinking fountain to remove all that was there. Of course, when a person gets something in the eye, there is what we call blepharospasm, or a tight closing of the lids, and the lids can be opened forcibly by the fingers if a

man is unable to open them himself. I am not familiar with what is present in first aid kits.

CHAIRMAN WHITING: Boric acid eye-wash and castor oil. Sometimes there is argyrol in the kit.

DR. COSGROVE: Castor oil would be the most efficient, although olive oil would be more efficient than castor oil.

CHAIRMAN WHITING: Would you recommend the use of some soothing oil before sending the eye case to the specialist?

Have a Bland Ointment In the First Aid Kit

DR. COSGROVE: I think it would be of benefit in the first aid kit to have a bland ointment. The ointment commonly thought of is yellow oxide of mercury, but that shouldn't be used. It is irritating and should not be used in a burn. An ointment which contains a small amount of antiseptic is good, such as a weak solution of bichloride or any mercury solution put up by any of the pharmaceutical manufacturers. There are some of them that contain butesin, which has a certain amount of antiseptic picrate, that would give a certain amount of anesthesia in the eye and prevents the pain. The only time I can see that an eye wash is necessary in a burn of the eye is when there is considerable slough and it is dirty with it. It should then be washed out. If there isn't any slough it shouldn't be washed. The original wash is necessary, but if there are other washes following, it is liable to irritate more than soothe the eye.

CHAIRMAN WHITING: Silver nitrate was also mentioned.

DR. COSGROVE: Silver nitrate is neutralized by a saline solution—a salt solution. It can be normal saline or it can be one or two dilutions of normal, then the neutralization of nitrate doesn't cause any damage. It is much better and the action of it is stopped quicker than by the removal with water. Of course, if you do not have a salt solution, water is the best thing. Water is always taken if you haven't got the saline solution.

Dealing With the Scar on the Cornea

Regarding the scar on the cornea, we have tried several things. I personally have never seen any benefit occur from much that you can do. Sometimes injections of normal saline increases the circulation of the eye and in the cornea and reduces the scar to a minimum, but once a scar is on the cornea, always a scar.

Potassium iodide was not used. I don't know anything about it as a solvent for iodine. It is quite unlikely that it would be the best thing, as we have shown by carbolic acid that it is the mechanical removal and not so much the dilution. I don't know how potassium iodide would affect the injured eye. It would not affect the eye that was not injured. That is where we come up against alcohol and the use of phenol. We already have an eye injured. We know that alcohol up to seventy-five per cent does not damage the cornea, but we have an injured eye and we put alcohol into it and we cause more damage. I believe the next question was about hydrated lime. Was it not?

MR. STEARS: No, it was hydrated lime dust and sulphur dust.

DR. COSGROVE: I am not familiar with sulphur dust. Hydrated lime would of course react with the cornea and form calcium carbonate. That can be removed.

CAPTAIN FISHER: I would like to ask the doctor if in a neutralizing element for strong alkalis it would be wise to say that two per cent solution of acetic acid would be sufficient in general.

DR. COSGROVE: I guess I didn't make myself clear, but that was what we used, two per cent of acetic acid for strong alkali and stronger solutions of acetic acid would be more damaging than two per cent. Two per cent would be good to use to neutralize it. I wouldn't like to have anybody use acetic acid of any strength in the eye.

Winking the Eye Also Would Benefit

CHAIRMAN WHITING: I want to ask the doctor whether the patient should be instructed to wink the eye during the irrigation. Would that be of any material help?

DR. COSGROVE: You mean when it is being irrigated? Yes, that would be of material help.

A. L. WATSON (The Koppers Company, Pittsburgh, Pa.): There is one point on which I am not quite clear, and that is whether or not it is the opinion of the speaker that there would be any advantage in the irrigation process of having a neutralizing agent in the water or whether it would be better to have the water without any neutralizing agent whatever. You spoke, for instance, of using a syringe full of water and that perhaps that was sufficient. Would there be any particular advantage in employing some neutralizing agent in the syringe full of water?

DR. COSGROVE: That question came up at one time and we had done several experiments using probably less neutralizing substance than water and we turned around and repeated those experiments and did further experiments using the same amount of neutralizing solution as we used water with the results that I gave you. In the results I gave you, we used the same amount of neutralizing substance as we used water. Does that answer your question?

MR. SMITH: In the average first aid stations there are not always physicians or nurses available. How is this ointment to be applied? It is simple enough to drop drops into the eye, but it must be more difficult to get the ointment in the eye satisfactorily.

DR. COSGROVE: The ointment comes in a small tube with a little nozzle on it and the lid is just pulled down like that and a little ointment is squeezed in the sack and the eye is closed and you can rub it a little bit like that if you wish. It is very easy to apply. It is just as easy to apply as the drops.

CHAIRMAN WHITING: In a few cases of exposure to chemical burns such as plaster, in building and general construction work, the drinking fountains will not be available. I would like to ask the doctor whether he would consider it adequate to have a wide-mouthed bottle of water on the job so the water could be spilled into the eye, using the bottle as an eye cup.

Use a Wide Mouthed Bottle to Spill Water Into the Eye

DR. COSGROVE: Yes, that would be adequate, providing the water got into the eye and not on the clothes alone. If there wasn't a drinking fountain around, the man could stick his head into a pail of water.

CHAIRMAN WHITING: A plasterer has no water near and he has to take his first aid with him, but would you consider a four-ounce bottle of water would be adequate?

DR. COSGROVE: That would be plenty.

DR. P. H. HOURIGAN (Larkin Company, Buffalo, N. Y.): We have always used this plain water treatment in the general plant. We instruct them to use the

water any place they can get it and there is generally water some place in a bottle, pail or tub. Up to two months ago, we haven't had any serious burns. We happened to get caught, however, with a bad caustic case two months ago, and the men worked this treatment, but the caustic did considerable damage to the eye, but fortunately did not destroy it.

Castor Oil Is Used in New York

Most of our first aid kits contain castor oil. I think the official kit in the state of New York contains this castor oil. After everything is washed off, they use castor oil. While the doctor may think it is a simple thing for anybody to put this ointment into an eye, it is not. It is easy to a doctor because he knows the eye. It is hard for a layman or even for a nurse to do this unless she is specially trained to do that work.

Regarding that collapsible tube, we find that at least fifty per cent of them when squeezed will first throw out a waxy, thick and hard matter instead of a soft ointment. Something has happened to it since it left the manufacturers and you have an irritant if it is placed in the eye. Castor oil as a practical thing seems to be the best.

DR. COSGROVE: Castor oil is perfectly all right. Of course, some tubes will spoil, there is no doubt about that. Something changes in them, but I think it is just as easy to put that ointment into the eye as it is to put the drops in. Our first-aid man at the Ford Motor Company uses an ointment all the time and he doesn't have any difficulty with it.

MR. RIEDERER: Would there be any effect from the use of a rancid oil? In the years gone by it was understood that the use of rancid castor oil was more detrimental than useful. It is said they use five per cent carbolic acid in the oil in order to prevent it from becoming rancid. I know that I have used five per cent in eye treatments and it has been all right. But I understand that olive oil stands perfect for years and never becomes rancid. Is that correct?

MR. COSGROVE: It sounds like a very good principle. I haven't had any personal experience with rancid oil. I don't know what it forms or what it would do under the circumstances.

W. E. DEUEL (E. I. du Pont de Nemours & Company, Carney's Point, N. J.): Referring to the question of the tube of eye ointment, I would like to say that I always insist when a new tube is used that it should be squeezed a little bit and first wiped on the forehead of the man or on a piece of gauze, but not placed into the eye. I would like to ask the doctor what the treatment is for burns or injuries with reference to argyrol, lunargen or two per cent mercurochrome.

Neosilvol Preferred In Injuries

DR. COSGROVE: We have used both mercurochrome and argyrol ten per cent and neosilvol ten per cent. I prefer to use neosilvol in injuries. Sometimes in using argyrol where you have a lost corneal epithelium you will get a brownish scar from the use of argyrol. I have never yet seen a pink scar from the use of mercurochrome, but that might be possible. I prefer neosilvol, but the only trouble with it is that it is not stable and you can't keep it for an indefinite time. It is not as practical as mercurochrome, which you can keep for a period of time. Mercurochrome is stable.

CHAIRMAN WHITING: Are there any other questions? One speaker said, "Stick your head into any pail of water you find." If it is a fire pail, you want

to be sure there is water in it before you do that. One man actually stuck his head into a fire bucket and found a dead rat floating in it.

ADJOURNMENT.

Thursday, September 29, 1927

The third session was called to order at nine-forty o'clock by the chairman, S. E. Whiting.

CHAIRMAN WHITING: We have a pretty long program so we had better get started immediately. We are going to have "Chemical Plant Safety" discussed from several standpoints and then there will be a general discussion. First, we are going to hear from the "Plant Management Standpoint of Chemical Plant Safety." Mr. A. B. Nixon, Superintendent of Hercules Powder Company will address us.

Plant Management View Point of Safety

A. B. Nixon, Superintendent, Hercules Powder Company, Parlin, N. J.

No one can deny that the subject of safety has received a well deserved proportion of attention at the hands of practically every division of our vast business, industrial and community life. I don't know that I can make any material contribution to the vast amount that has been written and spoken about this very interesting and important subject. I do feel, however, that too often in a consideration of safety, we ignore the relation of the safety factor to the other important factors of our every day life.

In some places we still see the safety subject handled with a vast amount of hurrah and noise, during the continuation of which, everything seems to take second place to the subject of safety and "Safety First" is truly a real thing. However, when the big noise has died down we are apt to find that much of the enthusiasm has been left behind.

Safety is an important factor in our life and must be recognized, but in a fairly well balanced life it is not the most important factor. Sooner or later we must realize that it is relative to the other problems of our day.

Perhaps no one and nothing is or can be absolutely safe. Progress is made by a certain degree of chance taking. We make our advances by stepping out ahead of experience. It is true that progress comes faster to those who make full use of old experiences, but any new venture is beset with difficulties and unknown hazards.

Our lives and bodies are endangered by some agency from the time we are born until we die. In spite of this constant danger we want to live. We could avoid some of the dangers incident to the great automotive traffic of today by refusing to use the automobile; we could avoid all the risk of railroad wrecks by refusing to ride on the railroad; we could avoid the hazards of industrial activity by closing our factories; we could avoid the risk of ptomaine poisoning by refusing to eat; but who wants to do without these things? In such a list of activities, safety is an important consideration and we should be careful to see that every reasonable precaution looking towards safety is taken, but in none of them is it perhaps the most important consideration.

We are dependent upon leadership perhaps more today than ever before. Some one or some group must continually help us to properly evaluate the several factors which enter into our every day life. The theoretical or ideal leader might be compared to the mythical prudent and reasonable man whom the law holds out as an example. Neither of them exists. However, there are several qualifications which to some degree are essential to leadership.

1st, there must be the ability to recognize the existence of a problem.

2nd, there must be the ability to think these problems through so that the relation of any particular problem to all other problems will be understood.

3rd, and following these in order, there must finally be the ability to plan the attack for the solution of the problem.

The individual does not live who can measure up 100 per cent to these requirements. Such a man would be absolutely unselfish, absolutely honest in every particular, broadminded to the Nth degree and omniscient. We are all selfish to some extent. We are narrow minded in the consideration of some subject and I fear that we are not always honest with ourselves and others. Just the same I am satisfied that the man who is able to circumscribe his actions the greatest percentage of the time by these precepts and considerations will be to that extent a better foreman, a better leader wherever he may be found, and no man can lay claim to real leadership who does not exhibit to some extent these qualifications.

All of the factors and problems which enter into any business are necessarily subservient to the basic purpose of the business. Now one and then another may be more important and may seem to be temporarily in need of stressing but we find them all linked together, each depending upon the other. Safety must always bear a relative position to the other problems and likewise the consideration of all factors must of necessity give a consideration to safety.

Most plants of progressive industrial establishments are fairly well equipped with mechanical safeguards. No plant is perfect in this respect. We all have room to advance in this direction. Those with the older plants are probably farther from the ideal for in the construction of a new plant many details of design looking toward ultimate safety can be economically provided while often the history and experience in the risk is not such as to warrant the cost of a change in existing equipment.

Accidents Continue Despite Mechanical Safeguards

Yet with all of these mechanical safeguards our industrial accidents go on. Sometimes I am inclined to believe that the multiplicity of mechanical safeguards has led us to believe that our plants are fool proof. There is nothing so dangerous as a "fool proof" guard. Our real safety job is first to lay out our plant in such a way as to make operations reasonably safe and then to realize ourselves and bring home to the men those hazards that still remain.

The real development of safety standards has only started when mechanical guards are provided. The real approach to safety has to do largely with the development of a safety sense on the part of the foreman and individual workman. A danger to be avoided is a general impression that safety considerations are the province only of the safety committees or safety engineer. These are only a means to an end. They are merely tools looking toward the ultimate education of the workman.

Many methods are in use, looking toward the propagation of the safety sense among the workers. All of them are valuable in the right place and they all have their advantages and I need not take the time to illustrate these various methods of approach. No matter what system you use or how good it is, it can be seriously handicapped if not completely spoiled by a single faulty regulation.

As a nation we must have laws in order that we may conduct ourselves individually and collectively in a manner which promises to be best for the common good. Likewise in industrial establishments we must have certain rules to guide our actions. We must have some sort of a system in order that we may get the most effective use of the energy which is applied to the work.

We are loud in our criticism of our law makers for the volume of prohibitory

laws which they turn out each year. But how many of us give sufficient heed to the volume of prohibitory rules that may be given out in our own establishments each year?

Certain rules and regulations which formulate an operating system are necessary. These for the most part should be rules for doing things and not against doing them. They should be kept to a minimum consistent with uniform practice.

Such care in the formulation of regulations breeds confidence and the men will know that you understand what you say. Then, if you are careful to see that no slight violation passes unnoticed they will understand that you mean what you say.

A few good general safety rules, energetically enforced, mean more to the development of a sense of safety than a multitude of detailed instructions. Once this sense of safety is developed, the individual will think of more detailed safety measures for his own particular problem than you could ever formulate for him.

We are frequently asked to evaluate the result of certain changes in procedure, certain safety campaign policies or what not. We find plenty of published records showing the wonderful achievement obtained as the result of certain particular efforts, let it be wage payment plan, safety campaign, plans for the prevention of losses or what not. We find a surprising similarity in the result achieved by all substantial establishments, no matter what particular problem seems to motivate the dominant study. In general, I feel that it is impossible to accurately evaluate the contribution of any one of these factors to the general progress that has been made. No matter where we start before any real progress has been made all factors have to be touched and all contribute to the result, and there is grave danger ahead for any of us who attempt to make any one of these factors appear as the dominant cause.

Your business may be large enough to warrant a special power division, a safety division, a production division, a general purchasing department etc., but nevertheless the success of the whole business and the separate divisions of the organization and the individuals who make up this organization will be proportional to the degree that each subordinates itself or himself to the general purposes of the enterprise.

CHAIRMAN WHITING: Will you kindly use the backs of your registration cards on which to make notes for any discussion which you desire to bring up on these four subjects this morning. We will have the main speaker on each subject first before we get into the general discussion.

The next phase of the subject will be as from the standpoint of the medical department and we shall hear from Dr. Hourigan of the Larkin Company.

The Medical Department

P. H. Hourigan, M. D., The Larkin Company, Buffalo, N. Y.

I have been asked to tell in five minutes what factor the medical department should be in the safety movement, so it will only be possible to touch the high spots, skim over others and neglect a great deal.

In a group of men such as I have noted here, men who have come from an activity that the future of the world, especially in this country, either in peace or war depends upon; men who think as you men think and as the last speaker has shown he thinks; men who have a fine sense of proportion and relationship; men who go after the facts—all the facts—and then list them and do not guess—why, a man is justified in being a little fearful of what he says or does in front of you. So.

I am rather reminded of the story of a question which was put to a great English financier as to why in their great English monetary system they had such a small piece of money as the half-penny and farthing. He was reputed to have answered: "It was put there to afford a Scotchman an opportunity to make his charity." And I need a little more than Scotch charity.

Of course the medical department is basically interested in the individual. We sense our social relations and the economic problems that surround us, but we feel that all your activities are in the final analysis for the benefit of the individual whom God created, and so that is quite natural. We have brought man into the world as a babe and we feel that interest which all feel in a babe.

We have seen them taken off handicapped with injuries in middle age and we have seen the family and industry deprived of the great value of his later years; so that notwithstanding the talk of the last speaker we insist on the final analysis, it is the individual that is the big factor.

What Is a Good Physical Examination?

Now, as to what the medical department can do in the safety movement. Of course, what we first do is to have physical examinations. Along that line, how can we help? In many ways. Let us consider a general physical examination. The first thing you look at would be a man's eyes. I mean that you see a man's eyes—and I notice in this crowd as I look about that almost every other man needs a pair of glasses. The general situation of the country is that 50 per cent of the people need eye glasses or rather eye correction—that is, 50 per cent of the people don't see well. Those eyes should be checked up by medical examinations and the medical service should consist in evaluating that eye, and in supplying the corrective lenses in an economic way for the workman. Then if the man is put to work, the department should know of the condition of those eyes and should consider it in their activities.

A man past 40 years of age is myopic. He must be fitted with glasses to do his work. If his work consists of handling something near, he must have glasses to correct his vision. He is myopic and can't see far. If his duties take up a line of work which requires a man to see far that is another condition. If the children have been neglected in their school years and they have the amblyopic or blind eye, that thing must be taken into consideration.

If you stop to think, in the state of New York we have probably the most liberal compensation law of the whole world. Notwithstanding the fact that before last year it did occupy that position, an Industrial Survey Commission credited—I won't say credited exactly, but after three years' survey they increased the compensation. In the state of New York an eye costs 165 weeks at \$20 a week. Twenty-eight is considered industrial blindness or a total loss of an eye.

When you injure an eye as much as 28 the injured man gets something like \$20, and when you figure the cost—and the clever industry puts the cost back on the department—if you damage that eye and it is figured back in the cost of insurance it will come, although spread out, to something near \$10,000. That is put on the wrong side of the cost in your department.

While you have a factor that does get a cost of what damage to an eye will be, yet society all along insisted that you either take care of the individual and his eyes or you pay the penalty. Industry in the state of New York, in union with labor I believe, is quite willing to assume the costs of industry because of accidents to the individual or diseases contracted because of the industry. I don't believe that attitude is going to be lessened.

Now we come down to the examination of your teeth. You can see big loose fangs and pyorrhea around the gums and bad tonsils. There is no question about it, many of the things about the body which make that man a danger to you when he

lives with the rest of the gang might be already in him. There is the heart: A man with a weak heart or a poor heart should not be put to work on certain types of jobs. If you have an industry that such a type of man would be a danger to, that man should not be accepted. Of course we in our organization have an opportunity for spreading a man to one place or another. We reject very few, but the decision depends upon the community problem of industry and all that.

We have the lung problem and that is a big problem. It is a problem which industry must recognize. There is the dust hazard to such an individual—the dust damage, the injury by fumes and irritating gasses. All activities and industries are telling you about the dust conditions and also remedial measures to take, in South Africa, England, Australia, to recognize fibril silicosis, and how those diseases are contracted. Laws are being introduced into legislatures in this country and I believe some have been passed already which make silicosis or fibrosis compensable. In our industries you can meet the problem. You have here the brains and you have the courage. If we don't meet the problem as we should meet it in this country, it is going to be met as in the old country, it is going to get into the development of a bureaucracy, and that is a state function or state activity, and there is none of that here which can compare in any way with the measure of efficiency which the men in our industries can display.

The Case of the Man With Weak Lungs

The examination which shows weak lungs should mean that that man shouldn't be put on a job where there is a dust hazard, and if you in your industry have that exposure the men in your department will help you to recognize it and will help you to see what it is doing to your men. Checking up on the men will mean that the poor-lunged man shouldn't be put into that hazard, and the man who is developing that fibrotic condition of the lung will afterwards have a superimposed tuberculosis. If that man is put on the job and he suffers from the effects of that dust he should within two years at the most be changed from that exposure. Statistics have shown that it takes from three to five years to create that fibrotic condition. Of course, then it is easier for the industry to recognize that exposure and to take measures for the gradual purchasing of new machinery to see that the new machinery eliminates that hazard.

That is part of what physical examination can do. There is much else which can be said along the line of weak backs, of hernia, of varicose veins and of degenerative changes of age in the workman. Then comes the matter of how we aid you in solving problems, as Dr. Congrove showed you yesterday, by handling at the right place the contact of injury of the eye and by helping you along with those problems, then when you get to the dispensary the immediate care of the injury lessens the effects. I think the compensation statistics show that 50 per cent of the costs were for infections after the injury. A very minute injury should be handled immediately in order to have the infection factor eliminated. Of course, this would lessen the danger and it would add to the safety, then the follow-up care of that case would be the proper thing, and the best service is the cheapest service in any line.

The best type of doctor and the best kind of surgery and laboratories are the cheapest, you all know that. Then comes the activity of the medical department as is shown in its relations with the sick benefit. Basically, a man is controlled by necessity. If you will take up the matter of sickness, or take up the matter of injuries which are outside of compensable injuries, if you take up the matter of operation outside of compensable operation and will help a man to solve those by your sick benefit associations, you are going to lessen the amount of claims you get of conditions in his body from compensable causes.

A survey of our state shows that only seven per cent of the working men carried any health protection or protection for required operations. So it is beholden to industry that they should think over this situation where only seven per cent of their workmen have anticipated sickness or necessary operations.

I think I have started enough.

CHAIRMAN WHITING: You have started many things, Doctor. Will you sit up here because they may ask you some questions later. We will now take up the question of safety from the standpoint of the foreman. Mr. L. C. Streeter, Superintendent of the Chicago works of the du Pont Company will address us on that subject.

Chemical Plant From the Standpoint of the Foreman

L. C. Streeter, Superintendent, Chicago Works, E. I. du Pont de Nemours and Company, Inc., Chicago, Ill.

The majority of chemical plant foremen are recruited from one of two sources. First, the efficient workman with considerable experience on his job is promoted to **foremanship**; or second, a man with technical training—more or less thorough—is put in charge of an operation. Either type of man has a very clear idea of the fact that he is dealing with chemicals which, if not properly handled, are potential causes of very serious accidents. The first man gets this idea through practical experience; the second, through education and training.

For the purposes of this discussion, we must assume that some thought has been given to the appointment of the foreman by his supervisor. We must assume that he is not picked up at random, rather that he is selected with great care, due consideration having been given to his qualifications for the particular work.

Accidents which occur in the area under the leadership of an incompetent foreman—incompetent because of lack of experience and training—are in my opinion, directly chargeable to management.

Given, then, a foreman, a man trained and experienced in his particular line of work, how does he view this whole safety problem?

Now my assertions are the results of my own observations in handling labor and foremen during the past twelve years, in four chemical plants owned by one company. They represent one man's opinion, and many of these opinions, I know, are debatable.

The foreman wants to earn more money. He wants promotion. He wants to step over the line from punching the clock to receiving a salary check. To attain these ends, there are just three avenues open to him—cut costs, increase production, improve quality. Any one of the three—any combination of the three—always results, or always should result, in prompt recognition. In any well-organized department where outstanding achievement does mean quick recognition, there is quickly developed a healthy spirit of competition between various groups.

We all know that there is an inherent sporting instinct in any normal group of men. Our gang ought to be able to do its job just a little bit better than any other gang on this plant. And the foreman, if he has the qualifications to make him a good foreman, is quick to seize this tool of friendly competition to further his own interests.

If we grant, then, that a competitive spirit can be fostered in the men, immediately there develops a spirit of friendliness. The men become something more than cogs in a wheel. There is a human interest developed, the value of which is incalculable. We don't want any member of our team to get hurt. We want no accidents to happen to our friends. The seed of the safety idea is right there. The foreman cannot cut his costs with one or two men in his crew partially incapacitated.

tated by injury. He cannot increase his production if he is shorthanded. He cannot improve the quality of his product if his gang is spread too thin to catch defects.

Accidents must be fought; safety must be followed up, to keep in the race. Your good, first-class foreman in a chemical plant is very alert. He is constantly asking questions. He wants to know always "Why?" And to accomplish anything along safety lines to protect his own men, he is constantly asking "How?" He must think along safety lines exactly as he thinks along production, cost and quality lines.

The first question that he will want to ask is, "What is the attitude of the men on top in this corporation?" The foreman must be thoroughly, one hundred per cent, sold on the idea that his company, from the board of directors down through the president, vice-presidents, departmental managers, plant managers, superintendents, etc., all want safety in the organization. He is very quick indeed to detect any insincerity in the safety movement—spasmodic bursts of enthusiasm, inspirational speech making, rallies. To the average foreman, a very large percentage of this sort of thing is pure hokum. All of these things may have their places, but 99 per cent, I believe, of the enthusiasm of a foreman for safety is engendered by his observation of the quiet, everyday, regular, sane, living of safety by his superiors. Precept and example—99 per cent example.

Practical Safety Work Teaches a Big Lesson

The plant superintendent who stops in his plant inspection long enough to turn down an exposed nail—to move an obstruction away from a fire escape—to do any one of a thousand little ten-second jobs of this sort, has done more good than an hour's speech-making will do.

I do not believe that many of us appreciate as we should that the foreman catches his stride from his superior, and that the men down the line get their gait from the foreman. The sincerity of officials in a safety campaign is to my mind by far the most important single element in determining the success or failure of that safety movement.

The foreman must be made to thoroughly understand that safety pays. He knows that the company is in business to make money, and for no other purpose. It must be demonstrated to him that it is actually cheaper in dollars and cents to spend money to prevent accidents than it is to pay for accidents. We all want him to believe that the top boss is a good scout—that he wants to conserve his men from purely humanitarian reasons. But he can be sold on this idea much more easily if he knows it pays the company to play safe.

Now let me get down to cases. We'll assume that I am a common, ordinary, garden variety foreman, that all of you gentlemen have executive positions and that every one of you has a better job than I have,—but we are all together, working on the same chemical plant. We are talking safety and it's time for the foreman to have his say.

I am sold on safety. I believe in it. I've got a good gang of men. I'll back them against any gang in the plant. I am thoroughly convinced that the top men in our company really want safety. I believe most of you men do also. There are some of you that I am doubtful about, but I believe the general idea of safety is pretty well instilled into the minds of our organization. However, there are some of you who have heard this safety business talked so long that familiarity has bred contempt. And lastly, I believe that safety pays. I believe it pays me individually to do my work safely, and I know that it pays me individually to see that my men work safely.

1. I want some rules to work by—rules that you will subscribe to. I want rules that will work—

A. Don't tell a man never to enter a tank without a life line, when his work

makes it necessary for him to go down into a tank in which his life line is going to get so hopelessly tangled up with agitator blades that he can't get out of the tank without cutting the life line, even if there is no accident. Think of the plight of the poor fellow if there should be a fire or an explosion.

- B. Don't insist that a welder wear goggles all the time he is welding or cutting, and then expect him to weld or cut one hundred per cent of his time. Let's give him something else to do part of the time to rest his eyes.

Make your rules workable rules, and then stick to them. No rule is much better than one habitually broken. Let me and my gang help formulate the rules. Bear in mind that the man who starts the motor, who does the charging and discharging, who operates the control mechanism, knows a whole lot of things about his particular operation that none of you can ever know. Use our brains as well as our muscles. Consult us.

2. Then what are we going to do about the man who breaks the rules? Are we going to have penalties for unsafe practices? What are the penalties? Are they to be the same for each person, regardless of past history? Personally, I believe we ought to have penalties for infraction of safety rules, but I am not at all sure that I would treat John the same as I would treat Joe for the same offense. I believe every case should be judged on its merits. As has been aptly said, discipline has a place in safety work, but in the long run we foremen must lead our men into safety—not drive them.

Rules that Are Practicable Every Day

3. When my area is inspected by the plant safety inspection committee, I want to be present. I thoroughly resent being written up in reports with copies broadcast throughout the organization, without a chance to defend myself. You don't know the conditions in my area as well as I do. Give me a chance to explain.

4. I want to be in on the safety meetings. I think there is a lot of bunk in many meetings because the man who knows best the subject under discussion is not present. I want an opportunity to tell the management what ought to be done by the management to make my area more safe—and if I can sell my idea, I want action, quickly. That's what the management demands of me.

5. I am going to take time to go around with my new men and tell them the whole story—what it's all about, where we are going, why we do it and how we do it safely. And if I do spend some of my time on safety work, in the instruction of new men, etc., I don't want to be criticised because I can't be two places at once. I am paid to do what my boss wants me to do. If he indicates that he resents my taking time from straight production to be devoted to safety work, I'll have to let up on the safety work.

6. And when the accident comes, I want to be in on the investigation. Send your committee—send your safety engineer—send everybody interested. But don't forget that none of you is as interested in the accident as I am. Get my ideas as to just what happened. Get my ideas as to how to prevent its recurrence. Write all the reports you want to, but pay a whole lot of attention to mine.

In conclusion: I can sum up everything I have said before in a mighty few words. Be assured that the foreman—the worth while foreman—will back you up on all of your safety work, provided he knows that you are one hundred per cent back of the safety movement yourself.

CHAIRMAN WHITING: Another viewpoint on that problem is that of the insurance carrier which, I dare say, most of you think is a nuisance, but sometimes a necessary one. Mr. A. S. Johnson, of the American Mutual Liability Insurance Company will tell us about that.

Chemical Plant Safety From the Standpoint of the Insurance Carrier

E. C. Jacobs, American Mutual Liability Insurance Company, Engineering Department, Providence, Rhode Island

At the outset let me explain that the insurance carriers' standpoint will be confined to the engineering standpoint, and touch somewhat upon the underwriting aspects of chemical coverage.

It is to the interest of the carrier as well as to the interest of the assured that the insurance engineer study the accident situation at the assured's plant and make recommendations, which, if carried out, will reduce the loss experience and consequently lower the assured's premium costs. This outline will touch upon the various methods of arriving at the premium rate, discuss the insurance safety engineer's activity within the chemical plant, and present a short resume of some of the more important items of accident prevention which apply particularly to a majority of chemical plants.

To establish a proper rate, the first essential is to classify the risk in accordance with the products manufactured and the processes of manufacture. With the enormous and rapid developments started during the war, it was necessary to establish a new method of rating chemical risks. A study of the problem by the Rating Bureaus of several states and the representatives of several of the insurance companies, comprising a technical committee, brought forth a system of rating that is known as the Chemical and Dyestuffs Rating Plan. This plan was adopted by most of the states on April 1, 1921. The plan provides for the classification of risks where the primary and governing hazards are of a chemical nature, although chemicals and dyestuffs may not be manufactured, including the bottling or canning of materials which are flammable, poisonous, caustic or corrosive, such as naphtha, potassium cyanide, ammonia, carbon bisulphide, etc. The plan measures the hazards by considering first, the flammable or explosive nature of substances used or manufactured, and, second, the hazard created by or during processes of manufacture. The plan contemplates the establishment of a single rate to cover all the chemical operations of a plant even though the operations are very complicated. A discussion of the complications and the relation of predominating and secondary hazards is purely technical and need not be dealt with here. It is, however, very essential to note that a great many chemical risks have their classification assigned from the Manual of Compensation Insurance and do not come under the Chemical and Dyestuffs Rating Plan. Such industries include acid manufacturing, paint and varnish manufacturing, smelting and copper refining, etc., and they comprise such a large proportion of this Section that the Section has little interest in a more detailed picture of the chemical rating plan than has already been given.

The basic rate established by either of the plans should produce a premium commensurate with the expected losses for the chemical operations of a plant which represents the average of that industry. The same Industrial Compensation Rating Schedule that is applied to other manufacturing plants is then used to modify the rate on the basis of a comparison of mechanical plant hazards to the average for the industry. The application of the Schedule Rating Plan allows credit or exacts charges by measuring the accident hazards which exist on elevators, power transmission, moving parts of machines, points of operations of certain machines, and, foot, leg and eye protection in some industries. It also provides for credit for standard safety organization, first

aid, dispensary or hospital. Schedule Rating offers the Chemical Industry the same incentive for safety work that is offered other industries. You will note that the premium credits or charges are immediate, and not earned on the basis of the actual accident loss experience of the individual plant.

The rate so obtained is subject to further adjustment by the Experience Rating Plan on the basis of actual loss experience. If the accident prevention work has succeeded in reducing the accident losses below those expected by the Schedule Adjusted Rate a further decrease in rate is allowed; and, conversely, if the safety work has been unsuccessful with a resulting loss experience greater than that anticipated by the Schedule Adjusted Rate an experience charge will apply. These rating procedures should indicate clearly the motive of the Insurance Safety Engineer in his strenuous efforts with a manufacturer to have him make every possible effort to reduce his accident frequency, severity and losses to a minimum, so that the risk may benefit from such efforts by a reduction in insurance cost.

The Safety Program a Part of the Production Program

During the period of growth, while the rating problem was being solved, the Insurance Engineers were making a study of the accident hazards in the chemical business in order to carry out their motive. These studies served as a basis for focusing the engineer's attention on the more typically hazardous features of the business so that as much assistance and advice as possible along accident prevention lines could be given. Partly due to the rapid change and development of the industry and the resulting lack of accident experience, and partly due to suspicion in a very secretive industry, much of the seed sown by safety engineers fell on sterile ground. This made the struggle for safety very hard and it was only after a discouraging and uphill fight for cooperation that safety interest and activity on the part of some chemical plant managers brought to the accident situation a new aspect. It is now progressing in the right direction.

The Insurance safety engineer has struggled to get the safety program made a part of the production program. It is a part of the production manager's business to know the cause and responsibility for all items of waste, a large percentage of which are lost time and cost from accidents.

Accident prevention, like any other line of endeavor, is conducted best when thoroughly organized. A standard form of safety organization is outlined in the Schedule Rating Plan. It contains the essential features but must be adapted to individual plant conditions.

The engineer recommends that great care be exercised in selecting the person to make plant safety inspections. The importance of this position and the work that the inspector does have not been fully appreciated in many places. Whether the Insurance safety engineer is endeavoring to establish a safety organization, is inspecting the plant for accident hazards, or is determining the conditions to apply the rate-making procedure, his motive is always to assist his company's risk to reduce the endless chain of losses from personal injuries and the lost time and physical suffering of employees.

In order that this paper may be constructive the third section of its outline will be a short resume of some of the more important items of accident prevention, which are common to a majority of chemical plants.

The maximum of success in accident prevention work necessitates a study of such tabulations as a classification of accidents by causes, a second classification showing who was responsible for each accident, another classification by either department, location or process, and a fourth by machines or materials

used. Statistics alone will not prevent accidents but a study and analysis of them are essential in determining what to do and where to direct the effort.

Carelessness advanced as a cause for accidents has retarded accident prevention work. Carelessness is not a cause, it is an alibi. Investigate accidents to determine their cause and responsibility. Until you do so, to get true facts the efforts of the safety committee are trebled.

Many of the plants now used for the purpose of manufacturing chemical products were constructed during the war or immediately after its termination. Some are inadequately ventilated and lighted. In some cases there are defects in plant construction to the degree that the most hazardous operations are not physically separated by fire walls or other suitable physical protection, or isolated from other departments in the plant. A large dyestuffs plant used a series of ball mills of the mush room type, for the purpose of pulverizing dyes. This equipment was located in the end of a long wooden building one story in height. At the other end, packing and blending operations took place. Two men were regularly employed on the ball mills. Fifteen men were engaged in the other operations. The departments were not physically separated, but labor did not interchange. A flare in a ball mill blew off part of the roof and side wall. One man was killed and two seriously injured. In this case instead of exposing two men to the hazard, seventeen men were exposed at least to some degree. Later the grinding operations were isolated from the remainder of the plant and located in a building constructed for this purpose.

Conditions such as this increase the accident possibilities as well as the fire hazard.

The Serious Hazard of Poison Gas

Another serious hazard is poison gas, which is well illustrated by a condition found in a plant making among other chemicals a very poisonous gas. The process building is of wood construction, with windows and skylight ventilation. The finished product is piped to a small wooden shed adjoining the building and is open on three sides. The steel cylinders used for shipping the product are filled by means of valve connections. A strong odor of the gas was noticeable near the shed and inadequate measures had been adopted to safeguard the worker. He was expected to stand in such a position that the wind would carry the gas from him. He should have been provided with a proper gas mask. Exposure to poison gas of employees from other departments by allowing them near those buildings is decidedly hazardous. Every effort should be made to study plant construction and operations with a view to isolating the greatest accident and fire hazards in such a manner that the workers in other departments will not be exposed to these hazards, and the number of workers who are connected with these hazardous operations should be reduced to a minimum.

In many chemical plants, unnecessarily dirty and ill-smelling conditions have kept away the better class of unskilled labor. This has had an adverse effect on the accident situation. Ignorance and bad habits are responsible for many accidents. Where these conditions prevail labor turnover will continue high and the class of help remain low. Clean up unfavorable working conditions to improve the labor situation. It will be reflected in the accident record.

Conditions conducive to the good health of the workers should be provided, and a check on their health should be maintained. Physical examinations should be given all new employees and a periodic re-examination at frequent intervals of all employees engaged on manufacturing process. Examinations should be made by a competent physician.

Process men should be subjected to daily inspection to detect symptoms of chemical effect upon them. Yearly physicals are not enough.

Washing and bathing facilities that are adequate for the needs should be provided and used.

Clean working clothes and underwear should be furnished to all process men. Daily changing from work to personal clothes is good business from the safety and health standpoints.

Much might be said on the attitude of plant supervisors toward the safety program. It means success or ruin. A favorable attitude should be established at once so that there may be no question about it in the minds of the safety committee. If the plant management has decreed that accidents shall be reduced and has organized a safety department, and is personally represented in that work by the safety supervisor, he should expect to receive automatically the cooperation of the supervisory force. To be sure the safety supervisor, by his ability, must continue to prove his worth to the supervisory force and not be carried on their shoulders. All too many safety supervisor's jobs degenerate into a clerical position of keeping the records and recommendations made by the Insurance engineer and operating force. They lack initiative, knowledge and ability to direct and lead.

Responsibilities for All Types of Plant Workers

Too many superintendents and safety supervisors avoid their obligations by issuing a long list of rules and regulations for employees. The conduct of employees is the direct responsibility of the foremen, and this responsibility is not lessened by the issuing of rules with penalties, which will be invoked only when an accident happens. Rules should be for the guidance and help of employees and be developed only by those who have the responsibility for, and full knowledge of the operations. While this statement may have general application it is especially pertinent to the chemical industry.

In a chemical plant the belts, gears, sprockets, dangerous moving parts and points of operation should be guarded and a big task of the Safety Department is the maintenance of the safeguards provided. Fumes, caustics and corrosives often make equipment unsafe and continued exposure without protection will ruin equipment. Guards must be painted, frequently renewed and in most cases acid resistant paint is necessary. Metal guards may be found impractical sometimes, but wood guards are not recommended for general use. Falls on wet and slippery walkways are common, so that constant attention to housekeeping is necessary. Provision should be made for the proper and immediate attention of chemical burns and a settling of the burn problem should be made to find proper equipment and safe guards to prevent same.

The safety department should review all proposed new installations of equipment and check the maintenance of all equipment in use, to make sure of the calculations covering the safe working pressure for tools, and the specifications for pressure control devices, relief valves and indicating and recording temperature and pressure instruments.

A consistent, systematic and efficient inspection service covering plant, housekeeping, relief valves, indicating and recording instruments, etc., should be inaugurated and maintained.

Earlier in this paper the question of cooperation between the safety department and the supervisory staff was covered. As a final point let us consider the cooperation between the safety department and the technical division. It would appear to be reasonable to assume that when the necessary research work

and tests are completed in connection with a new product that every reasonable step had been taken to manufacture the product in a safe and efficient manner. This is often not the case. During the development many dangerous conditions have to be met. Violent reactions may have to be controlled, dangerous sub-compounds or by-products made safe by the invention of new machinery, dangerous factors replaced by substitutes which work equally well, and process hands thoroughly trained to carry out the process. Let the technical division make known to the safety department and plant supervisors all the accident possibilities in connection with new processes employed so that no item of accident prevention can be possibly overlooked. All too often the safety inspector or safety director is a non-technical man and knows little of the manufacturing processes, and the technical men have little knowledge of safety or interest in it. Chemical plant safety inspectors have frequently remarked that they did not know the nature of the materials used and stored in certain departments and had little or no knowledge of the operations that were being conducted. A closer relationship must be developed, for little effort has been made by safety supervisors to make the technical men enthusiastic for safety. The technical division must educate thoroughly all who work with a new process to make the proper tests, handle the materials as they should be handled and keep careful watch for the possible but unexpected reactions. The close co-operation between the technical and safety departments is the high point of chemical plant accident prevention. That industry is a highly technical business, safe in the test tube; usually safe in the autoclave, but the steps between the test tube and the autoclave may produce anything new and interesting. Watch that they do not produce an accident.

Foremen Sold One Hundred Per cent on Safety

CHAIRMAN WHITING: We have a little time for discussion and I would like to have each one of you keep in mind the four forms of discussion we have on the program. I want to have you give your viewpoint as to how you utilize them in your own control of safety in your plant. I think Mr. I. V. Kepner can start on that line.

MR. KEPNER: Mr. Chairman and Gentlemen: I have been very, very interested in all these four problems. It so happens that the company I represent, the Pennsylvania Salt Manufacturing Company, has all of them, and we utilize all the various things which have been outlined here this morning. I still feel, however, that we have a long way to go and we have lots to learn. For instance, I am fortunate enough to have our plant management from the president all the way down thoroughly sold for safety, which helps to make my job much easier. The medical department in all our plants is well covered. We have a physical examination of all new employees and in certain departments we have an examination once each month.

I feel all our foremen are sold one hundred per cent on the idea of safety. We do not have any big safety rallies, but we just keep plugging at it all of the time and our accidents on the records show results, and a great part of that is due to the foremen and the manner in which they handle their men.

The insurance carrier—thank heaven we don't have much of him. We carry our own insurance but are inflicted with the state inspectors once in a while, but they are good fellows and I am always glad to have them visit our plant. It so happens that one is sitting in front of me now and I have to say something nice for him.

I would like to hear what some of the other plants are doing in those various subjects, particularly with their medical examination.

CHAIRMAN WHITING: Mr. Shaw, I wish you would very briefly give us your viewpoint on these four elements of safety.

MR. SHAW: Mr. Chairman, they have been very interesting to me. I feel as Mr. Kepner does that we have a whole lot to learn and a long distance to go. I was particularly interested in the statement that the workmen should be examined every day. Did I understand that correctly?

MR. JOHNSON: That statement covered only those process men who are possibly subject to the chemical reactions which cause serious occupational diseases—those that have serious chemical exposure.

MR. SHAW: Does that mean a fairly complete examination?

MR. JOHNSON: No. It means to keep them under observation and not let them drift away and allow them to get so far that they can't be cured easily.

MR. SHAW: We carry our own insurance with the exception of fire insurance in one or two of our plants, so we have a whole problem at home to take care of. We deal with the carrier. I don't know that I have any more points to bring up.

CHAIRMAN WHITING: Do you stress the foreman element in your safety work?

Accidents Are Really a Cost Item

MR. SHAW: Oh, yes. We are trying to give the foreman that freedom of expression which was spoken of by Mr. Streeter. I think that was an excellent paper in which he brought out the foreman's point of view.

I think the high spots in the management's point of view was that we have to put safety in its proper place, balancing it with all the manufacturing items. Safety has been harmed by some few who have been harping on safety alone and not balancing it. Safety is really a cost item. It is economically sound and it takes its proper place according to the proper analysis, but if we harp on safety alone we very often disgust the manager who knows the proper place in which safety should be and feels that we are too one-sided in trying to shove safety to the forefront.

CHAIRMAN WHITING: I see that the subject has come down to three points: management, foreman and medical department, and I know it is so with the Eastman Company. Mr. Armstrong, will you give us your views on those three phases?

MR. ARMSTRONG: Our safety work has developed into something new in our plant. It was started about two years ago and was an experiment. It may be in the experimental stage yet.

First of all, our management is very much behind the safety program. They are all very much behind it all the way down the line. What we have done was to establish a school. It is a room perhaps three-quarters the size of this one. In one end of it we have a laboratory and when we have new men to go to work in the chemical plant we take the men in and we show them what happens exactly under certain conditions. We also show them just how treatment must be given to men who are injured, how to protect themselves and what it means to them if they don't protect themselves with the proper method which we show.

As an example we show them that acid can be poured on the hand and washed off. We then pour the same acid on a piece of cloth and leave it there for a few minutes, and it is not necessary for me to say here what happens. You all know that the cloth will immediately burn by turning black and then smoking with some acids which burn very quickly.

We go with them into electric wiring, electric lights, static electricity, dust explosions, inflammable solvents, solvent vapors and so on. Although it was rather tough going at the start and rather hard to sell to the foreman, now we are unable to take care of the demands made on us by the different departmental superintendents who ask to have their men be allowed in. We have even gone so far as to take in our yardmen, the reason being that these men have to handle acids, and common labor of that type as you all know are rather hard to get to appreciate what will happen if they throw things around.

and be able to give those findings. While in my organization everything that touches a medical problem comes in to us, we haven't been able in common with many of the medical departments throughout the country to reach that condition where we could answer questions of that kind.

You want to know what percentage of accidents are due to eye conditions? A man holds up a statement that there are three percent less cases in the last year. We have only a general answer to make to your question: if 40 per cent or 50 per cent or as somebody insists 65 per cent of the people are in need of correction of their vision, and vision is such an important function in a man, it is very obvious poor vision must mean increased accidents and increased injury and of course lower efficiency. That would mean accidents and a lessening of safety.

CHAIRMAN WHITING: We will now come to the second subject of this morning, the Hazards of Spray Coating, a process you are all familiar with. Just as a preliminary to Dr. Winslow's presentation of the subject, I should like to get the background of this investigation from the chairman of the Steering Committee that worked out the preliminary details. Mr. Watson, will you give us some idea of that situation.

The Hazards of Spray Coating

A. L. WATSON (The Koppers Company, Pittsburgh, Pa.): Such a review must necessarily be very short because if I tried to cover the field thoroughly it would take the rest of the morning session, I fear. In general the Executive Committee of the National Safety Council determined to conduct an investigation into the hazards connected with the process of spray coating and made appropriations for that purpose. A Steering Committee was appointed by the Executive Committee to develop an investigating committee to carry on the investigation. That work was done largely through various sub-committees. I might mention that investigating committee was made up of representatives of national organizations that were most interested in the subject at hand.

The purpose of the investigation from the start was to determine in an open-minded, fair way just what the hazards were in connection with the process of spray coating and to find, if possible, ways and means by which those dangers could be guarded against. The work was completed a few months ago and a report was prepared and approved by a majority of the committee, which consisted of about twenty-seven or twenty-eight members. Upon the approving of that report a minority report was filed by two members of the committee. The main report, together with the substance of the minority report, were presented to the Executive Committee of the National Safety Council for determination as to what action should be taken on the minority report. The Executive Committee of the Council has referred the minority report back to the Steering Committee for action and that is the present status of the matter.

Spray Coating and Brush Painting Not to Be Compared

I might mention that in making this investigation, it was never the intention to make any sort of comparison of hazards as between the practice of spray coating and brush painting. It was not the intent to start anything that was going to cause legislative discussions, but it was simply to find the facts in as fair a manner as possible by perhaps the one body in the country that was in the best position to do that kind of work. So the present status of the investigation is that the report has been adopted by the main Investigating Committee, by the Steering Committee and in turn by the Executive Committee of the National Safety Council, and the minority report has been referred back to the Steering Committee for consideration.

CHAIRMAN WHITING: You all remember the Benzol Investigation made at the initiation of this Chemical Section, and the Rubber Section jointly, and how valuable that has been as a guidance in certain modern forms of industry. You all know without any introduction who the chairman of that committee was. He is also the chairman of the Spray Coating Committee, most appropriately. I take pleasure in introducing Dr. Winslow of Yale University.

Some High Points of the Investigation

PROFESSOR C. E. A. WINSLOW (Yale University, School of Medicine, New Haven, Conn.): Mr. Chairman and Members of the Safety Council: We had very much hoped that the final report of the Spray Coating Committee might be ready to place in your hands this morning. Unfortunately the large amount of tabular material has delayed the printing and I have here the galley proof alone. I will not read all of it to you, but I will present some of the high points.

This matter seemed to the Investigating Committee as it did to the Steering Committee, of very great importance and one on which it was desirable to reach a rather prompt and, if possible, convincing conclusion. The use of the spray coating process, as you know, has been very definitely increased since the war and the introduction or extension of any process is likely to bring in new hazards.

Attention has been forcibly called in some quarters to the hazards involved in coating surfaces with a spray gun and it had seemed at times that some very threatening and restrictive legislative action might be taken. It is the hope of the Safety Council and the committee that by an entirely unbiased study of the situation any precipitate or unreasonable action might be forestalled and a sound conclusion reached as to the ways in which the spray gun could be used with safety.

The committee organized for this purpose found at its disposal relatively little in the way of information in the shape of earlier studies. It found that a study of the principles involved in the subject had been made by the Industrial Commission of Wisconsin, and that a rather exhaustive field study had been made of the situation by the State Department of Labor and Industry of Pennsylvania. It was clear, however, that more direct information was needed as to the conditions existing in the plant with regard to the spray gun and the health of the man. There was only one way to attack a problem of this kind and that was to go into the industry and see how the particular process was used and the result.

Discussion Upon the Committee's Work

CHAIRMAN WHITING: Now we have ten or fifteen minutes for discussion.

W. J. PITT (National Paint, Oil and Varnish Association, Toledo, O.): Mr. Chairman, will we have an afternoon session to discuss this important subject?

CHAIRMAN WHITING: I think not. Our entire program closed with this morning's session and we will not meet again as a Chemical Section.

MR. PITT: Has this meeting the power to modify a report by motion?

CHAIRMAN WHITING: While I have some opinion on that matter I will refer the question to Mr. De Blois, who is a member of the Safety Council Executive Committee and a Past President. The question which Mr. Pitt asks is whether this meeting today has any power to modify the report of the Spray Coating Investigation Committee.

MR. DE BLOIS (National Bureau of Casualty and Surety Underwriters, New York City): If it is a modification at the suggestion of any member of the original committee or sub-committee I should say "No," because the report in its present form

has been adopted by the Main Investigating Committee and has been adopted by the Steering Committee and by the Executive Committee. The Executive Committee at the same time referred back to the Steering Committee for its consideration the minority report.

I should say there could be no further action by the Main Committee. Any possible recommendations for modification coming from within the Main Committee would not be in order because all members have already had their chance to make them and the committee as a whole had adopted the report.

Now, any recommendations for changes suggested by this meeting would naturally go to the Steering Committee and I don't know what could be done with them. It looks like a finished job to me.

MR. PITT: Do I correctly understand you to say that the Executive Committee read and approved this report.

MR. DE BLOIS: They did not read it in detail, but approved it as a whole.

CHAIRMAN WHITING: I might say that, so far as this meeting is concerned, we are open to any discussion on any of the papers presented.

MR. PITT: Mr. Chairman, I would like to ask Dr. Winslow if he would mind answering some questions for me? Did not the report of the sub-committee on respirators state that all these industrial respirators are efficient for at least a day or longer?

DR. WINSLOW: I have the data here which I could look up. My impression is that some of them were, and not all of them were. Of course they would naturally become more inefficient as time went on, because they would get clogged up. The only question is the relation between efficiency and what we may call wearability.

MR. PITT: It was my impression, Doctor, that the report of the committee was in straight contradiction to the conclusions made with regard to respirators. You mention 200 milligrams of lead contamination. Was there any plant examined by Dr. Smyth that showed anything nearly as high in lead contamination as that?

DR. WINSLOW: I will look that up.

Quotations Upon the Degree of Air Contamination

MR. PITT: Mr. Chairman, I would like to say these were the air contaminations which were abstracted from Dr. Smyth's summary which was sent in to the committee:

Plant 2 was 0.2; Plant 4 was 32.; Plant 5 was 164.; Plant 6 was 0.2; Plant 17 was 99; and that is all the report we have as to the air contaminations at these plants.

Did Doctor Smyth, to your knowledge, make any laboratory test as to the relation between air velocity and air contamination as to lead—I think you mentioned benzol? Has any such test been made in this investigation as to lead?

DR. WINSLOW: No. I can now answer your former question. The undercoat plant showed 164 milligrams lead per cubic meter of air. Was that the highest, Doctor Smyth?

DR. SMYTH: I should say so, offhand. I haven't seen the figures for some time.

MR. PITT: Doctor, you mention the fact that 65 spray painters, 17 of whom show lead in feces. Were any positive cases of lead poisoning discovered among any building or structural painters in this investigation?

DR. WINSLOW: There were cases, yes, among structural painters. They were those figures I quoted. Now I have that other point you asked about. In regard to the exhaust ventilation in the plant spraying lead, there was high atmospheric contamination in three undercoat plants. There was a suggestive evidence of plumbism at 130 feet and another at 123 feet. On the other hand, there were an under-

coat plant with an exhaustion of 160 feet and another 212 where no cases were found.

MR. PITT: I don't know whether you have had a chance to read this sub-committee report or not. The plant No. 2 is all auto or auto body plants. Plant No. 2 were an average air velocity of 75, lead content 10 and there were discovered five cases out of fourteen men examined. But plant No. 4 were 54 feet of air, 10 per cent of lead content, 32 of lead and no cases. Plant No. 5 were 52 feet of air, 11 per cent of lead content, 164 of lead per cubic meter of air and no cases. Plant No. 6 were 160 feet of air, 11 per cent of air, two-tenths milligrams and no cases. Plant No. 17 were 19 per cent of lead content, which was the highest of all, 99 milligrams of lead in the air and no cases. Now, you gave the range there as I understand it, the average range by plants, but is there anything in the report which shows what that would be by units, for instance, each booth?

DR. WINSLOW: No, I think not.

Technicalities Presented in the Minority Report

CHAIRMAN WHITING: I feel that so far as this meeting is concerned we are now getting into technicalities beyond our understanding without careful study, but if it is your pleasure to go on don't hesitate to tell me. The material that Mr. Pitt has just illustrated to us has been very thoroughly covered by him in his minority report, which is now in the hands of Mr. Watson's committee. From your standpoint of practical operating men, I wonder if you wish during the remaining quarter of an hour or so to discuss the respirator matter and some other practical phases of spray coating?

DR. WINSLOW: Mr. Chairman, I think Mr. Pitt should be given a reasonable time to present what he wants here.

CHAIRMAN WHITING: It is only a question of what the meeting desires. If there are many of you who desire technical discussion of the report to go on, will you make an indication to that effect?

MR. PITT: Mr. Chairman, I would like to correct one impression here. These are not technical details at all, they are very important factors in the question at issue. Doctor Winslow, you made a statement about some letters which you received. Did they come before the Spray Coating Committee?

DR. WINSLOW: I don't care to quote the individuals, but there came to me a number of letters from various officials of organizations in the United States urging immediate action and radical regulations. Mr. Cameron and I had quite a little trouble in urging these persons to wait until they had this report before taking drastic action. I do not care to quote the individuals who wrote these letters, but I can say they came from certain quarters with vigorous desires for administrative action and we have urged delay until completion of the study.

Copies of Minority Report Available

MR. PITT: Mr. Chairman, I would like to make an announcement with your permission. I understand that an Abstract Committee was appointed by the Executive Committee to fix up my minority report. I would like to announce that any gentleman present who would like a complete copy of this report will get one by writing to me, William J. Pitt, 300 Phelps Street, Toledo, Ohio. I should be glad to send a copy of the minority report to anyone. I had a summary of that report which covered a couple of pages, but owing to the pressure of time I don't feel like imposing upon the meeting by reading it.

CHAIRMAN WHITING: But I think the meeting would like to hear that summary.

MR. PITT: This is a summary of a minority report filed by the representative of the National Paint, Oil and Varnish Association.

Minority Report on Report of Spray Coating Committee

While we are in accord with many statements in the report of your Committee on Spray Coating, particularly as to the hazards in the use of benzol, there are other statements and conclusions expressed therein, of a fundamental nature, which we feel are not well founded and, in some cases, are diametrically opposed to the data placed before your committee. Our dissent from that report is explained in detail below, as follows:

First—The detailed facts of the Committee's study were not placed before the members until after discussion at the last meeting and just before voting on the adoption of the report. This data constituted such a mass of figures, there was no opportunity afforded the Committee to study such details, nor do we understand that such data was in shape for consideration. Only the summary of Dr. Smyth's investigation was in the hands of the members, and, at this shows the results by plants or groups of subjects and not by each individual, booth, person, or the material used separately, the inaccuracy of the conclusions derived from such information obviously is open to question.

We feel that the data made available to the committee, perhaps due to the combined manner of setting it forth, is inconsistent, inaccurate and fails to justify some of the conclusions expressed by the Committee on some very important phases of the subject.

Second—That your Spray Coating Committee's report, by its references to so-called historical literature, experiments with obsolete equipment, out of date investigations, meager and incomplete data on studies of antiquity, not demanded by literary style or a proper bibliographical treatise of such a subject, seriously impairs its effectiveness. We deem such statements are irrelevant to a study seeking to find existing hazards, if any, and to recommend reasonable correctives.

Preparation of the Report Is Criticised

Third—By improper construction of this summarized data, and not the basic detail facts of the study, and by the exclusion of late statistical data published by the Federal Government relating to lead poisoning cases or deaths in the United States, we feel this report, without warrant, seeks to unduly exaggerate the so-called hazards of the spray process, particularly as to the use of lead. In thus creating a phantom of fictional perils, not corroborated, we believe, by the limited facts available to the Committee, we believe it will tend to promote the disregard of its recommendations instead of furthering their acceptance as a wholesome medium for enhancing health protection among the industries of the country, who may, in some minor or greater degree employ such products in their finishing operations.

Fourth—By refusing to clearly differentiate building or structural painting (exterior and interior) from industrial or manufacturing finishing processes, involving vastly dissimilar facts, working conditions, type of equipment, and, in a measure, the materials used, we feel that its conclusions are misleading and fundamentally wrong. Such statements as "spray painters," "interior painting" and "indoor painting" unwarrantedly convey the impression that the conditions in the industrial finishing field are applicable to the building and structural

field. We think these classes should be segregated and treated separately and the report clarified.

Fifth—That its treatment of state regulatory conditions is incomplete and improper and omits pertinent and published facts, for instance the Massachusetts investigation and regulations, yet unduly stresses the Wisconsin regulations.

Sixth—That its conclusions and recommendations as to respirators are erroneous, unduly preferential to a certain type of respirators prejudices research and future development along this line, and are contrary to the facts and data embodied in the report of its Sub-committee on Tests of Painters' Respirators.

Seventh—That its conclusions and recommendations of frequent, periodical, medical examination and spray painters or finishers "employed within building, booths or *other indoor or enclosed spaces* in spray coating" are not supported by the facts of this study submitted to the committee in so far as building or structural spray painting is concerned.

The Matter of "Air Velocity"

Eighth—That its conclusions and recommendations calling for an air velocity of not less than "200 linear feet per minute" is wholly unwarranted by the facts submitted. The recognized standard of equipment manufacturers, based on extensive engineering experience, is 100 linear feet per minute. It is claimed that the study showed an average air velocity for all practical purposes to be 60 linear feet, and we recommend "an average *minimum* of 90 linear feet per minute or 50 per cent more than that found by the study and within 10 per cent of the standard of reputable equipment manufacturers. Considerable speculation is indulged in by this Committee throughout the report as to the proper air velocity requisite for reasonable protection and extreme or erroneous citations of the data submitted to the committee to support it. Stress is laid upon the tentative proposal of 125 linear feet in the pending Pennsylvania proceedings, but as the underlying data in that investigation has not been made public and a counter-proposal of a minimum of 90 linear feet per minute has been submitted, it is our belief that the conclusion of the Committee that not less than 200 linear feet per minute is absurd in the light of the facts of this study. No tests were made to determine the relation of air velocity to air contamination in the spraying of lead paints, as was done in the case of benzol lacquers and the conclusion of the committee as to air velocity with respect to lead paints seems only a guess.

The Michigan Department of Labor and Industry in their recent investigation of the spray process in the industrial plants of that state prescribed "*an average minimum air velocity of 90 linear feet per minute*" at the working face of the spray booth. No state authority that has investigated the matter has prescribed a definite air velocity. We feel your Committee has grievously erred in its conclusions and recommendations on this important phase, and that in the interest of all concerned this report should be modified by the National Safety Council to accord with the facts.

William J. Pitt
Wayne B. Thompson.

History of the Spray Coating Committee Outlined

MR. DE BLOIS: Mr. Pitt makes one statement of fact with which I wish to take issue. I think I had better begin by giving you a little more of the history than Mr. Watson did of what actually went on. There was a general non-technical main committee—the Spray Coating Committee. It had in it technical experts, Dr. Smyth, Dr. Greenberg and Dr. Winslow.

The field investigation resulted in a draft of a large report by the technical people. That report carried a summary of all the field data. The Main Committee held five meetings altogether, though I do not recall how many were devoted to preparing its own final report. There were also reports of the sub-committees to be considered and a separate report by the Bureau of Mines. The latter and Dr. Smyth's report of the field work will appear as appendices I and II.

The technical report was revised and more data was added to it. Then came strong objections from the minority members of the committee who raised the points that Mr. Pitt has mentioned today, although I do not think he has given them all here, by any means.

An Editing Committee was appointed to adjust, if possible, these differences. I was on that committee and so were Dr. Bricker of Pennsylvania and Dr. H. A. Gardner, who, I believe, represented the National Paint and Varnish Association or Institute.

Many Objections Were Incorporated in Final Report

The final action of the Editing Committee was to incorporate a large number of these objections, but not all of them. Its report was considered at a final meeting of the Main Committee at which every bit of the field data was presented. It was all there, but it could not be handed around because the data sheets and tabulations that Doctor Smyth and his staff made in the field were far too large. So I am really inclined to contest the point made by Mr. Pitt that the field data were never available to the committee.

Furthermore, the committee has gone farther. It realized after all that its conclusions are naturally open to question. At no little expense (because it will add considerably to the cost of printing the report) it is going to include every bit of the field data in the final report, so if you want to read it and reach your own conclusions you can do so.

This thing has been considered as thoroughly as any job I have ever seen done by a research committee. Mr. Pitt's and Mr. Thomson's objections were all considered by the main committee and their motions were lost in a perfectly open vote. The majority was heavily against them. The minority report has now been submitted by them, and, as seems perfectly proper, it was referred back to the Steering Committee for further consideration. I want to again make the point that all the data was placed before the committee members and will be placed before the public.

CHAIRMAN WHITING: Before Mr. Pitt speaks again I wonder if there is any respirator manufacturer who would want to say something.

The Question of Damage to An Industry

F. A. SMITH, JR. (Titanium Pigment Company, Inc., Cicero, Ill.): Isn't it possible that the publication of such a report might work irreparable harm to some particular industry? There seems to be considerable stress laid on the subject of masks and considerable stress laid on pigment lead, and it is generally accepted that there are adequate masks for lead and that there is no more danger in handling lead as a pigment than in handling a thousand of the other articles of daily commerce.

CHAIRMAN WHITING: My own feeling on damage to any industry from discussing its hazards is illustrated in the automobile industry, where we are harping on death cases by thousands, but I haven't seen any reduction at all in the growth of that industry. Again, coming closer to our present subject there were similar fears expressed of the Benzol Report when it came out doing great harm to certain

industries. That report has not abolished the use of benzol, because we are still getting occasional death cases in shoe shops, rubber goods plants and so on where the recommendations of the Benzol Committee were not followed.

Of course the Safety Council is endeavoring to diminish accidents and deaths. How is it going to be done if they do not call public attention to the hazards that technical investigations disclose? If they don't get the report before the public, how can any progress be made?

MR. SMITH: I am saying this just so the public don't get an erroneous impression. There are some things in that paper, which is a very able paper, that some people might misunderstand.

CHAIRMAN WHITING: That is probably true of any technical paper that was ever written. It can be misunderstood by those who are not able to understand it, and they may be the ones who are determining our legislation now. Aren't there any respirator manufacturers who want to have something to say with their masks off?

A Piece of Constructive Work Accomplished

MR. BLOOMSBURG (Davis Emergency Equipment Company, New York): I think we have received a great deal of interesting information this morning and it seems to me that a real piece of constructive work has been done. We are never going to know every last thing about a problem. We all have problems of one kind and another and we have got to keep on our jobs and continue to learn as much as we can. We never may have a final answer, but unless we make a start on getting some answers we never will make progress.

It seems to me that the report of this committee is a good start in getting knowledge on that thing in spite of the fact that there have been some doubts raised as to respirators and gas masks. I might take exception to some of them, but we can discuss the facts as we meet them in the field. I think the report is a real effort in constructive work.

One point I would like to make to prevent any misinterpretation is this: The National Safety Council is not a legislative body of any kind one way or the other. This report is being submitted to us for our information. We are not taking any definite and final action in saying that it is officially approved and finally adopted. It is merely something for us to use, and with the filing of the minority report, we will have the information on the other side of the question. Everybody interested will consider both sides of the question.

CHAIRMAN WHITING: Does any other manufacturer of safety devices involved in this hazard wish to say anything? I wonder whether Dr. Hamilton would care to discuss the matter.

DR. ALICE HAMILTON: No, I should only like to ask a question. I have been accustomed to go about and have watched spraying. I have noticed the pressure in the spray gun and I would like to know if the pressure were kept down to thirty pounds, would there be any danger in it.

CHAIRMAN WHITING: Are there any more who desire to add to the discussion before Mr. Pitt and Doctor Winslow close the discussion?

MR. PITT: Mr. Chairman, I only want to correct a statement that Mr. De Blois made. He spoke of Mr. Gardner's participation in this investigation. As I understand it, he has not voted for the adoption of this report. I am further informed—but I can't speak positively about this—that he did not attend the meeting of the Editing Committee.

MR. DE BLOIS: He attended the first meeting, but not the second.

MR. PITT: The second thing I would like to ask Professor Winslow or Mr. De Blois is if there was any contractor, painter or manufacturer of respirators or any practical industrial hygienist in touch with the problems of spray coating in the industry today who were members of this committee?

MR. DE BLOIS: I can answer part of the question by saying that there was not a manufacturer of respirators on the committee. I cannot tell you why unless they were overlooked by the Steering Committee. It might have been that they were guided by the fact that there is no national organization of respirator manufacturers. It is my personal opinion that if we do similar work again we should have them represented.

Adequate Technical Representatives on the Committee

As far as the people from industries with a practical knowledge is concerned, Dr. Bradshaw of the du Pont Company, who although he was not one of the first members, certainly knows a great deal about the practical and manufacturing side of it. He also was concerned with the Pennsylvania investigation. At the last meeting we had Mr. H. C. Mougey from General Motors Corporation, a research man. There may have been others whom I do not recall at this moment. On the matter of the practical hygienist, if you can find any more practical hygienists than Doctor Winslow and Doctor Smyth, I would like to know them.

CHAIRMAN WHITING: As to representation of respirator equipment, if you could find a more competent man than Doctor Sayers of the Bureau of Mines, I would like to have anyone answer. If there is no further discussion I would like to have Doctor Winslow sum up the various questions.

DR. WINSLOW: With regard to the velocity, we have the following data on three points: With benzol in the best booth we had practically 147 linear feet. Let me say to Dr. Hamilton that we did nothing much on the spray gun pressure. Of course that makes a difference, but there are also other things which may make a difference, such as the way the man stands, the size and shape of the work and of the booth. It was impossible to test out these numerous variations, to determine their comparative effects on the hazard.

Now, this linear feet is the linear feet of exhaust. Even in benzol we had 147 feet. For silicate, we had 130 feet in one case with marked symptoms which were suggestive of silicosis. That is the reason we did not feel we could put the velocity certainly below 130 feet. We got absence of any symptoms below two hundred. It may be that study will show that it can be brought to 150, 160 and 170 feet. We say that 200 feet have been shown.

In regard to structural painters, 37 were examined. They showed a very large number of subjective symptoms and three showed a complication indicative of plumbism. In other words, as far as our data goes the structural painter seems to stand below, as far as seriousness of hazards is concerned. I do think it ought to be made very clear about masks and respirators. As Dr. Smyth has said, it is perfectly possible to use a respirator of the filter type.

Finally, I want to make clear that there seems to be some difference between Mr. Pitt, De Blois and myself in regard to the extent to which material has been submitted to the committee. I think that is due to the definition of what you mean by material. In the first place, there are original data, the original records of analysis which were made in the plants; that is, the original sheets on which the files recorded each man and those have not been printed and not even distributed in mimeograph form to the committee. It would be impossible and absurd to do so, but every page was in the hands of the committee at the meeting and was available for consultation and the tables were made up of those. All the tables, summaries and collection of

that information was distributed twice in Doctor Smyth's appendix, and as I say, every scrap of paper was at the last meeting of the committee.

We have had five meetings, the last one lasting from ten o'clock in the morning until five-thirty o'clock in the afternoon continually, with luncheon on the table while we were continuing our proceedings. I think as Mr. De Blois said he did. I feel rather strongly on this, that it is an apparent reflection of the faithfulness of the committee in its performance to its duty. Every single point of criticism was brought up and I think about ninety per cent of the time of the last two meetings were devoted to points raised by Mr. Pitt. All those points were given great care and were met with the facts on hand.

I think the committee on the whole is in a position to be entirely responsible for the conclusions reached and for the study made of all the available material.

ADJOURNMENT.

SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Construction Section

New Section Officers

Tuesday, September 27, 1927

E. C. HARDING, Chairman

General Superintendent, Ferro Concrete Construction Company, Cincinnati, Ohio

The first session of the Construction Section of the National Safety Council was called to order at nine-forty o'clock by the chairman, E. C. Harding, general superintendent, Ferro Concrete Construction Company, Cincinnati, Ohio.

CHAIRMAN HARDING: Gentlemen, let us open the Sixteenth Safety Congress, the first session of the Construction Section:

We will begin the program with an address of welcome, presented by Mr. O. W. Rosenthal, president of the Builders' Association of Chicago, and the Chicago Chapter of the A. G. C.

MR. ROSENTHAL: Mr. Chairman, Gentlemen of the Construction Section of the National Safety Council: The address that I am delivering this morning is not mine. It is the address of welcome of Mr. Sumner Sollitt, the president of the Associated General Contractors of America, who was unable to be here this morning; but any welcome that I would offer you would be none the less warm, would be none the less encouraging, and I hope to say just a few words with reference to how I personally feel regarding your presence here.

However, this particular thing that I am reading to you is a summation of thought of Mr. Sollitt, and I wish you to treat it as such.

Address of Welcome

**Sumner Sollitt, President, Associated General Contractors of America,
Chicago, Ill.**

It is a great pleasure to welcome you to this Council. It has a serious problem to discuss and no section can recognize the seriousness of this problem to a greater extent than the Construction Industry. If it is possible, through any section we may take here, to save one life, to prevent one serious injury, even to the extent of a single man, our time will not have been wasted.

No firm, corporation, or individual can do its full duty to the industry, no matter how careful they may be, no matter how great has their progress been in safety methods, if they do not divulge to others the full results of the good they have obtained for themselves; if they do not impress upon their competitors or others in the industry the necessity of striving after these good results to the full extent that opportunity may permit. That opportunity is before you now, and the success of this conference depends wholly upon the use that is made of this opportunity for a free and frank discussion by all present of the problems that are sure to present themselves.

I note that the subject I am to present is an address of welcome. I take it that this does not mean only an expression of the pride that Chicago takes in having you here: the hope that you may make use of the opportunities that are freely presented to you for such pleasures as it is in the power of the City to give; the welcome that will be extended to any and all of you to visit the head-

quarters of the construction industry in Chicago, at our new building at the corner of La Salle Street and Wacker Drive; the invitation to such use as you may make of our automobiles and our guides in seeing the vast public improvements that are already made and going on, the vast industries that make their homes here; and the pleasure we shall all take in making your acquaintance; but that it does also mean a welcome to the discussion of the subject of safety in relation to our great industry.

I am not one of those willing to admit that accidents in construction work are entirely due to avoidable carelessness, neither am I one of those who are willing to admit that the majority of this carelessness is due to the employers—the employees must bear their equal share of blame. It is not without careful concern, however, that I glance over the statistical information that makes the construction industry responsible for what appears to be a very dominant place in the list of accidents. In the first place, we must remember that construction and the preparation and transportation of materials for construction are practically equal to all other industries combined, when the hazards of that occupation are taken into consideration. In building, we are concerned and compelled by law to make safe places for practically all other industries except agriculture to operate in. We must construct safe structures and in so doing are often compelled to hazard an accident to ourselves so as to make the proper protection for those who must come afterwards. It is true that often hazards may also be taken for reasons of economy. Such a reason is indefensible from any moral, financial or legal standpoint.

Vitally Concerned With Accident Statistics

We are vitally concerned with the statistics which show such a predominant percentage of accidents attributable to construction. I will not go into figures which at best would be only copies of what is so ably put down in the printed tabulations of accident reports in various states. Due to compensation laws, taking into consideration our industry more especially than other industries, probably a larger percentage of our accidents are reported and scheduled than is true of business in general. However, their showing cannot help but be a matter of special concern to us.

I regret that I shall not have the pleasure of personally addressing you, it being necessary on account of an engagement long since made for me to be absent from this city on this date. My intimate and close friend, Mr. Rosenthal, has kindly offered to substitute for me, much to your advantage. What he cannot say, however, in terms any more impressive than mine, is that—"Chicago welcomes you"—and the building industry of Chicago is proud of being able to entertain you.

MR. ROSENTHAL: I think that Mr. Sollitt has expressed about as well as it could be expressed the thought that is fundamental in safety. But to me the appeal of this great Congress is not upon the economic side, nor is it alone upon the human side of an effort to safeguard life to put industry on a sound constructive basis. It is the combination of all these factors: it is the thought that men are becoming kindlier, the thought that men are becoming more considerate. Although the economic phase in it should be sufficient to justify every action that could possibly be taken toward safety, just the economic side alone is not justification. Industry has approached this question of safety from a standpoint different from the economic, there is something kindlier, something more spiritual, something just a little bit friendlier. Chicago, my friends, is proud that this great movement has selected it as the place in which to hold this great meeting with its fine, spiritual side;

and I, as president of the Builders' Association of Chicago, wish to say that we are happy, we are proud that you have selected our city. Chicago is not big enough to feel that your visit here is just a casual thing; we feel that you have done us a distinct honor, and we feel that you have set Chicago apart and aside from other great communities by holding this great meeting here. Anything that the Builders' Association can do, anything that the movements that I am connected with in the building industry in Chicago can do, to add to your comfort and happiness, rest assured that will be done; and please feel that there is nothing that you could ask of us that would be too much.

CHAIRMAN HARDING: Thank you, Mr. Rosenthal. While we miss having Mr. Sollitt with us, I am sure we are very fortunate in having Mr. Rosenthal present his paper.

Next on the program are the reports of the officers and committees. Mr. Almstead, first vice-chairman, have you anything to report?

C. H. ALMSTEAD (Patent Scaffolding Company, New York, N. Y.): Nothing at this time. I don't happen to be the chairman of the Membership Committee. I am reporting on the progress of the committee with which I was connected. There are three, four or five contractors that I personally solicited, and I fortunately landed one of them in the Section. I sent in approximately 250 names of contractors in New York State, and I think the National Safety Council has followed them up with a three-letter drive, the result of which I do not know.

JAMES F. CONNER (The U. G. I. Contracting Company, Philadelphia, Pa.): I have no report to make other than to say that in the Philadelphia District I have been after the contractors there trying to get them interested in membership in this Section. I think we will eventually get a pretty good showing in that Section.

CHAIRMAN HARDING: Mr. Dalzell being Chairman of the Program Committee, it will speak for itself.

SECRETARY ROBINSON (Everett Winters Company, Detroit, Mich.): Inasmuch as I am also Chairman of the Statistical Committee, playing a double roll, I have combined the reports in this one report.

Annual Report of the Secretary

J. Wilson Robinson, Everett Winters Company, Detroit, Mich.

Your Executive Committee composed of

E. C. Harding, The Ferro Concrete Construction Company

C. H. Almstead, The Patent Scaffolding Company

J. F. Conner, The U. G. I. Contracting Company

J. W. Dalzell, The Ferro Concrete Construction Company

J. Wilson Robinson, Everett Winters Company

Wm. F. Tubesing, Wm. F. Tubesing Company

F. A. Davidson, American Safety Device Company

Col. D. H. Sawyer, The Associated General Contractors of America

W. F. Austin, W. E. Wood Company

F. L. Hurlbutt, The Patent Scaffolding Company

held one meeting this year, namely on February 25th at Chicago. Of the ten members of this committee, seven attended this meeting.

Besides the various committee reports the three principal topics discussed were: 1. Statistics, 2. Membership, and 3. Codes.

With reference to statistics there was considerable discussion regarding the movement on foot to upset the present basis on which statistics for this section are made up. The suggestion having been made to change the loss rates from 6,000 days for a death to 1,000 days and so on down the line, the contention

being that a loss of 1,000 days for a death was more nearly correct than 6,000 days. For various reasons your committee felt that for the present at least no change should be made in the present method and in accordance with instructions from the committee your secretary went on record to the National Safety Council opposing such a change.

There are equally good arguments for and against this change though the trend is in favor of the change, the Paper and Pulp Section being the first I believe to adopt the new method.

Only recently the Accident Prevention Committee of the Detroit General Builders Association adopted a new set-up based upon the Michigan Compensation Law. At the Annual Safety Meeting this year the Association voted to award a plaque to the firm having the best record for a three year average. When the Committee on Awards checked into the records they felt that an injustice would be done to award the plaque on the basis of the method now used to compute losses. For instance member "A" has a death loss and there are no dependents, so that the accident actually cost the association's loss experience report in dollars and cents, two hundred dollars. According to the arbitrary list, he is charged up with 60,000 hours. His neighbor, member "B", has no death loss but he has pretty close to 60,000 hours of actually compensable cases. Sixty thousand hours are 1,000 weeks at \$14 per week, making \$14,000 of compensation payment and approximately \$10,000 of medical expense. Our old method would give member "B" the prize over the member whose losses had cost but \$200.

Membership Must Be Increased in the Section

On the subject of membership your committee came to the same conclusion they had eighteen months previous at the committee meeting held in Detroit, namely that until such time as a paid secretary was provided for this Section that all we could expect to be able to accomplish would be the holding together of the organization as it is now constituted and mark time until such time as someone would step in and give his full time to the work. Your chairman, Mr. Harding, pointed out that up to then there had been but six new members added to our section and four cancellations since the Detroit Congress in October, 1926. In other words, the section was just about holding its own. We had been advised some time previous by the Council that the necessary funds had been provided for a full time secretary. Mr. Austin then asked Mr. Cameron of the Council to explain to the other members of the committee why a secretary had not been provided since same had been promised us for over a year. Mr. Cameron stated that the Council up to that time had not been able to find the right man for this position: It was pointed out, however, that shortly after the A. G. C., through the efforts of the Detroit General Builders Association, had made accident prevention one of their major activities, they had a man on the road visiting the various chapters. Major Richards was appointed to this work.

Though we have not had a full time secretary considerably more progress has been made this year in adding new members than in previous years, because I believe the safety conscience of our industry has been awakened. This I believe has been mainly brought about by the numerous articles that appeared in the Press and Building Journals in the year 1926 through the efforts of certain members of this section. As I pointed out in my report last year, never in the history of the country has so much space been devoted to the subject of safety in the building industry, and I believe that this nation-wide publicity has in no small measure been responsible in awakening the safety conscience of our industry and which in turn has increased our membership.

At the last Congress we had a membership of 86. During the year 1926, 17 new members were added and 9 memberships cancelled leaving a net increase for the year of 8.

We have at the present time a membership of 121. During the year 44 new members were added to our roster and 9 memberships were cancelled, giving us a net gain of 35 members this year. While the number of cancellations this year were the same as last year, our membership net increase was 35 against 8 the year previous. Of these 35 new members the Associated Pennsylvania Constructors have a membership of 136 firms, the Associated Building Employers of Detroit has a membership of approximately 200 firms and the Michigan Municipal Contractors Association has a membership of 20 firms, so that in reality we have an increase in membership by firms over last last year of 391.

No small share of this increase is due to the efforts of the A. G. C. under the guidance of Major Richards in the big work he is doing.

Improvement in the Statistical Records

Likewise there has been considerable improvement in the statistical records of this section since 1922. The following is the record to date:

Year	Man Hrs. Worked	Man Hrs. Lost	Hrs. Lost per 1000 Hrs. Worked
1922	17,527,467	1,049,820	59.9
1923	22,642,745	1,083,190	47.8
1924	20,531,761	952,640	46.4
1925	25,451,441	1,927,010	46.4
1926	43,709,696	2,422,420	55.4
Total	129,863,110	7,435,080	255.9
5 Yr. Average.....	25,972,622	1,487,016	57.2

The above figures do not include all of the members of the Construction Section, but they do provide a typical cross section of the experience of our industry.

Statistics alone will not prevent accidents, but the study and analysis of statistics are essential in determining what to do. In order to reach a maximum of success, statistics must be kept for study and future reference; they are what the compass is to a ship crossing the Atlantic—without them we would not know where we are going.

Statistics have proven that accidents can be reduced through organized and well directed effort. I therefore appeal to all members not to overlook this very important phase of this work and I know that a real concentrated effort on our part during the year 1927 to reduce accidents will bring us the desired results. The seed we have already sown is being cultivated in all parts of the country.

SECRETARY ROBINSON: There is just another phase I should like to call your attention to in our statistics here, that problems today are altogether different than they were in 1922. With the equipment and machinery that the modern contractor is using today, his problems have changed considerably from what they were in 1922, and it has now reached the point where we have not only to consider it from the standpoint of the detailed problems on the job but also from the manufacturing standpoint and go to the manufacturers, as we have been doing in Detroit. We have so far been able to get some satisfactory results. But therein I think lies a good share of our success in getting the equipment manufacturers lined up with us, so as to make their equipment safe for our men.

CHAIRMAN HARDING: To comment for just a moment on Mr. Robinson's report and requests for accident statistics. I think that is very important. He brought out the vital need for having statistics, as one year's statistics mean very little to us, but after a compilation of several years and going into them, we can then know where to put our finger on the thing that is doing the dirty work in the construction industry. It has always been urged at the Safety Congresses that the members send in their statistics and I again urge the various firms to do so. They are published under a key letter and the identity of the firm is known only to itself so there is no undue publicity which can come from it.

With your permission, and that of the speakers also, we are going to switch the fourth speaker next, inasmuch as he would like very much to attend one of the other sessions this morning. Dr. Carl A. Wilzbach, of the Ferro Concrete Construction Company, Cincinnati, Ohio, will address us.

Health and the Construction Industry

Carl A. Wilzbach, M. D., Ferro Concrete Construction Company, Cincinnati, O.

Health in the construction industry may not be different from other fields of endeavor and yet there are certain factors that favor and others that disfavor the health of the construction worker. The worker is usually a rather healthy individual to begin with, made so by the natural processes of elimination. Only those who are able to withstand the physical effort, as well as the effects of the out-of-doors with its varying weather conditions can remain long at this work. It is not a task for weaklings or soft-muscled individuals as can be testified by any who have watched the progress of a construction job.

On the other hand, there are many who start young in years and in good health who become expert, efficient workmen, valuable to the company, who over the years acquire all the usual ailments which result in ill health and poor production. At this period the need for medical examination and advice on hygiene is evident and valuable to the men as well as to the company.

We are told by reliable men who have gathered statistics that 3.5 per cent of the 38 million people gainfully employed in the United States are constantly ill and disabled, and of this number half remain on the job. This means that over 1,300,000 workers are ill at any given time. It is further estimated that at least half of this illness is preventable.

Those workers who are ill and still remain on the job furnish us a real problem and an opportunity for it is generally recognized today that there are degrees of health. It is not just absence from disease. It is not present when one is just able to do his daily work. Health expresses itself in satisfying work, in the ability to enjoy play and recreative activity, in the desire to cooperate with those about one in a common cause.

On the contrary, the worker who is in a low degree of health does not react normally and is apt to be surly. His attitude on questions to be decided is not what might be expected of one in a happy state of health and there is many times an unwillingness to cooperate. Altogether, this individual is not fit and efficient physically and therefore not a good workman.

The average health span or period of physical freedom and full vigor after maturity is between the ages of 18 and 31. That is to say, there is only 13 years after maturity on the average that the worker is free from disease. The work span, or period when men can compete in industry on a fair basis of equality is from 20 to 40 years. This fact is demonstrated by the great falling off in the number of men in industry about the age of 40, at which age their years of productive usefulness seem to be over.

I am sure that all will agree that these periods are far too short, especially when one remembers that the life span at the present time is about 58 years. The rapid accumulation of physical defects, the rapid lowering of physical resistance and working capacity with advancing years, reflect conditions and processes that should be controlled by the application of intelligent care of the body and rational adjustment to work.

What are some factors that influence health? We will admit the influence of heredity and pass on to those causes that can be changed and helped during the life of the individual. It is a generally accepted view today that the body does not simply wear out; it is infected out, poisoned out, starved out, or deficient out. A condition is produced in the body which changes it chemically. In disease there is a tendency toward acidity and death is said to result from acidosis. The factors that produce the above conditions have been combated successfully in dealing with lower forms of life and much can be done to help man in his fight for a longer, healthier existence.

Infections, acute and chronic, lead the list as the most potent cause of disease, the epidemic infections being chiefly responsible in the early years of life; but chronic infections later appearing as a tremendous pathological influence, this type of infection working insidiously and radiating from foci in the teeth, tonsils, middle ear, nasal sinuses, prostatic urethra, gall bladder and appendix.

This condition is evidenced by the man on the job who reports to the physician with a sore throat. On examination he is found to have an acute tonsillitis. This condition is followed by vague pains in the joints some weeks later and then still later by dizzy spells, headache and dyspnoea, resulting from a definite cardiac involvement, all caused by infected tonsils. High blood pressure, nephritis, even gastric ulcers, may be promptly relieved after the removal of an abscessed tooth. Careful attention to the nasal sinuses will frequently clear up a chronic upper respiratory affection which may have long been suspected of being a tubercular condition. It pays to search long and earnestly for some foci of infection especially in individuals who do not respond normally to the accepted treatment.

Food Deficiency a Big Factor in Health

Food deficiency is still a big factor in the health of men in the construction industry. While the standard meal of the worker, consisting of meat, bread and potatoes is still being seen as one goes among the men, there is also seen green vegetables, fruits and milk. We have seen the great value of the accessory food elements (vitamines) in feeding children, but there is also need for educating the worker to the great need of a mixed diet, including the mineral, vitamine, amino-acid and regulating foods. The effects of diet on certain diseases has been known for a long time but the newer knowledge of nutrition indicates that many other diseases are also caused by a lack of certain food elements. It is urged by these experts on the study of foods that there be included for adults daily a mixed diet that contains at least a quart of milk, leafy vegetables and a certain amount of raw vegetable food. If these principles are adhered to the remainder of the balanced ration can be derived from milled cereal products, tubers, root vegetables, sugar and meats.

Poisons are a factor in the health of the worker. The physician has educated the average individual to the need of avoiding constipation but it is surprising the number of men who are taking daily some form of purgative. The various drugs used as cathartics plus all sorts of proprietary preparations are being used. It is questionable what effects some of these drugs generally used will occasionally have upon the body when taken daily and over a long period of years.

Headache tablets are also quite generally used and it is no uncommon sight to see the worker on the job with his box of aspirin tablets which he takes as regularly as he does his meals.

Tea, coffee and tobacco also come under the heading of substances which may poison the individual. Alcohol is increasingly being found to be a factor in producing poisoning. Aside from the chemical impurities contained in the poorly made moonshine there has lately been found copper in quantities large enough to produce metallic poisoning and over a long period of time cirrhosis of the liver.

There is also a need for the man in construction industry to have an opportunity to relax after his day's work. The speeding up of the worker has increased the strain both physically and mentally and this often results in an over-fatigued individual who is not fit for the job. Recreation and hobbies that lead to different channels of thought and action are needed by men in industry just as much as they are needed by men in other walks of life. While there are exceptions, the average construction workers need exercise as does the clerk or business man. A man who merely stands is not exercising and if he does not stand or walk properly the slight amount of exercise he gets moving about the job makes insufficient call upon the heavier muscles. This fact can be demonstrated by a physical examination which shows how woefully deficient the muscular development is and how high the percentage of physical defects is in the average construction worker.

Insomnia Increasing Among the Workers

In this same relationship comes the question of sleep. There seems to be an increasing number of cases of insomnia among the workers. There is at first just an occasional sleepless night. These gradually increase in number, and before long the strain of work plus the loss of sleep becomes too great. All sorts of malconditions result, chief of which is stomach symptoms with indigestion and loss of weight. There can be no doubt that the push of modern construction plus the worry of paying for the car and the newly purchased home are some of the major causes of these conditions. Fear, grief and emotional excesses are most destructive to the health of many workers.

There should be special effort made to stress the need of at least eight hours rest for all workers and more if one is below par physically.

Lastly, there is the problem of mal-function of the endocrine secretions. A complete statement of the effects of the various hormones in health is beyond the scope of this paper. It is generally recognized that these substances do stabilize the body tissue and help maintain a normal state of health.

In closing it seems evident that progress is being made. The average worker is better paid, has more of the luxuries of life, is more intelligent, enjoys a better health state and lives longer than at any other period in American history.

But we must advance. There is no reason why the present health conditions can not be improved. "Health, vigor and working capacity are not functions of time, but physical states influenced by what happens in the course of time. Neither the life span nor work span of mankind is fixed by any law. It is within the power of man's intelligence profoundly to influence the length of these spans. To this end we must work with full vigor and driving force.

J. W. DALZELL (Ferro Concrete Construction Company, Cincinnati, Ohio): As to the effects of overtime, Doctor, what is the relation of excessive overtime and continuous overtime and accidents? Is there any relation?

DR. WILZBACH: I am quite sure that the man who is overly fatigued is not able

to respond normally to the activities that he would be called upon to perform in cases of accident, and I am sure that overtime and accident are bound to have a relationship, although I have no facts, no statistics to prove that. But it seems reasonable to suppose that the nervous mechanism of the body functions best when the body is in the normal state, when it is properly nourished, properly rested and working; so I should say, in my opinion, there would be a direct relationship between excessive overtime and accidents.

CHAIRMAN HARDING: Is there any further discussion? This paper is somewhat out of the ordinary for the Construction Section, in that it does not deal with accidents directly; nevertheless the subjects of accidents and health go hand in hand. I am sure this is an opportunity for asking any questions that might be in your minds on this subject.

The chairman has committed a serious breach of etiquette in the reports of the officers; we neglected the Poster Committee, our good friend Mr. Tubesing, of Milwaukee.

WILLIAM F. TUBESING (William F. Tubesing Company, Milwaukee, Wis.): The only reason I called our chairman's attention to it is that a lot of you men don't realize what work the National Safety Council does as regards posters. Now, the National Safety Council not only takes care of our Congress here, but throughout the year, if you are a member of the National Safety Council, you get monthly some of those posters. Every year we have a new set of those posters and they are distributed at certain periods throughout the year. So if you are a member of our National Safety Council you get these posters regularly, and if they appeal to you the National Safety Council will send you as many as you desire at a certain price.

Besides that, the NATIONAL SAFETY NEWS comes to you monthly, which also carries miniature reproductions of posters that are available, so that you can choose from them.

I am quite sure that the committee would welcome any suggestion for future posters, or any criticisms of the posters we picked out, because that is the only way we can give you what you want.

CHAIRMAN HARDING: What Mr. Tubesing says about the posters is very well put. I can recall a few years ago being chairman of that committee myself, and what a task it is to get material for the posters! To make up a poster is not an easy task, particularly after you have covered the field at hand, and I am sure the Poster Committee will appreciate ideas very much. If any of the members have a particularly well guarded hazard that they think would make a good poster, send a photograph of it to the Poster Committee. I understand also that the National Safety Council has a staff photographer. If any of the members have a series of particularly interesting subjects for posters it would be possible to send the staff photographer to this particular job.

We have next on the program a paper by Mr. D. D. McLean, Construction Engineer, Travelers Insurance Company, Hartford, Connecticut.

Why Safety in Construction Work?

D. D. McLean, Supervising Engineer, The Travelers Insurance Company,
Hartford, Conn.

This question, which is the subject of my talk, is put forward in the true spirit of inquiry and is a mark of that fine attitude of open-mindedness which the contractors and construction engineers of our country have ever maintained on every phase of the problems and activities of their noble and all-important industry.

It is not my purpose to discuss this question so much from the point of view of

the designer and architect, who work out their conceptions upon the drawing board and make their calculations with studious care within the quiet precincts of the drafting office. That phase of safety in construction work as it relates to the security of the structures which man erects to the glory of his Maker in the cathedrals of divine worship; or the palaces of commerce which he rears heavenward in awful and majestic splendor; or the mansions of the great; or the more frugal dwellings of the people; or the ornate and rugged theaters and stadiums which he raises for the purpose of his entertainment and sport; or the railroads, bridges, tunnels, and viaducts which he builds for the facility of his travelings back and forth upon the earth; that aspect of safety, I repeat, which relates to the inherent security of these wonders of man's industry and energy, is so well understood and its need so definitely recognized by the artist-engineer, and is so hedged about by public opinion and legal imposition that it may be said to overwhelmingly outweigh all other considerations combined. Despite the beauty he may have captured in the lines of his structure, the architect or engineer has made a failure of his building or utility is not conducive to health or does not admit of the maximum of usefulness with the minimum of hazard to its users. No one knows this better than they; hence, safety in all its aspects is the first and foremost consideration of all their calculations and is indeed their first duty to society.

Humane Motives and Noble Ideals

The purpose in raising this question is the same which for sixteen consecutive years has drawn together these hundreds of public-spirited leaders of industry, and has caused them at vast expense to send forth their best executives and workers alike to the National Safety Congress. That purpose is to confirm their faith in organized safety and personal-accident-prevention work as it relates to the men and women who daily toil in the ranks of industry; and to gather fresh inspiration and knowledge to go forward with the noble work of human conservation.

Humane motives and noble ideals are the rock and foundation of this convention, and it is because the contractor or industrial leader recognizes his responsibility and duties to his employee and realizes that his workers are entitled to the fullest protection against the hazards of their various callings, that he has gathered here today in such numbers.

And in this we see the first answer to our question "Why safety in construction work?" Why?—because the leader is responsible for his men. Is there a man killed on your job? You cannot escape some feeling of remorse unless you have done everything you could to prevent it. Is there a worker injured on your contract? What have you ever done to safeguard him? Has some unwary toiler fallen through an unprotected floor opening? Where lies the responsibility?

There is no escaping it. Reason and rationalize upon it as we will, the first responsibility morally lies upon the leader, the employer. That fact stands out in bold relief. Let us not fear to own it. Has Heaven blessed you with a frugality and enterprise that have raised you above your fellowman? Have the circumstances of life projected you into a position of mastership over some quota of human beings? Has the heritage of the past placed you in a posture of command?

Well, then, the higher you have risen and the more extensive your influence, so proportionately is your responsibility. Believe it or not; acknowledge it or deny it; be conscious of it or otherwise; you are answerable. No man can escape his destiny; and though he may stifle the promptings of his own conscience and avert the consequences of an earthly reckoning, there is a tribunal before which all must finally stand to receive the just rewards of their stewardship.

This, I aver, is the deep-rooted motive prompting this Congress, and the first and highest reason why the contractors and construction engineers and all other industrial leaders in this country seek more light on the business of organized safety and

accident-prevention work in their various lines of industry. It is a duty to humanity, it is a work that is in harmony with the divine order of things. We do not lack *strength* to make it a success—all we need is the *will*.

But it is well and truly said, "He profits most who serves best"; and again, "It is expected that every man shall have an enlightened understanding of his own best interests." It is universally true that you cannot improve the lot of another without enhancing your own fortune, and even if we should be unmindful of humanitarian motives, the promotion of accident prevention in our industrial enterprises is a profitable and dividend-paying business for its own sake and from a purely worldly point of view.

Hence, we have the second answer to the question: "Why safety in construction work?" Put bluntly that answer simply is: "It pays." And that, let me say in all modesty, is a perfectly laudable and legitimate reason why every contractor and construction engineer, as well as every other employer of industrial workers, should take a direct and personal interest in accident prevention. The reduction of accidents has a direct and elevating influence on the profits of every contract job and every other industrial enterprise.

Production Depends on Human Hands and Brains

These statements, I know, are general and broad and they require elucidation. The inquirer at once demands an explanation. He wants to know "How does it pay?" And the answer to that is "By increased and uninterrupted production," and "By getting the job done on time." "Old stuff" you say. "Yes indeed, but true, emphatically true, old stuff."

All production depends on human hands and human brains and on absolutely nothing else. Human workers comprise the only possible source and means of production in industry. Without them nothing in the shape of material wealth can be brought forth. You have a marvelous plant, you have magnificent equipment, you have powerful engines, colossal reserves of fuel, and an assemblage of every means, device, and raw material for the construction of your building or utility or for the fabricating of your product, whatever it may be—all in the first place, mark you, produced by human hands and human brains. But with it all, it is as nothing; and it will lie and rot and no edifice will ever be built until the human worker, marshalled by his leaders, bring his and her hands and brains to work on it.

This is a fundamental truth as old as the world; and if this is true in the larger sense it is equally true in every detail of your organization, for if but one worker is hurt production, so far as he is concerned, stops right there. It stops, and as his value and relationship to the job is calculated every hour of his absence or (in the event of a minor injury) while his reduced effectiveness prevails, the profits of that enterprise are reduced. No worker is ever injured, however, without affecting the production of another or, it may be, many others. Some will stop out of curiosity—one of the strongest human emotions—or out of sympathy and to assist the injured man, and for many other reasons, among which may be pointed out that the progress of one man's work often depends on the advancement of another's, so that it is an entire cycle of stoppages, all affecting the whole job, that often occurs. Indeed, it is not at all an uncommon thing on a construction job, to see a whole gang of workers quit for the day when one of their fellows is seriously hurt.

In the meantime, and while the reduced effectiveness and production of the workers are prevalent, the foreman, supervisor, or other executive on the job must necessarily have his attention distracted from the affairs of production; he must assist or arrange for the assistance of the injured man; he must investigate the accident; arrange for the replacing of the injured worker by another employee;

select, train and break in the new man; prepare state accident reports, and sometimes attend hearings before the Industrial Commissioner.

Further, where the frequency of accidents is such as to require it, a First Aid Hospital or department must be maintained with a staff (or at least a regular attendant) in charge, and where the cost of this is not compensated for by insurance it becomes a direct cost to the job.

Again, personal accidents often involve damage to machinery, tools and other property, and the spoilage of materials.

And also, on construction jobs in particular, all these delaying influences oftentimes bring on failure to fill orders or complete jobs on time, occasioning the loss of bonuses, the paying of forfeits, and other similar losses.

Where an employee welfare and benefit system is operated the cost to the employer is directly proportionate to the cost of the system. Upon the return of an injured worker who has not fully recovered either from the physical or nervous shock of an accident, there is a loss in the continuing of wages in full while his effectiveness or production may actually be worth but 50 per cent of their normal value. This further involves the loss of profit on that injured employee's productivity or effectiveness and on idle equipment.

Many, if not all, of these factors enter into the loss cost that must necessarily be paid by an employer out of the profits of the job. Nor are these all of the items that could be mentioned and that might well receive attention. But these are the more obvious factors that every employer may very well understand.

Still Additional Cost Items

In all of this no reference has been made to Workmen's Compensation and Liability Claims; or Statutory Medical and Hospital Cost; or Insurance Premiums; or to the cost of lost time when actually paid by the employer. The first three of these at least are measurable and directly proportionable to the calculated cost of any job, and these are the only costs that loom large in the mind of the employer, as a rule.

But most employers have been more or less conscious in a vague sort of way that something of the kind, such as I have outlined, also happens to their output and profit when an accident occurs. What it is or what it amounted to was never very definitely studied, so far as we know, until about a year ago, when the engineering and inspection division of The Travelers Insurance Company undertook an organized and scientific research of the problem by a review of some five thousand specific accident cases taken at random from its files.

The purpose of that research was to establish a gauge or measure of the actual "incidental" cost whereby the employer can determine under existing cost-accounting methods, and by means of factors known to him, the cost of accidents in his own industry; and it was discovered that this "incidental" accident-cost, paid by the employer directly, is four times the total cost represented by compensation and liability claims and medical treatment.

This "incidental" cost has never hitherto been brought down to a specific, concrete, or tangible basis—something that the trained business-executive's mind might readily grasp. We need no longer deal in generalities therefore with regard to the desirability of preventing accidents. We need no longer refer merely to national "economic waste." We can now point to a *measurable monetary loss* to the employer which cannot be compensated by insurance, and which demands a remedy. Granted that the analysis of another 5,000 cases might show a higher or lower ratio, and granted also that in the acid-test of application to industrial plants a variation in ratio will surely occur, yet the truth persists that a tangible incidental cost actually exists; that it must be paid directly by the employer; and

that it is sufficient in amount to justify the inclusion in plant routine of means to reduce it through systematic accident-prevention work.

We therefore freely admit the probability of a variation from the figures thus quoted in the "incidental" cost of accidents, when the facts come to be computed on a national basis, yet enough has been done already to establish the facts approximately.

Every contractor to whom we have thus far presented the thought of measurable incidental accident-cost has demanded, and has obtained to his satisfaction, proof and details as to the method of measurement.

A specific illustration taken from actual practice on a contract job is typical.

Total cost of compensation and medical aid.....\$ 25.00

Total additional incidental cost, paid directly by the employer.....\$169.50

While sinking a shaft on a large contract job in one of our big cities, the engineer on the hoist dropped the battleship bucket into the hole. Almost miraculously nobody was killed, but three of the men in the shaft were injured, and one was knocked unconscious by a blow on the head from a part of the bucket. None, however, was seriously hurt, although the unconscious man was rushed to the hospital and had the cut on his head dressed, while the others received first aid, and the whole job was at once stopped.

An Example of Incidental Cost

The incidental cost was computed as follows:

\$10 time spent by foreman away from the job, 5 hours for supervising the arrest of the engineer, laying charges against him, and having him jailed without bail.

\$12.50 time spent by superintendent investigating damage to the bucket, the bridle of which was broken, and arranging to get it repaired.

\$ 6 lost time of several employees who were required to assist the injured man.

\$ 6 time spent by several employees untangling the wreckage and getting bucket up out of hole.

\$15 cost of replacing the broken bridle and repairing the bucket.

\$60 time spent by twelve other employees working in and about the shaft, trimming, but otherwise unprofitably employed awaiting the repair and return of the bucket while the job was at a stand.

\$60 cost of three motor trucks at \$20 per day, their work being brought to a halt because of no dirt to haul.

This case is actual and typical and I am sure that every contractor and construction engineer can recall a great many similar cases in his own experience, equally representative of the losses that are contingent upon accidents in his own industry.

I might easily cite other cases, but I am purposely withholding a recitation of them because it is a phase of the safety problem that is so important, interesting, and in this manner of treatment, so new, that it has been assigned a special place in the program of the A. B. C. Session of this Congress, when Mr. H. W. Heinrich, assistant superintendent, Engineering and Inspection Division, The Travelers Insurance Company, will talk on "The Cost of Accidents." To all of you who are interested to learn more about the finance of accidents I most certainly recommend that you attend that session.

My purpose here is to reason the "Why" of safety in construction, and I have endeavored to show by the emphasizing of humanitarian motives and self interest, that common-sense demands that we adopt it as a regular and routine part of all construction work.

It is a duty to humanity, for the lives and limbs of the men and women who

It is a duty to our Country, for industry is the most important factor in our daily toil in the ranks of industry depend on it.

national life—our national prosperity is won in our mines and mills and factories.

And finally it is to our own best self interest morally, physically and financially.

CHAIRMAN HARDING: Is there any discussion on Mr. McLean's talk to us on the "Why" in construction work? I hope any of you will feel at liberty to bring any question up for discussion. A little later in the morning we will have a free-for-all on any particular point that may come to your minds.

The last topic on our program is rather a misnomer. The Program Committee was a little disappointed in the symposium that was to be presented and it slipped in on the regular program, and since it is here we are going to make use of it. Last year a very comprehensive symposium was presented along the same line and the committee felt it might be well to do the same this year. It is divided up into four parts, the state reports, A. G. C., publicity and new members; and I am going to call upon Mr. McMurchy of the Industrial Commission of Ohio, to tell us something of the state reports.

Methods in Ohio for Gathering Statistics

D. F. McMURCHY (Industrial Commission of Ohio, Cincinnati, Ohio): Mr. Chairman and Members of the Construction Section: I must admit that this is quite unexpected, as I was to be only a spectator and not a participant when I came up here. But last year in Ohio, we did several things in the matter of gaining statistics about accidents that previously had never been done. The division of Safety and Hygiene, a part of the Industrial Commission, through its statistical laboratory was able to get a pretty good cross section of the accident situation. An estimate of the number of construction firms in Ohio was gotten from the Bureau of Labor statistics, and the number is something in excess of 9,000. The 1925 reports show 8,407 firms submitted their employment schedules, and these estimate that they are getting reports from about 90 per cent of the firms doing construction work in Ohio, those firms which employ three or more operators regularly because they come under the compulsory compensation law in that state.

A summary of the accidents runs something like this: about 23,000 accidents in building and construction work, which includes construction other than building and erection; 189 fatalities are included in that; four permanent total disabilities and 98 permanent partial disabilities. I made some studies of the employment situation to find out something of my exposure. The Bureau of Labor Statistics receives from these contributing firms a schedule giving the number of employees on the fifteenth, or the nearest representative date to the fifteenth, of every month. Over a year's period they turn in the amount of wages paid to the various classes of employees, the wage earners, the bookkeepers, stenographers, and the salesmen. Since these accidents occurred to the wage earners—the men on the job, or the bulk of them—I was only concerned in the number of wage earners employed, and I used this method in arriving at this figure; I divided the average number of wage earners employed on the fifteenth of every month into the total wage payment for the year 1925 ('26 figures are not available yet), arriving at an average wage per year. This average wage I divided into the total pay roll exposure submitted to the actuary of the Industrial Commission. That pay roll exposure will cover in excess of 99 per cent of all of the accidents submitted to the Industrial Commission. The results of that division gave me a figure of 92,166 men continually employed in the construction industry last year, wage earners.

Now, the exposure and the number of hours per day, or number of hours per year which those men worked, were more or less matters of conjecture. We had to arrive at an arbitrary figure for that, which was arbitrarily set at 2,000 hours per year. I may be high or I may be low, but I want to get the idea across that it is an arbitrary exposure. On that basis, 92,000 men and 2,000 hours is a year's work,

our frequency work per million man hours worked figures 61.72 accidents. On the same basis our severity rate is 8.0 days lost per thousand man hours worked.

That is a computation of the frequency and severity of lost time accidents only, the number of lost time accidents being 11,788 out of 23,000 injuries. The balance of them were medical only, involving no lost time. These involve the loss of one shift, and I think that that is the same basis that the Council uses in computing its frequency and severity. It is not a very accurate record, I admit, but at least it gives us the first authentic picture of our accidents and how the construction industry in Ohio can be compared with the other industries in Ohio. It at least gives us a mark to shoot at this year and the years to come. It may be of interest to you to know that the Ohio State Federation of Labor passed a resolution at their convention held in Middletown wherein at every meeting of their various local bodies there would be a certain time in that meeting devoted to the discussion of accident prevention. They were to have in every local organization a Safety Committee. It signifies to us that they are getting behind this proposition. It is also a challenge to the employers that those fellows are going ahead regardless of what may be done by the employer or what may not be done.

I want to present one more proposition to you gentlemen. I am probably taking a lot more time than is allotted me. I was talking to Mr. Keefer about this same proposition last night. You gentlemen are here by virtue of the fact that you are interested in accident prevention. To attempt to sell you safety would be superfluous, because you are sold now, but we have before us in Ohio (and I guess it is pretty general all over the country), a number of contractors who are not as interested as you are in the accident prevention business. I speak now of the small operators which I estimate in Ohio amount to about 30 per cent of the construction work, those fellows who are not inclined to affiliate with any sort of a building organization. They don't know each other, they don't care to know each other. You have as much chance of selling them safety as you have getting them to build a skyscraper because they don't know what it is all about. Don't you think that it is a part of the larger operator's responsibility to get the rudiments of safety across to these smaller fellows? By example; yes, by more than example; by encouragement, not by fraternalism; but recognize them as potential builders, if not now, eventually, and give them the benefit of your experience in accident prevention. We can't do it by individual calls only and with our limited force we can't attempt to visit every two-story house under construction; but where you are located in any one locality I think that your companies by action of your organizations and your general relations among each other on the work, could foster a better spirit or a better feeling among these little fellows, and only in that way are we going to be able to reach that little fellow and cut out that 30 per cent of our accidents.

Need to Broaden the Influence of the Section

CHAIRMAN HARDING: I am now going to call on my good friend, Colonel D. H. Sawyer, Secretary of the A. G. C., for a few remarks.

COLONEL D. H. SAWYER: Mr. Chairman, I am not on the program. I am not prepared for any talk at all and I was sitting here having a good time. The thing that does run through my mind is the metamorphosis of the Construction Section. Three or four or five years ago when I attended this meeting, I think we met in somebody's bedroom, and today we have the walls kind of bulging out, and I think we are reaching the consciousness of the contractors. It is stimulating to me, and I know it is to all of you, that the contractors are feeling the necessity of doing something along accident prevention lines. Mr. McMurchy put his finger on a thing that we can't overlook; and that is, regardless of how faithful we people here in the

Associated General Contractors may be in spreading the gospel of accident prevention, we are occupying a limited field. All of the contractors of the country do not belong to organizations, they are not appreciative of their responsibility to their employees as others, and it is those people we have got to reach.

I think the answer to that is that if in our own circles we can develop thorough going accident prevention methods little by little, that gospel with the pressure of increased rates by the carriers will bring home to the people the contingent responsibility and little by little they will come along with us.

Speaking for the Associated General Contractors, I have to say that Mr. Richards is on the program, I believe, and he will give you a rather complete picture of what we are doing. The National Safety Council enjoyed a lot of hard work in trying to get our organization in step with the safety movement. I daresay they were very much discouraged for several years, as we of the staff and the officers were. It seemed almost impossible for us to convey the idea of mass necessity to our membership. Time and again at every board meeting and every convention we stressed accidents; and when I say stressed, I mean it, because we did it to the point that we really created resistance in our ranks to the safety movement. You can go so far that you can overstep yourself to the extent that fellows get tired and say: "What is the use?"

Entering the Activity Wholeheartedly

We finally brought our people around to the point where they saw the necessity for it. They not only saw the necessity for it and the dividends that it would pay, but they saw the contingent thing there, that if they didn't pick up this movement others were going to force them into accident prevention work; and so the two worked hand in hand. Some pressure from other sources, plus educational processes from within, have finally induced our people to go into this activity wholeheartedly.

We told you, I think, a year ago, that it was on our program to employ a high grade man whose major duty, if not his sole duty, was to inject accident prevention measures into our ranks. We made good on that promise. Mr. Richards here came with the staff last January, and since that inception we have gotten out a manual which has probably been in the possession of a good many of you which has no other purpose than to stimulate interest in accident prevention and tell our members how to proceed. Beyond that we have gotten out three standard accident prevention signs which have met with a very ready sale; and little by little as you go around the country and see an A. G. C. job, I think in a prominent place you will see one or more of those signs to inculcate accident prevention in the minds of the superintendents, foremen and employees.

Beyond that, we have three of our members, including Mr. Tubesing, who have given cups in order to stimulate chapter and individual contests in the reduction of accidents in their groups and in their individual companies. I don't want to say that that idea has met with as ready response as I wish it had, but I am quite sure if next year we have other prizes for contests, the results will be rather startling. Since I came to town a number of contractors have told me of the financial benefit they have received from accident prevention activities, reduction in rates and the reduction of hidden losses that they sustain when accidents occur on one of their jobs. Beyond that, all around the country we have had our officers and Mr. Richards meeting with the chapters for the sole purpose of having them as a group go into accident prevention measures, so I think I can report that so far as our organization is concerned, while you people may not be entirely satisfied today with what we are doing, we can see tomorrow we are thoroughly in step, thoroughly in accord with the National Safety Council, and that you will be highly

pleased not only with what we do but with our contingent efforts among the other contractors of the country.

CHAIRMAN HARDING: I am going to call next on one of the old war horses in the Construction Section, also interested in organization work amongst the trade associations. Mr. R. A. MacMullan, Secretary of the Builders' Association of Detroit. He needs no introduction.

R. A. MACMULLAN: I just told Colonel Sawyer that Major Richards would have to stay up all night now to think up a new speech, but I don't think I had better say anything.

I have been, of course, connected with both the A. G. C. and the Construction Section of the National Safety Council for quite a number of years, and I remember the famous meeting of the Construction Section in Buffalo four years ago next week. That same week the A. G. C. had its meeting down at St. Louis and I attended both of them, and I remember particularly the lack of interest when we talked safety at that meeting. During the past year or two we have had visitors in Detroit from the four corners of the country. We have had men from Texas up here, three of them at one time. We had a delegation from Buffalo. We had visitors from Denver, from Louisville and from Oregon, to talk about accident prevention. We have had letters at the rate of two or three a week from all over the country and it has been extremely interesting to us to see the wave that has been going over the country, the wave of enthusiasm for accident prevention work in the respective industries.

Influence of the Association Important

There is one thing that sticks in my mind. It is that the A. G. C., or the Highway Contractors' Association, whatever the national association may be called, has an opportunity to bring into the Construction Section here, a tremendous amount of additional interest. We have found that we have friends there in Detroit, sewer contractors, who have practically no statistics on accidents in sewer work. The Detroit City Gas had a serious accident on a trenching machine, and they couldn't find any record of any such accident over the country although these trenching machines have been used considerably. In other words, the public works contractor is considerably behind the building contractor today. Two or three years ago I was over at the Highway Association meeting and they had the Commissioner of Roads as a speaker, who said they had a \$100,000,000 bond issue being spent on roads. In Michigan, I suppose, we have spent \$100,000,000. The western states are going to spend tens of hundreds of millions, particularly through the middle section where the roads are so bad when they get a little rain on the gumbo. That will all have to be handled through some division or section on accident prevention, and it means a tremendous field for this Section, it seems to me, in the years to come.

Another matter should be stressed and stressed with a word of caution, because we fully realize that only a small portion of accidents are preventable by mechanical means; but still those that are preventable by mechanical means may be followed a little more closely, we think, by the plan of taking up with the manufacturer of equipment any inherent weakness in that equipment. As a specific example, we had a foreman, a very intelligent man, killed by the sinking down of a dipper on a steam shovel. We found that that break was a friction break and that there is no way of being sure that that dipper is going to stay up when you are moving your shovel without moving the dipper in without steam in the pistons. We are pressing that particular manufacturer now because that is something that can't be controlled on the job.

In regard to concrete mixers, we had an accident on a hoist engine we were working on, and we have taken it up with the manufacturers. They have studied

it now for a year or two and have given us blue prints of a suggested method of operation to control it.

If you men would bring in your problems that way, it would have a tremendous effect on the manufacturers. We haven't had a case of a manufacturer refusing to give any cooperation because naturally he has to sell his product.

I am now going to call on some of our new members. They may not be new, in so far as accident prevention work is concerned, but I understand they are new with the Construction Section. It has been brought to my attention that Mr. Charles H. Black, of the Insurance Department of the Stone and Webster Company of Boston, is here. We would like to call on Mr. Black.

MR. BLACK: This is the first Congress I have attended and the first Congress that Stone and Webster has ever sent a representative to, particularly to the Construction Section. Stone and Webster are sold on safety, but they are beginning to awake to the point now where they must assist the National Safety Council by giving it their ideas and experience and by helping others. They have on their jobs a large number of sub-contractors and they think that in this mutual field, much can be gained by swapping experiences. That is why I am here to see what you do in the Construction Section. I have no special program laid out; it is just more curiosity at this first meeting.

Good Results Secured in Safety Work

CHAIRMAN HARDING: Thank you, Mr. Black. I am sure you can get a world of discussion out of some of the members if you button-hole them and have a little talk with them.

We also have a man who, I believe, is new in the Construction Section upon whom I am going to call, Mr. George Widua, Superintendent of the Safety Department of Woods Brothers Construction Company, Lincoln, Nebraska.

MR. WIDUA: Woods Brothers became members of the National Safety Council when I accepted a position with them in May, 1926. Up to that time they were general contractors, especially in river embankments and protection. Our work deals mostly with sea walls, pile driving, making up retards, and we have just recently completed a sea wall. Our experience of past records shows that it was necessary to put on a safety man to go into this safety work on account of our excessive insurance rates. I didn't bring any statistics along. I didn't think I was going to be called on to speak, but I will say that in the past two years, in which I have been with them, they have done wonderful work in that safety line. The firm appreciates what has been done and we are in this heart and soul. We employ around 2,500 to 2,800 men all over the country, and with the assistance of the National Safety Council in providing bulletins and other safety devices and ideas, we are getting very good results. We have cut our accidents considerably, that is our lost time accidents, and we hope to be able to do better. It is a hard job of course to sell our superintendent's, who have been with the company for years and years, the idea of safety. Safety must be sold to the superintendents and executives. Superintendents must sell it to the foremen and the foremen must deliver it to the employees.

CHAIRMAN HARDING: Among the other new members (and I think this is the first Safety Congress he has attended), I am going to call on Mr. William H. Miller of William H. Miller & Sons Company, of Cincinnati.

MR. MILLER: Mr. Chairman, I am thankful to you for proposing my membership. I will say it has benefited our concern tremendously. We receive the posters and the men are taking notice. I think that is one of the principal things we want to do, educate the men, and see that we have their well being at heart. I am certainly glad to be a delegate to this Congress.

CHAIRMAN HARDING: We still have a few more minutes before the hour of closing, and I am going to call next on Mr. P. E. Wright of the Associated Builders Employers of Detroit.

MR. WRIGHT: Mr. Chairman, I thank you for calling on me. I don't see where I can lend anything to a Safety Congress or a safety meeting of this nature. Up until a few weeks ago I knew nothing about safety and cared less. I happened to go down to see Frank Austin one day, who was former chairman of this Section, who converted my Mohammedanism into Christianity. He converted me into safety, and I immediately got to trying to do something for the safety meeting.

I will say that to approximately 200 members who do not belong to the General Builders' Association of Detroit (and those members have been interested in safety), I sent out a questionnaire asking them to appoint a safety contact man. In one week's time I had sixty replies, with a safety contact man appointed in each organization. That takes in organizations employing from twenty-five men up. There is some interest in the safety movement there. We are going to try to do all we can to increase that interest and perhaps after we get to be war horses like MacMullan and a few other of the fellows who have been coming here, we will have a better report to give you.

Activities in the Engineering Section

F. A. DAVIDSON (American Safety Device Co., New York, N. Y.): About all your engineering representative can say this year is that he is glad to get a chance to look at everybody.

During the past year the Engineering Section has had no particular problems relating to the construction industry. We have devoted ourselves in the Engineering Section (as is quite regularly the case) to problems that are more directly concerned with the Industrial Sections. That is primarily the fault of our own Construction Section. We haven't been quite as keen as some of the other sections in deciding quite definitely on two or three problems in safety accident prevention that are specifically engineering problems, and it seems to me that that is something we must do—definitely pick out one or two specific problems that are obviously specific engineering problems and put them before the General Engineering Section and have them devote some attention to them during the year, not only at their periodic meetings, but also have them assign a committee to work on them. Of course the engineers who would make up the committee wouldn't be primarily construction men, and they wouldn't have the general construction viewpoint. Nevertheless, they would have an engineering viewpoint that would be very helpful in solving, or helping to work out, a particular engineering problem in our section.

If the matter of specific engineering problems is something that can be divorced from construction or iron and steel, or what not, there are some problems that are quite common to all that you may remember. They were brought out in a session of the Engineering Section of Milwaukee on the subject of hazards in circular saws. I am sure that that meeting developed some engineering principles as related to accident prevention in connection with the use of circular saws that proved a revelation to men in all the different industrial sections. I think that the chairman should, out of this meeting, or as a result of it, finally settle down and specifically define a particular problem that we have; and if that is put to me I will see to it that it is put quite definitely to the Engineering Section, so that we can have a year's consideration, and I hope next year that my report will be more specific than this.

CHAIRMAN HARDING: Along the lines that our engineering representative was just talking, it has been brought to the attention of the Section, rather as a suggestion offered, that next year each industrial section should complete three

safe practice pamphlets on semi-technical subjects, which are of specific interest to the industry represented by that section.

I understand we have in the Construction Section quite a few safe practice pamphlets. The field is by no means covered, but I am sure the incoming Executive Committee would like suggestions from the members as to the preparation of a safe practice pamphlet. Perhaps you have some particular hazard or some problem that is confronting you on which you want to get the benefit of the experience of a group, and in the preparation of these safe practice pamphlets these points no doubt will be answered. There are a few subjects that have been suggested. They are, by the way, the subjects of papers presented at the Congresses, the Construction Section meetings, in the past. One subject, "Safe Construction of Scaffolds and False Work," is quite a field for a safe practice pamphlet. "Safety in Steel Erection" has been suggested. Another is "Standardization of Accident Statistics and Their Value in Construction Work." Perhaps the safe practice pamphlet is a misnomer in that. I think we will hear more about the accident statistics before the session is over. Another subject is "Safety Work in the Ship Building Industry." I don't know how many of our members are interested in ship building, but there are no doubt some representatives who have some problems. Another subject has to deal with statistical work and also the keeping of records of accidents according to causes; and that, to my mind, is one of the big problems in this Section. If we can designate in the order of their importance the causes of our accidents, it is going to give us a very fertile field to work in. I don't know whether it can be stated now that this particular hazard takes precedence in frequency and severity over another hazard, but the necessity of this has been continually brought before the Construction Section.

Another subject has been suggested on "Safety work in the erection and demolition of the steel frame work of high buildings." Another one is suggested, "Analyzing the relation between accidents and the volume of construction"; another one, "Safety and efficiency in dam and other construction." I am sure the incoming Executive Committee will be only too glad to hear from the individual members, and what is true of one must certainly affect the majority in this case. So they will be very glad to have any suggestions that might be offered.

In closing the first session of the Construction Section, I want to call on a man who has been interested in construction work for years. I heard him speak quite a few years ago when he was interested in association work and I want at this time to present Mr. J. H. Ellison, past president of the A. G. C. and president of the Winston Dear Company of Minneapolis, Minnesota.

MR. ELLISON: Mr. Chairman and Gentlemen of the Construction Section: I don't know of any more important activity of construction than safety. I think that perhaps, like Mr. Wright, I have become more or less Christianized by my contact with Frank Austin and the gospel which he preached to me, and by my friendship with Mr. MacMullan and other people who have interested themselves in this matter. As a past president of the A. G. C., I put first in the agenda of our association, accident prevention as the most important thing we had to do for several reasons. First, because of its humanitarian appeal; second because it was our own job, because we don't have to ask somebody else to do something for it; and third, because it paid in dollars and cents.

The element of the spiritual, the righteousness in our business cannot be ignored or overlooked; unless our construction, of whatever nature it may be, is founded on righteousness, it cannot endure.

I want to say this word, that none of us are too small, or too insignificant, to get in and do our part in the carrying out of this safety work.

ADJOURNMENT

Wednesday, September 28, 1927

The second session was called to order at nine forty-five o'clock by the chairman, E. C. Harding.

CHAIRMAN HARDING: Gentlemen, the first order of business is the election of officers. The chairman of the Nominating Committee is Mr. Fred Hurlbutt. Has the Nominating Committee a report?

J. W. DALZELL (Ferro Concrete Construction Company, Cincinnati, Ohio): The Nominating Committee, as has been its custom in the past, has submitted only one slate, but that does not by any means do away with the probability or possibility of nominations from the floor.

Report of the Nominating Committee

Chairman, E. C. Harding, The Ferro Concrete Construction Company, Cincinnati, Ohio.

Vice-Chairman In Charge of Publicity, C. H. Almstead, The Patent Scaffolding Company, New York City.

Vice-Chairman In Charge of Stereopticons and Slides, J. F. Conner, The U. G. I. Contracting Company, Philadelphia, Pa.

Vice-Chairman In Charge of Program, J. W. Dalzell, The Ferro Concrete Construction Company, Cincinnati, Ohio.

Vice-Chairman and News-Letter Editor, George Widua, Woods Brothers Construction Company, Lincoln, Nebr.

Secretary, J. Wilson Robinson, Everett Winters Company, Detroit, Mich.

Membership Committee Chairman, J. F. Conner, The U. G. I. Contracting Company, Philadelphia, Pa.

Poster Committee Chairman, Charles H. Black, Stone and Webster, Inc., Boston, Mass.

Engineering Committee Chairman, F. A. Davidson, Chesebro, Whitman Company, Inc., Long Island City, N. Y.

Statistics Committee Chairman, J. Wilson Robinson, Everett Winters Company, Detroit, Mich.

Executive Committee, The Officers and—

Col. D. H. Sawyer, The Associated General Contractors of America, Inc.,

Washington, D. C.; W. F. Austin, W. E. Wood Company, Detroit, Mich.;

F. L. Hurlbutt, The Patent Scaffolding Company, Chicago, Ill.; W. G.

Wheeler, Exec. Secretary, Accident Prevention Committee, Building Trades

Employers Assn., New York City.

CHAIRMAN HARDING: Gentlemen, as the Nominating Committee reported, we are now open for nominations from the floor. There being none, what is your pleasure with the report of the Nominating Committee?

D. F. McMURCHY (Industrial Commission of Ohio, Cincinnati, Ohio): I move the report be closed.

WILLIAM F. TUBESING (William F. Tubesing Company, Milwaukee, Wis.): I second the motion.

CHAIRMAN HARDING: Are there any remarks?

(The motion was carried.)

CHAIRMAN HARDING: It will probably be in order to entertain a motion that the secretary cast one vote for the election.

MR. TUBESING: I move that the secretary cast one ballot.

MR. DALZELL: I second the motion.

CHAIRMAN HARDING: Are there any remarks?

(The motion was carried.)

CHAIRMAN HARDING: It is so ordered. Mr. Secretary, you will cast the ballot in your records and it will be complete.

With the election out of the way, we will now proceed with the second number on our program, by Mr. Frank Morris, Assistant Chief Engineer, Liberty Mutual Insurance Company, Boston, Massachusetts.

Keeping Out of the Rut in Safety Work

Frank Morris, Assistant Chief Engineer, Liberty Mutual Insurance Company,
Boston, Mass.

Twenty years ago I was on a construction job not more than 30 miles from Chicago. Safety in construction work was unknown at that time. We were setting roof trusses with a 50-foot span from an 80 foot gin pole and it was customary then for the men to ride the load. This gin pole rested on a 16-inch block and one morning I said to the rigger foreman, "Jim, your pole isn't anchored and supposing she slips off that block, you'll kill three or four men." The rigger foreman looked at me scornfully, gave the signal to hoist away and said, "To hell with them; we can get lots of men."

The Construction Section of the National Safety Council indicates (1) that today we hold different values, and (2) that accidents in construction work don't need to happen. While standing on the coping of the Multnomah Hotel one rainy day in Portland, Oregon, I saw a carpenter's axe fly from his hand—strike the ledge and bound far outward. I watched that axe, fully expecting it to cleave some innocent pedestrian in the street far below, but it landed harmlessly immediately behind a man who was hurrying along.

It was a few days after that incident that I stepped on a nail—that was in August. A doctor probed around and cleansed the wound immediately afterward but the foot bothered me continually. X-rays showed nothing. I hobbled around all winter and twice had the foot lanced. It was not until the following May that a piece of leather worked itself near enough to the surface so that I could dig it out myself and—the foot immediately got well.

I recite these personal incidents because they illustrate two common causes of accidents in the construction industry—falling material and stepping on nails. Fortunately most of the material that falls hurts no one, and only about one nail in 5,000 makes a puncture wound, and most of the nail punctures result in no lost time.

A bulletin issued by the New York Department of Labor last month called attention to the fact that five years ago only 10 out of 58 accidents reported were construction accidents and that last year the construction accidents were 22 out of each 100 reported. This increase might be due to several causes; fewer machine accidents, more building, better reporting, etc.; not necessarily indicating that we are slipping in our work; but these figures do show the growing importance of our job of preventing accidents in the construction industry.

This is a tough proposition compared to the average safety man's job. Obviously the grade of the average employee on a construction job—outside of the skilled trades—is inferior to the employee in a manufacturing plant. Many of them probably are "rejects" whose physical disabilities are not checked up before putting them on a construction job. The moral incentives such as

pride in workmanship, expectancy of promotion, or hope for steady employment are lacking among the non-skilled employees and under these conditions we may expect to find a sort of "dont-give-a-dam" attitude among the men. If we were to erect a mill type building, say two stories high and 100 x 1800 feet area, our problem to prevent serious accidents on that job would be rather simple, but if we were to turn this job on end and erect a building with 100 foot front, 18 stories high, our job becomes at once one that calls forth all of our ingenuity. This is largely because the law of gravity insists on pulling down to earth anything or anybody that is loose. The school teacher said, "Now children, it is the law of gravity that keeps us on this earth." A voice pops up, "But teacher, what held people on earth before the law was passed?" The careless way in which some men ramble around up aloft indicates that they don't know the law has been passed. There was a time when I considered a three inch stringer 50 or 75 feet in the air just as safe as a sidewalk, but lucky for me when my turn came to fall—and every careless man has his turn—I fell but 25 or 30 feet; since then I have preferred the sidewalk.

Fatalities on a Job in Boston

On one job—a 14-story building in Boston (that isn't a big building for New York or Chicago, but it's one of the big ones in Boston) we killed seven men, in spite of the fact that four men were delegated to put up guard rails, cover up holes, etc. The average non-skilled labor was 600, and the job ran a year and a half. One man was knocked off a building being demolished—fell 70 feet. One was crushed by a lump of falling earth. The third was struck in head by a board that fell from sling. The fourth fell 105 feet through a shaftway. The fifth stepped from one scaffold to another at different level and fell six stories. The sixth fell into a hole that he was about to cover up; and the seventh—you've been expecting this one—stuck his head in hoistway and lost it. These are typical accidents on a construction job and after they happened of course we could see how they might have been prevented. Closer supervision might have saved at least four of those seven men.

In a manufacturing plant with a constant supervising force and a constant body of employees, it is not much of a job to hold a safety rally or carry on other safety activities. One department can be pitted against another in a contest; the foreman is generally available to talk to and to talk with about accidents that may happen; the physical makeup of the workers' surroundings do not vary from day to day; once a guard is put on a machine in a shop it generally stays on. All of this is changed on a construction job. Who ever heard of a safety rally on company time on a construction job? When you want to talk to a gang boss about safety or anything else you find that he has just gone to another part of the job—like the Irishman's flea, you step on it and it isn't there. Moreover the non-skilled worker finds his surroundings change from day to day. True, one floor is much like another but they are at different levels, floor openings vary, and the progress of the job from floor to floor presents varying hazards.

Therefore, the safety engineer on a construction job must be more keenly alert than the average safety man and if he himself has ever swung a pick or pushed a concrete buggy so much the better for he can then be more human—more sympathetic with these take-a-chance fellows who after all are on the job to earn a livelihood in the best way they know how—just as you and I. Safety posters or bulletins, instead of being in a regular place, must be located strategically and just follow the job up. Slogans on payroll envelopes, stamped

on with rubber stamp costing a dollar or so, can be used very effectively because they can be made to refer to that particular job and they can be brought right down to the minute. A rainy day is the time for the safety man to get busy visiting the shacks or shelters where the men are congregated and if the safety man knows his job he will enter into their conversation and swing into a good talk on accident prevention. All of these tricks of the trade you are familiar with. The construction safety engineer cannot be a Sisyphus.

Sisyphus was the chap that was always falling down at the moment of supreme success. He could never get over the top. He pushed a huge stone to the top of a mountain and just as it was about to reach the summit a weakness overcame him and the stone rolled back into the valley. After pausing to get his breath, Sisyphus again started the stone upward, steaming and sweating, and this time he was sure he could and would give the rock the final push. But his foot slipped again and the rock rolled back. It is not recorded how many times Sisyphus tried and failed, but it was a large number of times for the Gods had sent him to Hades to do a great thing—and to always miss doing it.

The days of mythology are gone, but now and then we run across a Sisyphus in the safety engineering field. The original Sisyphus was handicapped—for the power of the Gods was greater than his own. But the modern Sisyphus on construction accident prevention work is not hoodooed that way, on the contrary the Gods are for us and if we but be of strong heart to persist to the end we are bound to attain success and Old Man Carelessness and all of his cohorts can't keep us from winning the victory.

Check Up on the Sub-Contractor

We hear a lot about sub-contractors removing guard rails and not replacing them. Every problem is simple after it is solved. Getting guard rails replaced is no problem. After the general contractor has instructed the sub-contractor that guard rails must be replaced if he finds this rule is not being obeyed it is a simple thing for him to delegate a laborer or carpenter to follow these subs and replace the guards, charging the sub-contractors for the carpenter's time, this of course is made a part of the contract with the subcontractor. This idea is so simple and it works so well that we wonder why this practice isn't generally followed. Most bulletins are 8½x11 inches in size. For guard rails they should be four inches wide so that they will fit a 2x4 and they should be of heavy paper well tacked on and they should be put on both sides of the rail so that the warning will be there on either side.

In manufacturing industries we have concluded that accident prevention is largely a matter of proper supervision and safety engineers are giving more and more attention to the attitude of the foreman. Why aren't the supervisors on a contracting job just as responsible for accidents? They should be—but construction foremen are likely to feel a divided responsibility because probably several causes contribute to an accident and several men might be responsible. There is a noticeable lack of contractors in meetings of this sort. This has been demonstrated by Mr. Leo Woedtke who more than once in safety congresses has asked the contractors or representatives of contractors present to stand up, and not a man in the audience arose. It is very obvious that safety in construction work is in the rear of the procession but, thank God, we are in the parade, we have made a start.

Sometimes I think that the company carrying the insurance on a construc-

tion job doesn't try hard enough to sell the big man on the possibilities of preventing accidents. What we want from him is his support—his backing. When he goes out on the job to give it the once over we want him to remind the super that he is holding the super responsible for the safety of the workers. And if a man is off on account of injury we want the big boss to inquire from the gang boss how the man is getting along—when can he come back to work and so on—in other words advertise his interest in accident prevention.

Necessary Details on the Progress Report

It would be a good idea for the general contractor to have on his progress reports not only number of men employed, percentage of completion of work, etc., but also a record of lost time accidents occurring. With only a minimum of effort the big boss can look over copies of the accident reports and he can check up to see that preventive measures are taken. His attitude will soon be reflected all down the line.

The general contractor is beginning to understand how his cost of insurance is affected by his accidents, he is coming to realize that accidents are not a necessary by-product in the erection of a store or a dam or a power house, and he feels at times that if he could personally supervise each operation he could reduce accidents to a minimum. Therefore, he is gradually passing this responsibility on to the super and to the gang bosses. The rigger foreman I referred to at the beginning who said, "We can get lots of men," couldn't get a job today with a first class contractor.

Organized safety drives in the construction business don't seem to have the proper punch to carry through—at least not in the east. An effort to have last May as a safety month didn't seem to get anywhere. The first news that my company had of this so-called drive (and we have a large volume of construction coverage) was some newspaper publicity about May 1. We tried to tie in and help the program along but we couldn't find the program anywhere. If a drive is contemplated for the month of May it should be worked out in January and all interested parties should be drawn into it. We understand that the A. G. A. doesn't do safety business that way and we hope that their influence for accident prevention may soon reach even to Boston. You may be sure that the trades unions will cooperate in any such movement.

Reasons Why Homes for Orphans Are Depopulated

Many differences of opinion may arise between the general contractor and the unions but there can be no argument between them about accident prevention. On one large job in Boston the union officials pulled the men off the job because unsafe working conditions were not remedied. The resultant loss, from low production, cost considerably more than adequate guarding would have cost in the first place. The trades unions are now backing a bill in our legislature to increase the number of building inspectors so they can get safer conditions. This is a sad reflection on safety progress in the construction industry. In the October number of the Century, Silas Bent says that there are three reasons why homes for orphans are becoming depopulated: (1) smaller families; (2) the successful war against communicable diseases; and (3) the decreasing death rate from industrial accidents. While we have made some improvement the construction industry cannot claim a very large share of credit for this third condition.

We are all working to beat hell—for an accident on a construction job sure is hell, but are our efforts availing?

In the statistics reported for 1926 to the National Safety Council by the various member companies, by sections, we find that "Public Utilities" and "Quarrying" are about on a par with construction work—from a hazard standpoint—and that only "Mining" is more hazardous. This may be a bit discouraging to those of us who are trying to prevent accidents in construction industry. It may seem that our efforts are futile—that we are getting nowhere.

Let us tell you a story which illustrates the power of your constant hammering away at this stupendous job. This test was made in a munition factory during the days of the war:

Parable of the Cork and the Steel Bar

A great bar of steel, 8 feet in length and weighing 800 pounds, was suspended by a chain. Nearby, a small cork, a bottle cork, was hung by a silk thread. The purpose of the test was to see if the action of the cork, lightly swung against the great steel bar, would have any effect upon it. Again and again the cork was swung against the bar and produced no apparent effect whatever. At the end of ten minutes, after hundreds of gentle taps, a tremor or sort of nervous chill, seemed to run through the bar. Another brief space, more tappings, and a distinct vibration was seen. At the end of 20 minutes the great bar was swinging like the pendulum of a clock.

That surely is an instructive parable for construction safety engineers for none of us is conscious of inadequacy comparable to the disproportion between a cork and an 800-pound bar of steel. If at the end of 20 years—not 20 minutes—we are able by our constant hammering away to move this tremendous problem we will have our reward for our faith, our hopes and our perspiration.

The Construction Section is not 20 years old, but less than 10 years old. The same figures I referred to above (the National Safety Council report) show that both frequency and severity in accidents reported by members of this section took a decided drop (7.57 to 5.44 and 69.54 to 57.70) from 1925 to 1926. So the little corks, you, me, and the other fellow, hammering away, are showing results. When I look at those figures I feel like saying with Florian Slappey, of "Bummingham"—"Hot dam, Boys, we's sure a gettin' somewhere."

CHAIRMAN HARDING: I am sure we all enjoyed this paper presented by Mr. Morris and we will allot a few minutes to the discussion of it.

C. H. ALMSTEAD (Patent Scaffolding Company, New York, N. Y.): Does your company in all its coverings show just how the construction industry stands, whether with its fatalities it is back of mining, or just how we stand with the other industries? Are we ahead or losing?

Relative Standing of the Construction Industry

MR. MORRIS: What Chris Almstead is asking me I guess is whether my company is making any money on construction business. We don't write mines, but our construction experience has been good; in the first place, because we don't take the contractor that won't play along with us on this proposition. Any contractor that isn't interested in accident prevention is bound to have bad experiences. There is absolutely no question about that. Unless the big man is interested and will work along with you, you won't get anywhere. It is absolutely futile to put in any effort at all on a job where the big boss won't back you up. We have no trouble with the gang bosses or the superintendent, or anybody else. They know

somebody is behind them and pushing them on the proposition. That is absolutely essential in contractor work, and more so than in a shop or factory. You can do something there with the foremen, even if the big boss isn't very much interested in accident prevention; but you absolutely cannot get anywhere on a construction job.

CHAIRMAN HARDING: Has somebody else some further discussion or questions?

R. A. MACMULLAN (General Builders' Association, Detroit, Mich.): I just want to ask one question, Mr. Morris. Have you any idea as to whether the tall building or the low building produces the greatest loss?

MR. MORRIS: The tall building is certainly the more hazardous, and we have the most accidents on the tall building.

That is because the safety men and the men on the job only kid themselves and think it isn't dangerous. Of course you are going to have accidents in both cases if you don't give attention to accident prevention. You have to use the same energy and the same efforts in either case but the hazard in the low building isn't comparable to that of the tall building.

Accident Prevention Month Is to Be Continued

R. E. PARI: (General Builders' Association, Detroit, Mich.): Isn't good housekeeping on a job necessary to the reduction of accidents?

MR. MORRIS: I didn't mention good housekeeping because we all recognize that that is absolutely essential to accident prevention.

WILLIAM F. TUBESING (William F. Tubesing Company, Milwaukee, Wis.): Mr. Morris asked whether there would be another safety month next year of the National Builders' Exchanges. I wish to state that there will be as long as the National Builders' Exchange is in existence, and it is kind of funny to me that you didn't get the bunch of posters that were sent out last year by the Exchange. Didn't you receive one with a little girl with her head in her hands wondering where her daddy was, what happened to him?

MR. MORRIS: I would have been perfectly willing to receive the little girl.

MR. TUBESING: It was sent out. It might not have been sent to insurance companies, but it was sent to all national exchanges for distribution.

MR. MORRIS: I don't mean to criticize any particular organization that has undertaken safety work, but I do think, as I said, that if you will only have in mind that the insurance company covering that job has a very vital interest in it, and they have a broad experience behind them in accident prevention work in that particular line or else they wouldn't be writing that line, and if that interest is only tied into your program, you will get lots of help and we will get lots of help because we are right there and right on the job. We are a long way from Milwaukee and if your stuff had only filtered through to us, your program there would have been effected.

MR. TUBESING: This came out of the Washington office of the Builders' Exchange.

MR. MORRIS: Let's all pull together, and we will get somewhere.

CHAIRMAN HARDING: There was one thing that impressed me, Mr. Morris. It was the statement in one of your answers to the discussion to the effect that you will not take a risk unless the contractor will play ball with you. I think your association should go along that line. The little fellow is bound to be pinched sooner or later, and it is one wedge that we can drive into some of the fellows who refuse to believe what it is all about.

If there is no further discussion on Mr. Morris' paper we will proceed to the next one, to be presented by Major W. R. Richards, Field Secretary, Associated General Contractors of America, Inc., Washington, D. C.

Accident Prevention Activities of the Associated General Contractors

**By W. R. Richards, Field Secretary, Associated General Contractors,
Washington, D. C.**

You are accustomed to hearing that the greater number of accidents occur in the construction industry and that safety work in this field presents greater difficulties than in any other. But I am here today to tell you what contractors, and particularly the Associated General Contractors, are doing to overcome the obstacles in the way of accident prevention.

As our second largest industry, surpassed by agriculture alone in the number of men employed, construction has held an important place in civilization from earliest times. Man has solved construction problems; he has conquered heights with towering skyscrapers, he has annihilated distance with tunnels, he has mastered the rivers with bridges and he has solved traffic congestion with subways, but there still remains the problem of carelessness and thoughtlessness resulting in injury and death.

Every year in this country we face the appalling fact that more than 85,000 deaths result from accidents of all kinds; while casualties, other than death, number over seven million. Of the total of industrial accidents, construction contributes a large percentage—from 15 to 20 per cent in Pennsylvania and New York, and a similarly large proportion in other states.

As a result, in too many cases the skyscraper, highway, railroad or other project, which is commonly looked upon as a monument to the architect's, engineer's and the builder's ability, is really a headstone for the men who were killed during the construction period.

I doubt if there is any industry that is confronted with more hazard, from the beginning of operation to its completion, than is construction. Accident prevention has not yet reached the average contractor. He thinks of it as a remote proposition, an unattainable ideal. He considers prevention of accidents as something beyond his control. His work, as he sees it, is to secure the contract and make all possible speed for completion of the project.

In promoting this safety program we find the most common objection made by contractors is that they believe the construction business has too large a labor turnover for accident prevention to be effective. They do not want to spend money on safety work when they know some men will be careless; they prefer to trust to "luck." They remind me of the Scotchman who paid his railroad fare from station to station, leaving the train at each stop to buy a new ticket rather than to purchase a ticket that would take him to his destination, because his physician had told him he was suffering from heart disease that might prove fatal at any moment. Just as with this old gentleman, the contractor's imagined thrift results in a waste of both energy and money.

No matter if the labor on construction jobs is a shifting group, education along accident prevention lines on one project will make the worker a safer employee on his next job. We are all travelers from post of birth to post of death, wanderers between the two eternities. Therefore, if we all cooperate on accident prevention it matters not where the workman is employed.

It is estimated that every year the construction industry in the United States is loaded with a charge of \$250,000,000 in personal and property damage. Faced by this problem and the mounting cost of both insurance and so-called "hidden losses," the Associated General Contractors of America at their annual convention in January, 1927, at Asheville, N. C., determined to begin an active campaign to turn these losses into profit for both the employer and the employee. A full-time safety engineer was

added to the headquarters staff of the organization, and work was begun at once.

To finance the undertaking the W. E. Wood Memorial Fund was inaugurated by W. F. Austin, president of the W. E. Wood Company, Detroit. This fund has now reached approximately \$15,000 and we are confident it will continue to grow as the results of accident prevention work convince other members of our organization of the value of the work.

Competition between local chapters and contractors is being encouraged by the offer of three cups to be awarded for the best records in accident prevention. An individual membership cup is being offered by William F. Tubesing, president of the William F. Tubesing Co., Milwaukee, Wis.; a chapter cup will be awarded by Robert L. Reisinger, also of Milwaukee, while Sumner Sollitt, of Chicago, is donor of a third cup.

Probably the biggest accomplishment of the Associated General Contractors up to the present time has been the publication of the "Manual of Accident Prevention in Construction," prepared by contractors for the use of members of the association and others in this industry. This 51-page book links up the new safety program of the organization with the fundamental ideals of the association in these words: "As construction is our business, and accident prevention our obligation, may we not show our *skill*, prove our *integrity* and meet our *responsibility* in this important matter of accident prevention in construction?"

Selling Safety to the Executive Is Important

In its introduction the manual points out that "maximum results can be obtained only by voluntary action on the employer's part. Technical, mandatory safety requirements formulated by others will not accomplish the desired objective." Practical suggestions for safety work are offered, but not until an argument has been advanced for cooperation—cooperation of the contractor with his local Associated General Contractors chapter and with such agencies as the local branch of the National Safety Council, cooperation with the subcontractors and cooperation with the workmen. Because we believe the only means of securing accident prevention is dependent primarily upon "selling the executive," we have begun the book with a plea to that executive. Then, because we likewise believe that seven out of ten accidents in construction are preventable by educational means, we have devoted considerable space to a discussion of the best method of undertaking such education.

The manual carries our message of information to the contractors of this country. It was published not to convey an atmosphere of compulsion or autocratic mandates, but in the interest of service and cooperation; and contrary to the accepted fate of men and matter so garbed, it has a place. It has gone to the far corners of the United States and is filling a need that nothing else has met. That it is breeding good will, friendship and mutual confidence, we are confident. The manual is not perfect—it was prepared by men for men—but if it fills the gap in information wanted by our general contractors it is serving its purpose.

At their spring board meeting the Associated General Contractors adopted a series of three accident prevention job signs, and a good number of contractors immediately ordered the signs. Our plan is to have these placed on every job on which one of our members has men working. Each sign measures 18x24 inches and bears the A.G.C. seal in red and black, with a safety slogan in the same colors. It is our belief that the Associated General Contractors' insignia, standing for cooperation and recognized as representing skill, integrity and responsibility, will impress the public with our interest in promoting safety in construction. At the same time, we feel that these signs placed on every job, whether building, highway, railroad or public works construction, will prove a continued warning and a constant reminder to our workmen of the dangers of being careless.

Before undertaking our safety program we found that with too many contractors

accident prevention was something to be talked of but not acted upon. It was in the same category with most folks' religion, which the old darky said "is lak dey Sunday suit. Dey ain' nevuh weah it frequent 'nough to shape it to deyse'f."

Construction accident statistics as compared with those of manufacturing plants are anything but encouraging from the standpoint of the contractor, and insurance rates are correspondingly high. Yet contractors, with few exceptions, have refused to follow the example set in other industries where accident prevention has been found successful. They have neglected to take a part in the movement which has placed safety work in the United States 25 years ahead of that in other countries.

The Associated General Contractors are attempting to make accident prevention an everyday objective, not only because of its economic benefits but also because of the humanitarian angle of the problem. Fewer accidents mean lower insurance rates, increased efficiency and greater production.

Insurance Rates Based on the Record of the Firm

Because the insurance companies have recognized the value of accident prevention work, they have adopted the policy of basing their rates on the past record of the firm. Contractors who have been able to take advantage of a lower compensation rating find themselves at a great advantage in competitive bidding. If one contractor has a 20 per cent credit on his rating while another must pay a penalty of 20 per cent, the spread between the two rates will be sufficient to win or lose the job. The man with the penalty cannot leave this charge off his bid any more easily than he can leave the bricks out of the building he is erecting or the sand and stone out of his concrete.

Insurance, however, amounts to only a small percentage of the total cost of accidents. In fact, statistics collected by casualty companies indicate the so-called "hidden losses" from accidents amount to approximately five times the charge for compensation. At least 85 per cent of all accidents are said to be caused by carelessness, while only 15 per cent are practically unavoidable. If this 85 per cent can be cut down through introduction of a safety campaign, the employer will benefit very materially.

At first thought these "hidden losses" do not appear so vital, but their true importance is seen when one considers the losses in equipment, time, efficiency, morale, labor turnover and men-power. Conservation of all these items is important in any industry, but in construction the shortage of trained workers makes the loss of even one man an especially serious problem.

On the other hand, it is the humanitarian angle of the safety campaign that appeals most to the employees. It creates a common bond between the employer and his men which is absolutely essential for the successful operation of accident prevention work. Considered from this viewpoint, fewer accidents mean a saving of lives: prevention of unemployment, illness and poverty; and raised morale among the workmen. The two ideas of economy and moral obligation, however, are so interrelated as to be inseparable. Whatever helps the employer also benefits the employee, and vice versa.

You will be interested, I believe, in a review of the actual savings realized by a number of contractors through accident prevention. Two branches of the Associated General Contractors have already applied accident prevention very effectively. These are the Texas Branch and the Detroit Chapter, which furnished the rules of safe practices prescribed in our manual as well as other material for that publication. This chapter has reduced accident insurance rates for its members 50 per cent. Several individual members, likewise, have earned a handsome merit rating through safety work. For instance, James Stewart & Co. have secured a credit of 60 per cent on their insurance rates, while Fred T. Ley & Co. have reduced their accident rate

54 per cent. In 1926 J. W. Cowper, of Buffalo, completed a job of \$400,000 payroll with a total cost for medical aid and compensation of \$1,614.04, while on other jobs this charge has been as low as 89 cents per \$100. Equally encouraging is the report of an insurance company which points out that a number of contractors, large and small, have been successful in having their rates reduced 20 to 30 per cent by accident prevention methods.

Another incident that I want to cite is that of a large subway contractor in New York who was about to have his insurance canceled. The premium which he had paid amounted to \$50,000, while the cost to the insurance company in 11 months for his 384 accidents during that time was \$39,000. Instead of canceling his insurance, he was induced to give *accident prevention* a trial. In the first month he reduced his accidents to 29, lost time days to 122, and medical cost and compensation to \$533. The second month showed 32 accidents, 230 lost time days, and \$696 costs. In the third month, accidents were again lowered, numbering only 21, with 217 lost time days and a cost of \$1,178. His records for the succeeding months varied but little from these figures, showing conclusively that accident prevention pays when given the proper attention.

Safety is like time—it is a valuable commodity, and should be recognized in terms of dollars and cents. The more effort and enthusiasm we put into accident prevention work, the greater results we will realize from our investment.

If seven out of every ten accidents are preventable, it is our duty to find out the means of prevention. Voluntary efforts in this direction will be more far-reaching and satisfactory than legislation, yet if construction does not take steps to clean up its house, the state legislatures will send in the statutory scrubbing brush and soap to do it for us. We must accept the challenge and not sit idly by, bemoaning the facts, like the dog who sat on his tail and howled all day because he was too lazy to get up.

Careful Organization Will Eliminate Accidents

It is important, too, that contractors differentiate between well-managed accident prevention methods and the careless, slipshod, don't-care procedure that has proved unsuccessful whenever tried, leaving an undeserved black mark against the safety campaign. Accident prevention, undertaken as part of the contractor's organization, will eliminate the majority of his accidents and make his employees more efficient.

Skill, integrity and responsibility are required of all members of the Associated General Contractors, and we are now interpreting this responsibility to include accident prevention. The public expects the employer to protect both the workman and the interested onlooker or the passerby whose life is often endangered by accidents on our work. If we are to live up to our motto we will accept this task as part of our responsibility.

The methods of applying accident prevention are practically the same in all cases and should be carried out along standard lines instead of being put on a plane of mystery. They must be made a part and parcel of the contractor's business and worked out in a practical way. In fact, the best plan is to use good commonsense methods. Properly applied, these are flexible—they fit any job and are adaptable to any kind of construction. Some one has said that it is the "horse sense of the driver that will save accidents, not the horse power of the car," and that statement is applicable here.

The first essential of accident prevention is the sincere interest of the employer in the project. Safety must begin at the top. The success of the program will depend largely on the confidence the "big boss" has in the activity and on his ability to inspire that confidence in each and every member of his organization. If the employer will stop for a moment to consider how he would feel and act were he in his workmen's shoes, he will be eager for the success of accident prevention, and will not postpone taking up the campaign.

Safe equipment, kept in good condition, represents the second important factor in any accident prevention program. It may cost more to provide a covered scaffold instead of a narrow plank for a bricklayer, but his increased efficiency will more than pay for the expenditure, aside from any consideration of safety. Likewise, a stairway is superior to a step-ladder because of the greater speed as well as lessened danger made possible by its use. No matter how many safety devices are put up, however, constant supervision and continued house-cleaning is necessary to keep them in place. Careless workmen will sometimes destroy them, or a subcontractor may remove guard rails and neglect to replace them. So, we urge contractors to clean their jobs internally and externally. The physical condition of any job shows the attitude of the employer to the work on the job. If the job is kept clean, the facilities for handling material are increased and the hazards are overcome to a great extent.

Proper supervision by superintendents and foremen and the instruction of workmen in safe methods are of practically equal importance. A little later I will tell how Associated General Contractors are carrying out this part of the program.

We have found two methods successful in conducting safety work in construction: First, that of safety organization within the company, and, second, the system depending on the assistance and stimulation of the local chapter of the Associated General Contractors.

The Plan Worked Out in Detroit

The latter plan, as worked out by the Detroit Chapter, consists first of all in appointment of a general safety committee of the association, composed of one representative—a responsible executive—from each company. This committee formulates safety policies and supervises all safety work. Decisions of the safety committee are carried out by the secretary of the association, assisted by an able insurance engineer who makes safety inspections of the larger jobs of the member companies.

Under direction of the safety committee and the secretary the following activities are carried on: Accident reports are sent to the secretary and comparative records are compiled and distributed monthly to the various member companies. All serious accidents are investigated at the accident location by a board of inquiry consisting of the secretary, insurance counsel, insurance engineer, and the safety committee member representing the employer. Testimony and recommendations of all eye witnesses are taken, "findings" are reached, and reports are distributed to all members. A set of regulations covering safe practices and equipment for various branches of construction work has been compiled by the committee and furnished to all superintendents and foremen. To encourage study of these rules a prize contest is held several times each year. Evening meetings for superintendents and foremen are held, for the purpose of instructing them in safe practices and in first-aid treatment for injuries. And finally, every week safety bulletins or posters are sent by the secretary to each job.

Naturally the most common means of carrying on safety work is that of safety organization within the individual company. The contractor who wants to inaugurate accident prevention on his jobs must organize. In this work, as in every other worth-while undertaking, organization and a definite program are absolutely essential.

First of all, it is advisable to have the services of a first-class safety man, either on an individual plan or through insurance connections. If possible, there should be someone in the general office of the company having supervision of all the safety activities on jobs and being held directly responsible to the employer for carrying on the campaign.

On large jobs running a considerable length of time, a safety committee is effective. This committee ought to consist of the superintendent, as chairman, the time-keeper, as secretary, and three or more foremen. Regular meetings should be held

and minutes kept for record. The committee should also make inspections of the job, at least weekly, investigate all serious accidents, report findings to the general office, and assist the superintendent in giving safety instructions.

If the job is not sufficiently large to warrant appointment of a safety committee, some reliable workman may be named as safety inspector to devote a small part of his time to inspecting the entire job at regular intervals and reporting to the foreman or superintendent all unsafe conditions and practices. The duties of such an inspector should include maintaining first-aid facilities satisfactorily, investigating accidents, reporting findings to the general office, at least on all serious cases, and assisting in safety instruction.

Careful selection of the men for these tasks is most important, yet in employing every man the contractor must exercise care if he wishes to be successful in his safety campaign. The experienced worker is much less liable to be clumsy than the new laborer; likewise, the healthy individual is a much safer man than one who is sickly or physically handicapped. Especially important, it seems to me, is the attitude of the superintendent. When hiring a new man for this position I think every employer should inquire what his opinion is of accidents on the job. Let him understand that one of your requirements of a superintendent is that he promote accident prevention. Only if he shows an interest and indicates a willingness to cooperate along these lines should he be placed in this position.

"Accident Disease" Not to Be Tolerated

The well-organized accident prevention program includes a careful record of all accidents to both employers and property. This will end continued employment of men who have what might be called "accident disease," and who are a menace to their fellow employees as well as a source of loss to their employer because of their repeated carelessness. It will also point out many other methods of correcting dangers. Such a report shows the nature and cause of accidents, their cost and the resulting lost days from each.

Accidents are caused; they do not just happen. So it is our task to discover how and why they occur, and then correct the causes. Safeguards cannot eliminate the 85 per cent of accidents which are due to the human element and result from carelessness, thoughtlessness and ignorance. Such accidents can be prevented only by teaching the workman safe methods and habits. Above all, the employee must be taught to use good judgment. Last year in a Michigan industrial plant there occurred 171 accidents. Investigation shows that in 170 cases the injured party had explained the accident by saying: "I did not think." This resulted in lost wages amounting to \$10,610 and cost the company \$17,000 in loss of production, all because those men failed to "think."

To prevent accidents one must go back to the circumstances leading up to the occurrence. If accidents result in no injury to persons they still should be listed and studied in order to avoid repetition. Besides, in accidents of this sort there is a hidden loss and a possibility of injury to persons. For many years there has been talk of the cost of accidents in addition to the expenditure for compensation. The principal factor entering here is the cost to the contractor of replacing a man, which amounts to from \$25 to \$100. When a new piece of equipment is placed on a job, orders are immediately given to exercise care in its operation because the machine has cost so many thousand dollars, but no mention is made of the employee who is to operate the valuable piece of equipment. Yet, like a machine, if he is not well cared for, he will soon be broken and unfit for use.

A thorough study of accidents reveals many causes. Perhaps you have heard of the little girl who was almost run down by an automobile, but was rescued by a heroic bystander who inquired why the child had not clung to her mother's skirts. "I did try to hold on," she explained, "but I couldn't reach them."

Accidents in construction result from a multitude of causes, but most of them can be traced to carelessness of some form. Although these are not always reported, the majority of accidents are scratches of some description which may easily be kept from proving serious if given immediate attention instead of being considered as "nothing to worry about." This is where an ounce of prevention is worth a pound of cure. Someone has said that accident prevention is that pound of cure for excessive compensation rates.

Of the so-called major accidents, the predominating causes are falls of various sorts—falls from scaffolds and ladders; falls from buildings; falls from runways, floors and stairs; falls from other elevations; falls into floor openings; falls into excavations; falls into quarries or pits and even falls on the level. Many very serious injuries result from men being struck by falling objects, while others are brought about by workmen stepping upon or striking against various objects.

To overcome these difficulties the safety engineer should work with the operating executives in formulating and applying a set of company standards or rules covering both safety of equipment and safe practices. He should also keep in touch with the safety men of other construction companies in order to pick up all available information regarding new and improved methods.

Education of the Employees Most Important

Because not more than 15 or 20 per cent of accidents can be prevented by mechanical means, the most important item in the program is the education of the employees. Different companies have worked out this plan in varying completeness, but practically everywhere such details are included as distribution of safe practice pamphlets and safety bulletin boards. The National Safety Council publishes 5,000 different safety bulletins yearly, many of which are applicable to the construction industry, while the Associated General Contractors' job posters are particularly intended for our members. Safety contests and prize awards encourage the men to take a personal interest in the movement, yet I believe nothing is more effective than the enthusiasm of the employer himself. While a contest is being held, or even after the awards have been made, many contractors have found it a good plan to use score boards to mark the progress of accident prevention work. These boards are provided with 31 spaces, one for each day of the month, and when an accident occurs a red plate is inserted.

Safety meetings, combining entertainment with instruction, have been found very satisfactory means of creating an interest in the project. Sometimes first-aid demonstrations are included in the program at these meetings. The more minute directions in first aid, however, are given only to the foremen and superintendents. If possible, the services of a physician should be secured for the latter purpose in order that the information given out may be dependable. Such instruction, followed by care in equipping and maintaining adequate first-aid medical kits on every job, has been found to be one of the most effective means of reducing the number of lost time accidents.

But we are diverging into the field of curing instead of sticking closely to prevention. Important as is first-aid, I believe it is even more essential to train the workman in the proper use of his machinery than to treat him for injuries received through ignorance of its operation. A man may be furnished goggles to wear for certain work, but he probably will neglect to do so unless he finds his fellow employees wearing them and unless he is thoroughly impressed with the advantage of protecting himself from possible injury. This statement, of course, is an admission that constant vigilance must be combined with education. But when we are careful to see that neither supervision nor training is lacking, we find increased efficiency going hand in hand with accident prevention.

Group liability and compensation insurance make accident prevention more easily

possible and profitable, yet it is not necessary that safety work be predicated on any insurance arrangements. It should rather be based on the desirability and advantage of accident prevention. However, energy spent on groups usually obtains better results, and where insurance is connected with the operation a still greater result is obtained.

No matter whether it be an individual company or a chapter of the Associated General Contractors that is undertaking accident prevention, cooperation is a great help in promoting the plan. First of all we urge our members to join their local branch of the National Safety Council. For best results it is necessary to cooperate with the insurance agencies, the manufacturers, the sub-contractors, labor, building departments and the architects and engineers.

Safety Is Not An Unattainable Ideal

Pessimists will tell you that accident prevention is simply an ideal, an unattainable dream, but remember that while the "calamity howlers" are complaining, progress is marching on. Shortly before the Civil War a writer in the Atlantic Monthly said of our capital city, "Washington has a monument that will never be finished and a capitol that lacks a dome." But the fact that such dreary predictions ever were made never occurs to the throngs of tourists who daily ascend the monument and visit the capitol. Nor will the doubts of the present hinder the ultimate success of our safety program.

You yourself can do more and better work if you take sane, practical care of your health. Then why not protect and care for your employees so that you will benefit from their better work?

Accident prevention is our obligation. Let us show the employees, the public and everybody that we are going to operate a humane industry, wholeheartedly attempting to live up to the slogan of skill, integrity and responsibility.

CHAIRMAN HARDING: To start discussion on Major Richards' paper, I want to call on Mr. M. S. Dearborn.

M. S. DEARBORN (Federal Mutual Liability Insurance Company, Boston, Mass.): It has been my pleasure to meet the Major on numerous occasions and this is one of the pleasantest, and I have been very interested in his discussion of how the A. G. C. has organized to carry on its safety work. He has covered the ground very thoroughly and has emphasized the fact that the only way to carry on this intensive safety program is to organize and cooperate in a definite program. I am somewhat at a loss to know just what to say. The Chairman rather took me by surprise. I think, though, we have all been enlightened by the wonderful paper presented by the Major.

CHAIRMAN HARDING: Is there some further discussion?

MAJOR RICHARDS: I say this, that quite a number of the chapters have joined the National Safety Council, or the local branches in their various localities.

R. E. PARIS (General Builders' Association, Detroit, Mich.): The Major talks about accident prevention about like Bobby Jones does about golf. Bobby said there are a great many different methods of learning how to putt, but he has found the best way to putt is just to knock the ball into the hole and cut out all the preliminaries; and that is about the place where it seems to me we are landing in this Construction Section now. I don't believe that accident prevention is in its selling stage any more. The size of these meetings as compared with the meetings we have had in earlier years in this Section rather proves that; and I think perhaps, maybe it is natural modesty on the part of the Major, that he wouldn't tell us the strides that the A. G. C. has made in accident prevention this last year, is because he has made it his business to get out around the country and talk accident prevention to contractors. He has taken the gospel to them by personal appeal rather than by circulars and pamphlets and magazines and that

sort of thing: and I am glad to hear that the Construction Section has been promised for more than a year now. By the Executive Committee of the National Safety Council, a field secretary for this Section, and we haven't got any field secretary.

Now we could do in the Section what the Major has done if we had as good a man as the Major for a field secretary. Maybe that isn't possible, but at least we could have a field secretary, and the A. G. C. can't do it all. Their membership is not representative over all the United States yet, and there are more contractors that are outside the A. G. C. than are inside and why not have our field secretary? Why not represent the attitude of this Section to the Executive Committee of the National Safety Council, if we really believe we ought to have a field secretary to carry this gospel to the contractors? I should like to read the resolution over to that effect.

CHAIRMAN HARDING: The Chair will be very glad to entertain a resolution to that effect, Mr. Paris. The question of the field secretary has come up before the past two Congresses.

Resolution Regarding a Field Secretary

MR. PARIS: To get the matter before you, I will read this:

"Whereas, Heretofore the great need of a field secretary to promote accident prevention in the construction industry was definitely determined, and

"Whereas, On representations of the Construction Section to the Executive Committee of the National Safety Council the employment of a field secretary was authorized but has not been carried out, therefore be it

"RESOLVED, That it is the sense of this meeting that the officers of the Construction Section shall bring emphatically before the Executive Committee of the National Safety Council the increasing need of the services of a field secretary and the great benefits to employers, employees and the public to be derived from the campaign of accident prevention in construction and the consequent loss from further delay in this important matter."

I move the adoption of that or an improvement of it.

MAJOR RICHARDS: I second that motion.

MR. ALMSTEAD: Mr. Chairman, I believe the Council has, in the past year, had various men under consideration for a paid secretary, but it seems at the critical moment this man either slipped away or got a better position and wouldn't take it. I think the whole Section should make effort (that is, if they have a man in view), to make recommendations to get him. They have been trying real hard for the past year to get a man. I know for an absolute fact, because I had one lined up myself for them.

CHAIRMAN HARDING: I am sure the managing director of the National Safety Council would appreciate any suggestions as to the man to fill this position, if you have any to offer.

S. LANGNER (United States Fidelity & Guaranty Company, Chicago, Ill.): I have always felt in these meetings, at lectures and moving pictures and so forth, the right men have not been present to get the benefit of this safety propaganda; and I have had occasion to meet a contractor in Chicago here who says the executives have not themselves realized the importance of the accidents on their jobs. I have in mind one particular man whom I talked to about accident prevention who didn't have any conception of the record of his accidents. When I brought to mind the number of cases of men stepping on nails, he decided to get out on his jobs with me, and when he saw the condition of the jobs he discarded the concrete forms lying all around the place and immediately instructed all his superintendents to remove the nails from the boards as soon as they took them down and burn up all the scrap material. That is an indication of the fact that when these men are

reminded, or when it is brought to their attention, that their jobs are hazardous, when they see the importance of this work, they will take it upon themselves to do something about it.

CHAIRMAN HARDING: We have a motion that hasn't been voted on. As soon as we dispose of it we will entertain your motion.

(The motion to adopt the resolution in regard to field secretary, was carried.)

C. H. ALMSTEAD (Patent Scaffolding Company, New York, N. Y.): I move that Mr. Paris be appointed a committee, and, if he finds it necessary to appoint his own committee to take it up with Council Headquarters, to see that we get a proper man, he may do so. While it is true that a man can be trained for the position, we would like to get a construction man into it.

JAMES F. CONNER (The U. G. I. Contracting Company, Philadelphia, Pa.): I second the motion.

An Eye Inspection Campaign in Detroit

MR. PARIS: I appreciate the compliment of it, but I think I will have to rise to a point of order, because it seems to me that is a natural function of the Executive Committee of this Section to take up the matter with the Executive Committee of the Council. I think that is the proper form in which it should be done.

MR. ALMSTEAD: I withdraw my motion and leave it that way, Mr. Chairman.

CHAIRMAN HARDING: The Executive Committee will present the resolution to the Executive Committee of the National Safety Council. We hope for luck this time.

In line with Major Richard's paper, I understand that Detroit is running an eye inspection campaign amongst all the workers and I think a few remarks along that line might be well at this time. I understand Mr. Buck is chairman of this committee. Mr. Buck, can you tell us something of this committee's work?

CHARLES BUCK (Bryant & Detwiler, Detroit, Mich.): The Industrial Commission is a new acquisition by the Detroit Safety Council. It was adopted at a meeting of our subcommittee and referred to the General Building Association for passage, to have an Industrial Commission, or Industrial Eye Company, which is formed in the locality of Detroit for the purpose of investigating the eyes of all employees in construction in all kinds of industry. It has become quite a proposition in Detroit so far as the manufacturers are concerned. About 50 per cent of them, up to the present time, have adopted that means of procedure; to have all their employees, not from a mandatory or compulsory standpoint, but from an advisory standpoint, examined as to their eyesight.

We started out on our job (the Bryant & Detwiler Construction Company of Detroit), one job of 400 men. They put a doctor right out on the job, a head doctor, with two assistants. We furnished them a room for their investigations. They brought all the equipment out on the job and those 400 men were given a cursory examination in about two days and a half.

They make a final report, with a card index on the condition of every man. They classify them as to whether laborer, cement finisher, form builder, form builder's helper, bricklayer, and so forth. They keep a record at their office and they furnish you a card index record of the same. They also give you recapitulation of the men who are affected with close vision and far vision afflictions. Practically 35 per cent of the laborers on the job needed glasses, but none of the bricklayers. The bricklayers on the job at that particular time were about seven or eight. Their eyes were in pretty good condition, although the jobs before they were finished had 60 or 70 bricklayers. They furnish a blank card to the man, telling him the condition of his eyes and he can, at his own option, either go to this eye sight bureau and get glasses from them to suit his vision at a nominal price of \$9; or if his eyesight

demands stronger glasses, they will furnish them for \$11. They are the best possible glasses obtainable with the best possible frames. You can pick your own frames or nose piece or anything you care to; and with that they will also furnish examination and glasses for any one of your immediate family.

The cursory examination costs General Builders' Association of Detroit nothing; the general examination costs the General Builders' Association nothing. The cursory examination of the man costs the man nothing. The general examination costs the man nothing. And it is optional with him whether he cares to buy the glasses from the Industrial Bureau or elsewhere. He is given a thorough examination and a thorough report so he can get the glasses from them or go to some other doctor and get them.

We can't give you any comprehensive report on it, as we have just started this, but from the experience the industrial plants have had which have been through this thing in the last six or eight months, the claim is that it has reduced accidents; and it has a general tendency to correct the morale of the man from the standpoint that his employer is interested in his own personal gain and is looking after him every moment for his entire safeguard.

CHAIRMAN HARDING: Is there a minute or so discussion on his little presentation? JAMES F. CONNER (The U. G. I. Contracting Company, Philadelphia, Pa.): I would state as a matter of information that on all large operations we have for the past several years had every man examined, not only as to the eyes, but thorough physical examination to see that the man was suited for the job. We have had occasions where, to all appearances, a man was gifted with good eyesight, yet on an examination of the eyes his vision was found deficient practically down to 20 per cent. We have had records. That shows the importance of the eye investigation, especially on construction work, where a man is exposed to the hazards of fall from heights; and in addition to that we go thoroughly into the question as to whether man is subject to any attacks of vertigo. We have had several accidents resulting from that, severe falls.

CHAIRMAN HARDING: We will proceed with the program, which has been termed the new members session.

Safety Campaigns and Stunts

Clifford Penland, Director, Safety Division, Memphis Chamber of Commerce, Memphis, Tennessee.

When I was asked to discuss this subject, I think the idea in mind of the committee was to tell you what is going on in other fields of accident prevention work in a community. I imagine you stick pretty close to your one subject in the deliberations here in the Construction Section. Those of us who are carrying on community programs in a more or less broad way, have to broaden out a good deal and get in the various phases of safety work. For instance, a community organized like Memphis is and like a good many other cities, many of which are represented here, that have local Safety Councils, does carry on an industrial safety work of all sorts. That is, educational programs, home safety, child safety, traffic control or public safety work and various other kinds of accident prevention activities that are designed to reduce and control your community accident problem.

For instance, I will just touch on a few of these things because it may be of interest to you. Consider for a minute the child safety work. It is an important activity, at least we consider it important, because we are teaching the young mind. That is the impressionable time, in the grammar and grade schools, to teach the simple rules of safeguarding his or her life when operating on their own hook. When children are under the supervision of their parents

or teachers in school there is not very much apt to happen to them. But when they are out on their own, by themselves, and they violate certain safe practices or safety rules, immediately our problem becomes an important one, because the child fatality rate is very high in a great many communities. So our programs in schools are designed to impress the young mind with certain safety rules of conduct so that when he is out on his own he acts in a safe way.

For instance, just a simple little rule—look first to the left and then to the right, when you cross the street. That is worked up in little rhymed verses to make it attractive. We feel that if the child, before he crosses the curb, looks first to the left and then goes to the center of the street and looks to the right, he will be in better shape to get across the street safely.

In connection with that activity we think it is important to organize it, and we let the children organize it, in what are known as Junior Safety Councils; and we teach them little stunts, teach them safety songs and have little playlets. The chief idea is to imbue that child with the safety idea. When he grows up we feel we are going to reap the reward in years to come, because when he grows to manhood or womanhood he will be a safe individual.

Teaching the Householder Simple Safety Rules

In connection with our fire prevention work we believe that one of the most important fields of educational work is in teaching the average householder or home owner certain simple rules of eliminating fire hazards from his home. We approach it through the schools. We ask twice a year that the child take home a little leaflet on which there are six questions relating to the safety condition of his home. We offer prizes to the schools that return most of those blanks filled out and signed by the parents. Those six questions that we ask are based on an analysis of our community fire records, causes of our fire loss. We find from a study of our problem in Memphis that rubbish and flammable material in attics and cellars is one of the principal causes of fire. We find also that defective chimneys and flues are another cause; heating equipment that may have to be taken care of, is another cause. Another thing is putting hot ashes into wooden containers and wooden barrels. We know there are six or seven things that cause the trouble and we believe through an educational campaign we can bring about a reduction in the fire loss.

This might give you some idea of how effective this campaign is. We started this two years ago and have conducted three campaigns. It was about a year ago that we actually got into it. We have conducted two campaigns and have had upwards of 20,000 homes in which the children go home and catch daddy by the hand and say, "Daddy, we have to inspect our home for six years." This year we had 400 less firm alarms and 254 less home fires, which indicates to me without question that a simple little campaign like that is effective in a community. You take the average home fire loss and you will see that it runs into real money immediately. If you can, through the child, approach the father and mother with certain simple things, it will be effective over a period of years.

The trend, I think, throughout the local council is away from campaign, safety week and safety months, the chief reason being that more effective work can be done over a period of time. Sometimes you can fan enthusiasm up to a high point in doing a certain job over a limited period, and then you suffer a bad reaction when the week or month is up and things are let down. If you haven't done a good job, haven't made an impression during the one week, you say, "What is the value of these things?"

In Memphis we don't run a week or a month's campaign, we run 52 weeks' campaign. We plan our program on the basis of a year's time. At the end of

the year we start another, with the fire prevention campaign. We observe National Fire Prevention Week because it is a national proposition with the proclamation of President Coolidge. Governors of the states and our Mayor: and we come along with a program of publicity in which we say, "This is the opening of the fire prevention campaign which will be in force 52 weeks in Memphis." We have posters on street boards, publicity in the press, moving pictures, home inspection contests in the schools, and we do a lot of things that sort of focus or put the spotlight on what we are trying to do over a period of a year. That is the value of a week's campaign or a month's campaign. It sort of waves the flag or rings the bell and tells the public what we are trying to accomplish in the community. We want your moral support if we don't get your active support. That, it seems to me, is the value of this work.

In connection with stunts, there are a good many things that can be done and have been done by local councils. I guess you are familiar with a lot of them. We believe that you can go along and do constructive work and dig pretty deep looking toward the roots or causes of your accidents or your fire problem, but you go along and the community won't know what you are doing. So we believe it is a good thing occasionally, as I said a minute ago, to sort of wave the flag and ring the bell and know that the community knows that you are actually interested in this problem and are trying to solve it, or at least control it.

Profitable Stunts in Memphis

We have conducted a few stunts in Memphis to keep the public's mind thinking along lines we want them to, and one or two of them I will mention because they may be rather interesting.

About a year ago we heard of a man named Art Hitchcox, who is an old speedway driver. He is in the field conducting safety campaigns. He will come into a community and stay during a week and will do certain definite things to awaken public interest in the public accident problem. He is only interested in public accident work. Because of the background of his being a racing driver, he immediately appeals to the children, so he drives around in his car which is decorated, "Art Hitchcox," all over it in colors. He has a broadcasting apparatus on the front of his radiator and he put an apparatus on his face and drives up to a playground and talks to the children through a megaphone and gives a safety talk or goes into the luncheon clubs and does the same thing. He is an attention getter, first of all, and second he puts over the safety message. Children like him, and he told them this, which is a sort of key of this talk:

"I have driven as fast as any human ever has driven. I risked my life every day for months and years on the track, and I came to the conclusion it was not worth it. I got out of it, and today I am driving a car and I never exceed a certain speed limit, and I am going to safeguard my life. And you children ought to feel the same way about it."

There is one thing he did which was very interesting. He wanted to stage an accident right down in the business section of town, so he dressed up as an old man. We got the permission of the Public Commissioner of Safety. He put on a wig with whiskers and an old coat and hat and my assistant said he would drive a car and hit him. Just at the busiest time of day he stepped off the curb on a pre-arranged schedule, and this car appeared and he hit it with his can to make a noise and the car was under control. Immediately the woman riding with my assistant screamed and the crowd came. The police

knew what it was about, and we had an ambulance spotted around the corner. The ambulance came up with a clanging of bells to make it as dramatic as possible. Here was Art Hitchcox, kicking and quivering, the last gasp, and here came the crowd, a tremendous crowd, I guess 500 people, in two minutes, and they were jammed as close to him as they could get.

The ambulance came and he was put into it. They started to put him on the shelf and when they did, he said, "Hey, wait a minute here." He pulled off his mask and said, "You are curious, aren't you? You are curious. The only time you think of an accident is when it happens." And he hopped off and gave as fine a safety talk as you ever listened to. It was dramatic. Newspapers played up the whole thing, as it was designed for just one thing and that was to focus the spotlight on accident prevention work in the community.

Another stunt that you may be interested in knowing a little about is one Harry Rogers conducts. He is with the Western Actuarial Bureau. He believes in working with kids, and he got up this little stunt of his, and he calls himself "Smoky, the Fire Clown." He dresses up in a clown's costume and goes to school or any place where he can get a group of kids and puts on this little stunt. He has them count seven about 15 times, and then he says that *seven* out of ten fires are caused by carelessness. When they are out yelling he gives them the safety talk. Very good psychology with kids, because if you talk to kids, they get restless. Harry has a lot of apparatus he sets up and he tries to point out by exact occurrences how these things happen, how fires start. He will take five or six causes of fires and do the wrong thing, make a lot of monkey-shines. The kids yell at him, "Don't do that, that is wrong."

They go home and tell about "Smoky, the Fire Clown."

Marvelous Work Among the Children

Harry Rogers is doing a marvelous work with children all over the country. He traced back one case where a little boy's clothes caught fire and he did the proper thing at the proper time. He rolled over on the ground as fast as he could, all by himself, and his life was saved because his clothes were burned very badly. Harry happened to be in that town and he thought, "I guess I will see who taught the kid to roll on the ground." Without the child knowing who he was, he asked the child some questions and the boy told him, "I learned that from Smoky. Smoky, the Fire Clown, came to our school a few years ago." So Rogers felt very good about it. He knew whether they were getting it, whether they were actually practicing the thing he wanted them to, with the result that he felt encouraged and he continued it; and I think it is a splendid work.

There is one thing I want to tell you about in connection with a stunt and then I am through. This is in connection with child work. I wish the boy that I have referred to was still in the audience. He was sitting there. If you will all attend the banquet tonight you will hear him. Safety Sam from Safety Town and Ready Eddie and Handy Andy. It is a broadcasting stunt that Gerard started in St. Louis. He extended it to the four limits of the country, the idea being that he wants to broadcast little safety stories to children, as a radio program once or twice a week. If you will write in and say that you listened to Safety Sam's story, we will send you a pledge card and a button and you can see it. He has grown to such proportions that he now has 390,000 members.

Handy Andy and Ready Eddie are the two boys that help get this safety work over to the children. I don't think there is any doubt that here is a corking stunt, to keep continually before the minds of children the hazards that are to be found on our streets and at play.

I don't know whether I have fitted in with your program or not. When I was asked to do this, I think it was with the idea of giving you a little cross section, or a little picture, of what a community can do and is doing in a good many of the local council cities to try to impress the public and the people with the importance of industrial safety, home safety, fire prevention, public safety and child safety—all those things we know control and have a very definite bearing on the community accident rate. We want to have our communities safety-conscious. We believe that you can strike specifically at some of these groups. If we can get the whole community thinking in terms of its accident problem and what to do to correct or solve it, or at least control it, why we will have a community which will have a very favorable accident rate and will be a happier place in which to live.

I want to say to the Construction Section that we have had the finest sort of cooperation on the part of the Section of the A. G. A. in Memphis. We were very happy to participate or cooperate in a meeting which they conducted last fall. We believe that through meetings like that a great deal of good can be accomplished, and I think you will find the Safety Councils willing and eager to co-operate and participate in your accident prevention programs. That is what we are there for. We want to help, and we believe that by working together we can accomplish a good deal.

CHAIRMAN HARDING: I am sure Mr. Penland has brought out at least two points for the Construction Section. As construction men we are very often apt to form the habit of our business and our business only. He has brought out one thing, that every effort should not be confined solely to our business, but our duty and our obligation belong to the community as well as to our business.

Another point that struck me was the appeal through the children; what a field that must offer for getting over the safety idea to the men! In some way the construction men can be keyed up through the little children at home. There is no question but what it will be conducive of very big results.

Gentlemen, the time is growing short. I am going to proceed to the next number on the program, "Protecting the Public," by Mr. Siegfried Langner, of the United States Fidelity & Guarantee Company, Chicago, Illinois.

Protecting the Public

Siegfried Langner, Industrial Engineer, United States Fidelity and Guaranty Co.,
Chicago, Ill.

By protecting the public the contractor protects himself. The value of good-will cannot be overestimated and progressive business people are realizing more and more the advantages derived from catering to public opinion and considering the public welfare.

Lawsuits are expensive. Insurance rates are based on experience for which the individuals carrying insurance are responsible. Investigating accidents takes valuable time of foremen and superintendents. An injured person must usually have immediate medical attention. The time of the superintendents and foremen who are present is just as valuable as the doctor's time. The insurance company pays the doctors and lawyers, but contractors pay the superintendents and foremen. The contractor contributes largely to the expense of gathering legal evidence. We wonder why we have such large overhead costs. Accident costs not covered by the insurance policy are not usually given their due importance. It is safe to say that in the long run these costs amount to more than the losses covered by the insurance policy. There are many accidents and near accidents which result in no

cost to the insurance company, but which interrupt the production schedule and take a great deal of time from the contractor's employees. Safety measures are certain to eliminate a large majority of these accidents.

There is an advantage gained from protecting the public which should not be overlooked. The employees are simultaneously protected. It is assumed that every executive appreciates the material advantages gained by the protection of his employees. I have found that large contractors readily see the wisdom of this work and it is the small contractor who is more likely to be lax.

Competition is a wonderful stimulant to trade and there should be competition in order to keep things moving in the direction of progress, but in order to afford public protection we must have *sane* competition. Today we are in an era of speculative building and there is a tendency to shop prices, which develops into cut-throat business which leads to disregard for the safety to which the public is entitled. For example, there is an instance where a large city contractor submitted his bid for a job and later discovered he had omitted his profit, his confirmed price being the bare cost of labor and material. He felt sure of obtaining the contract and was greatly surprised to learn upon interviewing the owner that his competitor had taken the job for 10 per cent less than his cost. This was done without refiguring or changing, just for the sake of getting the job. The contractor who takes a job under these conditions cannot afford the safety measures that are required and always tries to follow other methods, which have proved disastrous in the end. When the owner realizes that cheap competition does not pay, we will have gone far in a start toward protecting the public.

Isolation of the Big Construction Job Desirable

Of course, the most complete protection would materialize from isolating the public completely from the range of construction activities. Streets should be closed whenever practicable. In some parts of the country it is the practice on large jobs in heavy business districts to carry on hazardous operations such as hoisting heavy material and blasting at night or in the early morning. It is reported that this was done in constructing the Paramount Theater Building in New York City. The light pedestrian or vehicular traffic existing at these times facilitates such operations. Since it is not practical in the majority of cases to follow this procedure, it is necessary to analyze hazards and eliminate them whenever possible. Some people think that accidents just happen, but in reality every accident is caused. You can analyze any accident and find that the responsibility rests on a person who didn't think or who took a chance. Is it ever impossible to eliminate a hazard which comes to our attention? It is the duty of every executive who thinks that a particular hazard is inherent to his business and cannot be eliminated to ask for advice. Unfortunately too many contractors do not appreciate this; they think that because they cannot see a remedy there is none. The day of the jack-of-all-trades is gone. Today we are accomplishing things never dreamed of twenty and thirty years ago. This is due to specialization. In order to be successful today we must specialize in this new idea of safety and its promotion.

Children are the greatest sufferers and contribute the largest portion of public liability cases. In the child's mind a construction job is an ideal playground. We have a case of children playing in a sandpile located near an open manhole. One of the children sliding down the pile head first fell into the manhole and fractured his skull. In another instance some small boys were walking the edge of a mortar box which was left unprotected. One of the boys lost his balance and fell into the box, receiving third-degree burns on his body and limbs. One of the burns developing to such an extent that the tissues were eaten away from the knee to the bone. The ultimate results was a 50 per cent loss of one of his legs. On one of our risks,

children were allowed to play in the vicinity of the work during the working hours. One child was walking under the concrete mixer as the hopper was lowered. This resulted in a fractured skull. Children are continually being hurt while playing in piles of stone, brick and other material. If they are allowed to take wood away from the premises, this should be put in a place for them where they would not be exposed to hazards of the operations. These problems can best be met by isolating the job as far as possible by fences and railings and by educating the employees to the extent of discouraging their friendly relations with children around the premises.

Probably the most common cause of serious accidents to the public resulting from construction operations is that of falling articles such as planks, tiles, bricks, tools, hot rivets, etc. We have a case where a heavy windstorm blew a plank from the top of a building which was so near completion that the canopy over the sidewalk had been removed. The plank fell, hit the sidewalk, and on the rebound struck a woman breaking her hip. Tools and material should never be left in a position where vibration or wind would cause them to fall. Hot rivets should always be thrown toward the center of the building. Extreme care should be taken in constructing staging, hoists, etc. Trash chutes should be located so that the openings will be isolated as far as possible. Mechanical equipment on a job should be given frequent rigid inspections. Derricks, engines, cables, etc., should not be used to the point where they fail mechanically.

Fundamental Knowledge of the Strength of Materials

Every man connected with the design of hoistways, stagings, landings, runways, canopies, etc., should have a fundamental knowledge of the strength of material. The man on the job who designates work for the different apparatus should be familiar with the safety limits of the apparatus. Superintendents and foremen should be equipped with charts and tables showing the safe loads of the different mechanical equipment on the job. They should be told how to determine when ropes, cables and other equipment have depreciated to the extent that they are unsafe. Employees should be educated to watch for any conditions which might result in an injury to one of the public.

There are a great many causes contributing to the large number of cases of persons falling. Walkways should be kept in repair and there should be no holes or loose boards. Leaky waterlines in the winter time result in ice-coated walkways. These conditions invite groundless as well as justified cases of public liability. All protruding obstructions should be well marked, no loose material, tools or equipment should ever be left in the temporary sidewalks or walkways used during construction operations. Wherever railings are used they should be strong and substantially constructed to serve for something more than just a guide.

On one occasion we had a claim resulting from a woman who while attempting to board a street car fell into an excavation made for a sewer line. The street had been closed to traffic and the ditch was guarded by means of planks laid across small piles of brick about two feet wide spaced at intervals of approximately eight feet. Since these planks were simply resting on the bricks they were easily pushed away. While attempting to board the street car in company with a crowd of other people the injured woman was pushed against one of the loose planks and fell accompanied by the plank into the ditch. The plank contributed to her injuries. A lawsuit developed which resulted in her collecting for damages to herself and clothing. There are many hazardous conditions around a job which can be remedied by the night watchman. He could repair holes, loose planks in the walkways and straighten out protruding objects. It is important that a responsible person be employed as a night watchman, one who can see the wisdom of this work and will take it upon

himself to look for and eliminate as many hazardous conditions as possible during his working period.

Construction operations invite trespassing. There is no reason why there should not be a "No Trespassing" sign on every construction job. Superintendents and foremen should know when there is a stranger on the job, and instead of ignoring him should try to ascertain as soon as possible his business, and if he has none send him away.

In general, we have a great many accidents occurring from blasting, premature explosions, overloading canopies, cavings, nails and glass, hoisting heavy material, etc. I think the case of protruding nails should be emphasized. This is a common hazard which often results in a very serious condition, such as infection, which may cause amputation or even death. It is a simple matter to eliminate these nuisances if given attention. The contractor is seldom held responsible for motor vehicle collisions caused by blind corners, created by storing construction equipment and material in the street. However, he is morally responsible unless he puts up proper signs, warning drivers of the condition. Material which is protruding into the street should be marked and well lighted at night.

Three Principal Groups to Be Influenced

In a broad sense, education is the fundamental solution of these problems. When research and experience has proved a certain theory, any reasonable person will have faith in that theory if it is presented in the right manner. There are three principal groups, each of which must be educated in a different way, and each must be given a good reason why it should adopt safety measures. The first group is made up of architects, engineers, contractors and those officials responsible for the methods used in building. The contractor must be made to realize his responsibility to the public and his duty to himself. He can be reached through his trade journal, through his association with other contractors, and through sad experiences which are bound to come to him and others if they do not heed the call of safety.

The second group is the public. It is far more difficult to bring before the public the importance of avoiding construction operations. Complications of civilization have created innumerable hazards with which the public is unfamiliar and it will be a big job to thoroughly acquaint them with these hazards. The best plan is to keep people away from construction operations as far as possible. This can best be accomplished by teaching them that construction operations are hazardous. Education is a slow process and takes considerable patience. We are trying to sell an idea. We must take advantage of those selling conveyances which are at our disposal. We must advertise. We must give safety publicity at every opportunity. We should have safety organizations in every community. All news items dealing with accidents should be brought out with emphasis and contain safety comments. Safety should be advertised with the purpose of having it voluntarily adopted and not with the idea of inflicting it against the individual will.

The third group, the employees, must be made to realize that an important part of their job consists in regard for the public, regard for their fellow-employees and regard for their own safety. The most advantageous time to impress these men is when they are applying for work. If on being questioned as to their attitude toward safety they indicate favorable reactions, they will have no complaint when criticized for their carelessness when on the job, and it will be easier to organize them for safety meetings. It should be emphasized that a careless employee is a liability rather than an asset.

This problem should be dealt with from two angles. First from the humanitarian standpoint, and secondly from the standpoint of economy. Every individual can be convinced on these two points. Every employee should be made to prove

that he is a safe worker and the unsafe worker made to learn that he is not wanted until he has learned that safety is part of his job. To make a job safe it is necessary to have men who realize the importance of safety. When the employees are all on their toes and pulling for safety the most practical provision has been made toward the solution of our problem, protecting the public.

CHAIRMAN HARDING: Is there a minute or so for discussion on Mr. Langner's paper?

SECRETARY ROBINSON: There is one member of our Section who is not with us at this Congress, due to illness in his family. I am referring to Mr. Austin of the W. E. Wood Company, who was chairman of this Section for two years, and I don't know of any one who has accident prevention closer to his heart. I don't know of anyone who has done more in promoting accident prevention work in the Construction Section than Mr. Austin. I think it would be very appropriate that this Section send him a telegram letting him know that we have missed him at this Congress. I think this is the first Congress he has missed for some time.

WILLIAM F. TUBESING (William F. Tubesing Company, Milwaukee, Wis.): I second the motion.

CHAIRMAN HARDING: Mr. Austin has been a very faithful worker on the Construction Section and I am glad you made that suggestion. He spent a good deal of time and effort in the Construction Section. Will the secretary telegraph Mr. Austin? I understand he was not able to be here on account of an accident in his family. I think the Section would do well to go on record by sending a telegram to Mr. Austin.

Commendation for the Work of Mr. Austin

F. A. DAVIDSON (American Safety Device Company, New York, N. Y.): It is not often we have an opportunity to say what could well be said about Mr. Frank Austin in connection with safety. It has been mentioned in this motion that he has been a faithful officer of the Section, and so forth. He has done far more than that. I am sorry occasionally that I can't speak what I have in my mind with well chosen words because Mr. Frank Austin a most exceptional individual. The work he has done for safety is far more than any routine work or work as an officer in connection with our Section here. Mr. Austin's work, in my mind, can well be described as the work of a great man. There is no individual in the whole construction industry who has done so much for accident prevention. Mr. Austin is the president, and has long been one of the chief operating officials of his company, a large company in Detroit. Year after year, when numerous important individuals in the construction industry were sending down young men, assistants and so forth to pick up ideas and contribute to the Construction Section meetings, Mr. Austin, at a cost which I have realized more and more, has come down to these meetings in person.

He did more than any other single individual to promote accident prevention when the Construction Section was a pretty rugged, thin, red line (as Kipling said), a thin red line of chaps around here (and even today we are just getting started), and Mr. Austin, more than any other man, deserves the credit for the progress in accident prevention made in the construction industry of America.

CHAIRMAN HARDING: Now we come to the close of the Construction Section, the Tenth Meeting. I want to take this opportunity to thank Chicago for the welcome they have given us here. I want to thank the speakers who have contributed to these two sessions. I want also to thank the members of the Executive Committee who have served during the past year. I am sure any progress or any accomplishments that have been made in the Construction Section are due to the members of the Construction Section aside from the chairman.

In closing I want to bring before you the need, and more than the need, the necessity, for the cooperation of you members of the Construction Section of the National Safety Council. The success of the Construction Section depends not only upon the individual and collective efforts of the Executive Committee, but the burden also rests on your shoulders. The National Safety Council was organized some sixteen or seventeen years ago, at a meeting of some forty individuals representing perhaps forty different industrial activities, who got together in the face of some legislation and talked accident prevention. They didn't know whether it was going to cost them a million dollars or make a million dollars for them, but they got together. After talking this thing over they realized they must appoint one man whose duty it would be to search out, answer questions and ask questions on what these forty individual concerns were doing toward accident prevention work. They determined upon a man who was to devote his full time to it. One of the forty men would say, "Here is my problem." In turn the other thirty-nine would get this question. Maybe he got two responses and maybe he got thirty-nine responses. Those in turn were sent back to the original man who asked the question.

Those became quite interesting. Some of the industrial concerns put them on their bulletin boards or other boards in their plants so that the men might see them. The men took an interest in them, would read them, would read the first one with a great deal of interest and enthusiasm. They would read the second. Perhaps at the third or fourth they would glance at it and turn over a few pages and say, "Well, that is too long," and then they would pass on. Complaint was sent back, "That information is too long, condense it a little."

That was done. Suggestion was also made that they illustrate the point that was to be brought out. That was done. That was the inception of the poster as we know it today. These questions that were put before the paid man became numerous, the answers became quite lengthy as various problems were brought up. After a while they were bound up and sent out to the members. That was the start of the NATIONAL SAFETY NEWS.

The reason I have brought this up, gentlemen, is this: You have a problem and I have a problem and this man over here has a different problem. This man has been up against the same problem and has solved it. This man over here has done the same thing. If you will bring your problems to headquarters they will be analyzed, your questions will be answered. You will get the benefit of the National Safety Council's research. You will get the benefit of the individual members who have gone through the same thing. The National Safety Council, after all, is nothing more or less than the hub of a wheel in collecting and dispensing accident prevention work, and we as a Construction Section have our own problems. Our individual members have their own problems. Bring them before us. If we can't answer them we will admit it, but we won't drop the subject there. We will try to devise ways and means for answering.

And with this parting thought we will close this session. The strength, the growth and importance, of the Construction Section rests upon the members of the Executive Committee. We will try to do our part. Will you?

ADJOURNMENT.

SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Electric Railway Section

New Section Officers

- Chairman*, A. W. KOEHLER, The Milwaukee Electric Railway and Light Co., Milwaukee, Wis.
Vice-Chairman, H. K. BENNETT, United Electric Railways Company, Providence, R. I.
Vice-Chairman, E. K. EASTHAM, The United Railways of St. Louis, St. Louis, Mo.
Vice-Chairman, MELVIN W. BRIDGES, Chicago Rapid Transit Company, Chicago, Ill.
Secretary, J. E. STOTT, Georgia Power Company, Atlanta, Ga.
Poster and Slide Committee Chairman, L. R. BROWN, New York State Railways, Rochester, N. Y.
Membership Committee Chairman, W. H. BOYCE, Pittsburgh Railways Company, Pittsburgh, Pa.
Publicity Committee Chairman and News Letter Editor, BUELL W. NUTT, The Safety Equipment Service Company, Cleveland, Ohio.
Program Committee Chairman, GLENN H. SHAW, Northern Ohio Power & Light Co., Akron, O.
Engineering Committee Chairman, W. F. HANNA, United Railways and Electric Company, Baltimore, Md.
Executive Committee, THE OFFICERS AND—
R. W. EMERSON, The Cleveland Railway Company, Cleveland, Ohio.
G. T. HELLMUTH, Chicago North Shore and Milwaukee Railroad Company, Chicago, Ill.

Retiring Officers

Chairman, R. W. EMERSON, The Cleveland Railway Co., Cleveland, Ohio; *Vice-Chairman (Motor Bus Operation)*, A. W. KOEHLER, The Milwaukee Electric Railway & Light Co., Milwaukee, Wis.; *Vice-chairman (Interurban Transportation)*, H. K. BENNETT, United Electric Railways Co., Providence, R. I.; *Vice-Chairman (Urban Transportation)*, E. K. EASTHAM, United Railways of St. Louis, St. Louis, Mo.; *Secretary*, J. J. CONNORS, The Tennessee Electric Power Co., Chattanooga, Tenn. *Committee Chairmen: Program*, SAMUEL H. REID, Bureau of Safety, Chicago; *Poster*, J. E. SCOTT, Georgia Power Co., Atlanta, Ga.; *Membership*, W. H. BOYCE, Pittsburgh Railways Co., Pittsburgh, Pa.; *Publicity*, BUELL W. NUTT, The Safety Equipment Service Co., Cleveland, Ohio; *Recommendations*, A. L. HODGES, The Brooklyn City Railroad Co., Brooklyn, N. Y.; *Cooperating with Claims Assn.* A. E. R. A., G. T. HELLMUTH, Chicago North Shore & Milwaukee Railroad Co., Chicago, Ill.; *Engineering Representative*, CLINTON D. SMITH, Beaver Valley Traction Co., New Brighton, Pa.

Tuesday, September 27, 1927

RALPH W. EMERSON, Chairman
Vice-President and General Manager, The Cleveland Railway Company,
Cleveland, Ohio

The first session of the Electric Railway Section, National Safety Council, was called to order at nine-fifty o'clock by the chairman, Ralph W. Emerson, vice-president and general manager, Cleveland Railway Company, Cleveland, Ohio.

CHAIRMAN EMERSON: It is gratifying to see such a large attendance at this Sixteenth Safety Congress. At a convention held in Boston some eight years ago, the Electric Railway Section was represented by less than ten persons. In the years which have intervened, there has been a steady and very rapid growth in our membership. Such a phenomenal growth must have had a reason. I think the principal reason is the fact that the railways of the country are coming to realize the necessity of systematic accident prevention work as a very vital part of their operation. They are devoting as much time and attention, probably, to this new activity as they do to any other function of railway operation.

It is true that many railway properties have been slow to recognize the vital necessity for combating, in a systematized way, the conditions existing on our streets and highways; a condition which has been brought about through no activity or fault of our own, but which is the outgrowth of the tremendous increase in the use of gas propelled vehicles and the necessity for speeding up operation with safety.

The fact that our membership has grown in such a degree is evidenced by the fact that today we have over two hundred properties represented, drawn from all over the United States and Canada. The fact of this membership indicates that they recognize in the National Safety Council a medium which is most helpful to them in carrying on their individual activities.

I trust that you gentlemen will find the program which has been prepared for you of great helpfulness. Like modern dresses, we have tried to make it long enough to cover the subject and short enough to be interesting. We want the meeting to be snappy. We have allowed ample time for discussion, and I hope that anyone here who has a question in his mind about any paper will not hesitate to ask that question, and I hope that he will find the answer.

We are going to discuss a great variety of subjects. Our time is more or less limited, and in order to hold ourselves down to the limitation, I may have to call on this device here on the table which you all recognize. It may be necessary for me at times to turn on the red light. This is a safety meeting, and I want it to be absolutely safe for the audience.

We will now proceed with the presentation of new members. I would like to ask the representatives of the various delegations here to please rise and present the men they have brought with them.

(The Pittsburgh delegation arose.)

CHAIRMAN EMERSON: Are there any other delegations here?

(The delegates from St. Louis arose.)

(The Milwaukee delegation arose.)

CHAIRMAN EMERSON: We have a representative here from Canada. I have a letter from the Canadian Electric Railway Association stating that Mr. Arthur Gaboury is representing the Canadian Safety Section. Will you please rise, Mr. Gaboury?

Are there any other delegations that are newcomers?

(The Chicago, South Shore and South Bend Railway delegation arose.)

CHAIRMAN EMERSON: I understand that your property will be represented at each session of the Section with a different body of men.

Are there any others, individuals or groups that are newcomers?

(P. J. McGrath of the Amalgamated Association of Street & Electric Railway Employees of America presented himself.)

(M. Pasche of the Chicago Surface Lines, Chicago, Ill., presented himself.)

H. A. BRIGGS (San Antonio Public Service Co., San Antonio, Texas): I am from the San Antonio Public Service Company. I am equally divided between electric railway and public utility.

(G. L. Robertson of the Alabama Power Co., Montgomery, Ala., presented himself.)

(W. L. Fagan of the Illinois Traction System, Springfield, Ill., presented himself.)

(T. H. Kendrigan of the Public Service Company of New Hampshire, Manchester, N. H., presented himself.)

(W. J. Harvie of the United Traction Company, Albany, N. Y., presented himself.)

(F. W. Flannigan of the Chicago, Aurora & Elgin Railroad Company, Wheaton, Ill., presented himself.)

Reports of the Section Committees

EDWARD McMORROW (Amalgamated Association of Street and Electric Railway Employees of America, Detroit, Mich.): I claim a double representation. I am a member of the Pittsburgh delegation as well as being the representative of the American Association of Street & Electric Railway Employees of America.

A. J. VAN BRUNT (Public Service Corp. of N. J., Newark, N. J.): I want to say that the Public Service Corporation of New Jersey is very ably represented here.

CHAIRMAN EMERSON: We will now proceed with the reports of committees. I will call on Mr. Reid who has something to say to us about the Program Committee.

SAMUEL H. REID (Bureau of Safety, Chicago, Ill.): Arrangements have been made for the members of this Section as well as the Public Utilities Section to visit certain points of interest on Thursday afternoon. One trip is to the new Crawford Avenue Station of the Commonwealth Edison Company, which is, I think, the largest in the world. The other is the Chicago By-Products Company, which is about the last word in gas station construction and operation. Another trip is one or two of the shops of the Chicago Surface Lines, and part of the new shop of the Rapid Transit Company at Niles Center. We have arranged for free transportation to these points of interest.

CHAIRMAN EMERSON: Mr. Stott, will you give us your report of the Poster Committee, please?

J. E. STOTT (Georgia Power Company, Atlanta, Ga.): During the past year, two electric railway posters were issued each month. Very few suggestions for electric railway posters were submitted to the Poster Committee or to the National Headquarters. To those who did offer suggestions, the committee want to give thanks. Those who did not supply any ideas are urged to cooperate with the new Poster Committee and give them some material on which to work.

Posters play a part in accident prevention, the same part that advertisements play in selling the product. It is the silent salesman selling safety. The more and better posters we have, the more interest in accident prevention work we will create. Ideas are needed.

The new Posters Committee can usually think of new subjects, and can manage to get out a few each month. They may or may not, however, be the kind needed by the member companies. When every member of this Section takes advantage of

the opportunity to offer suggestions, the Poster Committee can publish more and better posters.

CHAIRMAN EMERSON: Mr. Boyce, we would like to hear from you in regard to your report on the Membership Committee.

W. H. BOYCE (Pittsburgh Railway Company, Pittsburgh, Pa.): I am very sorry, but I didn't know you had me scheduled to make a report.

I know this: That we lost ten old members and took in eleven new members. Fortunately for us, the majority of these that were lost were comparatively small companies, while we took in such companies as Winnipeg, Canada, Toronto, Canada, Brazil and Australia.

Thanks to Mr. Emerson and a number of the District Chairmen who agreed to assist me in this work, we have been able to make the record that Mr. Ernst will tell you about. I dictated one letter, and Mr. Ernst did the rest.

F. W. ERNST (Pittsburgh Railway Co., Pittsburgh, Pa.): The New York State Railways is new. The Department of Street Railway in Detroit is new; and that, by the way, is just one section. The Chicago, South Shore and South Bend is new. The Melbourne and Metropolitan of Australia is new. The Anglo-Argentine of Buenos Aires is new. The Toronto Transportation Commission of Canada is new. The Central Power and Light Company of San Antonio, Texas, is new. The Pere Marquette Railway of Detroit is new. The Cleveland, Southwestern Railway and Light Company is new. The Lake Shore Electric Railway Company of Cleveland is new.

Fifty-Seven New Railway Property Affiliations

CHAIRMAN EMERSON: I would like to ask Mr. Boyce about the railway properties that are affiliated with public utilities. I understand there are quite a number.

MR. BOYCE: There are 57 new affiliations, I believe.

MR. ERNST: As a result of our writing to various roads, we found there were quite a number that already belong. We also found a number who were already members of some utility corporation; 60 of them, I believe.

MR. BOYCE: I want to say this. That the most surprising thing to me is to find a small company, which would naturally mean a comparatively small membership fee, that says they cannot afford to belong to the National Safety Council. That is their excuse. One reason they give is, the receipts are too low. Another reason is, expenses too high. Probably a third excuse is, the company is in the hands of receivers. I ask you gentlemen here, boosters for safety, how do they expect to keep their expenses down and out of receivership if they don't belong to the National Safety Council and keep their accident expenses down through every avenue that is open to them?

CHAIRMAN EMERSON: Mr. Nutt, will you please give us your report on the Publicity Committee?

B. W. NUTT (Safety Equipment Service Co., Cleveland, Ohio): I assure you it has been a great pleasure to get some publicity for this Section. I think you are more or less familiar with what has been done. The getting up of the News-Letter was the one important thing we did this year. The changing from the mimeographed letter to the regular printed pamphlet was a big improvement.

We have also been very successful in getting into the various trade journals articles on safety. Probably a great many of you men have read them. We were also successful in getting the NATIONAL SAFETY NEWS to publish, I think, three major articles. Usually it is difficult to get more than one. We were successful in getting about three. I think all told we had something like 14 articles devoted entirely to safety in other magazines.

Our efforts have been helped along very much by the members of the Section. I don't know very much about railway operation. I had some fine cooperation

from the men who are capable of discussing the problems in this Section. I wish to thank those who did contribute for their time in getting these articles up.

I think a considerable amount of good can be done by furthering safety not only in the trade papers, but in other journals generally throughout the country. Newspaper articles could be very well worked up, inasmuch as you are in such close contact with the public. If you will make an effort to see that some of these articles are put in the local newspapers, it will be very helpful. I think that is a thing that can be done by the membership generally better than by a Publicity Committee. If you will help do this, you will get in your own Section some very favorable reactions.

The articles that have appeared have covered quite a range of subjects in safety, and I hope that next year you will help your Publicity Chairman, whoever he may be, by contributing more of these articles. I have received a number of comments, showing that they are really appreciated. If, when you read your News-Letter, you find a request for some suggestions for news or something of that kind, make it your business to get in touch with your chairman. He will certainly appreciate it.

The News Letter in Pamphlet Form Approved

CHAIRMAN EMERSON: Mr. Nutt, I am sure the Section and the officers appreciate very much the splendid work you did on the News-Letter during the past year.

MR. NUTT: We were fortunate in being able to get the National Safety Council to agree to publish the letter in the form of a printed pamphlet. I just want to warn you that unless some drastic steps are taken this year, we will have to go back to the mimeograph form of letter.

CHAIRMAN EMERSON: Mr. Hellmuth, do you wish to make a report at this time on your connection as chairman of the committee on cooperation with the claims committee?

MR. HELLMUTH: In 1926, as a result of action taken in 1925, and again this year, 1927, there has been a committee on cooperation of the Electrical Railway Section and the Claims Association of the American Electric Railway Association. That committee on cooperation in 1926 was appointed to arrange for the appearance of the president of the National Safety Council (last year, Charles B. Scott), before the Claims Association at Cleveland, and Mr. Scott talked to the Claims Association on the object and purposes of the Electric Railway Section and Safety.

There is so much similarity between the work of our Section and the Claims Association that we have many points in common, and indeed we have many members of the one who are also members of the other. I see in the back of the room now my friend H. K. Bennett, who is a past president of the Claims Association, and who has been very active in work for the Electric Railway Section.

Not to be outdone this year by what was done last year, and through the work of Mr. Emerson, our chairman, who has been tireless in his promotion of the work of this Section, it has been arranged that Lucius S. Storrs, who is managing director of the American Electric Railway Association, will address us at the joint luncheon to be held on Wednesday.

There will be a talk before the Claims Association at Cleveland next week by James P. Barnes, president of the Louisville Railway Company on "The Value of a Local Safety Council." He is to be the representative of the Electric Railway Section at that meeting. That, of course, is as good a subject and presents as good a speaker as the Electric Railway Section could possibly want to tender to the Claims Association. Mr. Storrs also is to preside while here at a general meeting.

CHAIRMAN EMERSON: I think that concludes the reports of Committee Chairmen. Before proceeding with the regular program, Mr. Reid has an announcement to make.

SAMUEL H. REID (Bureau of Safety, Chicago, Ill.): I just want to say a word with reference to the program. I want to take this opportunity of expressing our appreciation to those who have consented to discuss questions and certain subjects before this Section. When this program was prepared, we selected those whom we thought were competent to discuss the subject assigned, and no man was selected because of any position he occupied; at least, that was not the determining factor; but selected because we thought he was qualified to discuss the question assigned to him. I want to express the appreciation of this Section and the Program Committee for the splendid way in which all of these men have responded to these requests.

CHAIRMAN EMERSON: If there is nothing further, we will proceed with the program as outlined for Tuesday morning. I will call first on Mr. Truman Curtiss, superintendent of Transportation, Chicago, Aurora and Elgin Railroad Company.

Synopsis of the Best Things Which Have been Brought Out in Previous Congresses

**Truman Curtis, Superintendent of Transportation
Chicago, Aurora & Elgin Railroad Co., Chicago, Ill.**

The subject assigned to me would appear easy to write a paper on, but when we review the subjects handled during the past Congresses, as particularly for the past eleven years, we find them all not only interesting but each paper has filled some particular place in the building of this great Safety Movement, and if we were to eliminate any of them, it would be like removing a pillar from a great super structure. Probably never in the history of any organization has there been such a brilliant collection of master minds, all imbued with the spirit of the saving of human lives. These men were all thoroughly conversant with their task, because they came from the rank and file of the officials who handled the problems of accidents as their particular duty where they were employed.

During the 1916 Congress, we find the adoption of several safety rules that have been put into practice on nearly all transportation lines; all of which are recognized as foremost among safety achievements. I call your attention to a few of these:

First: Universal adoption of near side stops.

Second: Precautions against accidents at grade crossings by installation of uniform "Danger" signs. Providing crossing flagmen with a disc sign twenty-four inches in diameter painted white with the word "STOP" painted thereon in black letters five inches high, instead of the vari colored flags. The uniform paintings of all crossing gates with alternate diagonal stripes of black and white.

Third: Educational campaigns for employees to be followed by a regular organization of follow-up methods.

Fourth: Compilation of data in regard to car equipment, such as whistles, corrugated or anti-climbing buffers, controller lock, dead man's grip, signal lights for doors, safety signs on cars, safety tread on steps, tail lights, flags, fuses and many other details. Most of the Electrical Railway properties placed these safety recommendations into effect.

The mechanical part was easily handled; it only meant so much money for installation, but the education of the employees did not seem to progress as fast as it had been planned. Some properties sought to educate their employees by letters and printed matter while others called meetings of the employees and read a skillfully prepared paper to them and then dismissed them without

asking them to voice their opinions. Several properties appointed safety supervisors whose duty it was to enforce safety rules, but the individual interest was still lacking, the very thing needed for the success of this great movement. Mr. Hemming, of the Fort Wayne and Northern Indiana Traction Company, in analyzing the thing from time to time, stated he had found one obstacle and that was the fact that we were trying to cure all of the ills by mechanical devices. Mechanical devices are no better than the human factor behind them. It is the human factor we have to deal with and if that fails, your mechanical devices fail.

In the Congress of 1919, F. R. Phillips, superintendent of equipment, Pittsburgh Railways Company, in his talk on "The Human Factor in the Safe Operation and Maintenance of Rolling Stock," made an interesting reference to "The Personal Appeal" which so impressed me that I believe this paper would not be complete without it. He stated in part:—

Importance of the Personal Appeal

"A personal appeal, however, to be effective, must be clothed with sincerity and earnestness of purpose. We must neither preach, patronize nor command. Moreover, if a personal appeal to an individual is to be productive of the greatest good, we must first establish the right to make such an appeal. The mere fact of your being the superior officer does not give you that right. How, then, shall we establish that right?

"At this time of the golden harvest when the sower is reaping his reward, may we not with profit look to our farmer friend and his method? When he desires to secure the greatest result from his effort, does he take the seed haphazardly and plant it with the thought that since he is the owner of the seed and soil, therefore, by right of ownership and superiority to seed and soil, success must come? Hardly! He adopts more practicable and sane methods.

"He first chooses the field which gives the greatest promise and is best adapted to the particular crop under consideration. He plows and plows deep, and in a certain way, and at a certain time. He discs, harrows, and drags the soil, until it is mellow and sweet. In other words, he carefully prepares the seed bed. Furthermore, the seed is chosen after much thought and experiment before planting. Then he cultivates again and again, and in the fullness of time, his efforts are rewarded, we are told, an hundred fold. The plant endures through hail and wind and storm. Sometimes his efforts fail, but rarely.

"If we are to be successful in our relationships with men, we must eschew subterfuge and insincerity, and without other purpose than mutual good, meet them on their own plane. Cultivate their acquaintance until we know them and know them by their first names. Know their families, their associates, and home surroundings—their hopes, joys and sorrows. In other words, there must first be prepared the seed bed of mutual understanding. Judgment and due regard for the other's welfare and viewpoint must be exercised in planting the seed of desire, and the growing plant must be nurtured and cultivated until it blossoms forth into the maturity of accomplishment. Then, my friends, may the winds and storms of demagogism, bolshevism, and all other isms of social unrest come, a relationship founded upon such mutual confidence and respect will weather the storm.

"Perhaps the importance which a personal appeal to the individual occupies in safety work may best be emphasized by reference to the results of observations made by the writer during the pre-war period. A personal examination into the underlying causes of a large number of accidents of

major and minor degree covering a period of several months, showed that over 93 per cent were the result of man failure and less than 7 per cent to equipment failure. In practically all of the accidents charged to equipment, there were evidences of lack of proper care on the part of some individual. I can recall but two or three cases directly chargeable to defective material. One, a broken brake rod—one, a frozen air brake, and—one, a defective axle, which developed in the gear fit. The accidents under observation included collisions, derailments, controller burnouts, and others of a similar nature."

To me, the discussion by John H. Mallon, then safety engineer, Metropolitan West Side Elevated Railway, in that meeting, sounded the keynote for the stimulation of interest by the employees when he stated:

The Keynote for Stimulation of Interest

"It seems to me that cooperation in safety work on an electric railway should come from the top; that is, the example should be set by the heads of departments. Some years ago I worked under a general manager who had been with a steam railroad and his idea of railroading was to keep the various departments fighting all the time, so that they couldn't get together to frame up something. He was working, we now realize, against himself. The real big success of our organization is due to the character of our officials. Some three or four years ago our President, Mr. Budd, called in the heads of the departments and instructed them that in disciplining the men of whom they were in charge, the greatest patience was to be shown. 'Don't suspend a man on slight provocation; don't impose a hardship upon his family,' is our rule. We have gotten wonderful results. I met our president last Monday when he came back from his vacation. He was in a hurry but when he saw me he let the elevator go, came back and said 'Hello, Jack, how are you feeling?' That is the spirit that is all through our organization. You can't set yourself on a pinnacle because you are a step above the other fellow. That day has gone. When the boys began to return from the war, the president of our company said to me, 'I want to see any of those boys who come back. I want to say hello and to shake hands with them.'

"He would say to them, 'How do you feel? Do you need any money? If you do, Jack will fix you up.'

"If they needed any money I would give them advance pay until they had an opportunity to get settled again.

"I think the most effective way of getting real safety results is for the man who observes a violation of safety rules to tell the man at the time that he has done wrong. Strange to say, few of us have the nerve to do it. Instead, we go to the office and write a letter to some one else to tell him about it."

"Today we realize the wisdom of Mr. Mallon's statement and the far reaching effects of Mr. Budd's policies which have stood as a bulwark against all adverse criticism of the dissatisfied employee, until today a man who does not believe in safety is an outcast among the employees in all branches of the service by the action of the rank and file themselves. I do not know of any one act that would draw more disfavor from an employee co-worker than to have him scoff at safety.

Again in the 1920 Session, Mr. Mallon, then assistant general superintendent of transportation, Metropolitan West Side Elevated Railway Company, Chicago, forcefully brought out the following points in his paper entitled "Duties and responsibilities of Foreman and Men in Advisory Positions with Reference to the Safety of Men Under Their Jurisdiction."

"Selection of foremen: Attitude of chief executive reflects on subordinates. Interest must begin at the top, efficiency and safety are inseparable, the kindly word of caution registers"—and in closing he said, "I know of no better rule for the foreman to follow than: 'Do unto your subordinates as you would have your superiors do unto you.'"

With the education of the employees we should aim to impress them with their individual responsibility, that the matter of safety is their first duty which should receive their personal attention at all times.

I have reviewed with much interest the Bonus and Award Systems. I believe in some form of recognition of special service by an employee. It might be by letter, by personal compliment, by giving the employee a day's vacation with full pay or reimbursed for loss of time; but I hardly feel that it is proper to pay a man wages for doing his work and then a cash reward for safety. An employee should feel that safety is part of his duties and not a special duty for which separate money should be paid.

I believe that every accident should be thoroughly investigated by taking the employees involved in on the investigation. All details should be considered and a study made of how the accident could have been avoided. In all accidents there must be a cause, and a careful study will almost invariably reveal a contributing cause where an employee could have helped to avoid the accident, and the time to impress the employee is while the accident is fresh in his memory. Investigation of the minor accidents will no doubt prevent larger ones. Employees are not all alike, some of them may be reasoned with, an appeal to their pride may reach others, to compare the public with their own family may set other employees thinking, while others may need a more forceful handling; therefore no set rule of education can apply and it is the duty of the executive and supervisory forces to study their employees and try to reach each one individually.

The Comparison of Gross Earnings to Claims

In reviewing the past congresses I often noted the question "What part of your gross earnings is paid in claims?" Now that is a rather unfair comparison for safety, as nearly every Electric Railroad has different hazards in connection with their operation. It would not be fair to compare grade crossing accidents of an elevated railway with an interurban or street railway. Some railways have elaborate crossing protection while other lines have little or no protection; some lines have slow schedules as compared with the high speed lines. Therefore, we must study the existing conditions of operation before passing judgment as to whether they are doing their part in the promotion of safety.

The railway which I represent is an Insull property which is under the supervision of the Bureau of Safety with a regular organization of our employees. This Bureau has a staff of practical men as field men who attend all of our meetings. The field men are all different in their manner of addressing our employees so by this variation in the field men we can better convey the thought of safety to the minds of our rank and file. But even with the splendid organization and their years of training in their line of work, we feel that it is still our problem and that it is not for any individual or group to shoulder the burden; it is, rather, the load of all. That brings us back to Mr. Mallon's idea that safety must start from the top and permeate the entire organization to the humblest workman in his daily task.

CHAIRMAN EMERSON: We will now have a discussion on Mr. Curtiss' paper. I hope that the members here will take an active interest in this discussion. I think

we get as much out of the discussion as we do out of the paper. Don't hesitate to put any question you may have in your mind with regard to his paper.

W. H. BOYCE (Pittsburgh Railway Co., Pittsburgh, Pa.): I would like to ask Mr. Curtiss if he was quoting Britton I. Budd when he read about the suspension of employees?

MR. CURTISS: No, I was quoting from a speech made by Mr. Mallon in 1916.

MR. BOYCE: Do they suspend on the Chicago Elevated now?

MR. CURTISS: Yes. They do on our property, at least, which is under Mr. Budd's supervision.

MR. BOYCE: In connection with what you said about the safety work that is done on your property, I notice you have a system of crossing protection that I think is very fine and very effective, and it consists of the center installation of stop lights. These stop lights, as I remember them, are cut on and cut off.

Center Installation of Warning Lights

MR. CURTISS: Yes, there are two bull's eyes on a standard, and they flash on and off. The red light shows when the train is approaching. Then, there is a cut in the metal shield, which shields the light so that it can be seen in the daylight. Then, there is a green glass set in there so that the same bulb that lights the red in the light as you approach down the highway lights green on the side of the light to advise the motorman that the signal is in operation. Those stop lights are set in the center of the highway. They are protected by means of a concrete base which is large and substantial enough and striped black and white, so as to render it highly visible.

I think that is a very fine type of installation. They compare, for example, with the wigwag type of crossing alarm signal that you see set on the side of the highway. I think I prefer the center installation, and I can say that through this summer of heavy highway traffic and intensive train movement, they have proven themselves through the fact that there has been astonishingly few automobile collisions on those highways. I would like to hear that discussed.

MR. HELLMUTH: I think that is a proper branch of the paper that Mr. Curtiss has submitted. I want you all to remember, too, if you will, that you have come here from miles and miles and this is your opportunity to have a meeting of your minds. Bring out as many subjects as you wish for discussion. Confine, if you can, your discussion to the limits of the paper that is presented. Let us all get together and get to know each other.

J. M. LOFTUS (Pittsburgh Railway Co., Pittsburgh, Pa.): I would like to ask Mr. Curtiss if the cost of the signal just described is borne by the State Highway Department or by the railway company.

MR. CURTISS: The expense is borne by the railway company. However, the Highway Commissioners in the counties through which we operate agreed to leave an open space in their new pavement for these installations. They leave the opening in the center and that is filled in with the signal at the expense of the company.

MR. LOFTUS: Is your property in the whole state of Illinois?

MR. CURTISS: Yes.

L. R. BROWN (New York State Railway Co., Rochester, N. Y.): I would like to ask Mr. Curtiss the cost of that signal per crossing, and whether there is any difficulty at night with automobiles running into the signal which is in the center?

MR. CURTISS: The installation costs from \$1,300 to \$1,500 per crossing. There is no danger of anyone running into the signal at night. We have a yellow pilot light and a red flex 10 or 12 feet in advance of that. We have had two cases where automobilists ran into the signal, but in both cases the drivers were intoxicated, and we turned them over to the chief and they paid for the damage done.

G. R. WHITMORE (Illinois Traction System, Peoria, Ill.): I have consistently opposed the center installation of these signals. I think they produce more accidents than they prevent. They might prevent accidents with ordinary cars and trains, but I do think they produce accidents with automobiles. I favor the side installation but not the center.

In Peoria we have a center installation. I believe that most every week an auto crashes into that concrete base and injures two or three people. We are after safety all the way through and not for our individual companies only. That is the way I look at it.

MR. CURTISS: In answering your question the only thing I can say is that it hasn't proven so on our property. The standard for this signal is diamond shaped and the pavement is swung out around it in such a manner that the car would have to leave the pavement in order to strike the base.

I think that it adds to safety, inasmuch as one man going in the same direction as the preceding car cannot pass that car after it has come to a stop at the signal. The highway is just wide enough for one car to pass in each direction. In some places, we took the signal out and installed gates.

Deaths in Des Moines Due to Center Installation

MR. BOYCE: I would like to ask Mr. Curtiss if those signals are track circuited or operated from overhead?

MR. CURTISS: It is an overhead wire with a cut-in at a given distance from it.

MR. BOYCE: Trolley or track?

MR. CURTISS: We use the third rail; it is track contract.

D. W. FINCH (Des Moines City Railway Co., Des Moines, Ia.): We have the center installation in our city, and it is very unsatisfactory indeed. We have had at least ten deaths in Des Moines caused by center installations. We find that it is bad practice with us.

MR. CURTISS: We have no center installations in cities. We only have the center installations on the country roads. In the towns we use the gates. We have had the flashlights installed on the side, a sort of wigwag.

MR. BOYCE: I have just one other question. Who installs the signals and who stands for the damage?

MR. CURTISS: The Chicago, Aurora and Elgin Railroad Company install them.

MR. BOYCE: Are you responsible for aily damage done?

MR. CURTISS: We haven't had any as yet.

D. W. FINCH (Des Moines City Railway Co., Des Moines, Ia.): The signals that I speak of are installed by the railways themselves. At the dangerous crossings, the city installs them. As to the damages, the party who puts in the signal pays for it.

MR. BOYCE: You are only considering material damages. I am thinking of those ten deaths that you were speaking of. Is there any liability on the part of the company for those deaths?

MR. FINCH: No.

MR. BOYCE: On account of the erection of the signals?

MR. FINCH: We haven't had a case where it was on our own lines. These accidents happened on the lines of the steam railroad company, and there were damage suits connected with them.

EDWARD McMORROW (Amalgamated Association of Street & Electric Railway Employees of America, Detroit, Mich.): Mr. Curtiss, have you endeavored to have the authorities in the several counties where you operate bear the expense of those lights?

MR. CURTISS: No.

MR. McMORROW: The reason I raise that question is this: I am interested in

costs and it is one of the things where companies are charged with the installation and the liability as well.

As an employee of one of the oldest companies in this country, I hate to see them bear all these expenses. If we had nothing to protect but ourselves, it would be different. We are protecting the public, and we are running a necessary business, and I believe that this Section, represented by the many companies and associations, should start an effort to try and alleviate that enormous expense which comes from installing safety. If we are forced to install the safety device, the question raised by this gentleman from Pittsburgh will ultimately leak into the other expense resulting from damage to the individual or his vehicle that we are supposed to protect.

I am somewhat familiar with Mr. Curtiss' property and the country through which it runs. It seems, while we are seriously interested in the question of fewer accidents and the protection of life and property, and everybody seems to have a desire to pluck our industry, as an employee of one of those old companies, I would also like to get the fellow that needs protection bear some of the expense of it. I think the fellow running his automobile over the highways needs protection, and I think the authorities in these respective counties and municipalities should bear their reasonable share of the cost of these installations.

MR. BOYCE: Don't forget the safety platforms, too.

CHAIRMAN EMERSON: Does anyone else wish to discuss Mr. Curtiss' paper?

E. R. RAUCH (Illinois Traction System, Danville, Ill.): I am a motorman. We have these signals. My biggest problem is to get the public educated to stop when they see a red light. I would like some way of educating the public.

MR. CURTISS: In the city of Glenellyn we have the center installation, and at Manheim Road, which is a very busy thoroughfare, I noticed the people were disregarding the signals. I took it up with the Chief of Police. Now they have a uniformed officer there during the day. He takes them in if they don't observe the signal. A signal of any kind won't keep everybody off the crossing.

CHAIRMAN EMERSON: Before proceeding with the next paper, I understand there is a large delegation here from the South Shore. I wish the gentlemen representing the South Shore Road would please rise.

We will now proceed with the program, and I will call on Mr. Clinton D. Smith of the Cleveland Railway Company to read his paper.

Selection and Training of New Men and Their Relation to Safety

Clinton D. Smith, Superintendent of Personnel, Cleveland Railway Company, Cleveland, O.

Freedom has been taken to rearrange this subject to read, "The selection and training of new men in the sale of safe transportation." Safety must be the first consideration in our initial choice of applicants who are to serve as employees of the transportation industry.

The great advance of safety in transportation service calls for praise for the multitude of men and women who have worked so faithfully for humanity. The enthusiasm is so keen that we anticipate results which will be beyond comparison with present accomplishments.

In our desire that the advance be rapid, we gather here to check up on ourselves, to plan further, create new enthusiasm and analyze our problems.

A close study of the operation of our successful transportation companies reveals a fact, not new, yet not generally accepted. We find that management is securing satisfactory operating results from a scientific analysis of its problems. Each and every task is considered a job, is assigned a job number and given a position in a

priority list. By this method a problem must be solved: inspirations cannot die, initiative is rewarded, and all of the men involved learn to analyze this work with the purpose of eliminating lost time.

There is no mystery in science. The scientist merely observes facts, makes distinctions, draws inferences and passes judgments, but excels in his art by observing most accurately, distinguishing most clearly, inferring most safely and judging most soundly.

This habit of detail analysis that is now being adopted is worthy of our consideration in the selection and training of new men.

Is our accident prevention work, and particularly the training of our men, a little bit "hit and miss"? Is it possible that we organize a safety committee which is given freedom to function, but in its freedom, fails to reach the new man? Is it true that a new man is asked several questions regarding his ideas on safety, and, after squeezing through, is then called a safe man? Does the management merely express its belief in safety, and expect results without further effort? Does our investigation of an accident consist of indifferent conversation with the employee involved, or does it follow the order of the thorough research, demonstrated so forcibly to us last year; and moreover, are the results and conclusions given further analysis and made available for the rest of the employees? Our training of new men may be hit and miss or it may be scientific.

Three High Points in Training of New Men

In making particular comment on the training of new men, three items at least may be given special consideration.

1. Safety should be made easier to understand. It should be placed before the new man with the same assurance as mechanical instruction is given.
2. The responsibility of the training is one of management, and calls for as close daily follow up as any other detail of operation.
3. The employment manager is a powerful unit in the selection of a safe man, and should use his power to greater extent.

Taking up item number one. The new man usually is enthusiastic about his new work. If he has passed the regular requirements, the chances are that he is interested; the employment manager really has failed, unless he has secured a man who fundamentally shows interest. This new man is instructed in the mechanics of operation, to motor a car or to act as a conductor, and again, chances are that he is turned in as a satisfactory employee. The reason is that there has been something concrete about his instruction. He knows what happens when he notches a controller or applies air. He knows the results of changing gears, he learns the difference between smooth and rough starting or stopping of his power. With his enthusiastic mind he absorbs, although not all in one day, of course.

Are we making the safety instruction as easy as the mechanical? Perhaps we tell the new man that the safe employee is the man who thinks. Is there not a ton of challenge to that word, think? Should not our attitude be that the safe man is the one who analyzes, and should we not convince the new man in our instruction that we will analyze the accident prevention problem with him.

Think, in safety language means to "analyze", to "consider." "Safety suggests freedom from danger, and the man who escapes danger, generally is the one who considers, who analyzes. May we not avoid the blind use of the word "think" and substitute, "Let us analyze?"

A new employee in his enthusiasm will welcome safety instruction, if it is given to him with enthusiasm and by a routine determined by proper analysis. If we wait until the employee has been with us a few months, and then casually tell him we have a safety program, he will treat it just as we give it, as something distinct from regular routine of operation and as something in which personal whim is a factor in his going along.

This brings us to the second item, the responsibility of management in the training of his employee as a safe salesman.

Success of any kind is obtained only by analysis, consideration of facts, planning, and the maintenance of keen enthusiasm. Success in safety is impossible without enthusiasm. This must come and be maintained by management. The general manager and other operating officials must make safety an operating problem, and put their enthusiasm back of it, just as in other successful practices.

The general manager surely has a keen appreciation of safe operation, of the qualities that he desires to see in a new employee who is to be his salesman. Of all employees, we expect the general manager, or his representative, to be most enthusiastic and it is from him that we should receive the greatest inspiration on company policies. Moreover, the general manager sincerely wants the new employee to have the same keen conception of safety and company policies as he himself. How is the new man to receive them? Surely, not by relay from general manager to superintendent to employment manager and to instructor? Each one of these, to be sure, should share the same high degree of enthusiasm as the general manager, but should not the general manager take time to see the new man before he becomes permanently set in the organization?

The Normal Reaction of the New Man

Let us think it over. A new man. He receives the usual instruction established by routine. He is talked to by various officials, and then, very early in his start as a regular employee, he has the opportunity of chatting briefly with the general manager. What is the reaction? I know how I would feel. Every word of the general manager would sink into my mind so deeply, that after I left the office, I would keep repeating to myself all he had said. I would start to analyze. I venture, regardless of the size of the company, that this practice, if followed enthusiastically, would reduce turnover, reduce accidents, create inspiration in the new man, all of which would be the stepping stone in the development of a salesman.

Third, and last, but not the least item, the employment manager. He is a corner stone. Employing a new man is comparable to the exercise of courtesy. Courtesy is of three varieties. First, the kind that we cannot swallow, discourtesy. Second, the form that makes us smile and feel happy that it is extended to us. Third, that large volume of indifferent courtesy.

There are many people who are not discourteous, yet do not stand out by the performance of any particular attentive act of courtesy. This class of people are not offensive, yet we do not call them salesmen.

The analogy in employing a new man is this. We do not take on the undesirable applicant. We readily employ those who stand out as being courteous, but also allow the indifferent class to pass because we do not know any particular objection.

We know by experience that in the great indifferent group there are those who prove themselves to be exceptionally courteous and we reason that out of the great group of employees who pass as indifferent there are those who might display wonderful sales ability; but the unfortunate part of it is that we pass a large number of the indifferent who develop as discourteous employees and generally as unsafe ones.

It is easier to say "Yes" than "No." When a candidate for employment is once started it is easier to let him travel on an indifferent course than to stop him, even though we may have some doubt as to his qualifications.

This all boils down to the need of having the employment manager make a most careful analysis of his qualifications of new employees. The process of selection should be so exacting that no one is passed along as an indifferent applicant.

The selection will be more painstaking then, perhaps as the practice generally increases, but when we start to appreciate the need of having a safe salesman, and

getting my best men to break in new men. It is a hard task. They don't like to do it. How do you do it?

MR. SMITH: I feel sure I can't answer your questions satisfactorily, because I haven't worried much about that. In my two months' experience with the Cleveland Railway Company, I have found that the road instructors have been with the company a long time. I imagine there has been no real problem in that connection.

CHAIRMAN EMERSON: I might say that on our property those who are given the work of breaking in new men receive additional remuneration for their work, and the men appreciate the fact that they are chosen for the reason that they are better qualified to instruct new men, and we are very glad to have those men. We pay them an additional ten cents an hour for work while they are breaking in new men.

MR. POWELL: I am glad you mentioned that. Ten cents an hour is quite an inducement. We pay an additional sum also, but not that much.

I would like to ask another question. Do you select the new men just by oral examination or have you a written examination? Do you use any of the so-called psychological tests?

No Psychological Tests Are Used

MR. SMITH: At the present time there are no psychological tests. The applicant sits down and has a chat with the employment manager, even when the employment manager knows there are no vacancies. He works on the theory that here is a man that six months from now when there is a vacancy may be a very desirable employee. After this chat with the applicant, which may run ten minutes, he is able to tell him that he will take his written application and should there be an opening at a later date so advise him.

At the present time, it is purely observation, talking with the man a sufficient time to find if he is interested in taking up street railway or motor coach work, but also talking with him sufficiently to bring out some interest in him. As referred to previously, it might be that the mere filling out of an application and the examination by the employment manager would not reveal the true worth of the man. But, in the course of a few minutes, he may show some signs of interest which would cause the employment manager to take him at the time or mark his application so that when he is in need of a good man he knows where to turn.

MR. ISHAM (St. Louis): I would like to hear from anyone present who does go a step further in the original selection of men for motormen and conductors. I believe that Milwaukee does, for one: not particularly a psychological test, but seeing this arrangement on Mr. Emerson's desk reminds me of articles I have read, a test of their reaction, how quickly they can react to dangers and so forth. That is coming to the front. We haven't adopted it in St. Louis. I would like to hear the experience of some of the other companies that are using it now.

W. H. BARNES (T. M. E. R. & L. Co., Milwaukee, Wis.): We use the system that the gentleman spoke of. Whenever a man in our employ has an accident for which he is chargeable, this test is looked up, and I am given his name. I compare his accidents with the test, and invariably I find that the test is correct. I think that is what you are trying to get at.

CHAIRMAN EMERSON: Won't you tell us what the nature of the test is?

MR. BARNES: I am not very well acquainted with the nature of that test. The educational department takes care of that.

G. T. HELLMUTH (Chicago, North Shore & Milwaukee Railroad Co., Chicago, Ill.): I believe it was first introduced by the Yellow Cab Company of Chicago. It was devised by Professor Snow of Northwestern University. I believe Professor

Snow was in the Department of Psychology there and later employed solely by the Yellow Cab Company.

It is a sort of time reaction test. It consists of taking a candidate for employment into a small room and sitting him at an instrument board and telling him that he has certain things to do, and that in the event anything unusual happens he is to move a lever or press a pedal, and then an electrical circuit is set up. There is a flash, or something decidedly unnerving happens, and a stop-watch—the time element—is then used. The stop-watch starts in motion when that unusual occurrence takes place and it records the lapsing of seconds and split seconds until the man responds correctly. That is the test, I believe, that the Milwaukee Company has in mind.

One Vital Point in Training Is Emphasized

DWIGHT L. SMITH (Chicago Rapid Transit Co., Chicago, Ill.): I can't speak of transportation employees because the men with whom I have to deal are the electrical employees. I cannot say anything of the methods used in selecting these men. But, as to training, there is one point which we believe is vitally necessary when we get a new employee. In general, our electrical employees are drawn from the class of men who have been employed rather in light and power work than railway work. There are a great many more men in light and power work than in the electric railways.

The majority of us operate on 600 volts direct current. There are some exceptions, to be sure. We find that the man who is used to light and power work is used to handling circuits either below or above that on which the electric railways operate, and that he has very little appreciation of the dangers (if you wish to call them such) or the means for handling this 600 volts. We always make it a point when taking on a new employee to call his attention to the fact that this power with which he is going to work is a rather peculiar beast; it isn't a low voltage such as 110 volts, and neither is it a high tension, which means certain death; it is betwixt and between, and contact with it will not necessarily kill him; in fact the chances are that it will probably do him no damage.

There are very few of us in the electric railway work for sometime who haven't got a shock and have told the story. There are certain precautions necessary that he does not need to take in other lines of work, and by calling that to his attention we try to fix in his mind that this is a little different from what he has probably had before, and we try to impress this upon him so that he will know something about the way in which it should be handled and take proper precautions.

G. H. SHAW (Northern Ohio Power & Light Co., Akron, Ohio): I would like to ask Mr. Smith a question. After the man has been trained and given road instructions, is he given a definite examination upon operating rules, safety regulations and so forth?

MR. SMITH: He is given an oral examination by the division superintendent. This examination is more or less of a final test to see if the man has absorbed his instructions as given by the regular instructor on the cars and also by the trainmen instructor. There is no regular examination, that is, no written examination.

E. K. EASTHAM (United Railways of St. Louis, St. Louis, Mo.): What is the average time, or have you a minimum time, for breaking in conductors and motor-men?

MR. SMITH: There is no definite fixed time. The average time would vary between ten days to two weeks. I suppose there is a minimum time, inasmuch as you would expect that a man could be broken in thoroughly for a number of lines operating from any one station in less time than approximately ten days. The ten

to fourteen days of training follows a three-day instruction period at the employment office.

MR. HELLMUTH: I think some of the western systems today are requiring anywhere from one to three months of instruction.

MR. SMITH: I am not familiar with the details. I really believe there should be a longer period. I also feel that there should be some compensation to the men while breaking in.

MR. EASTHAM: You don't give any compensation at all, do you?

MR. SMITH: Not while he is breaking in. I think every man ought to have a month to six weeks of instruction. We could devise a course of instruction for that length of time. It would be fairly difficult to hold the men without some compensation.

MR. EASTHAM: You would have to have some, undoubtedly.

Safety and Production Go Hand in Hand

M. PASCHE (Chicago Surface Lines, Chicago, Ill.): I have been following very closely Mr. Smith's paper and some of the other remarks. It seems very clear to me that Mr. Smith intended to bring out just this fact, that accident prevention and good operation go hand in hand and cannot be separated. It is absolutely impossible to separate the two in any railroad company.

I am just new in this work. I have come out of the operating department as a division superintendent of the largest car house, which car house did win the accident prevention contest in 1926. When I was brought down as the accident prevention supervisor, I said to myself, "How can we best discuss accident prevention without trying to go clean up to Heaven and over the men's heads?" I took the matter up with Mr. Evanson. He suggested that the way to do the job would be to find a simple manner of classifying the accidents, and then later on discussing them with the division superintendents, who in turn would receive an education on accidents.

Now, here is what we do, and I believe it is simple: We classify the accidents into three grades; one means questionable; two means not chargeable; and three means chargeable. I mark each and every one of these accident reports every day. Then, the next morning, they go to the division. When the division superintendent gets them, he has something to guide him. He then calls the man involved into his office as soon thereafter as possible, and discusses the accident with him.

He then calls me up and tells me that the man said so-and-so. Just about that time, the division superintendent is in the place of the trainman when he is talking to me. He is bidding his experience against mine. I am watching carefully every day. I ride a great deal on the cars. This is what I find. I find that our men do not sound the gong enough. I find conductors do not call the streets enough. I find that conductors do not look outside of the door enough to see whether there are prospective passengers close to their rear end. I believe if those simple points of operation are brought to their attention that we will get our story home.

I have taken as my slogan in the accident prevention department just this: Accidents are prevented by efficient operation; efficient operation means better service; better service means more business; more business means more and better runs.

I think that is what Mr. Smith has been trying to do on the Cleveland railways. We have on the Chicago Surface Lines accomplished this since this method has gone in, that in the month of June (I am just quoting from memory now) after we had been classifying accidents for 30 days in the month of May, we showed a decrease of 282 accidents over June of 1926; in the month of July we showed a decrease of 609; in the month of August we showed a decrease of about 645. This month the record is not so good, but it is still a decrease.

I believe the idea is correct, because it gives you an opportunity to discuss the

matter thoroughly with the division superintendent. It teaches in a way how to carry on his discipline, how to standardize on his work. We don't shoot any more in the dark. In other words, we try to find the condition surrounding the particular accident and what the man did.

We often have calls on cases where the report shows or indicates at least that it was a head-on collision. I contend that if a man sees another man coming down the street in an unusual manner that he should use exceptional care in approaching that man.

We sometimes ask the accident prevention department to make an investigation along that line and we are getting fairly good results.

J. H. MYRICK (United Railways Co., St. Louis, Mo.): I would like to ask Mr. Smith if they require their new men to stand a medical examination? Do you examine their teeth and so forth?

MR. SMITH: Yes, each and every employee is given a physical examination. It is not a very thorough examination. It is an examination which would reveal any defect which would interfere with the man operating the car.

We are going to have a dental clinic for all employees which will bring about the examination of the teeth by a company doctor.

MR. MYRICK: We have a medical dispensary in our general office. It takes care of all employees and their families free, and it is compulsory for the employees to be examined.

High Blood Pressure a Common Handicap

MR. SMITH: We are following a program which might be a compromise between present methods. We don't know what the final outcome will be.

MR. MYRICK: Our greatest trouble now seems to be, especially with the older men, high blood pressure. We have a great deal of that. By taking the examination when they should, it will probably eliminate that.

D. W. FINCH (Des Moines City Railway Co., Des Moines, Ia.): Do you have an examination for sight, hearing, and color? How often do you have these examinations?

MR. SMITH: There has never been any re-examination, although the policy of having one is sound, and undoubtedly a program will be arranged for that.

MR. FINCH: In our experience, it would be wise for all of us to do that. We recently had an examination of our employees, all of them, and we found some startling developments. We found one man operating a car with one eye gone and the other very nearly gone and who couldn't distinguish colors. I think as a result of the examination that many of the motormen and conductors had to begin wearing glasses.

MR. SMITH: We have the examination, but we do not have any periodic re-examination.

CHAIRMAN EMERSON: In connection with this discussion, I understand Dr. Fisher is in the room. I wish Dr. Fisher would enlighten us a little.

DR. HART E. FISHER: I really just came in at the close of the paper, so that I am not thoroughly conversant with the discussion.

The companies that I happen to be associated with have been doing this for about 15 years. They require an examination every two years. The general employees are examined more frequently. Those that have defects are put in a tickler system, and those on that tickler system, every so often, according to the defects, are pulled in and re-examined.

We just completed an examination on one property and are now taking care of those defects. I might say that a man is operating a railroad under a hazard if he does not know the physical conditions of his employees, and especially of your front end men.

A simple medical inspection is not worth a row of pins. Forget about that. You want a thorough medical examination, the same as you get in your private factories, because the other things, the things that cause your disasters and cause your troubles, are the things that are never brought forward in a simple medical inspection. If the man is examined and put in physical shape, he is less hazardous and less liable to have accidents.

How often should the men be examined for color sense? Every man should be examined every two years for the special senses. Blood pressure is an insidious thing; if you don't have an examination, how do you know the man has it. He is very liable to fall down when he needs the complete control of all his faculties. Blood pressure is producing a lot of our accidents. You must have an examination on that. You can't be arbitrary on that blood pressure question. If a man's blood pressure is higher than normal, take him out, if possible, but if he has the symptoms that accompany it and after frequent observations you find that his symptoms are such that his blood pressure is equalized, you don't have to be afraid of him.

An Interesting Experience in Industrial Medicine

MR. HELLMUTH: Dr. Fisher happens to be chief surgeon of the companies with which I am connected. I have seen over a period of the five years or more the increasing number of employees who voluntarily come into his office for treatment. I wish Dr. Fisher would say just a word about what he is able to do for an employee to keep him in the service.

MR. BOYCE: May I say a word in connection with that? I had the pleasure of spending a half day with him six years ago. I want him to take into consideration that there are a lot of hard-boiled railway men here, and I want you in a few words, if you will please, tell them how you brought about this feeling of confidence in you and got the men to learn that you are doing a good work for them as well as for the company.

DR. FISHER: I am glad I am in the back of the room.

The first thing about bringing medical examination to employees, organized or unorganized, has been a very serious debate in the past. Why? Because medical departments and company doctors, as constituted in the old days, had an ulterior motive and purpose back of them; with the result that there was a lot of things done (not intentionally, a great many of them), and a medical department was looked upon as a place to take out those fellows who were radicals and the man that was getting too old to be in service any longer. That is the attitude that went around through medical department twenty years ago.

Then, since industrial medicine and surgery was only in its infancy (and it is only in its infancy now) a doctor was looked upon as a pioneer unless his value was proven. Now, in order to start with any company (and I don't care what the nature of the company is) you have first to sell your product; you first have to have salesmen to sell that product. Then, you have to have your company and your officials wholeheartedly back of you; to sell it to them first before you bring it to the employee. If you cannot sell the president of the company, you might just as well leave it alone. You have first to get wholehearted cooperation for what you intend to do.

Then, you take your employees into your confidence and tell them what you are going to do. I was just talking to a gentleman who is going to have the plan started on his railroad this month. I told him what I am going to tell you, that it is for detection of those incipient things that if undetected lead to accidents or disability on their part. You have to show them that it is not the company standpoint so much as it is their own. Tell them that the company wants the examination for their protection; they also want it because that man is going to be main-

tained in an efficient manner as long as possible, because it costs dollars and cents to break a new man in.

When an employee knows by past experience with your company that your medical policy is free and above board and you have nothing to cover up, and you show that by your actions, then that employee is very quick to adopt your methods and submit to these examinations.

Now, you cannot examine an employee with the idea that he is any different from a private patient. He must give all he can in courtesy and you must give everything you can in the way of human kindness. This hard-boiled egg business on examination and contact with employees is not the thing that brings success to a medical department or a medical policy of a company.

As to the employees' confidence in the medical examinations, we can say that over a period of some 15 years we can cite hundreds of cases where incipient diseases were discovered in time; that they were brought to the medical attention of their own doctors and as a result have been able to become a constant factor and work every day.

Then, we have the man that we keep under observation who comes in periodically. We had one man with a high blood pressure who was taken away from his front end work and put into another position earning the same money but doing less hazardous work.

The Health of Employees Should Be Known

You want and should know about the health of your employees. The employees want to know what their physical defects are. They are just as anxious as you are or I am to know what they are. I happen to be fortunate enough to have the confidence of the employees to the extent that their families come to me for medical attention. The number of children we have to take care of now is getting to be a problem.

We give the medical advice to them and suggest that they go to their own doctor. We, however, cooperate with them in every respect. If they haven't the means or happen to be financially embarrassed, we are glad to take the case over and give whatever aid we can.

We were the first industry to have periodical medical examinations. Our president had a big meeting, and all the men were invited. I was introduced at the time as a kid and was told to say from my own standpoint what I was going to do. I explained to them what I hoped to do. We started in with one man and one room. Today, we have a full medical department with some nine rooms, and we are going to take nine more rooms. We have 16 or 17 in our medical department.

Does it pay? It pays from the standpoint that safety engineers, coming in to check up the records of accidents, find fewer accidents in a place where medical supervision is in progress or in vogue.

Physical examinations in the transportation industry are absolutely necessary. I have two more papers to present this week. I am going to speak before the Public Utilities Section on Thursday, and my talk will cover this thing in detail.

I want to make a plea, that a medical man has a place with the safety organization; he is not a man that you should take lightly. You don't have to discharge the man out of the service; you can find a place where he will be less hazardous to himself and to his fellowman.

CHAIRMAN EMERSON: Dr. Fisher, we are indebted to you for coming in and enlightening us on this subject.

The time is growing late. We come now to the final paper of the morning session. I am going to call on Mr. Lemuel M. Brown, vice-president of the Interstate Public Service Company.

Courtesy and Its Relation to Accident Prevention

**L. M. Brown, Vice-President, Interstate Public Service Company,
Indianapolis, Ind.**

Safety is the first thing a passenger buys of a railway. You may think you are selling him transportation, but let him suspect your transportation is unsafe, and see whether he buys it. He wants to go safely from A to Z. He wants to go without risking an arm, a leg or his neck, and he will not buy unsafe transportation. The subject of safety, therefore, while perhaps an old and hackneyed subject, is nevertheless the most important thing an electric railway man, like myself, may discuss.

I should say the passenger buys three things when he buys a railroad ticket. He buys safety, then the transportation itself, and then comfort. Given all three, he is a satisfied customer. Substituting the word courtesy for the word comfort, we have the three essentials of railway service,—safety, transportation and courtesy; and I like to think of safety and courtesy as the "Gold Dust Twins" of the transportation business. They work together, and together they put over the job. Like pepper and salt, or cream and sugar, they work in pairs. They make the transportation dish more palatable to the consumer, our passenger.

Safety has been practiced on the railways since 1825, when the first steam train was preceded by a horseman carrying a red flag for the purpose of providing a safety zone ahead of the train. But the true worth of courtesy was never fully appreciated until after the abandonment of the "public be damned policy" in the early history of railroads and some public utilities. Today the terms courtesy and safety are used almost inseparably.

The need for courtesy has been emphasized so much of recent years because it brings peace, joy, happiness, contentment, safety and efficiency in all things. The practice of courtesy is the common sense application of the Golden Rule. Solomon said "A soft answer turneth away wrath," but "A grievous word stirreth up anger" and "A wrathful man stirreth up contention; but he that is slow to anger appeaseth strife."

The point at which courtesy should begin, not only in the prevention of accidents, but for all reasons, is at the top. Employees in dealing with each other and in their contact with the public reflect the attitude of their superior officers. The character and conduct of all officials must be such that it will inspire confidence in their subordinates and give them the proper respect for their superiors.

The majority of the employees in any concern take the official valuation of an idea. If the official scoffs at a project or effort the employee does likewise. If the official takes it seriously the employee does the same.

Not long ago a man in high public life told of his first job, which chanced to be in a coal mine. He was only a boy and had the boy's desire to idealize the man at the top. The boy learned that the "big boss" came every two weeks with the payroll, and he lived in constant hope of sometime being fortunate enough to meet his ideal. One day he went down the trail for two buckets of water. The trail was narrow and difficult and the boy was tugging along with right good will when he happened to see the boss coming toward him. A feeling of exultation filled him. At last he was to meet his ideal and perhaps have a few words with him as he might step out of the trail for the boy to pass.

Nothing of the sort happened. The boy himself was forced to step from the trail as the boss, without a sign of notice, passed by. From that time on

the boy's attitude toward his employer and his company changed and he soon left it because of lack of interest.

There is hero worship in all of us and there is always the possibility that a lack of friendly greeting or courteous treatment on the part of a person in even a minor supervisory capacity may cause anger or hurt feeling which would so fill the mind of a subordinate that he would not take all necessary precaution to prevent injury to himself or others. Thus we have as one of the big factors in accident prevention, the courtesy of the official for the subordinate.

Courtesy of the employees toward each other deserves consideration. Courtesy, as extended by one working man to another, should be that of a sincere wish that nothing may happen to injure either of them. After all, courtesy is merely consideration, and proper consideration for fellow employees will prevent accidents.

There is no courtesy in spite work; getting even or taking an unfair advantage among workmen tends to fill their minds with thoughts other than those of their work and makes them an easier prey of the accident bug.

Of no less importance is the employees' consideration of the public, for therein lies the reason for our being. To the public the employee is the company. This statement, though often repeated, is no less true, and employee courtesy is, after all, company courtesy. The conductor who meets his passengers with a friendly greeting and a smile usually puts them in the right mental attitude toward the company, and by creating this favorable impression helps to prevent accidents. Likewise a pleasant "move up," "wait until the car stops," "watch your step" or whatever the caution may be, will prevent accidents. The same words spoken by a grouch may cause accidents. Others meet you as you meet them.

Prevent Accidents by Little Courtesies

It takes but a few minutes to add a word of caution or remove the package over which some one might stumble. It is very little effort for the conductor to lift the bag or basket or give a hand which may save some one a painful fall. It is usually just as easy for the motorman to start and stop a car smoothly as it is to jerk it so that passengers and packages are thrown all over the car. It is courteous for a conductor to call stops clearly and distinctly and thus avoid possible accident to a passenger who realized it was his stop too late to be prepared to dismount from the car.

Examples of this kind might be cited indefinitely but would all tend to show the same results. Prevention of accidents to the public through the courtesy and consideration of the employee is a workable, practical thing.

The trainman who is courteous is usually in the proper frame of mind and maintains his equanimity particularly under trying circumstances. He is likely to have fewer accidents than the man who goes about his work with a grouch. Such a person inevitably and many times unconsciously creates an atmosphere which is conducive to safety both to himself and his passengers, who are in a sense under his care and protection.

In the selection and training of employees, consideration necessarily must be given to the matter of courtesy. A man who is discourteous is naturally careless. This is evidenced in dress and manners as well as work. The courteous employee will close the door or remove the obstruction to prevent another from falling. As one man has so well put it, "If the man's heart is right and he is thinking, he may be expected to perform satisfactorily."

Benjamin Franklin said "The way to be safe is never to be secure," which might be a good slogan for this group. In our experience we have found that

accidents began to occur after we had operated for a considerable length of time without any accidents, and had probably reached a self satisfied condition. We must have believed ourselves so perfect in the part of accident prevention that nothing could possibly happen. That really is the most dangerous period. That is the point where a general let-down begins, and as a result accidents will happen. I might suggest an epigram something like, "In time of no accident, prepare to continue to have none."

The company, as represented by the executives who determine its policy, may bear a large share of the responsibilities of accident prevention through courtesy. They are in a position to provide what might be termed "Courtesy equipment." Courteous treatment of passengers means more passengers and fewer accidents. This may be accomplished by the kind of equipment which prevents slammed doors, noisy operation, tardy opening and discourteous closing of doors.

A number of years ago one company changed the color scheme of their cars from a dark green to a bright orange. It was found much more satisfactory both in appearance and from an accident standpoint, on account of greater visibility. It was decided to have uniform interior arrangements so passengers would know the location of all equipment. Trolley wheels and poles were given the closest inspection so the fullest safety could be depended upon and the passengers not annoyed by trolley wheels that make a noise multiplied many times by the roof and headlining. This company was courteous in the larger sense, because it tried to supplement transportation with comfort as well as safety.

Condition of Offices, Stations and General Property

I may be digressing somewhat from the subject assigned, but I feel justified in including another factor in this paper because it bears so closely on courtesy and in some measure on accident prevention. I wish to mention the condition of offices, stations, platforms and general property. In a number of cases stations are reconstructed buildings. They are furnished with uncomfortable benches, are poorly lighted and unsanitary. They are improperly cleaned, they are cold in winter and hot in summer. As one man puts it, "The wayside station and the terminal and office buildings are the gateways to the utility—the portals to service; no matter how well advertised or maintained, they suffer by their unkept appearance, they are monuments of indifference to what the public considers essential to its comfort. Ten minutes in a leaky, unkept way-station has bred many a bitter enemy." And bitterness and discomfort in turn breed accidents.

Poor and improper lighting and loose boards in a station platform may cause accidents to public and employees alike. The courtesy of good lighting is essential. When the idea of courtesy and its relation to accident prevention is analyzed we find that after all it can be contained in the one word so often used—cooperation. Cooperation has been defined by the wizard Steinmetz, who said "cooperation is not a sentiment, it is an economic necessity."

Courtesy is that part of real diplomacy which tends to draw society into a closer union and a better understanding, whereby the individual can work at a higher degree of efficiency and do it in the safest possible manner. To conclude, and in a way re-word the sentiment of Steinmetz, I should like to paraphrase the language of the small boy in school who rebelled and told the teacher his answer was not merely good, but perfect. Safety and courtesy are not merely important, they are absolutely essential. If we do not give both as a bonus with transportation, our customers will leave us for some other service.

CHAIRMAN EMERSON: Before bringing this meeting to a close, I wish to introduce a gentleman who has charge of the destinies of the American Electric Railway Association. We have been privileged to have the managing director of the association attend this Congress. I am going to call on Mr. Storrs to say a few words to us.

LUCIUS S. STORRS (American Electric Railway Association New York): I get a great deal of kick out of these meetings, particularly because it is not only a meeting of the management but the men who are interested in carrying on.

The whole thing, of course, relates back to the question of the urge behind it all. Starting out with Mr. Smith's personnel relations, I am reminded of my own experience after having left college and for a number of years working with the most delightful and charming gentleman. The so-called silver panic of 1893 was the occasion of my losing my first job.

After losing the job, I spoke to the gentleman. I was wondering if I could get a letter of recommendation from him. He said, "Hell, yes; I will recommend you to anybody."

I said, "I have worked for you for five years and I never heard a good word."

"Well," he said, "you never lost your job, did you?"

I made up my mind at that time, if I ever became a man in direction of labor or a group of men, that once in a while I would comment on some of the things that they were doing.

Somebody said a few moments ago that you didn't have to consider the financial side, that it was a humanitarian interest. Of course it is humanitarian running these juggernauts of public service equipment through the streets. You have got to recognize the humanitarian side not only of the passengers that you carry but the motor vehicle fellow that tries to run you off the tracks. Let me call your attention to the fact that the financial side is of no less importance, when it takes the fares of a million and a half passengers a day to settle accident and damage claims of an industry, it does run into dollars and cents.

CHAIRMAN EMERSON: Before adjourning, I would like to call your attention to the fact that there were over 200 present at this meeting. I think that is an excellent attendance. On the other hand, we only have 133 cards signed. I wish that those who have failed to fill out their cards will do so either today or tomorrow, because we want it as a matter of record.

ADJOURNMENT.

Wednesday, September 28, 1927

The second session was called to order at nine-fifty o'clock by the chairman, Ralph W. Emerson.

CHAIRMAN EMERSON: In opening this meeting, I want to express to you the gratification that I feel about the meeting which we had yesterday. I think we had a very lively, interesting and instructive meeting, and I want to thank everybody in this room for the help they rendered.

The officers this year have rendered such wonderful service to the chairman that I feel more or less apologetic, standing here before you. There has really been very little for me to do, and I want to thank them for their assistance. I want to thank you gentlemen for your patience in bearing with the unpleasant conditions here yesterday, and those who took part in the discussion. I think that we get more out of the discussion of these matters than we do out of the papers. I appreciate the time that is put in by the gentlemen who have written the papers, and I want to say right here that we have 100 per cent representation of authors of papers. There are no papers to be read in this section of the congress by proxy. I think that is a splendid record.

I neglected yesterday to announce the committee on recommendations for new officers. I will take this opportunity to tell you whom I have appointed as members of that committee. Mr. Samuel H. Reid is the chairman, and Mr. Hellmuth and Mr. Bennett are the other two members. I would ask those gentlemen to get together some time this morning and decide upon what the recommendations are for the coming year and report back before the end of the session this morning.

We are going to make these meetings as snappy as possible. We are going to get as much as we can out of them, and we are going to adjourn this meeting in plenty of time to be prepared to go ahead with the joint luncheon of the Public Utilities Section and the Electric Railway Section at noon.

It gives me great pleasure indeed to present Mr. Harry H. Adams, superintendent of shops of the Chicago Surface Lines, Chicago.

Design and Maintenance of Equipment as a Factor in Safety

**Harry H. Adams, Superintendent of Shops and Equipment,
Chicago Surface Lines**

In the design of modern street railway equipment the safety idea is playing an increasingly important part. Safety in car design not only means safe riding conditions for passengers, but also safe operating conditions for operators. The entire car and all its equipment or auxiliary devices have to be studied from a safety viewpoint.

The feature of car design that, as a whole, has helped more than any other to make street cars safe, probably has been the adoption of the low-floor, low-wheel type of construction. This has resulted in the elimination of some of the steps with their attendant dangers to passengers.

The use of pneumatic doors has aided greatly in the advancement of safe car design. These have now been developed to a point where the design of a safe door installation has become a matter of choice of units. In regard to this choice, too much cannot be said about the study of conditions to be encountered and the careful selection of the units necessary to meet these conditions. The proper location and installation of these units also has a

bearing on their safe operation and maintenance. Pneumatic doors may be obtained with manual or automatic control and should be interlocked with car control so that they cannot be opened before the car has come to a stop with brakes applied, and the car cannot be started until they are properly closed in operating position. They should also be provided with some means of preventing their closing as long as a passenger is in danger of being caught by them. They may be provided, as a safe precaution, with a device that will arrest the door's operation as long as an obstruction is in the way, or that will cause the door to reverse and fully open, then close, upon striking any obstruction in its path.

Folding steps are frequently used in conjunction with pneumatic door design as a safety feature in surface car operation. These are so co-ordinated with the doors that they fold up out of the way as the doors close and open downward into place as the doors open. This prevents passengers riding on the steps, and accidents from that cause. They should be chosen of the simplest design and of adequate strength to carry the loads imposed. Attempts to reduce weight on a car should not be allowed to affect the design of such parts to a point where the steps are not safe. Pneumatic doors and folding steps have contributed to the safety of larger platforms. Any safety feature of the doors or steps may be entirely overcome by the failure to provide for sufficient lighting for use of passengers at night. One of the earliest safety features to be incorporated in step design was the use of a metal safety tread. These can be obtained in a number of designs, either for the full width of step or for a narrow strip along the outer edge. These treads are advantageous, particularly in wet or snowy weather.

Employment of Line Breakers

The use of line breakers is another feature that takes its place in safe design. Aside from their function of interlocking pneumatic doors with car control, they eliminate the breaking of overloads in the motor circuit from the car platforms. This feature is a well-known safety idea. The danger of personal injury to passengers from flashing controllers or circuit breakers is recognized, and with the use of line breakers and the new controller handles that have been developed all interruption of power in motor circuits is eliminated from the car platforms. The new controller handles provide for a definite opening of line breaker before any motor circuit is broken by the controller and the controller thereby becomes merely a commutating switch. Carrying this idea still further, comes the use of contactor control with which all motor circuits are removed from the car platforms and are closed and opened underneath the car body or in cabinets protected from passengers. This type of control is used for train operation also.

Another safety device that occupies an important place in one-man car operation is the dead man's handle feature. This handle can be fitted to any type of control and provides for automatically cutting off the power supply and applying the brakes in case of man failure.

The location of the lightning arrester on the roof of cars is another safety feature required by the Fire Underwriters. Properly installed, this provides a path for lightning discharge that will prevent breaking down of trolley wire insulation and the resultant flash and fire.

Trolley bases should be so located that the trolley wheel may be replaced on the wire without leaving the car platform. This requires, as well, that the vestibule design be such that the operator may lean far enough out of the window to see the wheel when it is in contact with the wire at an average

height. Proper care in this design will eliminate the necessity for operators going between cars to replace their trolley, or being hit by vehicles while in street incident to such replacement. In this day of congested traffic, this precaution is essential.

In designing cars for operation upon city streets and highways, due care should be given to see that the rear of the car is illuminated to give a proper indication to other moving vehicles. On double end cars this is usually taken care of by the general illumination of the platform or of the sign box. On single end cars, where the platform and sign box illumination is missing, it is desirable to provide some other designating signal, such as a red bull's eye, properly illuminated. A clear ringing gong of distinctive type is an important safety feature of car design. It should be properly located and protected so that it is available for use and dependable in operation.

Last, but not least in car design, comes the provision for adequate brakes. By adequate brakes is meant brakes that are so proportioned to the car weight that sufficient pressure may be exerted at the wheel rims to secure reliable braking without excessive piston travel. Cars whose braking ratios are excessive require close maintenance and are not safe if the brake shoe wear is not adjusted frequently. They are costly also on account of the high energy consumption usually encountered, due to close-fitting brakes. The proper ratio of the total brake shoe pressure to brake cylinder pressure should be about 9 to 1. Good practice also dictates that the total braking pressure for city cars should run from 85 to 100 per cent of the light weight of the car, although some conditions may require even a greater percentage. To obtain a 9 to 1 braking ratio may require a larger brake cylinder than usual, but the results obtained warrant its use. Coupled with the use of the larger cylinders and adequate brakes, is the use of a quick-service valve which passes air directly from the reservoir to the cylinder until the desired pressure is reached. This aids materially in securing high braking pressure in the shortest possible time and is an aid to safe operation thereby. On cars that are equipped with a great amount of air brake piping, or where two-car train conditions are encountered, the quick-service valve becomes more important on account of the length of time necessary to secure braking pressures in the rear car if all of the air required for same is passed through a motor-man's valve at the head end of the train. Accidents may frequently be avoided by the saving of a fraction of a second in securing quick brake applications. With the quick-service valve the air for each brake cylinder is fed directly to the cylinder from reservoirs on their respective cars. In designing brake systems, provision should be made for securing pressures that will insure high rates of braking. It has been found that rates as high as 3.5 to 4 mphps. can be reached in everyday service without discomfort to passengers if the braking action is smooth. A group of street railway properties are also adopting trucks equipped with magnetic brakes as an added safety feature for emergency use.

Maintenance

Safe operation is dependent to a great extent on good maintenance. What is good maintenance? One might say that safe maintenance is good maintenance. That is to say that it is not safe maintenance to use a given piece of material until there is danger of failure from excessive wear—neither is that good maintenance. Every equipment failure is not a factor in an accident, but some equipment failures may be potential factors in accidents.

Frequent close inspection of all main car parts, to detect weak parts or dangerous conditions, is one of the first requisites of good or safe maintenance.

All wearing parts that can be case-hardened or provided with case-hardened bushings, should be so treated to provide long wearing conditions, but even under these conditions excessive wear should not be tolerated. Certain parts which are more susceptible to wear than others, and also those which would create the greatest hazard in case of failure, should receive daily inspection. For example, it is good practice to make a daily inspection of all brake pins, hangers, levers and mechanism. Also, fenders should be tripped each night when the car is spotted, making it necessary for the trainmen to reset them before taking the car out the next morning, thus insuring fenders in proper working order, should the occasion for their use be met.

At regular intervals, based on work done by car in service, the car should be thoroughly inspected and lubricated. Brake pins inspected and lubricated. Wheel flanges inspected for excessive wear. Motors and controllers thoroughly cleaned and any adjustments made that are necessary. Gongs tested for proper tone.

When principal parts of car equipment are at the shop, careful inspection should be made of the same, and where vital parts are involved, they should be thoroughly tested. For instance, when an axle is in the shop for replacement of wheels, it should be thoroughly inspected for flaws before new wheels are pressed on. This would apply as well to truck parts when truck overhauling or rebuilding is being done.

Special Tests in Checking Electrical Equipment

As a part of our maintenance program we have developed special tests and instruments for checking the condition of our electrical equipment. Knowing that in the past flashing motors, controllers or circuit breakers have caused accidents and even passenger injuries, due to panic, we believe that anything that will prevent motor or controller trouble is a safety measure. These instruments are used for this purpose. And not only is it safe maintenance to provide for these instruments and tests, but we find it to be good and economical maintenance.

General and careful inspection and testing of equipment result not only in improved safety, but greater reliability and fewer interruptions to service. Considerable attention is being given to this particular question throughout the country, with an endeavor to reduce the number of equipment failures. Upon our own property, progress has been made along these lines to such an extent that for the month of June, 1927, our system averaged 31.042 miles between equipment failures, which compares with 14,948 for June, 1926, or an increase of 108 per cent. This is upon a system operating over 11,000,000 miles per month, and an average of 3,346 cars per day. It can be readily appreciated that improvements along this line in the matter of equipment failures, result in improved safety of operation.

In conclusion, it might be said that cars should always be designed with safety of passengers and operators in view, and from a maintenance viewpoint eternal vigilance is a great aid to safe operation.

CHAIRMAN EMERSON: Gentlemen, you have up here in this corner, where he can't get away from you, one of the finest authorities and one of the best maintenance men in the United States. He is here with his coat off ready to answer your questions. Let us have a frank and free discussion of these papers. I know you operators have thoughts in the back of your heads about the operation of your own cars that you want to ask Mr. Adams about, and you want to find out if his operation compares with yours, and what he does under certain conditions.

D. J. MAHONEY (Pittsburgh Railway Co., Pittsburgh, Pa.): I was very much interested in the address. It looks as though he gave great study to this subject and covered every detail. There was one thing, however, he omitted which is very important, and that is the sand. When the sand is applied, it should keep running until the car has come to a stop. On many of those newly adopted cars, the sand will only run as long as you hold your hand on the lever. That takes your hand away from the brake or the controller. That is a very important thing.

The next important thing is the gong. We have had a considerable amount of discussion in Pittsburgh on the question of the hand gong and the foot gong. It can be shown that you can miss the foot gong very frequently in the case of an emergency. You have to be standing in a certain position in order to hit that foot gong effectively. By the time you move your foot to get the gong, probably you are too close to the object. With the hand gong, you are always holding the strap in your hand, and you can use it more frequently and more effectively.

Discussing the Question of Sand

MR. ADAMS: The chairman has put me up against a real proposition. I did omit the question of sand, and I will be free to admit it. We make provision for that in our cars by having on double end cars four sand boxes, two of which will operate at either end of the car upon the application of a small air valve directly over the engineer's valve; so really the operation of that is taken care of at the same time the brake application is made by simply the movement of the thumb. It doesn't require any change of the position of the hand. The motorman has his hand on the brake valve and the little lever to apply the sand, so he can get as much of it as he needs. We find he uses a lot. I don't know how many yards of sand we have at our Lake Shore shop.

The question of the location of the gong is a very important one in the design of cars. I think I mentioned that the location of the gong was important. In the design of our cars, we give a great deal of study to the particular location of the gong and the gong pin, and in these modern cars where you have couplers and a large amount of air piping to contend with, it is not an easy job to get the gong located in the proper position for the motorman. After making any decision, we call upon our transportation superintendents to pass upon the subject to see whether it is in a position that they desire.

E. K. EASTHAM (United Railways of St. Louis, St. Louis, Mo.). Mr. Adams rather stressed as one of his safety features the folding step. What has been your experience as a safety measure between the folding step and the stationary step?

MR. ADAMS: Well, we perhaps do not have quite the same design of car that you have in St. Louis.

We have never used here in Chicago the weld step except where we have trailers involved, and our experience has been that with the folding step we get a little wider platform; we can carry our platform a little closer to the side of the car by folding the step up, and for that reason we have not considered the use of the weld step.

MR. EASTHAM: Don't you have any claims in connection with boarding and alighting accidents: people claiming that the step did not go all the way down?

MR. ADAMS: I presume on a system of this size, we have all kinds of claims along that line. Mr. Pasche, I am sure, can answer that, because he analyzes each accident every morning.

MR. EASTHAM: Our experience in St. Louis over a period of years was that in those cases they would always claim that the folding step did not go all the way down, whether it did or did not. We know, as a matter of fact, that in the best equipment kept in the best possible manner that now and then it will not quite go all the way down. We have spent quite a bit of money in converting our folding steps into weld steps. Only about 20 per cent of our cars have the folding step.

I thought it might be of interest to these gentlemen to bring up that subject, because there does not seem to be any standard practice even among the larger companies who have given a great deal of thought to the matter.

MR. ADAMS: I think, however, that the majority of cars built for the surface lines are of the folding step type.

MR. EASTHAM: I have one other question that I would like to ask at this time. You speak of inspecting the cars for different types of defects, which, of course, is very important, but I take it that it is impossible for your shop department to have enough inspectors to look at each car every day, to go over each controller every day. I am wondering what your system is in bringing to your attention defects with reference to gongs and brakes, controllers, which I believe is perhaps the most important thing in the whole subject of maintenance of equipment. In other words, how do you get your men to report their defects? They are out on the road, and can determine defects, as a rule, better than an inspector out in the yards, because defects will show up when a car is running that will not show up under any ordinary inspection out in the yards. I am wondering how you get it over to your men to insure a complete reporting of any and all defects?

MR. ADAMS: That is taken care of by the usual sign-in sheet. The motorman or conductor is supposed to sign in whether the car is O. K., or whether there are any defects. That sheet is turned over to the mechanical department for their attention, and the cars are taken care of along that line. That is the usual method in vogue here in Chicago.

MR. EASTHAM: Do you have any trouble in getting them to do that fully?

An Inspection of Brakes Made Daily

MR. ADAMS: We frequently find that they will not report defects, but we get a great many reports of defects, and we are constantly following the thing up. The matter has gone to the attention of the transportation department, and they get after the particular individuals who are lax in reporting defects.

H. ASHWORTH (Pittsburgh Railway Co., Pittsburgh, Pa.): I would like if Mr. Adams would give us a more detailed statement as to their brake inspection. At our meetings, that seems to be the greatest controversy. The men claim one way and the company claims another.

MR. ADAMS: Our brakes are inspected daily and adjusted if necessary. The regular brakemen in the car house cover those brakes every night to see that they are in proper adjustment. It is a daily performance.

P. L. SPECHT (Pittsburgh Railway Co., Pittsburgh, Pa.): I would like to inquire about the sand apparatus. Don't you find in throwing a car into emergency, your thumb will often slip off the sand apparatus? We have a great deal of trouble with that.

MR. ADAMS: I think usually that one application will cause the sand to run for some little time after it has been applied. In case of an emergency, in a good many cases, the controller is off, and the man has his other hand in case he has to meet a condition of that kind.

W. F. HANNA (United Railways & Electric Co., Baltimore, Md.): I would like to ask the gentleman if he made any deceleration tests to determine for various weights of cars the proper pressure in your air tank and your piston; and what is your standing on the piston for the surface cars?

MR. ADAMS: We have made a number of tests along that line. I haven't the data with me that I can quote from. When I made the statement in connection with the three and one-half to four miles per hour per second on our new cars, that is the result of some of our tests. We have spent a good deal of time along that particular line.

On the matter of the piston, we believe good practice dictates that it should travel four to five inches.

T. H. KENDRIGAN (Public Service Co. of New Hampshire, Manchester, N. H.): I would like to ask whether or not the gong has become obsolete. The gong we used with the old horse car and the original street car was adequate for the occasion. But with the inception of the automobile and the speed that the automobile driver uses approaching an intersection, I don't know what good, if any, it does to warn him.

I think personally, and speaking from experience, particularly since the inception of the automobile, that the gong as a warning at intersecting streets has become obsolete. This might be a good place to start a discussion, and I would like to have the men who drive automobiles enter this discussion in order that we may determine whether it is obsolete or not. I personally think it is no longer a warning to motorists approaching intersecting streets.

CHAIRMAN EMERSON: That let's you out for a moment, Mr. Adams. I would like to hear an expression from the other gentlemen present on this matter of gongs.

When the Controller Is on One Point

H. A. BRIGGS (San Antonio Public Service Co., San Antonio, Texas): My personal opinion is that they are not obsolete but are generally entirely inadequate. I think we need a better one instead of none at all. I think we can reduce our accidents very much by improving the condition of our gongs.

I have a question that I would like to ask Mr. Adams. Recently we purchased five line braker equipment for cars just as a trial. We haven't them rigged up yet, because we have a great deal of run-in on them. I notice a number of your cars run with the line braker. When the motorman has finished unloading at the front end, he closes his doors and sets the controller on one point, and when the conductor closes his door, the car starts. I believe that is right. Is there any danger of the motorman losing hold of just what he is doing at the time and striking a pedestrian when the car starts when he has his mind on something else? We are forbidden to use that practice in view of the fact that the men get into the habit of leaving the controller on one point. Do you think it good practice or bad practice?

MR. ADAMS: I would like to talk on the question of the gong first. There are gongs and gongs. If you are going to purchase a cheap gong you get a cheap one. We find it advisable to get a gong that has a real tone to it. Some of the gongs that have been properly tin coated will prevent the rust coming too soon. We find that by the use of a gong 14 inches in diameter, properly located, with a good mechanism and pin, we get a real sounding gong that is a warning, and it meets the requirements of our congested situation here very satisfactorily.

On the matter of the first point of the control, I think I will let Mr. Pasche talk on that, because he has had a good deal of experience with it from the operating standpoint.

MR. PASCHE (Chicago Surface Lines, Chicago, Ill.): On the line braker car and on the door being opened with our motorman having the controller on the first point, if he does not turn his door cutout button off, his car cannot start. We have had no accidents from our cars starting with the controller on the first point. The only time that he can start the car is if his door cutout button is off. That button is immediately over the motorman's head. If the cutout button is off, the car cannot start and does not start, and we have had no accidents from that source.

WILLIAM H. PONSONBY (Pittsburgh Railway Co., Pittsburgh, Pa.): In your statement that you brake three and one-half miles per hour per second, what effect has it had in the falling-in-car accidents, if any?

MR. ADAMS: The braking is smooth. You won't find any difficulty on that. I have personally stood in the cars when we have been braking at that rate, and I will

say I had hold of the strap, but it is not necessarily uncomfortable, and it is operable, in my judgment.

MR. PONSONBY: What effort do you make to control the time that the motorman uses in going from the first to the last notch on his controller, assuming that it is a hand controller and not an automatic control?

MR. ADAMS: The question asked was whether we put any limit of time on the application of the controller handle by the operator.

We do not limit it. We have no automatic feature on there or time element that would require him to take a certain amount of time to feed up. We believe that we want to have our equipment in such condition that it can be, if necessary, punished for schedule. We try to keep the equipment up so that they can make as high a schedule as it is possible to make in the city of Chicago.

My understanding is that we are operating at the present time at a scheduled speed of 11.2 miles per hour between terminals.

CHAIRMAN EMERSON: Pretty nearly as fast as Cleveland.

MR. ADAMS: We never hope to catch up to you, but we are after you. We do not limit the time; we leave that to the individual.

Chicago People Expect to Be Slammed Around

MR. EASTHAM: There apparently is a great difference in conditions in Chicago and other big cities, not only a difference with reference to traffic conditions but a difference with reference to your people and the people that make claims against the company. If in St. Louis we were to feed up the controller with a view to schedule alone, we would have 25 claims a day of people claiming that they fell in the car on account of the car starting with an unusual jerk. I don't know, but I imagine from the question of the Pittsburgh gentleman that that matter has come up there.

I think you are very fortunate here if your people fall and so forth without making claims, just considering that it is part of the game. But we have to watch that, and instruct our men that they shall make a smooth start even if they lose some time in doing it.

H. H. FENTON (Pittsburgh Railway Co., Pittsburgh, Pa.): I have three things that I want to bring up. Most of them are information, though. The first one is the matter of lightning arresters, the new lightning arresters, the condenser type. I would like to hear an expression of experience on other properties from accidents they have had from the body of the man who climbs the roof to renew a fuse on cars that are equipped with condenser lightning arresters. You know, the condenser lightning arrester will absorb a certain quantity of electricity. It being on the hot side of the fuse when the fuse blows, when a man attempts to put in a new fuse, his body as he touches the terminal on the trolley side of the fuse will absorb part of that shock. It is not dangerous, but it surprises a man. We had one man fall from the car and get hurt in just that way. I would like to know what is being done in other properties.

The second point is this: Some of you have had the privilege of being in Boston. In the matter of retrieving a trolley, I found there that on some of the cars they are mounting the trolley over the forward truck, and the trolley line for the conductor, who is in the center of the car, is put there to retrieve the trolley. That seemed quite novel and worth while.

My third point is on the gong. There seems to me a chance for a little study there as to the rapidity at which the going is struck. I think we should stick to the gong as against the claxon or a horn of any sort. They are being used on trucks and autos and the people have become accustomed to them. If we went to a claxon or a horn, the people hearing that might stop on the car tracks.

I think we should stick to the gong, but study the rapidity with which it is struck; as an example, an electrically operated bell controlled by a push button at the end of the controller handle.

On the matter of the piston, we believe good practice dictates that it should travel four to five inches.

T. H. KENDRIGAN (Public Service Co. of New Hampshire, Manchester, N. H.): I would like to ask whether or not the gong has become obsolete. The gong we used with the old horse car and the original street car was adequate for the occasion. But, with the inception of the automobile and the speed that the automobile driver uses approaching an intersection, I don't know what good, if any, it does to warn him.

I think personally, and speaking from experience, particularly since the inception of the automobile, that the gong as a warning at intersecting streets has become obsolete. This might be a good place to start a discussion, and I would like to have the men who drive automobiles enter this discussion in order that we may determine whether it is obsolete or not. I personally think it is no longer a warning to motorists approaching intersecting streets.

CHAIRMAN EMERSON: That let's you out for a moment, Mr. Adams. I would like to hear an expression from the other gentlemen present on this matter of gongs.

When the Controller Is on One Point

H. A. BRIGGS (San Antonio Public Service Co., San Antonio, Texas): My personal opinion is that they are not obsolete but are generally entirely inadequate. I think we need a better one instead of none at all. I think we can reduce our accidents very much by improving the condition of our gongs.

I have a question that I would like to ask Mr. Adams. Recently we purchased five line braker equipment for cars just as a trial. We haven't them rigged up yet, because we have a great deal of run-in on them. I notice a number of your cars run with the line braker. When the motorman has finished unloading at the front end, he closes his doors and sets the controller on one point, and when the conductor closes his door, the car starts. I believe that is right. Is there any danger of the motorman losing hold of just what he is doing at the time and striking a pedestrian when the car starts when he has his mind on something else? We are forbidden to use that practice in view of the fact that the men get into the habit of leaving the controller on one point. Do you think it good practice or bad practice?

MR. ADAMS: I would like to talk on the question of the gong first. There are gongs and gongs. If you are going to purchase a cheap gong you get a cheap one. We find it advisable to get a gong that has a real tone to it. Some of the gongs that have been properly tin coated will prevent the rust coming too soon. We find that by the use of a gong 14 inches in diameter, properly located, with a good mechanism and pin, we get a real sounding gong that is a warning, and it meets the requirements of our congested situation here very satisfactorily.

On the matter of the first point of the controller, I think I will let Mr. Pasche talk on that, because he has had a good deal of experience with it from the operating standpoint.

MR. We have had no accidents from our cars starting with the controller on the first point. The only time that he can start the car is if his door cutout button is off. That button is immediately over the motorman's head. If the cutout button is off, the car cannot start and does not start, and we have had no accidents from that source.

WILLIAM H. PONSONBY (Pittsburgh Railway Co., Pittsburgh, Pa.): In your statement that you brake three and one-half miles per hour per second, what effect has it had in the falling-in-car accidents, if any?

MR. ADAMS: The braking is smooth. You won't find any difficulty on that. I have personally stood in the cars when we have been braking at that rate, and I will

say I had hold of the strap, but it is not necessarily uncomfortable, and it is operable, in my judgment.

MR. PONSONBY: What effort do you make to control the time that the motorman uses in going from the first to the last notch on his controller, assuming that it is a hand controller and not an automatic control?

MR. ADAMS: The question asked was whether we put any limit of time on the application of the controller handle by the operator.

We do not limit it. We have no automatic feature on there or time element that would require him to take a certain amount of time to feed up. We believe that we want to have our equipment in such condition that it can be, if necessary, punished for schedule. We try to keep the equipment up so that they can make as high a schedule as it is possible to make in the city of Chicago.

My understanding is that we are operating at the present time at a scheduled speed of 11.2 miles per hour between terminals.

CHAIRMAN EMERSON: Pretty nearly as fast as Cleveland.

MR. ADAMS: We never hope to catch up to you, but we are after you. We do not limit the time; we leave that to the individual.

Chicago People Expect to Be Slammed Around

MR. EASTHAM: There apparently is a great difference in conditions in Chicago and other big cities, not only a difference with reference to traffic conditions but a difference with reference to your people and the people that make claims against the company. If in St. Louis we were to feed up the controller with a view to schedule alone, we would have 25 claims a day of people claiming that they fell in the car on account of the car starting with an unusual jerk. I don't know, but I imagine from the question of the Pittsburgh gentleman that that matter has come up there.

I think you are very fortunate here if your people fall and so forth without making claims, just considering that it is part of the game. But we have to watch that, and instruct our men that they shall make a smooth start even if they lose some time in doing it.

H. H. FENTON (Pittsburgh Railway Co., Pittsburgh, Pa.): I have three things that I want to bring up. Most of them are information, though. The first one is the matter of lightning arresters, the new lightning arresters, the condenser type. I would like to hear an expression of experience on other properties from accidents they have had from the body of the man who climbs the roof to renew a fuse on cars that are equipped with condenser lightning arresters. You know, the condenser lightning arrester will absorb a certain quantity of electricity. It being on the hot side of the fuse when the fuse blows, when a man attempts to put in a new fuse, his body as he touches the terminal on the trolley side of the fuse will absorb part of that shock. It is not dangerous, but it surprises a man. We had one man fall from the car and get hurt in just that way. I would like to know what is being done in other properties.

The second point is this: Some of you have had the privilege of being in Boston. In the matter of retrieving a trolley, I found there that on some of the cars they are mounting the trolley over the forward truck, and the trolley line for the conductor, who is in the center of the car, is put there to retrieve the trolley. That seemed quite novel and worth while.

My third point is on the gong. There seems to me a chance for a little study there as to the rapidity at which the going is struck. I think we should stick to the gong as against the claxon or a horn of any sort. They are being used on trucks and autos and the people have become accustomed to them. If we went to a claxon or a horn, the people hearing that might stop on the car tracks.

I think we should stick to the gong, but study the rapidity with which it is struck; as an example, an electrically operated bell controlled by a push button at the end of the controller handle.

There is a relation between the nervous system and the rapidity at which that bell can be struck. That can be easily seen if you think, for a moment, of the tolling of a church bell as against the rapid striking of the gong on an ambulance. I think there is a field there for study and something can be gotten up.

CHAIRMAN EMERSON: Won't some of you gentlemen answer all or any of the questions that have just been put? The first is in regard to the fuse. We would be glad to hear from anybody. Mr. Adams, have you any observation to make on that?

MR. ADAMS: We have had no experience with lightning arresters of that type here in Chicago.

CHAIRMAN EMERSON: His second question was in regard to the trolley on the Boston cars. You certainly have some comments to make on that subject. It is a new one to me.

W. F. HANNA (United Railway & Electric Co., Baltimore, Md.): We have that on the articulated type of cars in Baltimore. We found after a few weeks' experience, it was necessary to clear the roof in order to prevent it catching when the car was going around the curve. The conductor has to go out and adjust it to the wire.

I might say in that connection that there is a conflict sometimes. We found that a car of the articulated type would upset the automatic switches. We have to be very careful when the cars go around loops with that particular type to see that the trolley is always down and the rear trolley is always up.

CHAIRMAN EMERSON: How does the conductor see the trolley?

Further Discussion About Gongs

H. H. FENTON (Pittsburgh Railway Co., Pittsburgh, Pa.): There is a slot, a longitudinal slot across the car with a lid that the conductor can lift up to see where to place the trolley.

MR. HANNA: I should have said that our conductor has to get off the car to make that adjustment.

CHAIRMAN EMERSON: The gentleman asks about gongs and the rapidity with which they are struck and so forth: whether or not the gong should be supplanted by some other device?

MR. ADAMS: I would like to speak on that. In an experience with the old pneumatically operated gongs which carry forward the same thought, we had a number of those in operation here in Chicago along in 1912, and we found that there was considerable objection from the public to that type of gong. In addition, we also found that the plunger punched holes straight through the gongs and we had to keep turning the gong so as to get another place to punch a hole through.

W. T. HARVEY (United Traction Co., Albany, N. Y.): I don't believe that we should quite pass up this question of gongs as easily as we have. I am inclined to think that there is a good deal of merit in that suggestion. I submit that an operator of a car with a gong such as we have does not stand much show to be heard when there is a five-ton truck loaded with stone alongside of him in the street.

As far as the repetition of the stroke is concerned, in some places we are not permitted to use anything that approximates the fire department or ambulance gongs. It seems to me we ought to water up and see if there is a suitable whistle that isn't annoying and at the same time can be heard.

CHAIRMAN EMERSON: You have Mr. Adams in the corner now, gentlemen. Are there any more questions?

D. W. FINCH (Des Moines City Railway Co., Des Moines, Ia.): In regard to the gong, I think that we cannot do away with it. The only thing we can do that will give satisfaction and get away from the kick of the public is the gong.

In regard to the accidents at intersections, I have recently made a check of the accidents occurring on our road, and those accidents occurred principally on the cars that

had poor bells. We are now equipping our cars with a proper gong. I think the proper gong is one that is clear and one that can be heard distinctly. A whistle is deafening. People even raise Cain about ringing a gong, and they certainly would raise more Cain about the whistle. You can't get too good a gong.

MR. BABBITT (Pittsburgh Railway Co., Pittsburgh, Pa.): I think that we have come to a time when we should have an emergency gong as well as a hand gong. There are times when one ringing of the gong will save a life.

I would also like to ask Mr. Adams what he would think of a forty-eight hour inspection of city run cars instead of a daily inspection?

MR. ADAMS: For the very vital parts like the brakes, I believe in the daily inspection, absolutely. I don't want to take any responsibility with any other system.

E. HOLLIBAUGH (Pittsburgh Railway Co., Pittsburgh, Pa.): What I had in mind was the fact that we have had the gongs for a number of years, and we know that our body becomes toned to the condition in which we live. When we move into a certain community, we take on the habits of that community.

Is it necessary that we change the tones or go to some other device that the body hasn't become so accustomed to? Has our body become so toned to that that we don't notice it? I kind of think it has.

The Automobile Pays Little Attention to Gongs

GEORGE LANSTER (T. M. E. R. & L. Co., Milwaukee, Wis.): I should like to ask Mr. Adams what type of gong he uses, a steel gong or a metal gong?

MR. ADAMS: We are using a 14-inch gong which is a steel gong; it is zinc coated.

MR. LANSTER: It has been my experience that gongs that are new and those that come out of the paint shop are very clear and can be heard, but after a few months of use they become dead. Is there any company here that has thought of such a thing as changing the tone of the gong or the gong itself about once every three months?

MR. HELLMUTH: I would like to say a word about Mr. Adams' gongs, because I have observed them for many years rather enviously. Go hire an automobile this afternoon and drive down the street in front of one of his cars and hold back the progress of it, or watch a wagon on the track that is holding it back and hear the way that gong sounds. Those gongs can be sounded so loud that you can hear them a couple of blocks away. A good deal of the question of the volume of sound is up to the motorman in the way in which he taps the gong. They are very splendid gongs, in my judgment. I think if they are properly tapped they are as adequate a warning as you can secure.

You must remember that you can't, for example, put a locomotive whistle on a city street car. The volume of sound that you are allowed to give out as you go down the street is limited by the likes and dislikes of the people that live in the city. So, you can't get something that is going to be used just in the country. You have to have a gong that gives out the maximum sound that the public is willing to have. I think that these surface line cars here have just such a gong.

MR. ADAMS: If any of you gentlemen carry out that performance, please report any to me that are dead.

CHAIRMAN EMERSON: It seems to be agreed that the gongs used in Chicago are satisfactory. I would like to ask Mr. Adams who makes them?

MR. ADAMS: I cannot tell you the name of the manufacturer right now.

CHAIRMAN EMERSON: Gentlemen, are there any other questions anybody wishes to ask Mr. Adams about his maintenance of equipment in general? Let us leave the gongs out of it for a minute.

H. YOUNG (Chicago Rapid Transit Co., Chicago, Ill.): Irrespective of the fact that the brake pins and slabs are case hardened, do you find it necessary to inspect them every 24 hours in addition to the regular mileage inspection? If so, what is your average daily mileage?

MR. ADAMS: We inspect the vital pins daily; that is, those on the foundation brake levers and so forth. Of course, we couldn't make a daily inspection of all pins throughout the entire brake. We do, however, cover that particular situation on the general inspection, which is covered on a kilowatt hour basis, averaging about once a month.

With regard to the mileage we make a day, we run on the average, in round figures, about 600 miles.

E. HOLLIBAUGH (Pittsburgh Railway Co., Pittsburgh, Pa.): I have one question on the matter of sand equipment. With that button you use with your thumb at the same time you use your air valve, what experience have you had concerning the wearing out of the pin? I have noticed with our equipment that that wears or appears to wear very quickly.

MR. ADAMS: We have a very simple valve on most of our cars. We don't have much difficulty along that particular line. It is a very simple valve that we use and one we have made in our own shops.

I might add to that question on the application of the sand in conjunction with the brake valve, that on the modern cars where we have the M2S valve, all you have to do is press down the valve lever at any point and you can get your sand.

CHAIRMAN EMERSON: Gentlemen, we have four other papers, and we have the luncheon at twelve-thirty. I think the Program Committee made a mistake in putting any other papers on this morning's program.

Mr. Adams, we are very much indebted to you, and we thank you very kindly for coming here.

GENE R. NAUGHTON (Pittsburgh Railway Co., Pittsburgh, Pa.): I would like to ask Mr. Adams what his experience has been with people falling off the cars; that is, on the open door cars?

MR. PASCHE: We don't have very much of that. The only time we have anybody thrown off the car is when the conductor gives the bell too quickly. That is the only trouble we have.

Many Accidents Occur on the Back Platform

EDWARD MCMORROW (Amalgamated Association of Street & Electric Railway Employees of America, Detroit, Mich.): I notice the motormen around here are getting the best of it this morning. I would like to ask Mr. Adams or Mr. Pasche if they have made any arrangements for the conductor to mechanically handle the various rates of fare that he is confronted with.

I find in my travels throughout the country a great many accidents occur on the back platform. I find, too, that owing to the changing of fare and the different kinds of fare that our valuable older men are being gradually eliminated from the service because of the fact that there isn't attention enough given to the ordinary expediting of the work. For instance, I notice in St. Louis they have a specially made equipment for the conductor where he carries bunches of pennies and transfers. I have noticed in Chicago and Cleveland and other places that a man will get on the car with a \$2.00 bill and two pennies, which is a warning that he must have no pennies in return; he will get on with a five dollar bill and two pennies, which is another warning that he don't want any pennies back; he will get on with a quarter and two pennies, which is another warning that he don't want any pennies back.

The reason that prompted that question was because the chairman of this meeting yesterday made an observation about the conductor looking down the side of the car. I sometimes think that I am really cross-eyed from looking down the side of the car. I hope somebody will bring in a paper that will help us old, poor, decrepit conductors.

CHAIRMAN EMERSON: I think Mr. McMorro has asked several questions and

answered them himself. I am not going to permit any discussion on them, because they are complete in themselves.

We will now continue with the reading of the second paper by Mr. A. W. Koehler of the Milwaukee Electric Railway and Light Company.

The Organization and Functioning of Safety Committees

A. W. Koehler, Superintendent of Accident Prevention, The Milwaukee Electric Railway & Light Company, Milwaukee, Wis.

In discussing my subject I am going to take the liberty of reversing the order in which the two factors, organization and functioning, appear in the title of my paper.

It is because of the fact that the proper functioning of the safety committee determines the order and manner of organization that I prefer to give first consideration to the functioning.

To determine and fix the functions of a safety committee it is necessary first to have an accurate conception of what is intended to be accomplished by such a committee. In other words, why a safety committee—what should it do—what are its advantages, its limitations—what are its specific functions—what can it do on our property? Having satisfactorily answered these questions in the light of our individual conditions and problems, we may then consider the form of organization adapted to deal most efficiently and expeditiously with our own individual or particular situation.

If we are prepared to accept, as fundamental, that the functions of the safety committee will be just as efficient and productive of worthwhile results as those responsible for its conduct will permit and inspire, we may proceed to discuss and consider the matter of functioning and organization.

We are agreed, I think, that accident prevention work (safety work, if you please), is in its largest sense a matter of education. Mechanical guarding, important as it is, is only a physical manifestation of sincerity of purpose, or good faith on the part of the management. The electric railway business (and I have in mind now the transportation end of the business) does not lend itself readily to the application of mechanical guards. We must depend, in the main, upon educational effort.

This educational effort to be most effective must be through personal contact. Bulletins and posters have their place and are part of any efficient safety program, but the real, lasting results come from personal contact.

Every general manager, superintendent, division superintendent, supervisor or instructor will recall instances from his own personal experience where by a heart to heart talk he has been able to show a man the error of his ways and has been able to inspire and exert a very helpful influence upon him. Safety may be and is imparted to the individual in the same way.

It would be an ideal situation, but a manifestly impractical and impossible one, if the superintendent of each department might appeal personally to every man under his authority.

The function of the safety committee is to provide a substitute for the personal inspiration and influence of the superintendent through the person of the safety director. The influence of the superintendent is imparted to the members of the safety committee, who, in like manner, pass it on to their fellow employees until the entire personnel of the department is imbued with the spirit of safety.

The degree of enthusiasm and efficiency with which the safety committee functions is dependent, first, upon the degree of sincerity and enthusiasm of

the management, and, secondly, upon the ability of the man who makes direct contact with the members of the safety committee. By his sincerity, enthusiasm and personality, he can most effectively interpret the management's attitude and sell safety to the men.

Perhaps the most important function of the safety committee is to inspire confidence in and respect for the company's safety activities. This it can do only when its own members are fully in sympathy with and confident of the management's genuine interest and support, as evidenced by the adoption or rejection with good reason by the management, or its recommendation and findings.

A second function of the safety committee is to stimulate its own members, as well as the personnel of the department of which it is a part, to offer constructive safety suggestions intended to eliminate unsafe conditions or practices.

A third function of the committee is the dissemination of information concerning safety among other members of the department. Safety inspections in their own as well as in other departments are made by the safety committees, it having been found that the committee from another department will discover conditions which the regular departmental committee has overlooked by reason of the members being too familiar with their surroundings.

Another function is the investigation of accidents in the department. Fellow employees who have been involved in lost time accidents or those of a nature that warrant special attention are often invited to appear before the safety committee and make a full, detailed statement of all the factors which would enable the committee to find all of the facts in connection with the occurrence of an accident, to fix responsibility for the accident and recommend to the department head, with whom rests the final disposition of a case, the kind and degree of discipline to be administered.

This does not in any way encroach upon the prerogatives of the head of the department as a disciplinary officer, nor does it relieve him of the responsibility of administering disciplinary measures. It does, however, materially aid him when it is known to every man that a group of his own associates have fixed the penalty imposed upon him for carelessness or the infraction of a safety rule which has adversely affected the safety standing of the department, and that their chief is confirming the judgment which they have rendered.

Safety Responsibility Assumed by Committee Members

Another function, subconsciously developed, but nevertheless unmistakably evident, is the acceptance of responsibility by safety committee members which they know is not only implied but imposed upon all members of the committee. It is rare that members of the safety committee are themselves involved in accidents. By reason of their position as safety committeemen they are consciously and subconsciously aware of the management's faith in them as safety leaders of their fellow employees and accordingly by precept and example they demonstrate their fitness to be safety committeemen.

It is a function of the safety committee to keep the department head advised, through written reports of safety meetings, of all matters pertaining to safety, whether they be recommendations for newer and more efficient safeguards, supplanting old methods and practices with newer and safer ones—in short, to provide the head of the department with a running record of perpetual inventory of the safety situation in the department.

It has been the experience of those companies which have encouraged the development of safety committee activity that concurrent with the expansion of the regular functions of the committee there develops in the safety com-

mitteeman a keener pride in his job and a more pronounced evidence of interest in other phases of his work. He has been given recognition, he has been allowed opportunity to manifest his initiative and talents, and he has been given credit for ideas that may be useful to his company.

Service on the safety committee promotes group effort as well as individual effort, a desirable function in that it teaches men the necessity for subordinating individual preference, when the best interests of the division or the department are served thereby, to the collective judgment of the committees.

These by-products of the regular functions of the safety committee may become, if wisely and skillfully developed, invaluable to any company. It is not intended to convey the impression that the functions which have been described constitute the sum total of activities of the safety committee. They are but some of the more important functions which will furnish us a foundation upon which to build the superstructure of our safety organization.

Organization of the Safety Committee

Having now quite clearly in mind the duties which the safety committeemen are to assume, we may proceed with greater assurance of probable success to select the men who are going to discharge these duties.

Safety committees are organized in a variety of ways, the proponents of each plan enthusiastically endorsing that one which in their judgment holds the greatest promise of results.

The number of men constituting the committee depends upon the size of the property, its location (whether centered in one community or scattered over a number), upon the accident exposure, the manner of organization of the company itself and upon a number of other factors which will suggest themselves to those charged with the responsibility of organizing safety committees.

The controlling unit is usually a central safety committee, the chairman of which is a responsible executive of the company. He may be the general manager, vice-president, the assistant general manager or the head of one of the operating departments. The personnel of this committee usually consists of the heads of the operating departments, the medical director, claim agent, and the director of safety, who acts as secretary.

The central safety committee meets either monthly or bi-weekly and passes upon all matters of policy relating to safety. In the larger companies it may be divided into sections, each concerning itself with the more intimate problems of the more closely related departments.

The departmental safety committees, composed of the men on the platform, the men at the bench and those in the field, are the committees which supply the grist to the mill, and it is their organization to which we are about to give thought.

The most democratic method of organizing workmen's committees is to call a meeting of the men in a given department and invite them to propose the names of five, ten, or twenty of their number, depending on the number of men in the department, to serve on the safety committee. This will be preceded, of course, by a short, snappy talk by the head of the department, supplemented perhaps by a few words from the chairman of the central safety committee or the director of safety, during which the aims and objects of the committee, duties of members, etc., are outlined.

If there is any reticence on the part of the men to take the initiative, the department head may tactfully precipitate action by suggesting the names of two or three men who would make good safety committeemen. It will be found that the natural leaders, the men who are popular, who have the respect

and confidence of their associates, are usually nominated as members of the committee.

Their term of office should be not more than three months, so as to provide an opportunity for an influx of new blood to stimulate and keep the spirit alive. It is well to retain one or more members as hold-overs to act as spokesmen, to preserve the continuity of effort, and to supply the conservatism which may at times be needed to counterbalance well-intentioned but perhaps misguided enthusiasm.

When the safety committeemen have served their designated terms it is customary in some companies to permit them to name their successors. Here again, it is well for the department head or safety director to offer a few tactful suggestions reminding the outgoing committeemen that in naming men who are succeeding them, they are sponsoring these new men and that the success or failure of the men whom they have selected to succeed them will reflect creditably or discredibly upon them.

Sometimes a man is selected as a member of the safety committee because he is known to be out of sympathy with safety activity. He thinks it is "the bunk." When such a man comes into actual contact with the work of the committee and sees results, he often becomes an ardent booster.

Some department heads prefer to choose their own safety men from an intimate knowledge of their characteristics. This is less democratic than the method just described, but may serve just as effectively as the other plan. This is a matter of preference which must rest with the individual company.

Since the transportation department is confronted with the more difficult problem of contending with accidents, many of which arise out of dual responsibility—that of the employees and those not in the employ of the company—the organization and functions of the safety committee in the transportation department deserves special mention.

Separate Safety Committees for Each Division

On those properties whose transportation departments are divided into a number of divisions there are usually separate safety committees in each division.

It is well to include in the personnel of these committees—motorman or one man operators and conductors—one man from each of the lines operating out of the division. The selection may be further refined by choosing early and late men, since conditions in the same territory vary at different times of the day and the night.

The division superintendent may act as chairman, and the car-house foreman or another representative of the rolling stock department makes a valuable addition to the committee. The supervisory forces of the transportation department should not be overlooked, as these men certainly have an interest in safe operation and their initiative and talents may be employed to good advantage.

The form of organization for the transportation department lends itself admirably to various forms of competition which stimulate interest and promote additional incentive.

A dissertation of this kind would not be complete without mention of the character of the safety meetings held by these committees. The organization of the committees may be ideal, the functions set up for them beyond reproach and yet unless the *modus operandi* is congenial and conducive to sustained effort, the preliminary organization work will have been for nothing. The meetings must be interesting—they should not be permitted to drag. It is much better to

adjourn ahead of time than to sit through the full hour simply to "go through the motions" or because "we're expected to put in this time on safety."

The meetings need not be without humor; it is not necessary to sit with a long face that might be appropriate to an undertakers' convention, even though serious matters are being discussed. It is well to relieve the tension now and then by an appropriate story, as this brings home a point many times more forcibly than a more serious presentation would.

Suggestions made by the men should be considered seriously. They are offered that way and should be so received. If it is necessary to reject a suggestion, the reason for its rejection should be made known to the originator.

In conclusion, to achieve lasting results be sincere, be receptive and encourage the efforts of your safety committeemen. Endeavor at all times to show your appreciation of the work they are doing, for their energies and zeal depend in large measure upon the degree of interest and enthusiasm which you arouse and sustain in them.

The Committee Recommends the Form of Discipline

CHAIRMAN EMERSON: In calling for the discussion on Mr. Koehler's talk, I am going to ask you gentlemen to confine yourselves absolutely to the questions that you wish to ask him, because our time is getting short and we don't want to have an elaboration of the points Mr. Koehler brought out. We want to ask questions about what he said.

STEPHEN A. HART (Pittsburgh Railway Co., Pittsburgh, Pa.): Mr. Koehler's remarks specify that the safety committee recommends the form of discipline to be administered to a man in case of an accident. I would like to know the method he uses in Milwaukee.

MR. KOEHLER: In one or more departments, the committee makes a thorough investigation of the accident. If, as a result of that accident, it is a violation of a rule or by gross negligence or carelessness that the man injured himself, then they find the accident, the disability and lost time were occasioned by negligence, and the committee recommends that he be suspended for a day or two or even a week, depending upon the seriousness of the offense. That decision is confirmed or denied by the head of the department.

H. ASHWORTH (Pittsburgh Railway Co., Pittsburgh, Pa.): What is your method of getting the attendance at meetings?

MR. KOEHLER: We don't have any trouble on that score. In the first place, our safety meetings are held on the company's time. A definite and specific time is set aside for a safety meeting. In the case of the men in the transportation department, they are relieved from their runs and are permitted to come to the meetings. In the case of the men in the operating department and others, those men, too, meet at a given specified time, and that time is set aside for that and no other purpose.

MR. ASHWORTH: I mean your general rallies.

MR. KOEHLER: We try to make our meetings popular. We try to appeal to a man's reason. We don't try to cram anything down his throat. We appeal to him. We conduct our meetings in a way that we don't bore them. They are not too long. We try to make them short and snappy. We don't have some fellow talk for an hour. We inject a little humor into our meetings. We show a picture and have some refreshments and cigars and that sort of thing. That does the trick.

MR. ASHWORTH: Do you observe the violation or do the members of your committee do that? Do you feel that it would be more effective to report that man or have the safety director talk to him in a heart-to-heart fashion?

MR. KOEHLER: I prefer to reach a man by an appeal to his own reason. My own reaction would be this: If I saw a man who did something that I thought was un-

safe, and I felt that by an appeal to him and by calling to his attention the fact that he was jeopardizing himself and perhaps was denying his family opportunities that they might have, I would tell him about it. I should much prefer to go to a man and talk to him, and I am convinced that that is appreciated. Does that answer your question?

MR. ASHWORTH: We in Pittsburgh have a different system. We don't believe in any suspension whatever for a man. We give the men a new sheet every January. If he has an accident that looks very much like his own fault, he is given a note with his name on it, and if he thinks he is guilty he signs that and it goes against his record. If he can show that it was not his fault, there is nothing said about it. We get wonderful results in Pittsburgh on that. We put the men on their honor.

MR. KOEHLER: I think that is a good plan. We introduced an innovation last year, in that instead of the suspension or anything of that sort, we had the man who was responsible for an injury to himself appear before the general safety committee of his own department and there acknowledge his responsibility for the accident; tell just how it happened, what he did to contribute to it, and how he might avoid it in the future. That is a form of discipline that is perhaps more acceptable.

GEO. K. CONKLIN (Augusta, Aiken Railway & Electric Corp., Augusta, Ga.): I would like to ask Mr. Koehler if it is a good plan to have one meeting of all the conductors, and have one meeting of all the motormen, and then have all the members criticise the particular department.

MR. KOEHLER: I think that is a very fine plan. There is such a thing as not being able to see the forest because of the trees. You become so close to a situation that you no longer see hazards that are there, and by bringing in the men from the other departments, you get that interchange of ideas and opinions that is so helpful. I think it is a mighty good plan.

W. H. BOYCE (Pittsburgh Railway Co., Pittsburgh, Pa.): Do you pay for safety and other suggestions?

MR. KOEHLER: No, we do not.

CHAIRMAN EMERSON: I certainly am glad to hear this discussion. I think we get a lot of meat out of the discussions. Our time is limited. We still have two more papers. I am going to call now for the third paper of the session. I take pleasure in presenting Colonel Edward C. Spring of the Lehigh Valley Transit Co., Allentown, Pennsylvania.

The Power of Safety in the Electric Railway Field

**Edward C. Spring, General Superintendent, Lehigh Valley Transit Company,
Allentown, Pa.**

Upon the horizon of human events there appears a new agency destined to revolutionize the business and economic standards of the world. Flooded in all the glory of the morning sun it has already begun to radiate its influence over the land. This influence is destined to be world-wide and predominate in every vocation of life. It is the answer to thousands of problems yet unsolved.

For "Safety" is the most powerful word in the 5,000 languages and dialects of the earth. A universal language in itself, it is understood by all. Webster gives as a definition of safety "freedom from danger." What a power lies in that definition! What vocation in life does not have its dangers, which should be avoided!

If there is a guide or power that will safeguard all interests, is it not to be cultivated and adopted?

Safety, although known in theory as far back as the Creation, is a comparatively new word in industrial and commercial life. Brought into promi-

nence in 1912 by the organization of the National Safety Council, its real constructive meaning in modern civilization began to be more thoroughly understood. The activities of the National Safety Council have kept pace with the onward march of progress until today industry recognizes in the safety idea, one of its most potent powers for efficiency and production.

The safety department in all big business not only strives to eliminate the accident hazards of the plant, but ties all department and division employees and the management into a coordinate whole.

For 15 years industry has spent millions of dollars and made countless studies and analyses of safety problems.

What can the public utilities, particularly the electric railways, derive from the experience of industry?

There Are Four Outstanding Problems

There are four outstanding problems with which the electric railways are confronted today and which must be brought to a speedy solution, in order that the industry may cope with the many new developments in the transportation field:

- 1—Greater efficiency in operation.
- 2—Reduced costs in production.
- 3—Coordination of employees with management.
- 4—Better public relations.

Has industry not been confronted with the first three and worked them to a fairly successful solution?

Do we not find that the most effective work in connection with these three problems has been done in the past 15 years, during which time the plant safety organizations have functioned most prominently?

Is it not a fact that the safety departments have done more than any other agency in plant management to bring about a solution of these three important problems?

Every close student of economics and every industrial engineer will substantiate the affirmative of these questions.

What, then, is left for the utility to do, except go and do likewise? Profit from the experiences of others, knowing that their results have been obtained along the lines of good and sane American business management. Simple, is it not, yet how many public utility executives are ready to be convinced of its logic?

Unlike most projects, safety must work from the head downward instead of starting from the ground and working up. Unless the executive or managerial heads are in sympathy with the idea, that safety work is going to solve in a very large measure their major problems in operation, and have implicit faith in the results, it will be useless to enter into the work.

It is the example set by management that is reflected down the line to the lowest subordinate.

There is a wonderful ally awaiting the Electric Railway industry in accident prevention and safety work, if this is made an integral part of any organization. It must not be spasmodic in character but strenuous and persistent if it is to be successful.

Let us consider briefly the power safety offers toward the solution of the four important problems referred to:

First: greater efficiency in operation is gained through education, by a better understanding of work and coordination of interests. One of the most important influences in accident prevention is the proper selection of men. Great care should be taken that the very best material available is secured,

that this be followed by thorough training and close supervision, constantly emphasizing the importance of safety, and that this be accompanied by fair, reasonable disciplinary action for infringement of regulations.

Under a program of this character a high state of efficiency will be developed in every department.

In the study of accidents, both from a public and employee standpoint, every phase of safe and sane operation must be thoroughly investigated. What better medium can be mustered into service than the department organizations and employee groups? Almost instantly you have a highly trained force that is being educated through investigation and study. Its work will give the organization a better understanding of the problems to be solved and the coordinate interest is held secure by the various committee chairmen. Greater efficiency is almost automatic.

Second: reductions in cost of production are a result of constant study and close application to problems unsolved. Constant vigilance on the part of the foreman and worker are imperative for reduction in production costs. The trained safety committees are constantly on the watch for carelessness, waste and safety in the work of the department. They are trained to a keen sense of duty and loyalty to the management. They can impart this spirit to the worker as no other agency can possibly do.

With the elimination of carelessness, waste and imperfect work, costs are bound to decrease. In this connection the fact must not be lost sight of, that a safe man is not a careless or wasteful man, but a highly efficient man, made so by his safety training; therefore reduced costs in operation are secured.

Safety Offers the Common Ground of Mutual Interest

Third: industry has given the business world a wonderful illustration of the value of the plant safety organization in the relationship of the management and employee. In this case safety offers the common ground upon which all matters of mutual interest can be clearly met and discussed. Here enters the human touch so necessary to desired results in modern business management. Again, no other agency can function with greater success than the safety organization.

When employees are successfully grouped into working forces, encouraged by the management and marshalled by the department heads, superintendents and foremen, a better understanding of working conditions and problems is the inevitable result.

Fourth: better public relations is a problem akin to the utility and does not enter into the industrial problems. In the public utility field, and very pronounced in the electric railway field, the problem of public relations is perhaps the most important one to be solved.

To reach the attentive ear of the public so that we may tell our story in our own language is a diplomatic feat. Industry has found that the one common ground upon which the management and employees can meet and be understood is the ground offered by safety. We are fast realizing the same in the electric railway field. This being the case, should it not be easily understood that safety is the only common ground upon which the utility and the general public can meet and converse in the same language?

Already in the electric railway industry many companies have given much thought to this subject and have successfully carried out programs that have brought splendid results. Their work should be closely studied and followed.

Certain tie-ins with the public are most necessary for better public relations,

the most important of which are:

- 1—Chambers of Commerce.
- 2—Schools and playgrounds.
- 3—Churches.
- 4—Luncheon clubs.
- 5—Women's clubs.
- 6—Large industrial plants.
- 7—Motor and drivers clubs.
- 8—State, City and Borough officials.
- 9—Community and civic associations.
- 10—Parent-Teacher associations.
- 11—Boy scouts and camp fire girls.
- 12—Local press.
- 13—Broadcasting stations.
- 14—Local safety councils.

That all community activities should be closely in touch with their transportation interests is highly desirable for good service. The relationship between the electric railways and the community should be of such a nature that matters of mutual interest can be discussed and adjusted in a most friendly spirit.

Thorough Cooperation Secured Through Safety

The cooperation desired is accomplished best by the safety and accident prevention work. Tied in with the home, factory, highway and schools, an entering wedge is immediately made with the public, after which the introduction of other matters is a simple proposition.

There is not one of the fourteen tie-ins mentioned that cannot be won over through the safety idea. It will win where politics fail, and will overcome personal prejudice.

The safety organization of the electric railways is the one factor that can carry the management's message to the public.

In the field of safety the opportunities are exceptionally great for men of vision and power; they are also great for men of ordinary power and intelligence. Greater capacity is being conferred upon each man in this country to do something of note.

There is great need today for a better understanding of the conditions of our lives, national and industrial, in order that the forces making for national greatness and industrial happiness shall be shaped to better serve and protect our nation and communities.

The power of safety is destined to take supremacy over all other agencies in the civic, economic and commercial life of our nation in meeting some of the perplexing problems.

The power of safety is the one outstanding influence that can bind the public, the management and the work together into a coordinate whole, making success an assured result.

CHAIRMAN EMERSON: Colonel Spring, I want to thank you very much for reading such an instructive paper. I am going to ask the members to defer discussion on it until tomorrow, however. I think we will have a little more time tomorrow than we have today.

I now take pleasure in presenting Mr. P. J. McGrath, international fifth vice-president of the Amalgamated Association of Electric Railway Employees of America.

What I Think of Safety

P. J. McGrath, International Fifth Vice-President, Amalgamated Association of Electric Railway Employees of America, Pittsburgh, Pa.

The subject allotted to me should appeal to every man, woman and child, for surely there are none who are uninterested in their own safety, and they should also be interested in the safety of their fellowman. Therefore, I am strongly in favor of safety or any measure that would tend to promote safety, either by way of improved machinery, by the adoption of proper safety legislation, by the education of the public by personal contact through holding meetings along safety lines, by bulletins posted in conspicuous places where they may be read by the vast majority of the people, or by organized newspaper publicity in every large city of the country.

I am of the opinion that arrangements could be made (for little cost, if any) to have the newspapers print an article every day, on the same page of the various publications, (so the people would know where to look for it), dealing with the subject of safety. The people, I believe, would become interested and would look for that item, the same as our younger people look for the baseball news.

What I am trying to suggest is some possible way of constantly having the subject before the masses of the people.

We might hold our various meetings of employer and employee, and discuss the subject very diligently and with extremely good results; but that would only be between employer and employee, and would not be apt to reach outside of that group.

There is nothing more important to which a man may devote his life than safety in the interest of others, and the word "Safety" in meaning has an extensive realm.

No one realizes the importance of safety more than the wage worker. But for a wage worker to contribute to safety, aside from his own personal safety, he must possess a sense of freedom in the exercise of his duties to his fellowmen; and the expression "fellowmen" includes both employer and employee.

The first question that comes to the wage worker is, "How far am I, at liberty to participate in the safety of others and in the interest of the property with which I am employed?" A further question is, "How far can I participate in advancing my safety ideals?" But the latter question is wholly dependent upon the former and inclusive within it. Then what is the limit?

Wage workers are classified. One class of wage workers can have very little to do in the extension of safety plans. The other class really has all to do in the matter of extension of safety plans. I might take considerable time in identifying these two classes, but I feel it unnecessary. There is not a safety law on the statute books of the Federal or State Governments, (nor in the Dominion of Canada) in the interest of safety as applying to the wage workers, which was not brought forward and sponsored by that element of wage workers with which I identify myself.

I cite this fact to show that through cooperation of wage workers and the managements of employing concerns the safety plans can be instigated and extended, to a far greater degree than without this cooperation.

Safety plans come without the enactment of laws to enforce them. But there must be a liberty of action, without which such safety plans can be of little value. Employees must be interested in extending safety to others. There is only one way in which this can be accomplished and that is by a spirit of

freedom. That spirit leads the wage worker not to look upon his employment as a mere rain check, but makes him understand that it is his duty and a source of satisfaction to him to contribute to the advancement of his fellowmen, recognizing that in this is his own advancement.

I take pleasure in stating therefore that within my class of wage workers this spirit of safety is active and it inspires in each individual a concern for all others.

There is a common interest in safety among employing investors and wage workers. The wage worker recognizes that he has even a greater interest in the safety and success of the employing property than may be had by the individual stockholder or investor. His employment is the source of his income. Therefore, he has a common concern and interest in the employing property. His possibilities are dependent upon its prosperity. He knows it is to his own interest to protect the employing property and safeguard it to the extent of his ability.

Why should it be necessary to urge upon employers and employees the importance of cooperating in safety? Both are dependent upon the employing property for income; yet there are some to whom this common interest is not apparent.

This makes necessary special endeavor in the interest of safety so that these ignorant ones may be brought to a full understanding of their co-ordinate interest.

Then we may go beyond the immediate sphere of the employing property and its employees. Naturally, we observe that in transportation service it is imperative that the safety of the general public be conserved. There is a large element of the public in whose interest we must be eternally watchful. This requires rules and regulations in the operation of transportation service; and we may well know that the best service in conserving safety comes from those who harmonize in watchfulness, who cooperate and recognize a full freedom within that cooperating field. In the general association of wage workers in their various crafts, they are continually alert to this duty of conserving safety in transportation.

Every wage worker should be a safety expert. In so far as his concept of his personal safety is concerned, he is a safety engineer, but without proper association with his fellow wage workers of all crafts, he is without the possibility of extending his service in the field of safety to others.

There is no doubt that wonderful results can be, and probably are being obtained through thorough cooperative safety effort between employer and employee. But we may promote still further that spirit of cooperation and confidence and eventually obtain the goal to which I trust we are all aspiring.

Report of the Special Committee on Safety

MR. McGRATH: With your permission, I would like to read just a small item that was taken up at the recent convention held last week which I believe will be of interest to you, and will show that the street car men through their organization are becoming more and more interested in the question of safety.

It came about after the two general managers, Mr. Perkins of St. Louis and Mr. Fitzgerald of Pittsburgh, spoke at the convention of the street car men. Both gave a splendid talk on safety, and were given a great ovation. As a result of their talk, a safety committee was formed who brought back the report that I intend reading to you.

Birmingham, Ala., Sept. 16, 1927.

Mr. Chairman and Delegates to the Twentieth Biennial Convention held at Birmingham, Alabama:

It is only after careful consideration and study on the subject submitted to them that your Committee on "Safety First" brings back to you the following recommendations for your consideration.

Before doing so we desire to preface those few remarks.

First of all, we recognize that the question of "Safety First" is somewhat of a new question in our development as Street Railway Workers. We feel that while it is practiced by some of our members on some of our roads, it has not reached the great bulk of our membership. Therefore, it needs be given deep study and earnest consideration by our membership before putting into practice on our various systems, for while it may be practical and beneficial to our membership on one road or system, it may possibly be to the contrary on another, for we believe that unless there is a true spirit of co-operation between men and management, the question of "Safety First" will not be a success.

By that we mean that if there should be an ulterior motive, other than that of sincere and unbiased co-operation, then we can expect nothing but disaster and dissatisfaction as far as the question of "Safety First" is concerned. On the other hand, who is there among our membership who is not (or at least should be) interested in, to the extent of safeguarding the life and limb, not only of our men employed in our industry, but our people in general, whether it be in the mine, mill, factory, in the home or on the street car. We feel that we were not deserving of consideration among the human element were it not so.

Accident Prevention Resolution Is Adopted

President Mahon has given to us in his report figures taken from statistics as to the number of lives lost and the number of people maimed through accidents in the various industries every year that is appalling. For instance, let us take the year of 1926, where there were twenty-three thousand (23,000) men, women and children slaughtered on our highways of the United States, an increase of one thousand (1,000) over the records of 1925. So we say, Mr. Chairman, and Brothers, who is there among our membership who is not willing, with due care, judgment and precaution, desirous of alleviating as far as possible, this tremendous slaughter that is happening in our midst every year.

We have heard from Mr. Perkins, General Manager of the St. Louis Street Railway Company, where they have a Safety Committee System that splendid results are being obtained and that the amount of accidents are being reduced considerably. And again, from the city of Pittsburgh we hear from Mr. Fitzgerald, General Manager of the Pittsburgh Railways Company, where they have a co-operative, as well as a Safety Committee System, that their amount of accidents are being reduced considerably.

So while we, as your committee on 'Safety First', do not recommend that our membership should follow particularly either one of those systems, we do suggest and even recommend that our membership take up for earnest consideration some method whereby the tremendous amount of accidents happening will be reduced to a minimum thereby bringing due credit to the Amalgamated and its membership; bearing in mind whatever system there might be adopted, that our members see to it that their membership in the Amalgamated remain intact, for it is through it, and it only, that they will be sought, for either Safety First, co-operation or any other system that might be considered an advancement to civilization.

Resolution No. 22, presented by the St. Louis delegates, read in part as follows:

Resolved, that the Amalgamated Association of Street and Electric Railway

Employees of America make application for membership in the International Safety Congress and have at least one representative at their conventions.

Your committee recommends that this be amended as follows:

Resolved that if the Amalgamated Association of Street and Electric Railway Employees of America is requested by the International Safety Congress to affiliate with that body, the same be referred to the Executive Board, and if in their judgment there be no conditions restricting our affiliation, that President Mahon or his appointee act as our representative.

CHAIRMAN EMERSON: I am now going to ask Mr. Hellmuth to read the report of the Nominating Committee.

Report of Nominating the Committee

The Nominating Committee recommends the election of the following officers of the Section for the year 1927-28:

Chairman, A. W. Koehler, Superintendent of Accident Prevention, Milwaukee Electric Railway & Light Co., Milwaukee, Wisconsin.

First Vice-Chairman, H. K. Bennet, Safety Manager, United Electric Railways Company, Providence, Rhode Island.

Second Vice-Chairman, E. K. Eastham, Safety Director, United Railways of St. Louis, St. Louis, Missouri.

Third Vice-Chairman, Melvin W. Bridges, Safety Engineer, Chicago Rapid Transit Company, Chicago, Illinois.

Secretary, J. E. Stott, Georgia Power Company, Atlanta, Georgia.

Respectfully submitted,

Samuel H. Reid,

G. T. Hellmuth.

MR. HELLMUTH: The committee moves the adoption of this report and the election of these officers.

(The motion was seconded and carried.)

ADJOURNMENT.

Thursday, September 29, 1927

The third session was called to order at nine forty-five o'clock by the chairman, R. W. Emerson.

CHAIRMAN EMERSON: The meeting will please come to order. Gentlemen, the official registration of this section is now 227, by far the largest attendance ever had in the Electric Railway Section. Those of you who have not yet filled out the registration cards please do so. It is very gratifying to have 227 and we would like to make it still larger if possible.

The first paper this morning will be read to you by J. S. Kubu, assistant superintendent of Accident Department, Cleveland Railway Co., Cleveland, Ohio.

Specific Ways to Prevent Collisions With Other Vehicles In Urban Centers and at Grade Crossings

J. S. Kubu, Assistant Superintendent, Accident Department, The Cleveland Railway Company, Cleveland, Ohio

Chicago's initiative and successful leadership in the realm of human endeavor are facts of history. Her creative and aggressive spirit, characterized by "I WILL," has lent her world-wide fame. Today we are cognizant of association with minds that flash thoughts as stars flash light and we feel it an inspiration to breathe the atmosphere of this great city.

Only recently Chicago made a traffic survey at an outlay of \$50,000. Men experienced in safety work were represented in that survey. Some of them may be here and could enlighten us with abundant material upon this particular phase of the many sided question of safety.

Every automobile accident involves three agents: automobile, driver and place. The automobile is a significant factor in many disastrous collisions. The records of these collisions admonish us to insistently advocate regulation of the possible speed of all automobiles.

Upon bill boards and double pages of magazines are spread attractively decorated advertisements of automobiles, and we frequently notice that while manufacturers claim their product will wear well, they give a primary importance to the speed possibilities of their machine. Sometimes dates and places of automobile races are mentioned where this speed was demonstrated. And so we have organizations providing parks with speedways, charging admission to automobile races made spectacular beyond description, and attended by serious and often fatal accidents. We hold that the real purpose of these occasions is to give the widest publicity to the startling speed of the machines, and that the manufacturers are directly responsible for them. Who can question the psychological effect of such races upon the public and upon sensitive minds in search of thrills?

The automobile winning the race is purchased mostly by venturesome young men who care little or nothing about the mechanical construction and value of their automobile. The one word "speed" impresses them above all else; and having the speediest known automobile they test its possibilities upon urban boulevards and the common highways, and not only endanger human life and property, but often cause accidents most appalling.

As a means to prevent this whole panorama of thrills, wrecks and deaths, why not demand that our government institute laws forbidding the making of automobiles capable of being insanely driven?

In this connection where the institution of laws is imperative as a way to prevent automobile accidents we may mention Compulsory Liability Insurance. These laws should be instituted by the government and be universal, including every state. Such requirement might, for a short period of time, impose apparently excessive burdens upon insurance companies, but difficulties now magnified would be speedily overcome. Unsafe risks would be eliminated. A high grade of automobile driver would everywhere be found. Thousands of worn out and unsafe automobiles would not be on the street or road. Drivers of automobiles would enjoy a feeling of ease and safety, and a continuously increasing pleasure in the possession of an automobile.

Fundamental to all specific ways of preventing automobile collisions we may mention "education." It is an all inclusive term. It seems to be *the one way* to solve all problems confronting safety workers. It stands over against a multiplicity of appealing needs of a heterogeneous company of automobile drivers. It aims at awakening an ideal conception of human relationships, promises to create a refined and sympathetic state of mind and to so equip each automobile driver that he will invariably show a just and courteous regard for every other driver's rights. Each passing day furnishes abundant proof that laws and ordinances will not in themselves lessen the number of accidents; and we are startled by the educational needs of the general public upon all matters related to safety.

Education Sheds Light on the Problem

Education means light. It means light adequate to reveal to automobile drivers their personal deficiencies, and then to allure them into habits of safety. It means light for law makers, awakening in them the high purpose to have written at once into the statutes certain definite requirements and tests before the state will permit a person to drive an automobile.

Similar accidents are everywhere occurring, and the amount of light necessary in one neighborhood is demanded in all other sections of our country.

The Southern California Automobile Club made an eight months traffic survey. They reported that many automobile accidents are caused by "right of way" violators. The next highest number of accidents were caused by drivers incompetent to handle an auto. Referring to grade crossing accidents, the report states there were few accidents of that kind although those were spectacular and were given wide publicity. Consulting magazines and various publications in the interest of safety, you may be surprised to note that investigations in many places are in keeping with the California report.

Reports of surveys, and publications of safety organizations are parts of an educational process but they seemingly touch few individuals with commanding influence. Forward steps are slowly taken.

It is not expected that the whole country will be suddenly illumined and changed, but there may be gratifying returns from the good seed scattered; a more perceptible awakening would immediately result if some "National Committee on Safety" were endowed with legal authority, and that committee's efficiency would be immeasurably augmented if the government would make it a liberal appropriation to carry forward a comprehensive educational work in every urban and suburban district. The time has come for action. The ideals of safety workers must be incarnate in the life and conduct of the masses. Good things have been said. Specific things must be done.

In March, 1926, the Second National Conference on Street and Highway Safety assembled in Washington, D. C. Representatives of Governors of 43 states gathered there. The many questions and problems of safety were analyzed. What ought to be done in a myriad directions was indicated. The writer of this paper therefore urges the immediate doing of the things we see ought to be done.

Who will see to it that automobiles are so constructed that only sane driving will be possible, and that no such accident as occurred in California a few days ago will ever happen again, wherein young fellows in an automobile attempted to race with a railroad train and dashed out their young lives by running into a concrete wall?

Who will see to it that every automobile driver is subjected to a critical examination? First a physical test. Such test would eliminate people of seriously impaired physical strength, unsound heart, poor eyesight, color blind, the alcoholic, and those whose public behavior may rightfully be challenged.

Second, a test of intelligence. That test would disclose one's familiarity with the English language, knowledge of traffic laws, and ability to operate an automobile.

Who will see to it that compulsory liability insurance laws are instituted? Who will arraign those in places of authority for their indifference and laxity and for their prejudiced discrimination in the prosecution of offenders against the law? Sometimes people are arrested for violating a traffic law and causing an accident. Immediately thereafter a scheme is devised to escape punishment. Influences at the offender's command are enlisted and men sworn to protect society are threatened, and in many instances the ultimate outcome is that nothing is done. Who is going to see to it that all these wrongs are righted? How many cities and suburban districts have responsible committees thoroughly organized whose business it is to investigate and report every accident, and see that the negligent are justly dealt with?

To realize our ideals, to achieve the end toward which men have been striving, we believe that all safety organizations should at once be correlated in cooperative effort, and over all as one administrative head should be the National Committee, having back of it the authority of the nation. It should touch and command every individual through efficiently organized committees, and find every member of every home in all the land an evangel of "Safety First."

Similar Recommendations at the Hoover Conference

CHAIRMAN EMERSON: I don't want you gentlemen to think that Cleveland is taking a monopoly on this program. As for the discussion of Mr. Kubu's paper, I hope you will be as free about asking questions today as you were yesterday.

E. K. EASTHAM (United Railways of St. Louis, St. Louis, Mo.): I found a great deal of interest in this paper of Mr. Kubu's. It is a matter that the electric railway industry is more interested in perhaps than anything else—how to prevent collisions with motor vehicles. This matter embraces with most city companies more than half of the total accidents. I, however, only want to touch upon one feature of his paper.

He spoke of certain laws that he thought would help in cutting down motor vehicle accidents. I would like to say that most of the recommendations in Mr. Kubu's paper had already been covered by the recommendations made at the Hoover conference on uniform motor vehicle laws. I believe that the best way for the electric railway industry to go after this proposition is to back up in every possible way those recommendations of the several Hoover conferences which culminated at the last conference in the drafting of specific laws, suggested laws to be presented in all the states of the Union with the hope that they would be passed and in that way make our legislation along that line uniform.

I attended all those Hoover conferences. I think the electric railway industry was represented in a measure at all of them. However, I don't think this industry was represented as strongly as it should be. I would like to suggest to the electric railway executives present that when national moves of that kind come up, no matter how badly off you are financially, there is no way in which you can spend money, in my

belief, that will bring greater returns to you than to send a representative, or to go yourself (you, the executive), to those national meetings.

There was one thing that came up at the last Hoover conference when those proposed laws were drafted. It had to do with the passing of street cars by automobiles when those street cars were discharging or taking on passengers. Owing to the lack of representation by the electric railway companies, I presume, it was originally suggested by the conference to permit automobiles to pass cars while taking on or discharging passengers if they had a certain amount of clearance and if they proceeded slowly and cautiously.

Our experience in St. Louis under a similar experiment proved that people in St. Louis were killed, maimed and injured day in and day out by automobiles running into passengers while trying to get on and off cars.

With the help of a couple of friends, we were able to have that changed, and the final recommendation of the Hoover conference was put in such shape as to require that all automobiles stop eight feet to the rear of all street cars. That has gone all through the states now as the final word of safety covering that particular point.

Representation Necessary at Every State Meeting

I merely bring that up as an illustration showing how important it is that street railway men realize in full that it is up to them to protect their industry along these safety points, because they are better qualified to give an opinion on such matters, and have the information and experience along these lines which no other group has.

I would like to suggest, too, that when your states call state conferences along these lines that the electric railway industry be represented at every single meeting, and that every system in the state send a representative to those conferences. Also, when those laws are introduced in the state legislature, you men as citizens, you men representing in each particular state one of the biggest and most important of our industries, should get busy and see that you have a voice in these matters. Most of you know how to get busy, you are connected with board of aldermen and so on.

Let's have these Hoover laws passed in all the states of the Union. Some states will merely require a slight change, but when we make up some uniform, common-sense laws and get them passed by the respective states, the nearer we will come to carrying out what Mr. Kube had in mind in his paper. I feel very strongly on that, and that is why I have taken more time than I perhaps should on that matter.

CHAIRMAN EMERSON: We are very fortunate, gentlemen, in having Mr. Fitzgerald of the Pittsburgh Railways Company with us. I am going to ask him if he will say a few words to us at this time.

T. FITZGERALD (Pittsburgh Railways Co., Pittsburgh, Pa.): Gentlemen, I hadn't intended to say anything, but I just asked the chairman to let me say a few words about the gentleman who has just sat down.

I heartily agree with practically everything in the paper. I feel the time has come when strenuous pressure will have to be brought to bear on this question of vehicular collisions. I think the suggestions made are well worth while.

The provision I wanted to speak to you about particularly is the suggestion that representatives of the electric railway industry attend the Hoover conferences, or other conferences of this nature in the future. I plead guilty, gentlemen, I was a part of that representation, and I had to do with this question of automobiles passing street cars at stops.

I can realize the force of what the speaker has said. But we have traffic conditions in a metropolitan community like ours, where it is a question of either choking the traffic back more than absolutely necessary, or to allow it to flow as freely as possible. It may be a safer proposition to allow more freedom of movement than to have the automobiles come to a complete stop.

My position at this conference was, where ample room was had to pass street cars, and get them out of the way, allowing traffic generally to operate, that it would be the proper solution to the problem.

I plead guilty to the lax representation of the electric railway industry. It is a pretty hard job in itself, and I want to say for the Electric Railway group that I believe they have done everything they could think of doing, and it is only a lack of brain power to cooperate in the safety movement and in the regulation of traffic.

Mr. Storrs, I know, is doing everything possible to reach that end, and in so far as I know, the Electric Railway group is trying as hard as it can to cooperate with all agencies. I think that criticism of this kind is just what we need. We are doing what we consider possible, but we are still out to go a little bit stronger. I hope it will stimulate us to greater efforts than we have made in the past.

MR. EASTHAM: The freedom of movement, Mr. Fitzgerald, was taken care of in metropolitan sections by allowing them to pass if there was a properly designated safety zone. Safety zones are what we should have in cities like St. Louis and Pittsburgh, otherwise if you merely say eight or ten feet clearance, there is no way to enforce that. A man will edge in one, two or three feet and the policeman cannot make a case and prove that it was less than that clearance. It is from actual experience in St. Louis that we have insisted on real safety zones, something that would protect the passengers.

Education More Necessary Than Laws

EDW. McMORROW (Union A. A. of S. & E. R. E. of A. Detroit, Mich.): During the various meetings, I have made observations, and I believe what we need is education more than laws. I think we have too many laws. In the city where I work, when we hear others talk of additional laws, we look upon them with a holy horror. Education, in my mind, is better than law.

While there might be some good features in these proposed laws, my friends, I approach any law having to do with the electric railway industry with a holy horror. We are lawed here and lawed there, and practically lawed out of existence. If they keep it up, we as operators of street cars can see nothing in the distance but the poor house, because all the money that is to spare has been legislated for in the most foolhardy, ridiculous manner I can think of.

I am one of the street car men who don't like automobiles. I don't like to see the management run vehicles that are in competition with our industry. I don't believe that an automobile is a necessity in our industry. I surely don't believe that it is an asset. I have never seen an automobile yet that was an asset. It is a liability in our industry.

So I say to you men, coming down here today some 12 miles from my home, I saw the result of law affecting this industry. I saw a large body of men paving the public highway at the expense of this industry. We are paying for it. We, who are in this industry are doubly and triply taxed. Therefore, I say when you talk law to me, I approach that in a measure of holy horror. But, when you talk education—that of which I never had enough—then I appreciate it.

There is only one real law—one real rule to operate this industry by, and that is good, common, everyday horse sense.

D. C. KING (Pittsburgh Railways Co., Pittsburgh, Pa.): I think that the question of the enforcement of law is a different proposition. In the city of McKeesport, they seem to have very little enforcement of laws enacted. If an automobile runs in front of a street car, there is no use of the policeman arresting that man because he will get off clear anyhow. Pennsylvania has had a uniform traffic law passed recently, but what it is, I don't know. However, there is no use in having these laws unless they are properly enforced.

I have been informed of an agency selling automobiles guaranteeing to the purchaser that they will get a driver's license, in order to sell the machine. If these things are going on, there is no use of passing strict examinations, because if they have pull enough to get the purchaser of a car a license, we will have dangerous conditions throughout the country.

C. E. ROGERS (Chicago & Joliet Electric Ry. Co., Joliet, Ill.): Can you give me information on whether they have done anything in the cities to warn pedestrians of the overhang in street cars when going around corners? You take a 45-foot car going around a 35-foot radius curve, and the car overhangs on the rear end about three and a half or four feet. Have they done anything in marking lines around cars to warn pedestrians and motorists of just how far they can pull in without being side-swiped?

WM. H. WILSON (Pittsburgh Railway Co., Pittsburgh, Pa.): We take care of that by painting yellow lines on the streets at all curves where the car makes a corner, saying, "Watch cars turn here!" We also have markers on the street in different portions of the city with a white cross with the number of people killed at that point marked on it.

MR. MERRICK (United Railways, St. Louis, Mo.): We have a complete system of this in St. Louis. Every curve is marked with the width of car when it swings around a corner. The front and rear of the car are also marked. Some of the cars extend further on one end than on the other platform, but any curve where there is any possibility of a car catching an automobile, in every suburban district and even downtown, there is no place where the corners are not marked. Most places downtown a place about four feet wide is marked for passengers to stand while waiting to board and leave the street cars. There is also a post about four feet high marked "Safety Zone," and on the outside of that, the street is wide enough for an automobile to pass while the street car is standing still.

The Overhang of Cars Plainly Indicated

MR. BENNETT: Regarding the overhang of cars, in Rhode Island we have some one hundred of those white markers in the city where we think they are necessary. Prior to the installation of these lines some three years ago, we had accidents almost daily at some streets. Since that time you can count them on your two hands. The improvement is almost inestimable.

Mr. KUBU, what did you mean by reckless driving, speeding?

MR. KUBU: It doesn't mean miles an hour—not at all. It might mean reckless driving when going through some districts at the rate of nine or ten miles an hour. What I had reference to was to enact laws prohibiting the manufacture of automobiles that will develop such a high rate of speed. I notice in one of the magazines that Mr. Keating, in the Research Department of the General Motors Company, is trying to perfect a car that will go faster than any of the present cars. He compared the gas explosions to that of a gun. A rapid firing gun will shoot 1,250 shots a minute. This engine now perfected can fire sparks at the rate of 1,600 a minute, which probably gives an automobile a speed of 85 miles an hour. They ought to be checked on the speed so that they wouldn't have so many serious accidents.

W. F. HANNA (United Rwy. & Elec. Co., Baltimore, Md.): What do you think of compulsory accident insurance?

MR. KUBU: Just as I read in my paper. It will eliminate the fellow that has a \$25 automobile from going out and having accidents. It will eliminate the fellow who has a good many accidents. If he has a license, as he should, he will be free from accidents. They won't insure the reckless driver. The State Workmen's Compensation does not make any difference, but there should be some device to eliminate that kind of people.

MR. HANNA: In Massachusetts there is a compulsory insurance law, but up to this time I am unable to say that the law has had any effect in the reduction of accidents. In view of the many features of the compulsory insurance law, I think it would be very appropriate to have a committee in this section to study it.

MR. KUBU: Of course, the insurance company is opposed to liability laws. They fear the heavy verdicts rendered by the juries. They sometimes give the limit when they really don't deserve it.

MR. HANNA: In Massachusetts and Connecticut this law has been modified. So many think of this from the standpoint of having responsible people only, own automobiles that I think it would be a very helpful thing to study these features.

CHAIRMAN EMERSON: Do you make that a motion?

DR. C. P. SEGARD (Third Ave. Ry. System, New York): Before that motion is put, I should like to voice my humble protest regarding any law upon the restriction of automobile manufacturers in the speed of cars.

You may remember, those of you who were at the Hoover conference, that this subject came up in the form of a proposed recommendation covering that suggestion, that all automobiles come to a dead stop at all railroad crossings before crossing the tracks.

The Department of Motor Vehicles in North Carolina put a crimp in its having effect by saying, "Yes, we would do that provided that the traffic on the railroad was greater than the traffic on the highway. You may know of cases where there are not more than one or two trains a day, and in this case the steam train would have to stop where traffic was greater on the highway than on the steam road. I am afraid that there will be a back-kick to any such proposal of this kind.

Opposition to the Marking of Safety Zones

CHAIRMAN EMERSON: Mr. Hanna, will you state the motion again please?

MR. HANNA: I move that a committee be appointed by the Electric Railway Section, National Safety Council, to go into the subject of compulsory automobile insurance and find out the experience in other states, particularly Massachusetts, and to report to this Section on what their findings are.

CHAIRMAN EMERSON: Is there a second to that motion? I hear no second, Mr. Hanna.

D. W. FINCH (Des Moines City Ry. Co., Des Moines, Iowa): With reference to the gentleman's statement with regard to the safety stops in St. Louis, I am opposed to the marking of safety zones. Our experience recently in Des Moines was this: A car was coming east, making a turn to the left. A woman came across the street going north, and stopped within the safety zone. Another car going north hit her. The decision was against us when the verdict was reached, because she was in the safety zone. I would suggest that all safety zones be changed to "loading zones." Ours have been changed. The safety zone will only lead to trouble in my opinion, and you will get more judgments against you than you want to take care of.

CHAIRMAN EMERSON: I will ask you to defer any further discussion on this subject until later when they can be taken up with those who wish to discuss the last two papers read yesterday.

This has been a very successful and profitable meeting. There are several things that have happened to show that this Section is meeting with recognition, and is stirring up the industry as it has never been stirred before. We are very fortunate to have the managing director of the American Railway Association, Mr. Lucius Storrs, with us for a few moments. We know he has been here, and the Congress as a whole knows he has been here. I am sure we are very grateful to

him for coming. His time is valuable, and before he leaves I want him to say an additional word to us.

MR. LUCIUS STORRS (American Railway Assn., New York): You know, they coined, or rather derived, a word at the meeting last night, and I think we can all use it. You can get a lot of "kick" out of this—even the President of the University of Chicago.

It has been a perfectly wonderful experience for me to see the interest, the serious interest of the groups in the work they are doing and in achieving the results. The only suggestion I have is, that I wish you could have a group of electric railway executives at least as large, if not larger, than this to come in and hear matters of prime moment at all times.

Another thought in this work brings forth the possibilities in using a power which this industry has that has been dormant, latent and not used to the maximum extent. You have the possibility of using the large mass of interested workers to carry on the propaganda and education to the public in their constant contacts with them, and that is what you need.

Transportation Agents Should Lead the Safety Movement

One thing we have lacked that other industries have utilized, is the possibilities through customer and employee ownership. This cannot be done as yet in our industry with returns to a full financial success. You have a power that is shown in the fact that McMorrow here has been delegated to represent the labor side, and I do hope that can be capitalized and used and its full effect obtained.

I could go on, but I just want to give you a little picture in connection with the Hoover movement. I have maintained for a long time that in matters of safety, and in matters of traffic and civic affairs—all these matters that refer to the mass of people moving through the highways—the transportation agents in the community should take the lead in regulatory and educative measures. They are all too sensitive of criticism because these things happen to be of particular interest to the corporation that does serve the community as transportation agents for 75 per cent of the public in daily life. This is a great inarticulate mass which nobody knows anything about, and the transportation group should take up and keep alive such questions of vital moment.

If representatives are sent to these Hoover Conferences, the Electric Railway group should take on the leadership and its purpose should be to have a committee not solely of electric railway men, but under the sponsorship of this group, representatives of all civic organizations, service clubs, national and local.

I had the privilege of talking with Secretary Hoover two or three times at the time Mr. Coats was president, and we went down to talk with him. He believed in this work and talked very strongly, but we failed to get it across simply because the executives in our own industry were not alive to its possibilities at the moment. I wish such a group of 200 or 300 people as there are here, could be interested in things of that kind.

CHAIRMAN EMERSON: Another indication of the recognition which the Electric Railway Section is gaining was the action taken yesterday afternoon in the election of officers of the National Safety Council. Among those officers is Mr. G. T. Hellmuth, of the Chicago, North Shore & Milwaukee Railroad Company, Chicago, Illinois, who was elected treasurer of the National Safety Council. On behalf of this Section, I wish to congratulate him. If I had any finances of my own, I would be perfectly willing to leave them in his charge. We will now proceed with the reading of the next paper, by Mr. G. R. Whitmore, General Claims Attorney, Illinois Power and Light Corp., Peoria, Ill.

Statistical Review of the Accident Experiences of Electric Railways

G. R. Whitmore, General Claims Attorney, Illinois Power and Light Corporation, Peoria, Ill.

We suspect this subject sounds to you as it did to us, fearful in its dryness, and to be covered only by a lot of meaningless figures. Well, we will do our best to get away from a lot of figures and hope that the paper will not be meaningless.

It is not our endeavor to touch upon accident costs, claim department expenditures and the like, but our principal object is to discover, if we can, how electric railways are getting along regarding the frequency of accidents.

When a basis is to be figured out upon which accident frequency can be determined most justly, each one of us probably will have a theory of his own. Some would figure the number of accidents per million passengers carried, others the number of accidents per ten thousand car miles, while to the writer the most appealing and most common sense basis is that of number of car miles per accident. With this method you do not have to stop and figure in millions nor make mental calculations, but if you find that your cars are operating 5,000 miles per accident, that is a final statement in itself.

The data for our figures are the reports emanating from the offices of the American Electric Railway Association and are about as complete as it is possible to find on this subject. No individual company is to be cited in any way in this paper, but the figures are for companies from all parts of the United States, which have made reports to the American Electric Railway Association. The number of reporting companies varies from year to year and the figures vary with the number of companies that have reported. We have gone back to the year 1923, the first year reports are available to us: at that time 104 companies reported complete figures for both 1923 and 1924; in 1924, 105 companies reported complete figures for the years 1924 and 1923; in 1925 and 1926, 113 companies reported complete figures for 1925 and 1924 and for 1926 and 1925 respectively. It would seem that when more companies report, a greater accident frequency is shown; however, it is also apparent that the accident frequency is greater when reporting companies show a greater proportion of street railway over interurban and combination street railway and interurban companies. From the 1926 reports it is possible for the first time to give separate figures for street railways, interurbans and companies having combined street railway and interurban operation.

Comparisons are said to be odious but we know they are interesting. Many conditions should be considered in connection with comparative figures and they should not be taken as absolutely accurate, yet we have tried to figure out the average car miles per accident and per injury for electric railways in the United States as based upon the reports to which we have had access, and to give comparative figures for five years.

The table used in connection with this paper, shows the car miles per accident and per injury, based upon reports made by various companies to the American Electric Railway Association in the five years beginning with 1922, where the companies reporting have given all the figures requested by the association.

From the table, you will note that, taking all accidents into consideration, in 1926 there was one accident for every 2,680 car miles, or, stating it another way, electric cars operated about the air mail distance from New York to San Francisco for each accident that occurred. For street railway companies alone.

the car mileage was 300 miles less in 1926 than the average of all companies; the interurban mileage was about 10,000 miles greater, and the companies having combined street railway and interurban operation showed 1,000 miles more per accident than the average of all the companies. If you will look back in 1922, you will see that electric cars operated over 3,000 miles for each accident, which figure should be compared with the first figures stated for 1926, namely 2,680. This comparison shows that there has been an increase in accidents, in view of the fact that the mileage is less now than in 1922 for each accident.

Automobile accident figures are always of more or less interest, and we find that in 1922 the electric cars operated 6,380 miles for each automobile accident, while in 1926 they operated only 5,110 miles for each auto accident. In 1922, the automobile accidents constituted 44 per cent of all the accidents, while in 1926 they constituted 52 $\frac{3}{4}$ per cent of all the accidents. It would seem, from these figures, that automobile accidents are increasing considerably; but it is a wonder that we have as few automobile accidents as we do when all circumstances are taken into consideration.

Car collisions are more frequent now than in 1922, and the figures show that the mileage of cars per car collision is practically equal to the distance of five times around the world. From the information we have, it appears that all accidents, other than those in which automobiles are involved, are decreasing from year to year.

Personal Injuries Are Decreasing in Number

Now, passing from accidents to personal injuries, we find that in 1922 the cars operated 14,250 miles for each personal injury, while in 1926 they operated 13,880 miles for each personal injury: the words "Personal Injury," in this sense, include injury to passengers, employees and others. We find that the car mileage per passenger injury is increasing, meaning a decrease in personal injury to passengers, and that the cars travel more than the distance around the world for each personal injury to a passenger; employees are injured 35 per cent less frequently, according to the latest figures, as compared with 1922, while persons other than employees and passengers, are injured about 37 per cent more frequently now than in 1922. In view of the fact that there is less frequency of injuries to passengers and employees and more frequency of injuries to others than employees and passengers, it would seem that the increase in automobile accidents accounts for the increase in personal injuries as a whole.

Fatalities, including passengers, employees and others, have increased to some extent, but even now we find that the cars operate considerably over one million miles for each fatality.

Again in 1926, for the first time are bus accident figures made available, and we can make a comparative report for the years 1925 and 1926. The chart shows that the accident frequency is much less in bus operation than in electric car operation, and we further find that the accidents in connection with bus operation increased in 1926 over 1925. It appears, however, that there are more frequent injuries to persons as a whole in bus operation, while the injuries to passengers and employees are less, and the injuries to persons other than passengers and employees are much more with reference to bus operation than electric car operation. Interurban buses have much less accident and personal injury frequency than buses engaged only in city operation.

With this table before you, giving the average over the country of the number of car miles operated per accident and per injury, if you will take the time to figure out the car mileage per accident and injury for your own companies, you can tell whether or not your company is operating better or worse than

1925	11,850	16,070	278,540	835,630	1,671,270	557,090
1926	14,620	22,760	179,840	359,670	899,180	599,460

the general average of electric railway companies. We have figured the mileage for our own street railway companies in connection with accidents and injuries for the year 1926 and we are pleased to know that our record is generally better than the average. However, our bus record is not quite as good as the average.

It is interesting to note in this connection, that not long ago it was announced from Louisville that the street cars in that city operated over 10,000 miles per

accident; this, we believe, being the record for one month. This is certainly a target at which all of us can aim and the Louisville company is to be sincerely congratulated upon this marvelous record, which is about four times as good as the average shown on the chart.

We believe that the electric railway companies, and particularly the safety organizations thereof, are to be congratulated upon their accident record. Why? Because accidents and injuries over which the electric railway companies have some control show a general decrease from year to year and, in our opinion, their good work is keeping the other accidents and injuries from mounting to overwhelming heights. However, we must not stop here, but must carry on, always aiming at a more perfect record. Let our aim be "5,000 Car Miles Per Accident"—then, raise this 1,000 car miles per year. When we can say truthfully that we operate our cars a distance equal to that around the world for each accident, we will have accomplished something truly remarkable, but very possible.

Motion to Continue News Letter Form

CHAIRMAN EMERSON: One of our group, Mr. T. G. Brabston, of the Birmingham Electric Company, Birmingham, Ala., has received recognition from the National Council. We congratulate you also, Mr. Brabston.

Gentlemen, one of the outstanding things during the past year has been the news letter. This news letter has been such an improvement over those preceding it, that I myself, think it is a very splendid thing. I understand that there is some danger in that it may not be continued during the coming year. I think we should go on record in regard to this.

A. W. KOEHLER (Milwaukee Electric Railway & Light Company, Milwaukee, Wis.): Mr. Chairman, I suggest that we adopt a motion expressing the sentiment of this group and request that the National Safety Council make it possible for the Electric Railway Section to continue the excellent news letters in the same form in which they appeared during the past year.

(The motion was seconded by Mr. E. J. Harrington, Cleveland Railway Company, Cleveland, Ohio.)

CHAIRMAN EMERSON: Gentlemen, you have all heard the motion. Is there any discussion of it? If not, all those in favor please say "aye." Those opposed, "no." It is unanimously carried.

I would like to announce, gentlemen, that part of the last paper is going to be broadcast over the radio. Mr. Bennett will talk to us first on his subject and at the conclusion of his paper, the microphone will be placed on the table and he will talk to the school children of Chicago from this room. I want you all to stay to hear his message.

The time is getting rather late and we will have the discussion of Mr. Whitmore's paper now. If any of you gentlemen have any questions, I wish you would ask them at this time.

B. C. BELL (United Railways, St. Louis, Mo.): I don't know how it is in other cities, but in St. Louis they do include cars running into barns and things of that kind. I didn't know whether Mr. Whitmore's paper included the figures on that sort of accident or not.

MR. WHITMORE: I am taking the figures from the reports made to the Electric Railway Association. I believe that is coming up for discussion at the meeting next week of the American Electric Railway Association.

PAUL HODSON (East St. Louis & Sub. Ry. Co., East St. Louis, Ill.): This question has come up every year since I have been attending conventions. This statistical

question is still a mystery to me. I can readily understand how some companies arrive at such good figures, but it is still a mystery to me.

Some companies consider any accident an accident. Other companies consider chargeable accidents; and what a chargeable accident is, I still don't know. I think we should arrive at some way of keeping accident statistics so that everybody will keep the statistics in the same way. I am keeping statistics on accidents, and I try to show the number of actual accidents in accordance with car miles. When you get down to chargeable accidents, you are getting into discussion.

I had occasion to investigate some of these reports sent in by some of the companies, and I find that the highest record is only made on chargeable accidents, which gives them a good record. I can cite statistics put out for advertising purposes which mean a lot when you run 60,000 car miles per passenger fatality. We have had passengers killed getting off cars. That is done by figuring that as soon as they are off the car and in the street they are no longer considered as passengers. Statistics are very misleading. As far as they are considered, a yardstick is the only thing capable of accurately measuring them up. I believe some means ought to be arrived at whereby we can have some way of comparing our statistics. I don't compare mine with anyone else unless they are keeping them the same way I keep mine.

Official Registration Two Hundred and Fifty-Two

CHAIRMAN EMERSON: Is there any other discussion of Mr. Whitmore's paper?

Our official registration has grown to two hundred and fifty-two.

CHAS. R. HENRY (Pittsburgh Railway Co., Pittsburgh, Pa.): Don't you think this would be the proper place to adopt a uniform system in regard to keeping these accident statistics?

CHAIRMAN EMERSON: We expect to bring it up at the round table discussion. There is a resolution to be presented along that line.

The time has now come for me to sing my "Swan Song." I am about to relinquish the chair to my successor. Before doing so, I wish to express the gratitude I feel toward this section for having made me its chairman.

I have never been associated with any group of officers which rendered more enthusiastic and helpful cooperation. My job has been an easy and extremely pleasant one. I wish to thank the membership for its patience under trying conditions in attending and remaining at our meetings. It has been an interesting year, and I think we have made progress.

In Mr. Koehler you have chosen a capable, conscientious man, fully able to carry on and enlarging the work of this section, which has grown so much in such a few short years.

I ask your hearty support of Mr. Koehler during the coming year.

(Mr. Koehler took the chair.)

CHAIRMAN KOEHLER: This is the first opportunity that I have had to express to you my appreciation of the honor which you have bestowed upon me. I am sensible of the responsibilities that the office carries, and I pledge you my best efforts to carry on during the coming year.

I accept these responsibilities cheerfully, and I am confident that with the help of the officers and the members of the section, we will have a year which, I hope, will compare favorably with the one just passed.

Our retiring chairman, Mr. Emerson, has served the section faithfully and well. It has been a great deal of pleasure to me, and I have derived a lot of satisfaction out of the meetings which I have attended with him and other members of the section. My recollections of those occasions are very pleasant.

Much remains for us to do, and I think it is encouraging and we should all take heart in the knowledge that an operating executive like Mr. Emerson has given

so generously of his time and thought to the affairs of the Electric Railway Section.

Our time is growing short, and I am not going to take any more of it, but I want to take this opportunity to introduce to you the other officers of the section. I should like to ask H. K. Bennett to step forward, please.

Mr. Bennett is your first vice-chairman. Mr. Bennett has been active in the affairs of the safety game with problems which have come to his attention, and I know he is going to make a very valuable man to us during the coming year.

Mr. E. K. Eastham.

Mr. Eastham has also been very generous in the time and thought that he has contributed to the affairs of the section, and I am sure as second vice-chairman, we are going to receive many helpful bits of the not only useful information which Mr. Eastham has at his command, but I am sure his efforts will be equally untiring.

Mr. M. W. Bridges.

I don't believe Mr. Bridges is unknown to you. He, too, has been very active in the affairs of this section, not only in the National Safety Council, but in the American Railway Association as well. We have served together on a number of committees, and I know Mr. Bridges will contribute generously during the coming year.

Mr. J. E. Stott.

Mr. Stott is one of the newer members of our group, and during the past year has served as chairman of the Poster Committee. He has attended every meeting we have had and has been very active and done a good job. Mr. Stott, too, will prove that our confidence in him has not been misplaced.

MR. EMERSON: I don't want to let the occasion go by without saying a word about the work and enthusiasm of Mr. Connors during my work as chairman. Mr. Connors has been a great help to me and he has been very active in the affairs of the section. He has been one of the leaders in the discussion for the past few years, and I think the section should be very grateful to him for his contributions.

E. K. EASTHAM (United Railways of St. Louis, Mo.): Mr. Koehler, I believe one of the first actions, or really the first motion before you as the new chairman, would be that of recognition of the very splendid work that retiring President Emerson has done for this section during the past year. You have handed him compliments, but I think this section should give Mr. Emerson a rising vote of thanks.

(The audience arose and applauded.)

The General Round Table Discussion

CHAIRMAN KOEHLER: Our next order of business, gentlemen, is the General Round Table Discussion. I think, perhaps, as a means of precipitating this discussion, we might well be guided by the questions submitted to us on the cards provided for that purpose. We will also take this opportunity to discuss papers that we have previously heard, and for which there has been no time for discussion.

The first question I see is this: "What color street car is most visible at night and during fog?" That is a question submitted by a member of the Pittsburgh Railway Company. Is anyone prepared to offer any suggestions?

H. K. BENNETT (United Electric Railways Co., Providence, R. I.): We have just started during the last two weeks, for the first time on our streets, a car painted yellow from the sash down around the vestibule on the front and rear ends. The sash is painted white and the top deck a light buff. We believe that yellow and white are the best colors for visibility at night and in the daytime as well. I also understand from the management that every one of some 600 cars will be painted in yellow and white.

G. H. BOLLMAN (T. M. E. R. & L. Co., Milwaukee, Wis.): We have the red and yellow cars, and we believe they make a greater attraction for the people. We have the one man car and the two men car. The two men car is yellow.

W. T. HARVE (United Traction Co., Albany, N. Y.): We have the yellow car with cream above the window on the new type of cars. They are very visible at night.

SANFORD BABBITT (Pittsburgh Rys. Co., Pittsburgh, Pa.): We have about 20 cars with the front painted white, and really haven't had time to find out a whole lot about them. I find that in coming out of a fog, the white is very visible.

CHAIRMAN KOEHLER: The question is sometimes asked, "What color is best for an automobile driver to see in stormy weather. Has anyone had any experience with the white car in winter time? I am thinking particularly of the interurban cars moving at high speeds with snow banks. Does that reduce visibility or introduce hazard? Has anyone thought of it from that angle?"

J. J. CONNORS (Tennessee Electric Power Co., Chattanooga, Tenn.): We have gotten away from green colors in order to prevent the hazard of those colors comparing too favorably with the foliage. I imagine the white car in snow would be along the same line—you would want to get away from the white so as not to compare with the snow.

CHAIRMAN KOEHLER: Is there anything more on this particular subject?

The Advantage in Certain Colors of Paint

E. HOLLIBAUGH (Pittsburgh Railways Co., Pittsburgh, Pa.): It is my impression, and I would like to get the reaction of the men here as to whether it might be well to change the colors once in a while—if any change might be of some benefit. When we see the same colors day after day, we are inclined to become more or less prone to the color that is familiar to us. It doesn't stir up the proper sensation that a changed color or something new would, so I wonder if any change might not have a desirable effect.

As far as snow is concerned, and in considering green from the standpoint of blending into the foliage, why not consider the probable duration of the snow, and the probable duration of the green foliage. Then compare it and see whether the benefit derived from a white car or a green car would be greater.

MR. THOMPSON (Augustus, Ga.): We don't have snow, but we do have trouble with the lights on the dash. We have a circuit of five lights on the dash, which has now been painted white. That has been approved by the people in the city and also by the car operators.

A. H. SHAW (N. O. P. & T. Co., Akron, O.): I might say a word about changing colors, as we had some experience with that in Akron. About a year ago we painted a lot of buses with fancy stripes and shades, but finally decided that the best color to use was a light yellow. Now all the cars and busses are coming out with the light yellow.

CHAIRMAN KOEHLER: Before passing on to the next question, I want to call on Mr. Eastham, as he has something to present at this time.

E. K. EASTHAM (United Railways of St. Louis, St. Louis, Mo.): This is the committee that has to do with the committee appointed last year, and it also has to do with one of the papers just read and discussed. That was the paper by Mr. Whitmore with reference to accident statistics. Mr. Hodson of East St. Louis has also spoken of finding some basis for each company so that they could definitely know what they were doing as compared with other companies, and that the figures for all companies be uniform.

Report of the Committee on Uniform Accident Statistics

The Committee recommends the adoption of the following resolution:

WHEREAS, It appears that practically every electric railway reports its accident statistics in a different manner; and

WHEREAS, There is a great need for a uniform system of accident statistics, for the purposes of comparison of records and in order that one company may profit by the experience of another, therefore be it

RESOLVED, That the members of the Electric Railway Section are in favor of the keeping of accident statistics in such form that uniform reports will be made by each company to central clearing houses such as the National Safety Council, American Electric Railway Association, authorized committees, etc., and, be it further

RESOLVED, That a copy of this resolution be transmitted by the Secretary to the Claims Association, American Electric Railway Association.

E. K. EASTHAM, Chairman.

G. T. HELLMUTH.

Now, gentlemen, before moving this for its adoption and throwing it open for discussion, I want to say there is no thought of the peculiar conditions of different companies making it advisable that they separate accidents as chargeable, non-chargeable, questionable and so on for their own record. The thought before us is: That we agree on figures to be sent to central bodies and in turn transmitted to you on your request for information, and that we be able to know they are sending out this information on the same basis which we are sending our figures out on. Then when they translate the figures of all companies, taking into consideration the place of operation, and operating conditions, we will know whether someone else is doing better than we are, and vice-versa.

I present this report, and leave it to the crowd as to whether it will be accepted or not.

MR. BENNETT: In moving the adoption of this resolution, I want to say that the question of keeping accident statistics has been very close to me for many years. Some ten years ago I served as committee chairman in this section of the American Electric Railway Association, and worked for three years trying to whip the fellows into line to know what each other was doing, but was unable to do so.

The resolution presented, I think, is going to clarify the situation in knowing what each company will consider as chargeable and non-chargeable accidents. I think it is a step in the right direction. My company would be just as much at a loss without the proper classification of accidents as it would be for the auditing department not to have the proper information. I hope this resolution will prevail.

CHAIRMAN KOEHLER: Is there anyone else who would like to be heard on this matter?

A. H. SHAW (N. O. P. & T. Co., Akron, O.): In this resolution, is it proposed to have chargeable and non-chargeable accidents, or is it proposed to call everything an accident and give out reports accordingly?

CHAIRMAN KOEHLER: I believe it is meant that we adopt one uniform way of sending in accident figures. Probably, I would say, of counting everything. That is the way most companies do it.

MR. EASTHAM: This term "uniform report," I believe, covers the proposition. That is just what this is designed to cover. If this goes through, they will be uniform. For instance, some people have made a splendid record; aside from figures we will say 10,000 car miles per accident, not counting a large number of accidents before sending out the figures for 10,000 miles. When we send out figures from St. Louis, we send out everything that goes in as an accident. This is designed to have a thorough understanding so that all companies in making reports (we don't care how they keep the figures for themselves), but in reporting to other com-

panies and the central clearing house, these figures will be sent in in a uniform way.

CHAIRMAN KOEHLER: What is your pleasure, gentlemen? We have had a motion. Is there a second?

(The motion was seconded.)

CHAIRMAN KOEHLER: All those in favor will signify by saying "aye," those opposed, "no." It is carried unanimously.

The next question I find before me is: "Do you think a one-man car operated in a large city is a safe proposition with one man operating an ordinary two-man car?"

Is there anyone who would like to talk on this subject?

ISAAC HARRIS (United Railways, St. Louis, Mo.): We have the one-man car operating on Sunday on four lines. There is a great deal of discussion in St. Louis as to whether that one-man car is a safe proposition for one man when it is a two-man car.

CHAIRMAN KOEHLER: Is there anything else that anyone would like to contribute?

MR. BENNETT: I can give a short answer to that question. We went into one-man operation in 1923, and it was practically complete throughout the city in 1924. The reduction of accidents has been very great.

Discussion About the One Man Car

EDW. McMORROW (Union A. A. of S. & E. R. E. of A., Detroit, Mich.): I would like to discuss briefly that question of one man cars, especially that of the two-man car operated by one man. I have run into that car in every part of this country, and to intelligently get my thought across, I will have to go back to the beginning of the one-man car.

I don't want this section to get away with the idea that the present one-man car, whether the real or Birney or so-called two-man car, is the original one-man car. The first car I ever operated was a one-man car, and I used to talk in some pleasant language as to the motive power of that car. With the advent of the Birney type of car, there was a book of instructions or rules, and we as operators were told that in taking these cars into service it would do two things:

First, it would not increase the number of employees; and second, it would increase the service. And that rule book said that a man should do only one thing at a time. But after operating these cars for a short time, what did I find? I found our men violating all the rules of safety. For instance, they were conversing with passengers, issuing transfers, making change, and the car running pell-mell down the street. That condition is tolerated and encouraged by the management, and nothing is said except when an accident is concerned.

I have had a rule book for 36 years, and I only know one rule, and that is to use ordinary horse sense when the other rules don't apply. I contend that a two-man car propelled through the streets in the large city by one man is not a safe vehicle. I contend further that if the original intent surrounding the one-man car were carried out, as a matter of increasing the service as the public demanded it, the speed would be seriously impaired.

If you will go back to the original rule book or the intent behind the Birney car and compare that with the method necessary to keep the cars moving, where would we be? We would become a nuisance on the street instead of a benefit.

I think that in some instances the one-man car is absolutely necessary in order to serve the little places. Some people would have to go out of business if we didn't have something to stop intrusion. Chicago, St. Louis, San Francisco, Pittsburgh, Cleveland, and several other cities I could mention, will never be able to operate the one-man car through the thoroughfares successfully because while it is our intention to win against accidents, we are meeting with accidents. This

can only be accomplished when the desire on the part of the people for speed is forgotten, and the cars operated as they were originally intended, and that was to do one thing at a time.

In Seattle, where they have a municipal system, the city took over a lot of property, and at that time they had a lot of what was called old "camel back" cars. These cars were about half a block long, and one had to go up three steps to get to the platform. One morning I dropped in to see the innovation of new cars.

About the first thing I saw was one of those Birney cars operated by a young fellow. First, he got his passengers on, then closed the door and started the car on its way. He started to work, dishing out transfers, making change, talking with everybody, and to make it worse, he had a nice "Jane" sitting on the sand box, paying more attention to her than to anyone else. That same day, I heard a speech in the city council of Seattle on "Safety First."

You can't have safety except when the companies cooperate in operating those cars as they were originally intended—to do one thing at a time.

You can't expect a man to do seventeen things at once with a one-man car and then come here and preach safety, because it can't be done. I do not dislike the one-man car, except in so far as it relates to safety. I would like to see this industry built so that these laws I spoke about a minute ago would be eliminated and the revenue from that business would be so directed that the two-man car operated by one man would not be a necessity anywhere.

CHAIRMAN KOEHLER: Gentlemen, we have just ten minutes left, because Mr. Bennett, our next speaker, must go on at five minutes of twelve.

There are a number of questions still to be discussed and I ask you to be as brief as possible.

One Man Cars Satisfactory in Akron

A. H. SHAW (N. O. P. & T. Co., Akron, O.): In regard to the one-man car, I would like to say that we operate them in three cities, with 100 per cent one-man car operation. They are properly equipped with treadle doors and other safety devices. In fact, everything is on those cars. We are making as good headway, carrying as many passengers, and with fewer accidents than we ever did. In our experience, it is the safest operation we have ever had.

If any man ever visits Akron and talks to the old employees that have been with the company 15 and 20 years, and asks them what they think about the one-man car, and if they don't say that it is better than any other car they ever operated I'll eat my hat. We had a split service, and made comparisons as regards passengers carried per accident and miles operated per accident. The one-man car, at this time, a year and a half ago, operated 600 or 700 miles more.

When one man is responsible for the operation of the vehicle through the street, he has no one in back to depend upon to watch the side or the rear of the car. The result is that he operates cautiously, glances around to watch the overhang on curves, making fewer accidents than when we had a man on the rear end.

There was no lay-off of employees. We simply ceased, probably, to employ any additional help for some length of time, and the situation just took care of itself. Our men are better satisfied today than they ever were when we operated the two-man cars.

T. FITZGERALD (Pittsburgh Rys. Co., Pittsburgh, Pa.): We have had about the same experience in Pittsburgh. I find myself again in disagreement with Mr. McMorrow. I sympathize with his viewpoint, but our records since the installation of the one-man cars in Pittsburgh show that the one-man car operation has a slight favor over the two-man cars. There has been no indication of any increase in danger. With reference to the speed of the cars, we do not put on for the same amount of traffic more one-man cars than two-man cars. This has resulted in a

slowing up of the service or operation between stops due to the lesser number of stops to be made. The people on one line complained of the speed of the one-man car. That schedule can be speeded up with the one man car, but we are not doing this from the standpoint of taking a chance. We believe in perfect safety operation, and we believe it is a safer operation.

The service could not have been improved had it not been for the perfectly splendid cooperation of the trainmen of the Pittsburgh Railways Company. They deserve much credit. They have not been favorable to the one-man car, but the men, as well as the leaders, have been absolutely on the level in their attitudes. We do believe that before things are over they will find the one-man car has been a friend to them.

CHAIRMAN KOEHLER: In Milwaukee we have had identical accident statistics, indicating that the one-man car is making a better record than the two-man car.

The next question asks: "Do you think sixty pounds of pressure on the brakes of the average car safe in the handling of a carload of passengers?" Does anyone have anything on that?

Are Sixty Pounds of Air Sufficient for Brakes?

HENRY G. BAMBRICK (Pittsburgh Rys. Co., Pittsburgh, Pa.): In regard to 60 pounds pressure of air, that all depends upon where you are operating the car. Sixty pounds pressure on the brakes would hardly do where you are going up one hill and down another. We run as high as 90 pounds, and I find that in doing that and having plenty of sand, we get mighty good service. If you cut down from that and also on the length of the piston, you are up against a bad proposition. On level streets, you could get away with that, but not in Pittsburgh.

W. E. GOODMAN (United Railway Co., St. Louis, Mo.): I have had a great deal of experience with the 60-pound air pressure. Where you have to go up and down hill, the most difficulty we find is in running a little beyond the destination. This doesn't suit the passengers, but this is all we are allowed. The thing is, when you are coming down the line trying to make the schedule and an automobile pops up, or a child runs out in front of you, what can you do when you only have 60 pounds air pressure?

CHAIRMAN KOEHLER: Local conditions, of course, have a lot to do with it.

E. HOLIBAUGH (Pittsburgh Railways Co., Pittsburgh, Pa.): That all depends upon the brake rigging, the size of piston and cylinder, as well as the braking ratio. I don't see how that could be intelligently answered unless you were in possession of all those facts.

SANFORD BABBITT (Pittsburgh Railways Co., Pittsburgh, Pa.): Sixty pounds of air isn't sufficient whether you are on level ground or on a grade. The fact is that automobiles shoot out in front of you, and where you have a distance of 10 or 15 feet in which to stop, the air has hardly started through the pipe with 60 pounds pressure before you ram a car. I don't think a company is justified in allowing the operation of cars with such a low pressure.

CHAIRMAN KOEHLER: I believe this is a question that is of interest to many of us: "Can you give devices used by other companies, or methods employed to protect trackmen while working in city streets?"

MR. BABBITT: We have a great many trackmen in Pittsburgh carrying a red light on their backs while working at night on switches and track. I haven't heard of any of them being struck at the present time. They say it is a mighty good proposition.

CHAIRMAN KOEHLER: Do you have a white belt on which this thing is fixed?

MR. BABBITT: Yes, the "Sam Brown" type of belt. During the day time they use the white belt alone.

PAUL HODSON (East St. Louis & Sub. Ry. Co., East St. Louis, Ill.): We have experimented along this line, but there seems to be absolutely no protection from automobile drivers. We have used two methods: That of having a man selected to use the red flag, standing some distance from the work going on, and still they hit them. They hit a man with a red flag the other day and put him in the hospital. We are also using the signs 18 inches square, similar to the state highway signs in Illinois, which are set back from where the men are working. This sign says "Danger! Men Working." That has proven the most effective. These signs are set back about 25 feet, both in front of the men and in the rear. At one time we used the barricades, completely shutting off the street, but one of the most prominent business men didn't see the barricade one day, and killed two men.

MR. RAMSEY: We have a bracket with two red flags attached which is used while construction work is going on, but we had a case of a man getting hold of some moonshine and he ran into a cage where the men were working with an acetylene torch. That happened with all those precautions.

CHAIRMAN KOEHLER: We must necessarily close the discussion, as definite arrangements have been made to have Mr. Bennett speak over the radio to the school children. It is a pleasure to me to now introduce Mr. H. K. Bennett, of the United Electric Railways Co., Providence, R. I.

Utilizing the Radio

H. K. Bennett, United Electric Railways Company, Providence, R. I.

To the question, "What is the value of the radio in safety work?" one need but say "invaluable" and he would give the shortest and perhaps the best answer. However, being so positive in my valuation of this safety accessory, I must enlarge a bit in order that you may be entirely sold on the proposition and fall into line with my opinion.

If you could feel the very presence of approximately 50,000 children listening to you for a half hour every Friday evening; if you could see through the "Mike" this number augmented by perhaps thousands of others not members, and thousands of fathers and mothers near and far; if you had the living testimony of this mother, that father, and the thousands and thousands of letters right from a child's heart—would you believe then?

Well, that is my position every Friday evening, and when I call this meeting to order and ask each member to stand and repeat the pledge of the club—"I will always be careful"—I see them doing it just as plainly as I can see your faces today. Why can I see them? Because, in the first place, I have sold myself this God given touch of humanity, and I believe, from the soles of my feet to the crown of my head, that the salvation of this nation and of the coming generation lies in the child of today, and that unless we do everything in our power every day and hour in the week to keep before them the necessity of "Always being careful," wherever they are—in school, at home, at play, on the way to and from school—then we have neglected the greatest opportunity of saving human life and limb that is before us.

Last November, one cold Friday evening, "Uncle Red" broadcast from station WEAN, the Shepard stores at Providence, an invitation to every child in range of his voice to join the first A. B. C. club ever formed in this country over the radio. He told them at the outset that the only cost would be the promise to "always be careful," and that he would have a few rules for them later on. He also firmly impressed in their minds that his identity would not be revealed and that he would be known simply as "Uncle Red," and that if

PROVIDENCE SAFETY COUNCIL*This Is to Certify That***THE BEARER***Is a Member of***UNCLE RED'S
A. B. C. CLUB***As a Member of**Uncle Red's A. B. C. Club**I Will Try To***Always Be Careful**

Name

Date Address

he appeared in that character at any public gathering, he would be masked, and he has kept that promise religiously.

At the same time Uncle Red told his listeners that he would send a membership card, pin and a personal letter to each member. This has been done, but only Uncle Red and the Providence Safety Council, backers of the broadcast from a financial standpoint, know what a ball they started rolling. It was thought that one or two thousand children might respond. They did, and then some!

At the first meeting Uncle Red said that the club was to be officered and that the first eight names received in response to the first broadcast would be the president, vice-president, secretary and directors for one year. Letters came

by special delivery to the station and the election was conducted strictly in accordance with the agreement.

At the second meeting the rules of the club were given and they were simple: "Always Be Careful; never play any game, roll hoop, ride a scooter, play ball, fly kites, hook rides, or slide on streets crossing car tracks; but to play on the sidewalk, in the home or school yard and the public play grounds."

Immediately letters began to arrive by the hundreds from the children telling Uncle Red that they would do just as he had asked them to. Right here let me quote a few of these letters to show the mark of sincerity:

UNCLE RED'S A. B. C. CLUB

STATION WEAN

Providence, Rhode Island

DEAR CLUB MEMBER:

I received your nice letter telling me all about yourself and your wish to join Uncle Red's A. B. C. Club, and I am very glad to welcome you as a member.

As I promised, I am sending your membership card and button with the name of the club on it. I want you to keep this card nice and clean, for maybe some day I'll come around to see you and I surely want to find that your card is as nice as the day I sent it to you. I want you to always wear the button, and to be proud of being among those who belong to the first Uncle Red's A. B. C. Club in the whole United States.

I never knew I had so many nieces and nephews before, and some of the letters I received were decidedly affectionate but that did not hurt Uncle Red's feelings a bit. He will always remember you and keep your letters to read over again some day.

I hope you will like this letter paper and I am sure your officers will be glad to hear from you any time you wish to write.

With lots of love,

UNCLE RED.

Dear Uncle Red:

When I joined the A. B. C. Club, I learned a lesson, because I was a bad boy. Now, I am a good boy because I am doing things right.

Dear Uncle Red:

Before I belonged to the "Always Be Careful Club," I was careless in many ways. I have a nice wagon but I will promise you that I will not go on the street in my wagon.

Yesterday, I saw a boy hooking on an ice wagon. I showed him my member-

ship card. I told him not to steal any more rides on wagons. I will always be careful.

I belong to the A. B. C. Club, I am going to ride it on the sidewalk hereafter since I have heard your safety talks over the radio.

My brother was riding me on the cross bars of his bicycle and a boy threw a scooter in front of the wheel and I fell off and hurt my side but I am all right now. I am never going to get near the bicycle again since I heard your safety talk.

JEAN SULLIVAN.

Dear Uncle Red:

I take great interest in our little club. Since I started in your Club, I have stopped roller skating because when I skated it was right on the main street.

I have also told my little friend to join and she is doing like myself and will always be careful. When we are going to school we look up and down like the little mouse you told us about. Your niece,

RITA WARREN.

Dear Uncle Red:

I am writing to tell you a few things that I have been doing to be careful.

I have not been running out in front of automobiles, or playing or walking in the street. Your niece,

NORA FEELEY.

Will Keep His Scooter Off the Street Now

Dear Uncle Red:

I have not ridden my scooter in the street after that talk you gave us.

I always look carefully before crossing the street. Your loving nephew
—STANLEY BLANCHARD.

Dear Uncle Red:

I used to play ball in the street but now I am careful and play in the yard. I hope some day you will come around to see my card. I am keeping it very clean.

LOUISE TESTA.

Dear Uncle Red:

I have been very careful since last Friday, the day I joined the Club. I have a scooter and a pair of roller skates. I used to ride on them in the street but I have not since you told me the rules of our Club.

When I cross the street, I wait until the road is clear every time.

Will try to always be careful everywhere all the time.

GERTRUDE NEWCOMB.

Dear Uncle Red:

Since you have established the A. B. C. Club, I think I have been 100 per cent more careful.

I had a habit of wheeling my little sister's carriage in the street but now I know it is dangerous for both my sister and me.

I used to cross the street anywhere even if there were cars and machines coming, but now I look both ways before crossing. I used to slide in the street with my sled, but this winter I won't. I have asked my little brother and sister to be careful in crossing the street. I hope the A. B. C. Club will do for others all it has done for me.

I always wear my A. B. C. Pin and think it makes me always remember to "Always Be Careful." Your niece,

MAY GAUDET.

V. H. KUPFERER (The Studebaker Corporation, South Bend, Indiana): I move the adoption of this resolution.

(The motion was seconded.)

CHAIRMAN BOSWELL: You have heard the motion, and it is properly supported, that we are in favor of this resolution as a Plant Publications Section. Is there any discussion?

(The motion was put to a vote and carried.)

It has been suggested that the committee appointed yesterday to recommend whether or not we would have a change in name of this section from Plant Publications to Employees' Publications, or some other name, report after Mr. Dempster gives his paper tomorrow, and if there is no objection to that I will call for the report of the committee at that time.

We will now proceed with the next number on our program. Mr. R. G. Conover, of the Yale & Towne Company, is here. Mr. Conover is editor of the *Yale Panel*.

Some Editorial Problems

Richard G. Conover, Director of Publicity, Yale & Towne Manufacturing Company, Stamford, Conn.

Two general problems confront plant publication editors. One is how to sell their editorial selves to their employee readers. The other is how to sell their editorial selves to their employers. They stand in a midway of industrial publication accomplishment. They have a strong man's job before them either way they face.

Many will say that the more important of these two general problems is the winning of the employee reader. It will be claimed that the publication is issued just for that one thing. But the deeper analyst of plant publication objects will be likely to maintain that the winning of the employer by the employer's editor is the far more important, as well as the far more difficult problem to solve.

Certainly a plant publication editor has an opportunity to interest, please and benefit the employee reader solely because his employer affords him the chance. It rests with those who pay the publication bills to make this chance a permanent feature of the service. Therefore the worthwhileness of the plant publication must be brought home to the conviction of those who are the powers to say whether the publication shall live or die.

It is the editor's problem, the editor's prime and particular job, to give the employer constant assurance and evidence that the plant publication is performing an indispensable mission. It is likely there are superficially-thinking editors who will say that there is no need for them to feel concerned about the continuance of their publication. Such editors take it as a foregone conclusion that once their plant magazine or paper is launched, it must automatically go on merely because the employer has started it.

They take the view that everybody admits the plant publication is of great benefit to the employer and therefore the employer will subsidize it eternally. That being settled, all there is for them to do is to interest and convince the employee reader through the material they print in their publication columns.

Now and then there comes a bulletin from employers announcing the suspension of the plant publication and it is only the shock of this bulletin that brings full comprehension of the other problem to the superficially-thinking editor.

Employers as well as employees like to have it proved that their judgment is right. Employers like to be reassured that their policies are sound and profitable. When employers decide to publish a plant publication or magazine, they often wonder how much good that publication is going to do their busi-

ness. At best it is somewhat of a guess and a hope. When the red-ink totals appear in the ledger during one or two bad business years, the employer is apt to go over his figures and speculate on whether or not this or that outlay can be stopped without much hurt to the business.

It is possible at such a juncture that the employer may run his finger down the figures of outlay and coming to the plant publication item, begin to waver in his conviction that this expenditure is a paying service benefit. For the most part, whatever results come from the plant publication, they are of an intangible nature and the employer has no way to prove publication advantage except through faith. Is it anything surprising if he should reach out for some new arguments, new reasons, new faith and new hope to justify the continuance of the publication?

Who is the man who should be best able to furnish all of these to the employer? Who is the man who should have at his finger ends the facts and figures—so far as facts and figures are obtainable—to place before his half-doubting employer, and thus prove to him that his plant publication is of such vital and organic necessity that to cut it out would work as dire a result as removing an organ from the human body.

Why, the editor is the man who should be a veritable fortress of facts and well-spring of enthusiastic reassurance.

Sell the Plant Magazine to Your Employer

How many plant publication editors have considered this problem of selling their enthusiastic conviction of the worth of their magazine or newspaper to their possibly pessimistic employers? How many have armed themselves with good arguments, with sound arguments, with honest arguments, so that if called in by the general manager, or the president, or in fact by the whole board of directors, to give good reason why the publication should not be suspended, would be able, because of their study of the subject and their intense conviction after such study, to stiffen the wavering determination of their employers and point out the magnificent results that surely must follow the published word in a plant?

Solving this one general problem is not solving it for the preservation of the editor's job. If that be the sole reason for the editor's enthusiasm and study of the worthwhileness of the plant publication, it will be very transparent to the employer before the middle of the first argument is reached. It is rather by the assembling of all data obtainable, and all proofs of welfare promotion, and all instances of uplift accomplished through the medium of the plant publication that the heart of the employer will be gladdened.

He wants to hear that the plant publication is worth while. He wants to know that the cost of the plant publication is money well spent. It is for the editor to tackle the problem by arraying argument that will foster his employer's faith in the publication as a decided service benefit, and will likewise buck up his drooping confidence in the plant publication enterprise.

Of the two general problems outlined, the writer considers this, of the editor selling the plant publication to the employer, far more important than selling the content of the publication to the employee reader. If an editor cannot solve this first problem, there is always danger that his plant publication, following a year or two of bad business, may be discontinued by the depressed or apprehensive employer.

This has happened in the case of both large and small corporation employers. If it does happen; then there will be no longer an employee reader because there will be nothing more to read. It still may be insisted that the task

of interesting and benefitting employe readers is more important than anything else, because (it may be contended) even though there be no demur as to cost of publication, there will be no use in issuing a magazine or newspaper that does not manifest its power to grip and hold and convince and lead the employee. Granted, but you must build a church before you can worship in one. You must build a boat to cross the river if you wish to address an audience in a grove on the opposite shore. Without the boat and without the church you cannot obtain the object proposed. By the same reasoning the plant publication must be assured of continuance or you necessarily cannot make your appeal to the employee reader.

From the foregoing, it will rightfully be deduced that this article has not for its prime object a suggestion or an argument for the use of certain details and methods whereby the employee reader shall be interested and convinced. Such tasks are very important, but plant publication editors will be wise to take them up in a secondary way as their other general problem.

Some things said here will perhaps help in the solution of this second general problem, but in the main the writer will address himself to points bearing upon the first or more important division of the editor's big task.

First of all cultivate a keen realization that even before you sell your editorial self to your employer, you must sell to yourself the idea of plant publication worthwhileness. Certainly if you are not convinced of the value of the plant publication, you cannot go a dozen editorial steps without revealing that you do not believe yourself in what you are talking about. You must be enthusiastic about this conviction. You must argue it out with yourself. To get the very best results, you must look upon it as a subject on which you have pronounced ideas—just as pronounced as you may have on religion, politics or finance. You must prepare yourself to debate the worthwhileness of the plant publication at the drop of the hat.

The Editor Must Know the Real Value of His Paper

You must have an answer in case somebody should say: "Oh, you're just talking to bolster up your job as a plant publication editor." You must be able to tell such a one all there is to be said in favor of a plant publication, and show him where he gets off if he thinks you cannot have an opinion, and an enthusiastic opinion, unless it be measured in terms of dollars and cents.

As a plant publication editor, who may be called upon to bring a change of belief to his employer, you must learn how to solve the problem of this employer's doubt and how to define clearly your own positive convictions of how enormously valuable a plant publication is.

How to do this best is of course a nice problem. But it is a problem that should be solved and must be solved by you, the plant publication editor, if you expect your magazine or newspaper to continue permanently, and also if you expect to convince your employer that you are the man to direct it as a worthwhile asset in the company's business.

And this brings us to this very pregnant question: Assuming that the employer is willing to meet the cost of a plant publication if it continually manifests its usefulness to him and his purposes, what is the magazine or newspaper really published for? What does the employer hope will be accomplished through it?

Like the mariner taking his reckoning and then starting straight for a definite port, the plant publication editor should first ascertain exactly, and in detail, what he hopes, or what his employer hopes to effect through the publication, and then go forward to carry out his employer's policies and plans.

It is a flamboyant habit of some editors to forget all about the practical side of publication. They are self-deceived into supposing that their gripping English is all that is needed. They consider their fine-languaged arguments irrefutable and their pleas and appeals certain winners. But suppose the employer in a practical way, looks at the cost of the publication and says this to his editor: "Yes, I know your appeals and precepts and other writings are good, but what have you to offer me in the way of evidence, or indication of evidence, that the cost of this publication, measured in dollars and cents, and compared with the practical return, makes it worthwhile to carry it on?" This significant query brings us back again to the prime question:

"What is a plant publication issued for?"

The Paper Must Pay Its Way

The writer confesses to being somewhat of a utilitarian. As such his answer to the query must be that the plant publication is issued to help the employer make money or save money. Every plant publication editor may have received varying instructions or intimations as to why his particular newspaper or magazine is published. Every editor knows whether or not his employer wishes to publish a plant paper regardless of the cost or results of publication.

Perhaps there are employers who have advised their editors that they issue the publication as a sort of good-will gesture and that they never consider the ratio between the cost and the good that may come from publication. Perhaps some employers have told their editors that even if they could trace no benefit at all from publication, they would still publish regardless of cost totals.

The writer believes, however, that there are many others holding the opinion that the real goal and the real mission of the plant publication is to help the employer make money or save money. His employer, if a corporation, came into being for the purpose of making money. The plant publication is merely one of the accessories to this end. It is all very well to feel thrilled over your editorship, and to preach that your magazine or newspaper is lifting your readers to greater heights of mental, moral and physical excellence. But the blunt fact remains—and I think it remains in a majority of plant publication situations—that the flights and heights essayed in your paper are vague and impractical accomplishments unless you can point out that your employer's interests are surely advanced.

It is true that when you print something in your paper that tends to make an employee a better man and a better citizen, that accomplishment—to a degree—is commendable. But your employer is not incorporated to make better men and better citizens as a first desideratum. He is incorporated to make money along particular lines.

As an editor you may print finely written stuff, but it may be but a mass of generalizations that has little if anything to do with the progress of your employer's business. Seek first to make every letter, every syllable, every word have a practical acceleration to our employer's business, and following this editorial route, you will make it clear that you understand what your paper is published for.

It is true that good advice and uplifting appeal printed in your paper may have a modicum of good effect on your employer's business; some good effect although through very remote and indirect interpretation. But why not aim to help improve your employer's business directly? Then if an employee through your written argument is made a better citizen and a

better man generally, that particular result is "all velvet." Do not, however, treat your plant publication, which is issued primarily to help make money for your employer, as you would treat a general newspaper, published with a miscellany of purposes.

If your employee readers are interested in golfing, motor boating, sociology, birth control or divorce, there are numberless publications devoted to these subjects. Discussing them in a plant publication will make no appreciable advance in your employer's prosperity. Dilating on general questions of the day brings no advantage in the way of helping to make money or save money for your employer. A good employee golfer might be a poor workman who needs bucking up. A divorced employee might be a fine, loyal and industrious worker.

In other words, if we concede that our plant publication is issued to aid our employer to make money, then we must stick close to this set purpose. We should not wander off in generalities. We should publish nothing vague of design even if uplifting generally. How can this be done? The writer follows three general lines.

Labor Turnover One of the Biggest Handicaps

First: what can you print, and print, and print, in your publication that will help to lessen labor turnover? Lessen labor turnover and you save money for your employer. Save money for your employer and you make money for your employer. Play on this harp of a thousand strings—lessen labor turnover and again lessen labor turnover.

Second: what can you print that will tend to increase the punctuality, constancy of service, loyalty, efficiency, contentment and ambition of the employee reader? There never has been a completely satisfactory answer to this query. But one thing you can do. You can, with the greatest honesty and sincerity, boom the town where the employee reader works and the plant he works in. You can laud them as being magnificent places to reside in and to toil in.

In scores of ways this can be driven home, and in the end is bound to have weight in influencing the employee reader to remain contentedly, or reasonably content, where he is. This again has a big influence in lessening labor turnover—an advantage to both employer and employee, for if shifting help is a loss to an employer, so it is frequently to an employee who pays for transportation from one point to another and has no assurance that his new job will be congenial.

Third: constant improvement in your plant publication as to quality and quantity of appeal. Constant attempt to economize in its cost. It is this last division of editorship that should make attendance at the annual **Plant Publication Conventions** worthwhile. The plant publication editor should attend these conventions, asking these questions of his fellow editors:

Can I help you, or can you help me—

(A) get out just as good a publication as we are getting out but at less expense?

(B) get out a better looking or a better made up publication typographically?

(C) get out a more forceful publication?

(D) get out a publication more novel or attractive?

If the plant publication editor who attends the annual convention can improve his magazine or newspaper along any of these four lines, he will be helping his

employer make money and save money. He will know that he has gone far toward solving one of his main publication problems.

There are many things of interest to employees that you might write about in your publication that have no value at all in helping a corporation to make money.

It is admitted that a word hidden here and there in what you write, although it has no direct bearing upon helping an employer to make money, nevertheless, may be of very remote benefit. Just where we shall find this benefit, however, will be like trying to find the proverbial needle in the haystack.

If you set out to do something beneficial, do not take to the side paths, but pursue the straight road from your starting point to your goal.

It is a nice thing to observe a plant publication editor getting out his magazine or newspaper the same as if he really owned the plant, and the paper, and was responsible only to himself. It indicates a commendable zeal and enthusiasm. But in our discussions at conventions, and in advocating this or that as good policy in putting forth a plant publication, we must ever bear in mind that we are subordinate to the policies of our employers, and that there are many things which we would prefer to do as editors that we cannot do because the business wisdom and foresight of those who engage us define what the limitations of publication shall be. This should be kept well in mind when we are suggesting that another editor should do so and so, or wondering why he does not do so and so. If we knew his limitations, we might get out exactly the kind of a publication that he is getting out.

Two Points of View on Publishing the Accidents

As an illustration of the restrictions imposed by management policy, in some cases plant publications print a vivid recital and list of accidents in the manufactory. It is supposed that printing this will serve as a beneficial warning to other employees to be more careful.

On the other hand, a management will take the ground that printing reports of such accidents in a publication that goes abroad, and is seen by people who are interested in a corporation in a financial way, may give the impression that there are more accidents than there need be at the plant, and there must be an undue percentage of carelessness or they would not occur.

If a management laid down as its policy that it was unwise to print accounts of accidents at a plant, you can see how futile it would be for a man to arise in a convention of editors and insist that all plant publications would be benefited by printing a list of weekly or monthly accidents, with details.

Let us hope that at these annual conventions we may be able to aid one another in solving these problems by recognizing that plant publications are of many kinds with various policies and various budget totals.

Let us help one another by first ascertaining the policy, the facts and the budget governing or influencing each editor's publication task. Let the papers we read and the addresses we deliver at annual conventions take into consideration all these varieties of publication and editorship, so that we shall not be speaking of things too high on the publication peak to be of value to the smaller editor, nor too crude and simple to be of advantage to the editor associated with the larger corporation.

CHAIRMAN BOSWELL: We wish to thank you, Mr. Conover. You have made interesting deductions here and I am sure it will be worth while to consider with great seriousness some of the things you have propounded.

I am going to ask Mr. Ward, who was appointed yesterday, to give us the report of his committee as to how we may get some sinews of war.

C. A. WARD (Pure Oil Co., Columbus, Ohio): The committee consisting of Mr. Mahaffey, Miss Cade and myself met after the meeting yesterday and we unanimously decided to recommend a fee of five dollars. However, we saw the big bosses this morning and they vetoed that proposition. Mr. Ashe suggested a membership fee of two dollars, in which the committee very readily acquiesced, and we now make that recommendation.

CHAIRMAN BOSWELL: I would like to correct Mr. Ward. The president, Mr. Ashe, did not dictate at all. Mr. Ward was talking to us and we told him that we felt that five dollars was maybe a little too high, because we felt we didn't need that amount of money. Mr. Ward had in mind, and I think the committee also had in mind, that the printing of the News Letter the cost of printing it had to be borne by the chairman of this section, and when I informed him that such was not the case, that the News Letter was being printed at the expense of the National Safety Council, and was being mailed out at their expense, it cast a little different light on the question. So that the real expenses are in seeing that these panels are taken care of and that they are sent to the next Congress; and the resolution which you have adopted, if it is finally carried, is going to preclude the expense of express or freight if the conventions are to be held here in Chicago. We did have it in Detroit last year. That is going to save that transportation, although, while the chairman of this section for the coming year is a resident of Chicago, a subsequent year might find your chairman in some other city and he might want to have those panels sent to him.

Question of the Registration Fee

But there are a few expenses that must necessarily arise and the question is before you. The committee proposes a fee of two dollars as a registration fee for the members of this section, to be imposed in some way or another. What is your pleasure?

S. W. ASHE (General Electric Co., Pittsfield, Mass.): I second the motion with the modification that the membership fee isn't anything of a compulsory nature. There are a number of people present, connected with big companies, that usually aren't faced with the problem of expenses when it is a matter of this sort. I know that in the three years I have been connected with this body I have had no difficulty in getting all the money I needed. That is one of the reasons I felt five dollars was too much, because some of the smaller companies are faced with the necessity of curtailing expenses.

CHAIRMAN BOSWELL: Is it your idea that it should be a voluntary fee rather than a compulsory fee?

MR. ASHE: Yes, there might be some instances where even two dollars would be difficult to put on their expense sheets. We have a strong section here, getting to be one of the biggest and most powerful in the Council, and I don't want to see anything come in that is likely to stunt its growth, even though it is a matter of a few dollars.

CHAIRMAN BOSWELL: Mr. Ward, would your motion or resolution be that an involuntary fee or something along that line be imposed?

MR. WARD: All right; anything to help the organization. What we want is a little money to use in reaching the other 600 or 700 editors who don't get to these meetings.

V. H. KUPFERER (The Studebaker Corporation, South Bend, Indiana): It occurs to me that we would probably be able to reduce that to one dollar if we simply asked every editor who wished to become a member to pay one dollar. In that way we could probably raise two or three hundred dollars.

CHAIRMAN BOSWELL: Do you wish to make that as an amendment?

MR. KUPFERER: These fellows get the News Letter and other things we are trying to do, and if they don't get to the Congress it is unfortunate. I think they would be willing to pay a dollar as a membership fee, which would put the cost where it belonged. I would like to make that as an amendment.

CHAIRMAN BOSWELL: The amendment is that the membership fee be placed at one dollar.

F. L. GREENYA (Fisk Rubber Co., Cudahy, Wis.): I think there are one or two points that should be clarified before going farther. The matter of assessing the sum of one dollar, or any amount, is a good one because there is a certain amount of expense necessary in carrying out projects, but I think this body should decide positively here and now whether or not that is going to be an actual assessment, and whether or not the privilege of receiving the monthly News Letter will be confined to those who pay it. I think the status of the membership in this organization should be determined here and now.

I like the idea of assessing every one a dollar and I think that every one should be sufficiently interested in our projects to contribute that amount. I don't care how small or how large the company, that isn't going to break them, and they can get more than a dollar's worth out of that monthly News Letter. I think that if they don't pay they shouldn't get the News Letter, and I think that should be definitely set forth and it would be an inducement to pay the dollar.

CHAIRMAN BOSWELL: Is that suggestion agreeable to the members assembled? How would it be to word the amendment to this effect—that there be a membership fee of one dollar to the members of this section, which would include the monthly News Letter? Will that be satisfactory?

MR. ASHE: Of course I presume our friend here had in mind that the National Safety Council would pay the expense of that News Letter anyway and that the dollar could be used for other purposes. My thought was that you are agreeing to give service which the National Safety Council is now giving and use your dollar up that way, and then you wouldn't have any money left. I presume that the National Safety Council would still be willing to continue the service they are now giving.

The News Letter Contains Much Valuable Information

CHAIRMAN BOSWELL: They are sending this News Letter out to several hundred editors of plant publications.

MR. GREENYA: My thought was that the matter of who shall receive these particular News Letters was determined more or less by the membership in this particular body. If that is not the case there is no particular need of stressing that point. I think this body should have supervision over who shall and shall not receive that particular News Letter because they can induce membership in this body by that means. It is all right for the National Safety Council to send out the News Letter on their own stationery and on their own time, but if they have a unit in their organization doing definite work in that line that unit should have something to say as to how that work shall be done and controlled. If we have no jurisdiction over who is going to receive this News Letter then my thought was all for nothing.

A. H. RICHARDSON (General Electric Co., Erie, Pa.): The thought was expressed yesterday and has been expressed again today that inasmuch as the plant publications contest is the cause of this expense, that the editors entering the contest be assessed a small fee to take care of the expense of transporting the panels. As I understand it, this News Letter is now sent to these plant publication editors, regardless of whether the editors attend the Congress or not, and I would not like to see that changed; but I think that a fee assessed to the members entering the plant publications contest would be allowable.

E. AUGUSTUS (Mead Pulp & Paper Co., Chillicothe, Ohio): I think if you do

that you are going to get into trouble with the postal authorities. It came up just recently in Washington where some very worthy ladies were trying to raise funds for a certain purpose and they decided upon the idea of staging a contest and charging a fee for anybody entering the contest; and the postal authorities said that it was the same as a lottery, and couldn't be done.

I think the idea of letting each member pay an assessment of a dollar or two and have that entitle him to receive the News Letter is a good one. I think that the members who have been receiving this News Letter were not arbitrarily picked by the National Safety Council, but the National Safety Council sent us a list from which we picked out some 200 or 300 names.

Personally I am in favor of a two dollar assessment. I would make it two dollars with the understanding that that assessment would entitle the giver to the Monthly News Letter.

Council Membership the Determining Factor

S. P. WILD (Armour & Co., Chicago, Ill.): I think before we go any farther we ought to have a little more definite understanding. I think there are others in the same boat, as to what constitutes membership in this Section and what limitations we have over it. It is my understanding that the membership of a company in the National Safety Council in the past has entitled the representatives of the company to membership in the sections *per se*, without any further authority.

I think that the idea of a dollar or two dollar fee is very good, and there wouldn't be any question as far as we are concerned about being able to pay it, and if I were with a small company I would pay it myself.

I don't think we have the authority, however, to limit membership in this Section to the people who pay the dollar if their company is a member of the National Safety Council.

CHAIRMAN BOSWELL: I was going to call attention to that thing.

MR. ASHE: I believe he is right. That was one of the thoughts I had in mind in putting it up as a voluntary contribution.

CHAIRMAN BOSWELL: I think, with that thought in mind, which is a fundamental rule of the National Safety Council, that any member company is permitted to send any of its employees to any of these sections without additional registration fee, the only registration fee is the two dollars which we pay to get our badge; and with that in mind I think we will have to pass that idea up.

This money which we are trying to raise is for incidental expenses that are not borne by the registration fee which the National Safety Council receives, nor the membership fee. Now I think if that is clear to us all we are just asking ourselves to raise some money to carry on some things which we don't feel we should ask the National Safety Council to bear.

The amendment is this, that we charge a membership fee to all the members of this section, and that would of course mean those who attend here from year to year, I should judge. If we need any definition along that line we may have the officers-elect for the coming year lay that down for us. Are you ready for the question?

A. H. RICHARDSON (General Electric Company, Erie, Pa.): I would like to offer a substitute motion in that the chairman present a bill of expenses to the section each year and ask for contributions to meet the expenses. That would take care of it and there would be no discussion as to the membership fee.

(The substitute motion was seconded.)

CHAIRMAN BOSWELL: The substitute motion is that the chairman of the section present a bill of expenses to the section each year and ask for contributions to meet the expenses incurred during the preceding year, or during that present year, which would obviate the necessity for a membership fee. Is that your substitute motion?

MR. RICHARDSON: Yes.

CHAIRMAN BOSWELL: And that substitute motion is supported.

MR. ASHE: I would like to hear a word from the incoming chairman on this subject.

R. H. FERGUSON (Bureau of Safety, Chicago, Ill.): The suggestion was made that if this matter were presented to Council headquarters we probably could get \$200 or \$300 to cover the current year's expenses, but I believe that it would be well to let that matter rest. I feel sure that such expenses as we may have can be taken care of easily, and if they do run high I think we can get that from the National Safety Council.

CHAIRMAN BOSWELL: We have a substitute motion before the house which must be voted on unless there is a motion made that it be laid on the table.

MR. GREENYA: I move that the substitute motion and everything that goes with it, after the words of the incoming chairman, be laid on the table.

(The motion was seconded.)

CHAIRMAN BOSWELL: The motion is that we lay the substitute motion on the table.

(The motion was put to a vote and was carried.)

CHAIRMAN BOSWELL: We now have the amendment before us.

MR. GREENYA: I move that the amendment be laid on the table.

(The motion was seconded, put to a vote and carried.)

CHAIRMAN BOSWELL: The committee appointed yesterday is still operating.

Now we have 20 minutes for our final speaker, Mr. Kupferer. Mr. Kupferer is editor of the *Studebaker Cooperator*, of the Studebaker Corporation, South Bend, Indiana.

Rewards for Contributors to Employees' Magazines

Victor H. Kupferer, Editor—The Studebaker Co-Operator, The Studebaker Corporation, South Bend, Indiana.

This presentation was originally to have been in the form of a debate on the question, "Resolved, That contests for contributors to employees' magazines, with tangible prizes for winners, are a good thing." It has been deemed wise by the program committee to have this matter presented in the form of a paper, which is much more satisfactory to me.

We are all pretty much agreed that it is a good thing for us to accept contributions from our employees, and to encourage them to contribute to our columns. Tom and Dick will enjoy reading something that Harry has written for the plant paper with more avidity than they will those sections of our pages which are marked "Editorial." But certainly no one will contend that we should pay an employee for submitting a news item, or even a poem. I have been in the position sometimes where I would almost pay employees for not submitting "poems."

Where regular reporters, correspondents or associate editors acting as correspondents form a part of the staff of the plant paper, I am of the opinion that they should not be paid for their work. An excellent idea, and one which I believe a number of editors use, is that of having periodical dinners for the group and an occasional social gathering, possibly with the families of the reporters included. At the dinner meetings, problems and ideas could be discussed and the items submitted can be thus maintained at the desired standard, from the standpoints of both quality and quantity.

When a regular artist, cartoonist or photographer is used, it is sometimes desirable to pay such individuals for the work they do inasmuch as it frequently involves spending a great deal of time and effort in connection with the work submitted.

I will now present several reasons why I believe contests with rewards for prize winners are valuable in producing good material for use in the employees' magazine.

In the first place, I think the announcement of a contest stimulates many employees to contribute material along specific lines such as safety, thrift, health, education, loyalty, etc. From our own experience, we found that a prize contest for articles on "How the Employee Can Help Prevent Accidents" produced contributions from many employees who otherwise probably would not have contributed. A first and second prize were offered and the winning articles were published; in the case of the first prize, the photograph of the man was printed with the article. The prizes were \$25 and \$10. At least one employees' magazine reprinted this winning article complete and the employee who submitted it was recognized further by a promotion. Concurrently with this contest was one for foremen and the subject of the article was: "What the Foreman Can Do to Prevent Accidents." This contest not only brought us this material for our paper, but incidentally was the means of getting a lot of employees and executives thinking about this question of safety.

Secondly, the fact that the article is a prize winner, aside from the fact that it was written by one of their colleagues, will tend to make employees read the article from a curiosity standpoint and thus the message is at least read, which is not always true of "tailor-made" editorials.

The Contest Idea Well Established

And then it is not strange that we should adopt the contest idea for our publications. Consider the national advertisers who use this method—Liberty Magazine in their name contest; Sears-Roebuck & Co., with their tire naming contest; other concerns with their slogan contests; even the National Safety Council has run prize contests at various times; and many others, too numerous to mention. Many of our employees' magazines use contests for cartoons, stories, photographs, limericks, etc., and, from those I have followed up, it seems to have worked out very effectively.

That there should be a tangible reward in this type of contest can hardly be questioned. It is a parallel to our employees' suggestion system and we know that the reward held up for valuable suggestions is the incentive to employees to submit them.

In their "Modern Management Trends" series, the Working Spirit Builders of Chicago, make this statement: "In exceptional organizations, well-oiled by high-working spirit the reward of personal pride and satisfaction may outweigh a money prize. But it is doubtful if management convincingly expresses to employees its appreciation of valuable ideas without giving them something of tangible value." Amen! You know Harrington Emerson, in his book on the twelve principles of efficiency, includes the efficiency reward as one of the fundamental principles.

As before intimated, we find that many employees who would not otherwise contribute to our magazines, due to modesty or some other cause, will contribute when a contest is announced and thus we may uncover talent which we can use regularly. Maybe we will find that cartoonist we have been looking for since "Hec" was a pup. Perhaps we will locate a better reporter for that department which has been falling down in the matter of news items. Perhaps we will find a man whose hobby is photography and who can furnish some excellent illustrations for our use. And not infrequently we may find a man who will be more valuable for the company in a different job which will mean a promotion for him, as was true in the case I have mentioned from our experience.

It was said of a certain physician that he charged eight dollars for a house

all, five dollars for an office call, and two dollars for a telephone call. Whereupon some one asked what he charged to say, "Good Morning." There is an all too common tendency these days to consider everything we do in the light of how many dollars and cents it will bring to us. But I do not think it is unduly catering to this tendency to offer tangible prizes for specific contributions when made under the conditions outlined above.

In concluding this paper I would like to make a few suggestions as to contests, which I trust will be enlarged upon and added to in the discussion which is to follow:

First: Choose practical subjects. Among these might be included, safety, health, thrift, education, garden contests, "My vacation," "My hobby," safety slogans, how to build various features making for convenience and beauty of the home and grounds; and for the women, recipes, household hints, dressmaking ideas, etc.

Second: Make the prizes commensurate with the value of the material. Perhaps \$5 is sufficient for a prize snapshot or a recipe for sponge cake, but when a contest calls for hours of work on a subject, \$25 is not too much.

Third: Do not make the contest of too long duration. State a definite date when contributions must be in and state when prizes will be announced. Bulletins about the plant should be used as well as announcements in the magazine. This enables you to keep the contest before your people which is helpful, whereas mere announcements in one or two issues of the publication might not be quite so effective. Run your contest on schedule and award prizes promptly.

Fourth: Select competent, impartial judges. Use prominent people when possible, being sure to use those whom your employees will agree are competent and fair.

J. J. PLZAK (Consolidated Water Power & Paper Company, Wisconsin Rapids, Wisconsin): I wonder if Mr. Mahaffey would say something about time exposures on pictures.

P. L. MAHAFFEY (Pennsylvania Railroad Company, Pittsburgh, Pa.): I cannot tell you how to handle time exposures successfully nor can anybody else. I mean indoors and under conditions where there isn't a general diffusion of light from the sky or other means. We have to use our own judgment.

Time exposure is the hardest thing in the world to judge accurately. There are many little contraptions and devices on the market, but for the ordinary amateur photographer who is working with a \$25 camera I have found the "Harrold Exposure Scale" helpful. It is made by a chemical engineer by the name of Elmer Harrold, of Leetonia, Ohio. It gives you the time of day, any day in the year, any place in the United States and Canada; any speed of lens from an ordinary \$2 Brownie camera to the \$300 Graflex. Supposing you want to take a portrait. It is 22 minutes past twelve. Suppose you are going to take a portrait in shade, using a kodak film. You put the stop at GA with the conditions of lighting outside, which I would call rather dull. Now under these conditions, reading from this chart, about 1/25 of a second will make you a nice portrait.

I have fellows working on our railroad who take pictures with almost a hundred per cent success. If you want to pay ten dollars you can get a machine that makes it absolutely impossible to fail. However, with this chart it is almost positive, and you might miss it once or twice if you misjudge how dull a day it is. This chart is graduated for portraits, buildings, average landscapes, moving objects, light colored objects, semi-distant views, extreme distant views, clouds, snow, and sea.

I might also add—don't use a roll film if you can get away from it. The roll film is only for snap-shots. Use the plate camera or the cut film.

ADJOURNMENT.

Friday, September 30, 1927

The third session was called to order at nine-forty-five o'clock by the chairman, Forrest W. Boswell.

CHAIRMAN BOSWELL: I am glad to see that we have so many who have stayed over for this final session. It shows that the interest certainly deepened among members of this section.

There are many here who have looked forward with a great deal of anticipation for the first part of our program this morning, to get a report of the judges, and Mr. Ashe who has been the chairman of the Judges Committee for some years past, who really launched the idea of the contest in the Plant Publication Section, is here and holds the coveted jewels. I am going to call on Mr. S. W. Ashe of the Central Electric Company to present his report at this time.

Report of the Judges Committee

In presenting the report of your Judges Committee, after three years of service, we are giving you in brief form not only the observation of your present committee but also the cumulative opinion of the judges based on three years of judging. The task of judging 260 plant papers, sent in by 130 companies, covering diversified industries, and attempting to analyze the quality, or real value of these publications, from an employee's as well as a company's standpoint, is a job.

Every magazine must be gone over carefully about four times by each judge before it is possible to make an accurate estimate of its value.

Naturally each judge sets his own standard, and while these standards vary it is interesting, in looking over the judges report to see how uniform, as a general rule, the system of judging is carried out. For instance, Hord might rate as low as 45, Wheelock, 66, and Ashe as high as 71, but the average of these three ratings would be comparable with another group judged on the same basis. The ratings in other words, are comparative, and if one magazine had an average rating of 80, another 60, and a third 40, this would be a measure of the relative value of this particular group. We must bear in mind however that this rating is based on a safety contest. Some magazines might be perfect in all other respects, but have no safety or health material, and the maximum rating that such magazines could possibly receive would be 75. This should be taken into consideration in regard to the judging, and also as an explanation as to why some magazines which, to all appearances are excellent publications, received lower ratings than their editors probably expected, due in a large measure to the absence of safety and health material.

The changes in the ratings this year over last, we felt, were a decided improvement, and the present committee would recommend to the incoming committee that this scale be followed another year, until the new committee's experience warrants further change. We all know in industry how difficult it is to arrive at a standard of quality, and how wise it is once this standard has been adopted to move slowly in making changes.

The system of dividing the magazines into two classes has also been an improvement; naturally with each subdivision further complications arise. There is a possibility that a third subdivision might be made, such as the strictly newspaper classification. Whether, however, there is sufficient of this type of magazine to warrant this third classification is something the incoming committee would have to decide. For instance, there would be little advantage in

having the third classification if there were only five or six types of newspaper magazines that entered the contest, three of which would have to be rated as the prize winners.

In the high standing of certain magazines in the contest, the outstanding result is the very large percentage of magazines in "Class I" group which come from telephone companies, and we suggest to all editors that they secure copies of these magazines, and see what a wonderful job the editors are doing. I know that all three judges this year felt that they could take lessons from some of these editors on the especially fine piece of work they are doing.

Last year the magazines did not come in as rapidly as desired, so we sent out an urgent call, which increased our entries from 50 to 150. This year the total of 130 entries came in after our first announcement. No effort was made to force the entries, and those who entered magazines were, therefore, doing so with the idea of really securing a rating, or of being a true sport, and entering the contest to help the idea along.

We were also pleased to see so many magazines entered by editors in the contest this year who also had magazines entered last year. Some few have dropped out, but still we have as many new entries this year.

Some Editors Plan Unusual Numbers

Suggestions have been made that the judges should arbitrarily during the year select or call for two issues of certain months, which should be the entries. We do not believe this is practical. An editor should have the opportunity of looking over his twelve months issues and picking out what he believes are his best issues. In other words, he should feel free to submit his best efforts rather than have someone pick out the numbers.

It is true that some editors include special safety numbers with this method, but every editor has the same privilege in this respect, and if two special safety and health issues were produced each year by the editor, it would help focus attention to the importance of safety work.

Looking over the best papers critically it is realized that some editors put an enormous amount of thought, and originality into the preparation of their papers. They are constantly alert to news, and also are constantly thinking out ways of humanizing their papers, which in the final analysis is a test of the publication's effectiveness.

Many editors are doing splendid work, which is of incalculable value to their company, but still in some cases it is evident that too little thought and labor is being put into some of the publications to warrant their expense.

While the task of judging the papers these past three years has been a heavy obligation still it has been a privilege to do the work, and we hope the results of the efforts of the judges will prove worth while in your estimation.

Spencer Hord

Ralph Wheelock

Sydney W. Ashe, Chairman.

MR. ASHE: One word more before I give you the information which I know you want to hear. We did one more thing that was interesting. We thought that as the editors, as a rule, were such hard-working individuals and as their papers represented such a fine grade of work, it wouldn't do any harm to let the presidents of their respective companies know about it. We, therefore, selected the three prize winners and seven honorable mentions in each group and wrote the president of each company informing him what splendid papers were produced, who had won first, second or third place, and congratulated his company asking further that a representative be sent to this meeting. I know today that we have a number of representatives from companies who have come as a direct result of the personal

interest of the presidents of these companies. We felt that was something well worth while. One president of a paper down in Washington thought enough of it to call me on the long distance phone to find out where the meeting was to be held, in order to have somebody here.

Our friend Garry from the *Northwestern Bell*, who was the prize winner last year, has come from Omaha in order to be here this morning. That gives you a little idea of the real interest in this thing and it is not only a very important activity but there is a tremendous amount you can do among yourselves in getting acquainted with these meetings.

In the magazines of the Class One division we have the rather interesting result that the person who won the first prize this year is the same individual who won first prize last year. Mr. Sigurd U. Bergh of the *Northwestern Bell Telephone Company* who was undergoing a serious operation last year and couldn't get his award, will now come up and receive his award and tell you how he did it. Mr. Bergh of the *Northwestern Bell*.

The Northwestern Bell Given First Prize

SIGURD U. BERGH (*Northwestern Bell Telephone Co., Omaha, Neb.*): It is a little hard to believe, but here it is, so it must be so. It is more than a surprise, for why should our magazine be selected as being worthy of this high honor.

Since the judges have been so good to us, I want to thank, on behalf of the *Northwestern Bell Telephone Company*, on behalf of our 19 employee correspondents, on behalf of the members of the magazine staff, the judges. I want to say that if the magazine has merit, it is because we get wonderful cooperation and 100 per cent backing from every member of our telephone family—11,000 strong, from the president down to the newest operator. It is a big pleasure to be here today to meet you, and I want to thank you for this opportunity and for the kindness you showed me last year and the flowers you sent me while I lay in the hospital. I want to say that if the *Northwestern Bell Magazine* is doing its bit in furthering the cause of safety and helping the cause of promoting house organ journalism, I am extremely glad.

MR. ASHE: We are going to ask only the three prize winners in each group to say a word and in that way we won't use up too much time.

The second prize winner in Class One is *The Transmitter*, the *Chesapeake & Potomac Telephone Company* publication. Mr. Oliver Martin is the editor but I believe they sent a representative in his place. His president was enough interested to have him come here in order to get this little award.

JOHN VANDEGRIFT (*Chesapeake & Potomac Telephone Co., Washington, D. C.*): I am very keenly interested in this publication of ours, *The Transmitter*, of the *Chesapeake & Potomac Telephone Company* of Washington. We believe that publications of the sort you see here are very important, certainly in an organization such as ours, in tying employees together. In the first place by letting them know something about the policies and problems of the company, in making them keenly alive to the things or the big thing that the company stands for. In our case it is service.

My interest directly in this magazine is to see that it carries a proportionate amount of accident prevention fuel, and you know I have realized for several years that the magazine has been a real influence in the matter of accident prevention. Without it, frankly, I don't know how we could have done the job that we have done in cutting out accidents, cutting them down, I should say, to a minimum; because the magazine, it seems to me, shows the worker that the company is 100 per cent seriously interested in his welfare. It gives authority to accident prevention. This magazine of ours has been a real support to the safety movement in our field.

I know if Mr. Martin were here, he would say a lot more and say it a lot better than I can. We like him. We think he is a keen editor. This proves our suspicion. We employees always thought our magazine was good. Now we know it because it takes a pretty good magazine to run second to the *Northwestern Bell* and to beat the magazine which I have been informed has taken third place, so on behalf of the Chesapeake & Potomac Telephone Company and its employees, its editors and the rest of us, I certainly want to express our appreciation of this great honor.

MR. ASHE: The third prize winner is our old friend Sterling Patterson of the *Western Electric News*. I believe Mr. Patterson has a representative here.

W. A. TITUS (Western Electric Co., New York City): I am speaking for Mr. Patterson. It is unfortunate he can't be here to receive this tribute to his work. We are proud of the *Western Electric News* and we are glad that the committee found it good. The *News* is perhaps somewhat unique as a magazine, in that it must serve as a medium of exchange of information for an organization scattered all over the United States and of immensely diversified interests all the way through research, design, manufacture and marketing of an extremely complex problem.

For that reason its state, from the editorial standpoint, has to be a pretty broad and general interest, and we have found it somewhat insufficient for our needs, for that reason, because it can't by any stretch of the imagination be called a newspaper.

A Magazine Going to 60,000 Readers

Things are happening pretty fast in the telephone industry so we have introduced, quite generally, types of newspapers; and if Mr. Ashe has any doubt about the ability of the section to develop a third group of strictly news sheets, I think I can set his mind at rest from that angle alone. In fact I have already told our local folks to see to it that our local news sheet is in next year. The *News* is 17 years old this year and is now going to 60,000 people who are scattered all over the United States and abroad. It is edited by a very small staff. It is almost wholly an employee contribution effort in the original, as far as editorial standard will permit.

I want to thank the committee on behalf of Mr. Patterson for their generous appreciation.

MR. ASHE: We will not be able in the limited time to hear from the honorable mention except to have them come up and smile and then go back to their seats, otherwise Neubig won't be able to tell them about the job they have done.

CHAIREMAN BOSWELL: If you will permit me, we have a long program and we must expedite things by curtailing on the time.

MR. ASHE: You will notice the telephone companies have made a clean-up in most of the first division.

The first blue ribbon goes to the *Telephone News*, The Bell Telephone Company of Pennsylvania, Mr. Milton B. Herr. The next blue ribbon, which is No. 5, goes to *The Monitor* of the Mountain States Telephone and Telegraph Co., Denver, Colorado, Mr. A. U. Mayfield. The next is the *Southern Telephone News* of the Southern Bell Telephone and Telegraph Company, Atlanta, Georgia, Mr. E. R. Austin. The next is *Telephone Topics*, of the New England Telephone and Telegraph Company, Boston, Massachusetts, Mr. R. C. Farnham.

No. 8 is a railroad magazine, the *Louisville & Nashville Employees Magazine*, Mr. Thos. E. Owen. No. 9 is the *Vacuum Oil News* of 61 Broadway, New York. No. 10 is *The Ohio Bell*, of the Ohio Bell Telephone Company, Cleveland, Ohio, Mr. H. E. Bonar.

In Class 2 the winner of the first prize is *Mead Cooperation* of The Mead Pulp & Paper Company, Chillicothe, Ohio, Mr. Ernest Augustus.

The second prize goes to our old friend Wilkins of the *Schenectady Works News* of the General Electric Company.

The third prize is *Gas & Electric News* of the Rochester Gas & Electric Corporation, Floyd Mason.

No. 4 is the *United News Letter* of the United Electric Light & Power Company, New York City, Mr. F. S. Blodgett.

No. 5 is *The Edison Round Table*, Chicago, Mr. R. W. Liddle.

The next is *The Synchronizer* of the Adirondack Power & Light Co., Schenectady, New York, Mr. A. G. Strickrott.

No. 7 is the *Harrison Radiogram* of the Harrison Radiator Corporation of Lockport, New York. No. 8 is the *Norfolk & Western Magazine*; Holcombe Parkes is the editor.

No. 9 is the *Eric Railroad Magazine*, Mr. William F. Hooker. The tenth is our little magazine, *Tick Talk* of the Western Clock Company, La Salle, Illinois, Mr. B. G. Richards, editor.

Detailed Rating of Some of the Contestants

I won't take the time to give you the whole list of percentage ratings, but I thought I would run five down on each scale.

Northwestern Bell	93.16
The Transmitter	91.16
The Western Electric News.....	90.66
The Telephone News.....	90.00
The Monitor	89.33
Southern Telephone News.....	88.16
Telephone Topics	87.66
Louisville & Nashville Employees Magazine.....	85.33
The Vacuum Oil News.....	83.3
The Ohio Bell.....	82.5
Safety Service Magazine.....	81.66
The Telephone Review.....	81.66
Long Lines	80.83

In Class 2 *Mead Cooperation* started off with 82.6 per cent, *Schenectady Works News*, 78.5; *Gas & Electric News*, 77.3; *The United News Letter*, 77.00; *Edison Round Table*, 76.83; *The Synchronizer*, 76.3; *Harrison Radiogram*, 75.16; *Norfolk & Western Magazine*, 74.83; *Eric Railroad Magazine*, 74.00; *Tick Talk*, 74.00; *C.C.C. Mutual Magazine*, 73.66; *Florida Power & Light Co. Magazine*, 72.83; *Current News* (Philadelphia Electric Company), 72.66; *The Hardwood Bark*, 72.50; *Flash* (Nebraska Power Company), 71.16; *The Commonwealth*, 71.33. I will be glad to let any of you know, after the meeting, what your individual ratings are on the sheets.

CHAIRMAN BOSWELL: I am sure we are deeply indebted to the committee for the prodigious amount of work was necessary for them to go through in order to submit this report. I know last year Mr. Ashe, who was chairman of that committee, reported they put in a good many hours all told in doing this work.

I am going to ask our chairman-elect, Mr. Ferguson, to come up here so that you will get acquainted with him and next year when he is conducting your sessions, you will know who he is. Some of you haven't met him.

I am going to remind you again of the matter of registration. We would appreciate if everyone who has attended here will fill out the cards.

Mr. Ashe suggested that a telegram be sent to Aunt Mary, Margaret Talbot

Stevens, as we know her, because of her inability to be here. They are celebrating the hundredth anniversary of the Baltimore & Ohio and she happens to know something about a part of that anniversary. As editor of their woman's magazine it was necessary for her to be in attendance this week and next. What is your pleasure?

E. T. WILKINS (General Electric Co., Schenectady, N. Y.): I make such a motion.

(The motion was seconded and carried.)

CHAIRMAN BOSWELL: Our next speaker is Mr. Liddle who has already appeared before you as one of the blue ribbon winners. As Mr. Ashe informed you, he is editor of the *Edison Round Table*.

How Money is Wasted on Employees' Magazines

**Ralph W. Liddle, Editor, Edison Round Table,
Commonwealth Edison Company, Chicago**

Tradition and precedent, valuable guides as they are to future action, often become actual obstacles to progress, and to economy. They may become not a reason, but an excuse for doing things a certain way. Having written this entire paper in advance of its introductory note, we now seize upon these two ghosts and say that they are to blame for many of the shortcomings of employees' magazines, as we can find no other reason. If you do not like these inanimate victims we leave you to explain why some employees' magazines are as they are. In a perhaps narrow and certainly nervy fashion, we have tried.

To the extent that money expended on an employees' magazine fails to promote the objects of the paper it tends to become a waste.

Having selected this method of approach to the problem, it is necessary to define the purpose of an employees' magazine. We believe there are two major objectives:

1. To inform, and educate, and broaden the employee. To inform him as to the company's policies and operations; to educate him as to the history and future of his job, his company and the industry; to broaden him and aid him in his individual progress.
2. To promote a feeling of comradeship among all employees, to improve cooperation, loyalty and "morale." To encourage good work and initiative.

We know that the average employee—and this means a good employee—will not read as much so-called "solid" material as might be to his advantage. The first of our objects, which for brevity we may term education, is concerned with this solid type of material. We must agree, then, that our educational matter must be diluted or altered or mixed with more generally interesting copy, to be effective. Up to a certain point this is not waste.

The second objective mentioned for an employees' magazine, which may be generally designated as good-will, could be attained with a minimum of solid matter and an abundance of personal news, cartoons, pictures, etc. Such a course could obviously be wasteful if the company were paying the bill.

How far, then, can we depart from straight educational and company news copy and still "make money" on the investment in our papers? On both sides of this dividing line, wherever it is, there is waste.

In any study of employees' magazines, account must be taken of the individual character of papers and of editors' problems. It has seemed to me, however, that this point, and the necessary variety of method it involves, is over-emphasized, and that it sometimes serves as an excuse rather than an explanation.

In the title of this paper fair warning was given that it would indulge in fault finding; an easy task and one not guaranteed to enhance one's popularity. I think some of us need a good shaking up more than we need idle pats on the back. When this paper gets down to cases, if I fail to dodge well, or choose the wrong exit, I will carry through defeat the conviction that this thankless job needed doing.

It would be both improper and foolish for me to presume authority for the opinions that follow, nor is it necessary. It is enough to point out likely cases of waste and wrong doing, and wax a little vehement perhaps in an effort to penetrate the crust of habit. Revamping a paper on the basis of readers' suggestions is too often a case of locking the barn after the horse is stolen. We must depend mainly on our own alertness and good judgment, and on the compliments and criticisms of fellow editors. It is the criticisms that are difficult to obtain.

With the idea of diving first into the deepest part of the lake and then working out into safer territory, I venture the opinion that the editor is to blame for nearly all the faults, for nearly all the wastes of his paper. This unpleasant theory grows out of a conviction that more can be done with limited funds and facilities than is done, and limited funds and limited facilities are the common lot, and the prize alibis of an editor.

Example of a Small West Texas Publication

I recall a striking example of getting a great deal for almost nothing in an employees' magazine—through good editorship. This was in the monthly publication of a small utility company in West Texas. It was a 5x8 size, four-page paper, one sheet folded once. There was only one size and style of headline, only one size and style of body type, and very seldom did it have any illustration. Here were limited funds and facilities with a vengeance, and yet the paper, as an employees' magazine, was a notable success. It was neat, attractive, and harmonious in appearance. It had no suggestion of economy or stint. If it did not print all the news, it obviously was printing the best of it, with no apology. It stood out among a host of much more elaborate papers. It was extremely well written, and probably pleased the executives as much as the employees. The paper paid big returns on its investment.

The answer to this apparent impossibility is in the editor. He could have judiciously spent four times as much money on his paper, but the money wasn't available to spend. Instead of bewailing the lack of this, that and the other, he proceeded to turn out the best paper possible. This is not a Horatio Alger or an American Magazine story, but our hero is now publicity and advertising manager of a company whose assets run over 100 million dollars.

We should get out of the notion that our papers cannot be improved—very much improved—without more money or better facilities. The crying needs of the average employees' magazine are better writing, better selection of material, better make-up, better harmony as to type, heads and illustration. All these can be secured at the same and perhaps a lower cost than now obtained.

I am aware that it is no use to try to bag elephants with a pea shooter, but my firm conviction is that a flock of our employees' magazines are large enough, and expensive enough, to do their jobs better than they are doing them. This brings us to the conclusion that one of the biggest wastes of money in an employees' magazine can be caused by giving it a poor editor, or giving it one-third as much of a good editor's time as it should have. It costs about as

much from a production standpoint, to publish bum copy bum pictures and a messy appearing job, as it does to publish a first-class paper, and a little more money spent on an editor who has ability, judgment and taste could be literally stolen from the present budget with good results.

The whole purpose of this paper is to stress the need of such a study of individual papers by their editors as will diminish the misuse of funds and energy that seems to be so widespread. It is much easier than it should be to select papers, all of about the same cost, which rank almost from the top to the bottom of the scale in effectiveness.

The Most Common Faults of the Magazine

If I were asked to list the most common faults of employees' magazines (and I have not been) the following would be included in about the order given:

1. Unattractive and inharmonious appearance; poor make-up, bad combination of heads, body type and stock; etc.
2. An inaccurate and uncomplimentary estimate of the mental caliber and reactions of the reader, as evidenced by:
 - (a) The character and quantity of so-called inspirational copy used.
 - (b) The awkward and unwarranted "playing-up" and complimenting of the company, benefit plans, new projects, officials and even regular employees.
3. The injudicious use of illustration and the apparent insistence on some kind of art work.

These faults will be touched upon again, but it is worth while to note here that more money is not a guaranteed cure for any of them, and that better editing would eliminate all of them.

The practice of imitation and duplication belongs in the list of common faults, but it requires some elaboration. Many editors are not satisfied unless, in their company paper, they can enter every field in which any considerable number of employees are interested, and so we have in some employees' magazines women's sections, boys' sections, girls' sections, children's stories, straight out-and-out fiction, budget and household economy sections, fashions, radio sections, instructions for dressmaking, gardening, building furniture and playing the ukulele; crossword puzzles, joke sections, and so on.

How much more than half of the money and space devoted to these special sections is a waste for all concerned, cannot be determined, but I doubt if the proportion is less than half. The company cannot hope to gain any more than some added reader interest and a modicum of heightened living standard and happiness on the part of a small number of employees. The trick is that even the employees directly interested in the special section gain so little. These fields cannot be adequately covered and the quality of material is seldom equal to that easily available and already at hand in newspapers, magazines, and books.

Even if these special sections are not syndicate material, even when they have the rarely combined advantages of authority, local authorship and interest, they must be incomplete. With these factors in mind, and remembering that special sections are off the main line to the goal sought, every one of them should be brought on the carpet and made to justify itself. A special section of any kind has a tendency to take up its quota of space, issue after issue, even when the character of its material declines temporarily in value. In many instances special articles, appearing at regular intervals or only occasionally, will preserve the advantages of variety of material and employee authorship, without the permanent disposal of costly space.

Every new activity, and most fads, draw a following which at once asks for

a special section in the paper. It is not often easy to convince these groups that broader attention will be secured for their copy by straight news treatment. Fast readers, who still feel obliged to scan the news headlines, will positively "duck" a special section unless they are certain it contains something of special interest to them.

Another determining factor in the problem of how far afield an editor may go without wasting money is the matter of competition for readers' time. The railroad magazines, many of which go into small town homes, where magazines and newspapers are fewer, are more justified in running special departments, but even here, except in case of the larger magazines, their usefulness is open to question. I believe the average reader of an employees' magazine has access to more and better specialized information than the paper can hope to supply. It seems obvious that employees' magazines with city circulation should go very slowly indeed in pretending to compete with the special features of metropolitan newspapers. It is worth noting that such devices as the questionnaire are unreliable for determining whether or not a certain section is desired. People will recommend, for social or theoretical reasons, a section which would be of only slight interest to them personally. Such a plan only obscures the responsibility for the bad result.

The One Big Interest for the Employee

Greater consideration should be given the fact that the one permanent and certain basis of interest in the employees' magazine is the company, considered as an operating industrial unit and as a family. In this field the magazine is supreme, it competes with no one, it has a sure source of material that is of interest to readers. If this were not true employees' magazines would not have developed as they have, and if it is true editors may increase reader interest and save money at the same time by "sticking to their lasts" a little closer.

First place in the list of common faults of employees' magazines was given to "unattractive and inharmonious appearances." Appearance involves the general style of a paper, its page make-up, the styles of type used for body and headline, the paper stock and binding, illustrations and art work, and the combination of all these. One need not be an expert to see that in this respect many employees' magazines miss the mark, and carry along a handicap for which good copy, good printing or good policy cannot make amends. It is unfortunate for them that this condition does not give, in most cases, even the advantage of economy. It has not a redeeming feature.

We cannot expect to be a good editor, a talented artist, and a make-up expert rolled into one; but all of us have the opportunity of studying the make-up and style of magazines and newspapers that are prepared by experts. We have the opportunity of making little changes from issue to issue. We can cut and try—experiment—on a moderate scale. There is no excuse for producing, time after time, a messy and hodge-podge paper.

It has been suggested that very often insufficient attention is paid to the attitude of the reader. It is an error to assume that the sun rises and sets on one's own company exclusively, or that employees are wrapped up, heart and soul, in their company. It is entirely unnecessary as well. Paternalism, the bugbear of misguided industrial relations work, sticks out so strongly in some magazines that it seems to an outsider that many employees must be disgusted by it. Such a policy certainly diminishes the influence and effectiveness of the whole magazine. If the interest of employees is the first requirement of a successful paper, their confidence is a close second in importance. I suspect that this second factor is very often undervalued.

Grandiose, enraptured descriptions of personal and company accomplishments eat up a good deal of costly space in employees' magazines. If that were their only fault the situation would be of consequence, but the more serious result is the offense to the intelligence of the reader, who suspects uncalled for enthusiasm in such matters anyway. If he finds it he is disgusted; if he finds, instead, simple and interesting statement of the facts, with the privilege left of drawing his own conclusions, he is pleased. He will believe what we say on some occasion when it is especially important. Distinct from the use of inappropriate superlatives and adjectives, is the danger of plain long-windedness, the giving of a lot of unnecessary detail. Such a practice is not an encouragement to read many items in the paper.

Another alleged waste, which recalls the idea of imitation, is the wide use of so-called art work. The editor who can obtain good art work at a moderate cost, and can afford it, is fortunate. The editor who cannot get it, or cannot afford it, need not weep or wail; and more important, he can leave the common garden variety strictly alone, to his advantage. Much of the art work one sees in employees' magazines actually lowers the effectiveness of the illustrations, and in layouts puts the picture captions so far away from the individual picture that they are never referred to. In all but the more elaborate magazines art work can be eliminated entirely, and simple and effective layouts made by the editor himself when they are necessary.

As an example of the little crimes that cause waste may be cited the practice, in mailing magazines, of folding them several times, or rolling them tightly in a snug-fitting wrapper. This plan is effective only as a guarantee that the marginal reader will never open the magazine at all, and that the interested reader, only annoyed at first, will finally be conquered by the nuisance.

Even if there were time, it might not be necessary to elaborate on all of the points mentioned in this paper. In the interest of controversy, some possible exceptions to the positions taken have not been stated. The purpose has been to provoke a fresh and detailed study of individual papers, and to encourage all of us editors who must turn out an effective paper without unbridled access to the company's cash drawer.

A Change Necessary in the Service Committee

CHAIRMAN BOSWELL: I wish to take a moment of time now. I have just conferred with your new chairman, Mr. Ferguson, with reference to the Service Committee. Mr. Augustus, editor of *Mead Cooperation*, of the Mead Pulp & Paper Company, is absolutely unable to serve as chairman of the Service Committee for the ensuing year and in consultation we thought it would be proper to propose this morning that Mr. McReynolds who was a member of that committee last year, who did some very effective work, in fact got out the September News Letter, and who is also on the new committee, be the chairman of that committee, and a motion to that effect would be in order.

MR. ASHE: I so move.

(The motion was seconded, put to a vote and carried).

CHAIRMAN BOSWELL: It will require another member on that committee to fill the vacancy. With your approval we would appoint Mrs. Betty Short, of Rockford, Ill., of the Barber-Coleman Company, editor of *B-C-A News* as the third member of that committee.

There is another thing that occurred to me. I thought it might be well for Mr. Doeller who was chairman of the Program Committee this last year, to be instructed by this body to write a letter to every speaker who has contributed of his time and money without any compensation whatsoever from the National Safety Council

Sixteenth Safety Congress

or from this Section, expressing to them our appreciation, and I thought a motion to that effect would be in order. What is your pleasure?

MR. ASHE: I so move.

CHAIRMAN BOSWELL: Mr. Ashe moves that Mr. Doeller of the Program Committee who arranged this program and arranged for all the speakers, send a letter of appreciation, what is the action of this body?

(The motion was seconded, put to a vote and carried.)

MR. ASHE: I suggest that ~~somebody~~ send Mr. Doeller a letter. You know how much good work Mr. Doeller has done in getting up the program.

CHAIRMAN BOSWELL: I have, before this body, expressed to Mr. Doeller in person our appreciation, and I think perhaps that might be a little more effective than to write him a letter.

MR. ASHE: I said write his president a letter and let him know.

CHAIRMAN BOSWELL: That would be fine, I think. We will take action on this first motion.

(The question was put to a vote and carried.)

Miscellaneous Motions Are Adopted

CHAIRMAN BOSWELL: The motion is that we send a letter to the president of the Dayton Power & Light Company of Dayton, Ohio, expressing appreciation for the services of Mr. Doeller in arranging this splendid program.

(The motion was seconded and carried.)

E. T. WILKINS (General Electric Co., Schenectady): While you are passing motions, I would like to make a motion that we put down on the minutes of our meeting a motion of appreciation for the services of Miss Margaret Stevens for her work in connection with NATIONAL SAFETY NEWS, in conducting that page. I think it was a wonderful proposition, and also to the Judges Committee for their splendid work, to Mr. Ernest Augustus for the News Letter which he sends out, and to all committees who have been actively engaged in the preparation of this wonderful program and the arrangement for its being carried out in good detail.

(The motion was seconded.)

CHAIRMAN BOSWELL: Who is to be delegated with this job, the secretary of the past year or the new secretary? I should think perhaps the secretary of the past year might be instructed to do that.

MR. WILKINS: Mr. Chairman, I would suggest you do it.

CHAIRMAN BOSWELL: I will be glad to do it.

(The question was put to a vote and carried.)

R. G. CONOVER (Yale & Towne Manufacturing Co., Stamford, Conn.): It is moved that the Membership Committee in cooperation with the Service Committee or proper officials, be asked to embrace within its activities the assembling of the following information:

First, the name of every plant publication whose editor has participated in our annual conventions, the name of the editor, the size and number of pages of the publication, how often issued, whether or not it carries paid advertisements, whether the editor works in full or part time as such, how many employees are in the plant, and if the editor does not object, the annual amount of his publication budget.

Second, the zoning or sectionalizing of plant publication cities to the end that groups of editors may be assigned to zones and conveniently attend quarterly or half-yearly meetings with the least expenditure of time and money in such attendance.

I offer that as a motion.

CHAIRMAN BOSWELL: You have heard the motion as presented by Mr. Conover.

MR. WILKINS: I second the motion.

MR. ASHE: I move that Conover get the dope on it.

CHAIRMAN BOSWELL: We will include that in the original motion anyhow.
(The question was put to a vote and carried.)

CHAIRMAN BOSWELL: I am going to ask Miss Ruth Cade, your new secretary-treasurer, to stand up.

Miss Cade has been one of the hard workers in this section in the past and has made a very definite contribution to the success of it.

A. H. RICHARDSON (General Electric Co., Erie, Pa.): Is it planned to distribute these proceedings in a separate pamphlet again the coming year as it was done last year?

CHAIRMAN BOSWELL: I think so. I don't think there is to be an exception. We will see that it is done.

I am going to introduce to you now Mr. K. D. Pulcifer, editor of the *Pennsylvania News* at Chicago, who is going to speak on the subject of "A Plan for Using Paid Ads in Employee Publications").

Advertising What the Reader Will Buy

**K. D. Pulcifer, Editor, The Pennsylvania News, Past President,
American Railway Magazine Editors Association**

Several years ago there was founded and successfully promoted an organization now known as the American Railway Magazine Editors Association.

One of the first major accomplishments of the organization was the final formation after more than two years of effort of a group of railway publications into one advertising unit. These publications, numbering eleven, associated themselves by contract with an advertising representative and his organization was incorporated as The Kellogg Group.

The Kellogg Group, then, was created to do two things: to obtain advertising that would be of personal interest to the bulk of our readers and to provide the most convenient way for such advertisers to get big circulation in one lump.

The Kellogg Group is out after national publicity advertising—and is getting it. The October issue of some of our magazines will carry a back page color cover of "Lucky Strikes," the first time any industrial publication that I know of ever carried a piece of national advertising copy of that kind. The Kellogg Group is able to get that kind of advertising because it offers the circulation of 11 publications totalling 654,911, distributed in every state in the union to a class of people who have steady jobs. And most of them receive a copy of one of these publications on the first or the fifteenth of the month, or both, at the same time they get their pay checks.

To the advertiser, the group offers numerous advantages. He deals with one agent, yet receives representation in more than a dozen periodicals. He furnishes one piece of copy, ok's one proof, receives one bill and pays one check. The distribution of plates and proportioning of revenue is all handled by the agency.

The agency maintains its own separate offices, with its own office and sales force, in Chicago. The publications supply the needed data—circulation, with details on the number of men and women readers, classifications of readers, what they prefer and what they buy, whether they own their own homes, have an automobile, radio and whatnot; the publications supply sales arguments in the way of instances of reader interest, what their employees like most about the publication; what are the best potential markets offered by their circulation and all such information that may be of assistance to the solicitors in laying their case before the prospective advertiser.

Now, one of the axioms of successful selling, 'tis said, is to find out what

News in advertising stirs people's curiosity and imagination. It has been proved time and again that certain newspapers can credit a majority of their circulation to their department store sales ads. People will read news, whether in a column of reading matter or a block of paid advertising space. The railway publications in The Kellogg Group are endeavoring to give our railroaders advertising news in which they will be interested. Prospects are bright for the future. We believe that it is one of the most forward steps taken in the industrial publishing world in recent years.

CHAIRMAN BOSWELL: Mr. Pulcifer has no doubt raised a good many questions in your minds and that brings up the matter of discussion which I had forgotten. I am going to offer you an opportunity a little later for the discussion of all the papers that are being presented to you this morning.

I want at this time to have Mr. Charles E. Kane of the Illinois Central Railroad Company, editor of their magazine, stand up. He is chairman of the Program Committee for the ensuing year. Mr. Kane. He no doubt will get in touch with you as editors and ask you for some suggestions for the program for the ensuing year.

At this time I am going to introduce to you Mr. Dempster of the Canada Cement Company, Limited. Mr. Dempster is editor of the magazine of his company. He has given a great deal of thought and time to this subject. He is at the present time a member of the Employees' Mutual Benefit Association, secretary of that body and chairman of their program this past year.

Employees' Publications, Plant Papers, or House Organs?

Jack Dempster, Canada Cement Company, Ltd., Port Colborne,
Ontario, Canada.

Plant papers may, for argument's sake, be divided into two classes. In the one are the publications sponsored and printed by the company, advertising and pointing out the merits of its products, and circulated primarily with that idea in view. The other class contains the publication printed for and to the employees, the rank and file, for their mutual benefit and safety, to act as a conveyance between the office and the plant; to bring the point of view of the men in the ranks to the executive and to carry the wishes of the man higher up to his subordinates.

As this gathering is a Section of the National Safety Council, held under its auspices and working under its name, it follows that the plant publications we represent would be intended mainly to act as the voice of a body devoted to safety and the welfare of humanity. Advertising of goods and advancement of trade are taken care of by associations with their conventions and periodicals for that purpose. That brings us to the question I am going to ask and the answer that I intend to make to it: "Are we, the Plant Publications Section, which, personally, I believe is an unfortunate name—gathered here today seeking to aid in the promotion of the welfare and safety of the readers of our publications, or are we seeking further ways to advertise the product of those for whom we work?"

I claim, first, that the name of our Section should be changed to that of the Employees' Publication Section, and then that our publications, if they are intended to be in the second class I mentioned at the beginning, be devoted solely to the uplifting, welfare and safety of the employee, and I shall base my arguments on that stand alone.

Our publications cannot be compared with, likened to or judged by any other magazine, periodical or newspaper; they are in a distinct class by themselves. The success or failure of the plant publication is not judged by its circulation, for, since the company pays all expenses in connection with it, 100 or 1,000 copies printed, as a number alone, can convey no idea of the return on the investment or the results obtained by the issue. The degree of success is computed from the number of employees who take the interest and trouble to read the publication. If you buy a paper, the chances are that you will read it, but if a paper is wished on you, you won't read it unless you are in sympathy with the policies of that paper and interested in its matter. One hundred copies divided amongst three times that number of employees is doing far more good than 300 copies if a number of them are left lying around, unread and disfigured and just a joke to the men. You see, we are dealing with human nature. On the other hand, the editor must be able to judge his readers and if a copy for each man is advisable he must see that they get it.

The Magazine Must Mark Confidence of the Reader

All this talk seems apart from the issue. I assure you, it was only to lead up to this statement, and I emphasize every word of it. "The success of the employees' publication and of the object with which it is issued, depends upon the degree of confidence you can instill into the mind of the humblest employee, that the paper is printed for his welfare and safety alone, and that absolutely no ulterior motive, in the way of financial profit, defrayed or partly-defrayed cost, enters into it in any way. Once let the employee think that certain statements or advertisements printed in his paper are paid for by the advertisers and you have nullified at one stroke the work of the publication since its inception, and perhaps done irremediable damage to the morale."

I have heard it stated that the cost of each issue of some of our plant publications is so excessive that the management feels that the expense should be met, partly at least, from outside sources. They look on the publication as an investment and, like good business men, they either want to see returns on the investment or have the cost met in some other way. Now is there any editor here who will dare to set a limit on the amount of good his paper accomplishes? You will never know where the four winds of Heaven blow the words you have scattered, and they may come to rest in a spot so far remote that you will be astounded.

Now, is the large expense necessary? I have seen some magnificent specimens of plant magazines, illustrated, ornately embellished, printed on the finest stock and conveying splendid material, turned out by some companies. Of course they cost a lot! I'll claim that some of them cost, per issue, as much as some of our leading periodicals. Of course it is only reasonable for the management to feel that part of this cost, anyhow, should be met, and if a merchant wishes to advertise in the publication and pay for the privilege, that meets the difficulty.

But is the expense always justified? It all depends upon the material carried on the pages. I recently received, through the courtesy of its editor, a 36-page magazine that is absolutely in harmony with the stand I have taken. It is the production of a big company, has a large editorial staff and is issued to employees scattered in small units over half the United States; but every page of it is filled with live news of interest to all its employees. No doubt that publication costs a lot, but I have no hesitation in believing that the mutual interest, benefit, good-will and safety of its readers constitute a great return on that investment.

Don't you think that this expensive magazine has stepped a little out of the class in which it belongs? Don't you think that the employee-reader, being human, is liable to compare it with, say *Collier's* or the *Saturday Evening Post*, and forget the object of its issue? And don't you think there is a possibility that the employee might think that the publication is patronizing and high-hatting him? If you have the right material to convey, if you have the correct spirit in your writings: if you wish to be truly a go-between, between the hardy son of toil and the executive; if you wish to remind him that men can be saved from industrial injury, their standards of living raised and their lives and homes made happier, don't you think you can give it to your fellow-workers on a humble carriage, and let them feel that it is their paper, for them alone? You would be surprised to learn how small the expense of the publication can be, and yet attain its object.

Not the Form, But the Message Is the Thing

Many of us have perhaps received a letter from the mother of our grand-mother, across the sea. I did recently. Was the paper good? Did you feel insulted if the letter was not written in elegant script on decorated parchment? You did not! You didn't care a thing if a letter came in a torn paper bag. You exclaimed with gladness, "Too a letter from home!" and the only thing that counted was the news it carried.

As some of us sat around the luncheon table, during the meeting of this section at Detroit, last year, the question was raised by one of our fellow-editors, "Should the cost of printing the publication be partly met by accepting 'paid outside advertisements?'" As the time was limited that day, I understand that discussion of that question was to be laid over until this year.

"Paid Ad's," in an employees' publication? I hate to disagree with any of my friends here to-day, but don't let us for a minute lose sight of the motive that prompts the publication. Let us forget the desire for the approbation of art critics and writers, and just try to preach safety and welfare in our humble way and win our readers' confidence.

I'll grant you our lot sometimes is not an enviable one. We sometimes must stand between righteous wrath and stubborn rebellion, and as for sneers and jeers and scorn, why, we must just keep smiling through. But we can at least keep our publications from being a great expense and yet convey the message. "Paid Ad's"! I should hope not! If the boys in our plant ever thought that the Canada Cement Company was trying to meet the expenses of the *Plantate News* by advertising "Sammy Slocums Safe Suspenders," our paper would do more harm than good.

Prefers the Designation "Employees' Publication"

I have given you my reasons for claiming the name "Employees' Publication" for our Section and for our papers, yet I have heard them designated as "House Organs," "Plant Papers," etc. I cannot see where these last two titles are suitable at all. "House Organ!" What a dry-as-dust, unsentimental, heartless, coldblooded business sound that seems to have! Taking it literally, too, it does not describe our efforts. How many employees think of their plant as the "House"? How many of them know what an "Organ" is outside of a musical instrument or a portion of one's body? Remember, our publications are primarily for the rank and file and while it is well to maintain a certain amount of dignity and inspire respect for the paper, we should avoid expressions that mean little or nothing to them. I know how I feel when "Employees' Publication" is mentioned; that's *our* paper; but when some one says "House

For purposes of illustration, I have selected half a dozen magazines to represent the nation's railroads geographically, and these are: The New York Central Lines Magazine, representing the northeast; the Baltimore & Ohio Magazine, the central east; the Louisville & Nashville Employees' Magazine, the southeast; the Illinois Central Magazine, the central west and the Mississippi Valley; the Union Pacific Magazine, the northwest; the Santa Fe Magazine, the southwest.

All but one of these magazines—the Santa Fe—are published in the now popular size of roughly eight by eleven inches. That magazine is still issued in the size in which it was first published, about $6\frac{1}{2}$ by $9\frac{3}{4}$ inches. All employ supercalendered paper, though coated stock is used on covers. Four of them print their covers in monochrome or duotone, but the Illinois Central has been using covers in 3-color process since March, 1923, and the Baltimore and Ohio, especially during the present, its centennial year, is employing covers in full color. Of the six magazines being considered, only two employ artists on their staff, the Baltimore & Ohio, which has two, and the Illinois Central, which has one. All six of the magazines endeavor to show on their covers spots of scenic or other interest on their lines, though at present, during its centennial year the Baltimore & Ohio is featuring scenes incidental to its early history.

Organization of the Editorial Force

Each of these magazines, except the New York Central, has so organized its staff that each operating division has a magazine representative who edits the news gathered by his correspondents in the shops, stations and offices under his jurisdiction. Semi-annual meetings are held of the home and field staff on the Illinois Central, and most of the others follow some similar plan. Discussions and exchange of ideas at these meetings redound to the general welfare of the publication.

The average number of pages of the New York Central is 112 and cover; the Baltimore & Ohio, 128 and cover; the Louisville & Nashville, 96 and cover; the Illinois Central, 88 and cover; the Union Pacific, 64 and cover; the Santa Fe, in the smaller size, 144 and cover.

The Santa Fe Magazine does not appear to have an editorial department to express the opinions of the staff, although that feature is common to all the rest. The Illinois Central Magazine for several months past has published a page devoted to well-known men on the line, as they were in bygone days and as they are today. That feature is known as "When You and I Were Young," and the inspiration for it came from the Baltimore & Ohio, which carries a similar department. A department devoted to promotions is carried by four out of the six representative magazines, the exceptions being the New York Central and the Santa Fe. "The Roll of Honor," devoted to those employees who have been retired after an honorable service record, is common to all but the Santa Fe. Each magazine, except the Baltimore & Ohio, has a section devoted to sports.

The important subject of safety is represented by regular departments in four of the six publications, the Santa Fe and New York Central being the exceptions. These two publish special articles on safety from time to time. No worthy innovation, no important movement in the interest of safety in general, escapes attention in any of these magazines. The Baltimore & Ohio Magazine, for example, supplements its regular safety department with an additional one devoted to the interest of employees who have achieved meritorious mention in the cause of safety.

The managements of these magazines have always felt that the most substantial type of loyalty is reared in home environment, and for that reason much space

is devoted to the workers' families, their homes and their hobbies. Regular departments cater to home interests. Under subtitles, space is devoted to the children, to fashions and to houseplans. The Baltimore & Ohio has a separate page for boys known as "The Whistling Post." Another department, known as "In the Realm of the Riddle," furnishes amusement for young and old. The New York Central publishes each month a page of pictures of dogs, birds, monkeys etc., for the children. The Illinois Central and Union Pacific each month print single page groups of pictures of children, and the Louisville & Nashville devotes two pages to that purpose.

All but the Baltimore & Ohio have pages devoted to jokes and humorous sayings. The New York Central and the Santa Fe have in common a foreign railway department. The Louisville & Nashville Employees' Magazine and the New York Central Lines Magazine both have department devoted to those employees who have passed into the beyond. The Louisville & Nashville and the Union Pacific both have departments devoted to the solicitation of business, in which those employees who have gone to some trouble in obtaining passenger or freight business for their company are publicly commended.

Minor Incidental Notes Are Important

The Union Pacific Magazine has as a regular feature each month a 3-column department known as "Seen and Heard Along the Way." This is given over generally to miscellaneous railway news, as are two departments in the Santa Fe Magazine known respectively as "Along the Trail" and "General Railroad News."

In concluding the discussion of the departments which these magazines have in common, we come to the notes of the divisions. This department includes pleasant chit chat about employees and their activities and hobbies, and invariably employees will turn to these pages before anything else. That this is a favorite department with the majority of railway folks is also evidence by the number of pages devoted to it. The New York Central Lines Magazine, which represents an extremely large railroad, is the only one of the six that does not have such a department. The average number of pages for a period of four months devoted to that section averages 57 for the Baltimore & Ohio, 17 for the Louisville & Nashville, 26 for the Illinois Central, 22½ for the Union Pacific and 37 for the Santa Fe.

I shall now take up a few of the features by which the various magazines differ from one another.

The New York Central Lines Magazine goes in for fiction, each month running an illustrated story. It also has a separate department devoted to radio. The New York Central also has a department devoted to the traffic on its lines and another given over to agricultural pursuits on its system.

Two outstanding features on the Baltimore & Ohio Magazine are the departments devoted respectively to the maintenance-of-way men and to the spirit of cooperation. The department on cooperation is a big thing on the Baltimore & Ohio, as much of its work, especially in the shops, is done on a co-operative basis. The Baltimore & Ohio Magazine also maintains a department in the interest of books, fiction and otherwise.

The Louisville & Nashville Employees' Magazine is the only one of the six which maintains a distinct department in the interest of homemade poetry. The Louisville & Nashville also carries a regular space for those employees who have rendered meritorious service of some kind.

The Union Pacific Magazine carries as a regular feature an illustrated story

of some town along its line. One illustration in each case is a double-page spread incorporating views from every angle of the town described.

The Santa Fe Magazine has a column each month known as "Communications." This contains letters in which employees express their views, offer suggestions in a constructive way and gossip about their personal exploits.

An outstanding feature of that same magazine is the department known as "Per Diem." A subtitle in one issue explains fully the purpose of the department, which is: "to answer inquiries concerning car service, per diem and reclaim rules and their application." I know of no other railway magazine having such a department.

In the Illinois Central Magazine one finds four departments that have no counterpart in the five other magazines. The "Public Opinion" columns carry reprints of editorials from newspapers along the line. "What Patrons Say of Our Service" is explained in the title itself. The department known as "Waste Avoidance" is a warning to all employees to practice economy in the use of supplies, everywhere, at all times. No other railway magazine devotes regular space to air brake problems, where one finds questions and answers for the benefit and instruction of all those interested in that subject.

I have tried to point out to you the similarities and the differences in these six representative magazines. In conclusion, I shall call attention to the type of material other than departmental which these magazines print.

Types of Stories that Interest the Reader

One of the most popular types of stories with the average reader is that which deals with some hobby or avocation of employees. Some raise fruit or flowers, others have large gardens, some raise bees, some play in orchestras, some collect rare books or coins or stamps, some have political affiliations. The list of avocations is so extensive as to embrace practically all known occupations or hobbies.

Big business interests along the line, which incidentally are big shippers, are frequently featured. Historic places are given space in all the magazines, as are employees' picnics, special birthday or wedding celebrations, dinners and meetings. Well-known institutions of learning in a company's territory are frequently featured, as are hotels. Frequently entire trainload shipments of some particular commodity are given prominent space.

The acquisition of unusually large or powerful motive power or the reconstruction or modernization of old motive power is always given adequate space, as in the construction of shops, stations or hospitals or the modernization of them.

Speeches by officers, lectures on safety, loyalty or patriotism always find preferred space.

Early railway history or old-time photographs of stations, engines, trains or groups of employees are always featured.

Some roads own their own coal mines, and views and descriptions of them find space readily in these publications.

Attractive or otherwise interesting spots along the line are always written up with adequate illustrations, as this will help promote travel to the spots in question.

In short, the contents of these magazines are so diversified as to offer interesting reading to anyone who will peer within their covers.

CHAIRMAN BOSWELL: I received a special delivery letter this morning from Mr. Frank J. Ryan, who is the next five minute speaker. He enclosed a copy of his paper and stated that an emergency prevented his attendance at this meeting. I have

asked Mr. Doeller, the chairman of the Program Committee of the past year, to read it to you.

Report on Public Utility Publications

Frank J. Ryan, Director of Publicity and Editor of "The CEICO Motor," The Cleveland Electric Illuminating Company, Cleveland, O.

The author of this report has reviewed the employee magazines of a number of representative public utility companies. He has compared issues of the past year with those of former years. They are better than they used to be, but not enough better. Too many are still subject, in varying degree, to three common errors.

- (1) They don't recognize the full extent of their opportunity to render substantial service to an industry which is built solely on service.
- (2) They don't have a well-conceived and pre-determined purpose.
- (3) They don't have a clearly defined editorial policy and program.

With the enumeration of these three deficiencies, this report ceases to be statistical, and confines itself to the critical.

In mentioning these deficiencies no primary account is taken of context, illustrations, style, typography, paper or ink. To the degree that these deficiencies exist, to an equal degree will the magazine itself be defective, regardless of the technique of the writers, illustrators and other craftsmen who produce it. Craftsmanship can camouflage a poor publication, but it alone cannot make a good publication.

The value of the employee magazine depends entirely upon ideas.

The prime idea should be the answer to this question; why is this magazine published?

The idea next in importance should answer this question: How is the aim of this publication to be achieved?

All the other ideas incorporated in the magazine—in its reading matter, its illustrations, its style—should be blood-brothers of the Why Idea and the How Idea.

One editor of an employee magazine says this is why his magazine is published:

To inform the employees about the progress of this industry.

To interpret information about the industry in the light of the employee's self-interest.

To inspire a disposition to render the highest possible standard of service.

To instill the importance of efficiency and economy.

To inculcate a spirit of cooperation.

To instruct the employees in regard to health and safety.

To indicate the opportunities for individual advancement.

To impress on the organization the industry's aims and ideals.

To invent ways and means of accomplishing this composite purpose without preachment or uplift.

The editor's idea of how to accomplish his purpose is quite as definite as the purpose itself.

He plans every issue of his magazine far enough in advance, even before a word is written or a picture is made for it, so that every article, each item, editorial and illustration will contribute, in a well-balanced way, to the promotion of the publication's purpose. In his field he broadly includes scientific research, engineering, construction, operation, business promotion, group and individual achievement, welfare, social and sports activities. In an industry like his, he reasons, his problem is not to find material, but to choose it, so rapidly are inter-

esting discoveries, inventions and improvements made in modern public utility service. He does more than tell about these developments; he imparts to the reader their significance, as they relate to the industry, the individuals in it, and the public it serves.

In regard to service, efficiency, economy, cooperation and individual self-interest, he takes the broad attitude that they all are affected by safety. In a fundamental way, he reasons, the safety of our country and its people depends on public utility services. Without modern transportation, communication, light, heating and power services, we could not feed our industrial and commercial centers, we could not safeguard the national health, manufacturing and trade would be prostrate, national defense would be but an empty shell. With the national safety dependent on the public utility industry, it is of paramount importance that the industry should surround its employees with every safeguard. Rules and regulations and safety devices are not enough; every employee must be imbued with safety-consciousness. This becomes a matter of education and inspiration which is properly a prime function of the employee magazine.

The ideal plant publication, call it house organ, employee magazine or what you like, should be a perfect mirror of the institution for which it is published. It should mirror something more than the institution's physical nature; it should show something of the institution's heart, its brain and its soul.

There are such plant publications in the public utility industry. There will be more of them. With the development going forward in the utilities, with organizations multiplying from hundreds of employees to thousands, and even to tens of thousands, the employee publication becomes more and more a reliance of managements in maintaining institutional morale and the spirit of service on a high plane. The public utility industry, it must be remembered, is reared solely for service; in such an industry, the potentiality of the employee magazine to render substantial service is unlimited.

CHAIRMAN BOSWELL: Mr. Earl E. Neubig, editor, *The Hammermill Bond*, Hammermill Paper Company of Erie, Pennsylvania, will present the report on Plant Publications of Manufacturing Companies.

Report on Plant Publications of Manufacturing Companies

Earl E. Neubig, Editor "The Hammermill Bond," Hammermill Paper Company, Erie, Pa.

In making an analysis of manufacturing companies' employee magazines, this particular editor was very much pleased to revert again to the status of a mere reporter, a gatherer of facts and not a director of the destinies of men and institutions, strong on telling them what they should do and weak in telling them how to do it.

Making an analysis these days usually means the chemist is supplied with a sample. This he breaks up into its various components and determines whether the amount of fusel oil makes it fit for consumption or delirium tremens, both serious ailments.

This same technique was used in analyzing 40 representative employee publications issued by manufacturing concerns. They are literally reduced to atoms. That number of such publications could not have been secured but for the kindness of Mary B. Day, librarian of the National Safety Council, and several fellow editors who thought they saw a chance to get their names in the papers.

Supplied with these magazines, a pair of dividers, a pica scale, an 18 inch rule and several reams of Hammermill Bond we went to work. Let me state

right here that had I realized the amount of work involved, I would never have been inveigled into this job. Some one else would be making this report, a much better one likely, and I would be in one of the back rows asleep with the rest of the brothers.

When the last of the 40 plant papers had been completed and consigned to a niche in another land, 42,172 square inches of copy had been investigated and classified under 25 different headings. Some could be included in Emerson's Essays without injuring Emerson's reputation; some could be published in "Whizz Bang" and receive the approbation of the readers of that magazine. The rest could stop off at the way stations in between.

Of the magazines studied, 22 had covers and ten had not. This we give without comment, as this is a report and not an editorial. The size varied all the way from compact little things that could repose with ease and comfort in a lady's vanity case to pretentious affairs like the "Woman's Home Companion" that could not be folded and put in a man's pocket.

This we also relate without comment. The type ranged all the way from nonpareil to 12-point, leaded. This, too, needs no remarks.

To establish a working basis we averaged all these sizes and the 42,172 square inches of copy and found we had a magazine 7x10, containing 1,054 square inches of 25 different kinds of material. That is equivalent to a 16 page magazine. 8½x11, with or without cover, as the editor preferred or his boss decided.

A Composite of Forty Plant Magazines

From here on you would have difficulty in following by ear alone the make up of this composite magazine. Being an average of 40 manufacturing companies' plant papers, it should represent the best thought in that line. To help you to understand just what this publication would contain, a chart has been prepared that shows graphically the amount of space each kind of copy would fill. Please remember this is a composite magazine, made up from an average of the 40 magazines. For one issue to contain everything in the proportion shown would be ridiculous. It does show, however, the exact proportion of the different kinds of material the editors are using and where they might or might not show better judgment. No attempt was made to deal with makeup or layout. Next year's program committee ought to have something left to work on.

As you can see, halftones take up 20 per cent of the space, line cuts 1.4 per cent and cartoons 3.5 per cent. The subject matter of the illustrations was not classified, but a cursory examination showed that it follows closely the same proportions as the printed matter.

Editorials compose 8 per cent of the whole, too much or too little, depending entirely upon the writer. Editorials were restricted carefully to something the editor had to say about his business or shop. The scissors and paste pot variety were relegated to their proper place.

Technical articles are copy written to explain some process or product used or made by the readers of the paper. Economic articles deal with the more general phases of business and commerce and find their principal use in acquainting the workers in the mill with the intricacies of the more important jobs in the office. They are instrumental in bringing about a better understanding between men and management and can be distinguished by their scarcity.

Personals mean just that and nothing more. They are gossip about people in the plant and they take up 23 per cent of the plant paper. This is not

RELATIVE AMOUNTS OF DIFFERENT KINDS OF COPY FROM 40 INDUSTRIAL EMPLOYEES' MAGAZINES

too much space. Whatever may be the purpose of the paper, unless it gets itself read, it fails, and we know of no better way to accomplish this first essential than by the use of personals. If you don't believe it, get a job on a country newspaper.

The women's page, jokes, athletics, safety and mutual benefit news needs no explanation. Filler is that material that relates to everything in general and nothing in particular, and could be replaced with something else of the same nature and never be missed. You all know how convenient and necessary it is so why elaborate?

Community news finds a place in those papers whose shop usually represents the sole industrial activity of the town. The much discussed children's page we all recognize. Shop news differs from personals only in the amount of territory covered. It involves a department, group or several groups as the case may be.

Suggestion system reports, articles on Americanization, employee representation, group insurance, ads free to employees, poetry and a health service, all have their share in the make up of this composite magazine. Three of the plant papers had an index. The average would allow this one to use .03 per cent of its available space for that purpose, scarcely enough, as you know, but we are merely trying to show what is being done.

An analysis is important only if conclusions can be drawn from it. Its importance will vary in accordance with the practical applications of those conclusions to the work one is doing. I told you what we did and how we did it. The chart shows you what we found. For any of you to sit there and get all the points and draw a chart like this one with which to compare your own magazine would be impossible.

For that reason we have prepared a little folder. It contains a reproduction of the chart which you may use to see how your paper compares, with sufficient explanation to make the chart clear.

In addition we have prepared the following Employee Magazine Editor's Guide to help you with your work. Our aim is to show you how the job can be done, not to tell you what to do.

Guide for Editing Employee Magazine

To Create Good Will

A. Establish Fellowship Between Workers.

1. News of athletic events.
2. News of picnics and social affairs.
3. Publish list introducing new employees.
4. Show pictures of workmen on the job.
5. Use personals, extending from brief mention to articles.
6. Report department activities.
7. Make judicious use of cartoons.

B. Secure Understanding of the Management.

1. Pictures, news and cartoons of the executives.
2. Publish articles written by department heads and executive officers, telling of the work done under their direction.

To Develop Pride in Job

A. Show Yours to be the Best Shop in the Community.

1. Pictures of men doing very good work.
2. Tell about the library, restaurant, orchestra, etc.
3. Publish list of promotions.
4. Capitalize on athletic victories.

- B. Recognize Continuous Service.
 - 1. Print list of service awards.
 - 2. Use pictures and stories about men old in service.
 - 3. Tell about benefits accruing from steady work.
- C. Write Up Suggestion Awards.
- D. Give Prominence to the Breaking of Production Records.
- E. Relate the Compliments Paid to the Company and its Products by Uninterested People.
- F. Publish the Company's History.
 - 1. Show the company's interests and the employees' interests to be mutual.
 - 2. Tell about new developments and proposed expansion.

To Secure Mental Improvement

- A. Publish Articles on Thrift.
 - 1. Explain budgeting.
 - 2. Tell about banking and investments.
 - 3. Relate advantages of good insurance, all kinds.
- B. Use Inspirational Articles on the Growth of Men in Business.
- C. Acquaint Readers with Principles of Economics.
 - 1. Use short articles on elementary economics.
 - 2. Publish articles by executives on business conditions.
- D. Encourage the Unnaturalized to Become Citizens.
- E. Conduct a Job Education.
 - 1. Have technical articles written by one who knows.
 - 2. Tell about the other fellow's job.
 - 3. Explain the importance of all jobs and their relation to the whole scheme of things.
 - 4. Impress upon readers the dignity and necessity of all work.

To Interest Employees' Families in Plant Paper

- A. Publish Attractive Page of Baby Pictures Occasionally or Use Pictures Singly as Preferred.
- B. Announce the New Arrivals.
- C. Report Illness of Employees and Their Families.
- D. Report Home Affairs, Vacations, New Cars, etc.
- E. Encourage Home Ownership.
- F. Publish the Vacation Lists.
- G. Supply Space for Employees' Ads Free.
- H. Have a Woman's Page Regularly or Occasionally as Warranted.
- I. Explain the Relation of Home Conditions to the Job.
 - 1. Proper diet necessary to good health.
 - 2. Home worries are carried to the job, distracting attention from work, causing work to suffer and often endangering worker.
 - 3. Tell discreetly how man works for no company or organization but to supply his family with the necessities and some of the luxuries of life.
- J. Congratulate the Newlyweds.

To Help Reduce Accidents

- A. Use Entire Page or Even Section of Magazine at Times.
 - 1. Have it highly dramatized with local action both in picture and printed matter.
- B. Turn Accidents Into News.
 - 1. Use of the victim's name.
 - 2. Impress the cause for the accident.
 - 3. Play up the suffering involved.

4. **Emphasize** the loss of time, pay, suffering involved and possible serious results.
5. **Tell clearly** and show how such accidents can be avoided.
6. **Avoid placing the blame.** That's the Safety Director's job. Avoid anything that will allow paper to be criticized.
- C. **Have Employees Act for Photos.**
 1. This interests the actor and teaches him a lesson.
 2. Fellow workers are likewise interested.
- D. **Publish Health Articles by Plant Physician or Other Reliable Authority.**
 1. Tell the employees about common ailments, their cause, treatment and effects.
 2. Stress the importance of prompt first aid treatment.

CHAIRMAN BOSWELL: Before we devote any time to discussion, we have 15 minutes left and I am going to ask the new chairman, Mr. R. H. Ferguson, of the Bureau of Safety, Chicago, to give you some idea perhaps of what he has in mind for the coming year. I am sure we are going to pledge to him our wholehearted, 100 per cent cooperation.

R. H. FERGUSON (Bureau of Safety, Chicago): The few remarks that I would like to make are not going to be in the nature of an address. They are merely spontaneous ideas, as I have collected them from time to time during the meetings this week.

Full Cooperation Asked for the Coming Year

I am sure that the incoming officers realize the responsibility that has been placed upon them. We ask that you members of the section give us your cooperation. If you have ideas which will help us improve the service of this section, let us have those in writing. We will appreciate it. We need all the help we can get.

One idea that I would like to have expressed from those present is that matter concerning regional meetings. It has been the custom during the past several years to hold those meetings between the congresses. You no doubt will recall that we had one meeting here in Chicago. Mr. Ashe has had several in Pittsfield. I was glad to hear Mr. Conover make the resolution this morning concerning the zoning and placement of the various editors who are members of the section.

With this particular work, we will be able to know just where we can hold regional meetings with the greatest success. I have in mind at this time possibly a regional meeting in the central portion of the United States and probably one on the East Coast. I would be very glad to have your ideas on that and any other questions which will enable us to further the work of the Publications Section.

CHAIRMAN BOSWELL: To repeat, I am sure we will all be glad to cooperate with Mr. Ferguson and the officers and the committees of the section as we are called upon.

I wish to take this opportunity to express my appreciation to the chairmen of the various committees and to the committeemen themselves for the very splendid work which has been rendered during this past year. I have done very little myself, but you can see with such an array of talent a lot of work has been done. Mr. Doeller has done a tremendous amount of work himself and Mr. Devendorf, the secretary-treasurer, who has been here at every meeting, has been on the job throughout the year and has done a prodigious amount of work. The same may be said of Mr. Augustus in getting out the News Letter, and the Publicity Committee did some work. Mr. Wilkins is chairman of it, and so on through, and I wish to emphasize what I said the other day, that I personally appreciate all that has been done.

F. L. GREENYA (Fisk Rubber Co., Federal Division): I would like to ask a

question about the division in this contest. I have heard the question asked back here half a dozen times and I think it would clarify the matters in the minds of several of the members. Just how did the judges make the division in Classes A and B? Some said they thought it was left to the discretion of the editors to choose the particular group in which they cared to enter. That is my impression. I don't think that is quite the way to do it. I think that the judges should be in a position from the magazines they have at hand, to determine whether or not it is eligible to enter Class A or Class B and be governed accordingly, rather than have an editor say he prefers to compete in the A or B group. It is the fairest way, after all is said and done.

CHAIRMAN BOSWELL: I will have to call on Mr. Ashe.

MR. ASHE: The judges left it to the members to say which class they wanted. When the magazines came in, the judges looked them over and if they didn't feel the editors had shown good discretion, they changed it.

I will say honestly, though, that only a small proportion of them were changed. There were a few that we were in doubt about whether we shouldn't move them into the first class, but in those cases, as the editors had asked to be included in the second class, we thought we would leave them.

The Judges Will Classify Magazines in Future

MR. GREENYA: I think it should be definitely settled rather than have the editor say. I think the results of the work should speak for itself rather than the editor.

CHAIRMAN BOSWELL: You would leave it up to the judges?

MR. GREENYA: Yes.

CHAIRMAN BOSWELL: Does this body wish to so decree? Do you make that as a motion?

MR. GREENYA: I will, to get it on the floor.

CHAIRMAN BOSWELL: The motion has been made that the judges have the discretion to determine to which class any magazines that may be submitted in the contest shall be placed. Is that supported?

(The motion was seconded.)

R. W. LIDDLE (Commonwealth Edison Co., Chicago): As I understood Mr. Ashe's remarks, practically that situation exists now. It is probably a time-saver for the judges to have the editors say which class it should go into. I favor leaving that situation as it is.

CHAIRMAN BOSWELL: This won't exclude any editor saying which class it goes into. I understand that is the motion.

(The question was put to a vote and carried.)

MR. ASHE: Could I ask one question? While I have talked a lot, there is one thing I should like to get a little advice on.

There has been a good deal of discussion here, a splendid paper by one of the representatives, where so much stress has been laid on photographs and the use of photographs. I was wondering why in so many cases the inferior grade of paper was used in the magazines; whether some of us overestimated the value of the paper in the presentation of the picture or whether those photographers who use those pictures on that type of paper were perfectly satisfied from a shop standpoint so long as that picture was shown?

S. P. WILD (Armour & Company, Chicago): As far as Mr. Ashe's question is concerned, the same problem has come up in our company, between the two magazines or papers which we get out. One of them is intended for our sales and executive force throughout the country and the other is issued locally at each of eight plants. The largest circulation of the plant papers is about 8,000 at the Chicago plant. Both of the publications, no matter where issued, are intended to be full of cuts, which, if they are to be of any use at all, have to show up properly.

but we have arrived at the conclusion that there is no use spending good money on papers any better than you have to. We have been using recently for the magazine forty-pound stock and for the *Armour Oval* somewhat lighter, which is super calender paper that with proper care taken by the engraver in making the cuts, and particularly with proper press work, turns out a job good enough for our purposes. Frankly, we could use a better grade of paper and have our cuts show up better, but they wouldn't show up enough better to pay for the difference in price.

We found that this stock, if we watch the pressman, is plenty good enough to turn out a good looking half tone. The big point of the whole business is in getting the printer who knows his business, because we have had printers who think they know the job and tell you all about it, and the first thing they slap the ink all over the place and let it run.

MR. ASHE: From the employees' standpoint, do you think it makes any difference?

MR. WILD: If it shows up good enough to illustrate what you want it to, it is all right. You can make it look like a newspaper cut or like an illustration. If the newspaper cut style shows the points of the picture, I don't think it makes a lot of difference. My experience is that if the picture is worth anything at all, it must have a point. If the paper and illustrations are good enough to illustrate that point, the extra money you put into a super value half tone isn't worthwhile.

R. W. LIDDLE (Commonwealth Edison Co., Chicago): I was just going to ask what in this questionnaire if it isn't too much trouble, I think it would be interesting to a good many to know whether the papers are magazine or newspaper in style. I know most of them are magazine, but those of us who work on newspapers would be interested to know what the proportion is.

CHAIRMAN BOSWELL: Mr. Ferguson, as we adjourn, we turn the thing over to you for the new year and wish you Godspeed and hope you have as good a meeting next year as we did this year.

ADJOURNMENT.

*SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL*

Employees' Publication and Benefit Associations Luncheon

Tuesday, September 27, 1927

An Important Function of the Plant Magazine

Whiting Williams, Cleveland, O.

What I have to say today can best be tied up with the story of two friends who went a-hunting.

One of them, a stutterer, failed to pull the trigger quickly enough and, therefore, missed his squirrel. The other suffered from St. Vitus' dance. After drawing an extremely wavering and uncertain bead upon the squirrel, he pulled the trigger. To the general surprise the poor thing fell dead.

The hunter's look of triumph got poor consolation from his stuttering companion.

"W-W-W-Why shouldn't you?" he retorted. "W-W-Why shouldn't you hit it? Y-Y-Y-You aimed all over the w-w-whole d-d-d-damned tree!"

As I look over the many employees' or plant publications which come to my desk, it seems to me that too many of their editors are plainly trying, like the hunter, to cover the whole tree without, however, putting their eyes upon the center of their target.

I have no objection whatever to the attention paid by the average editor to such matters as safety, health, thrift, hobbies, humor, athletics, etc. All these have a legitimate part in the employees' magazine—as does also, generally, the mention of the wedding or the new baby, or even the fact that, according to the correspondent from the Steelville Plant, "Everybody's asking Joe Spivis in the accounting department about the roadster noticed outside a certain house on West 14th Street last Thursday night. Perhaps Gertie, the popular new member of the filing force, can answer! Ha, ha!"

If all these help the readers to look forward to the next issue, they are to that extent good. But all these represent little short of an industrial crime if they indicate the editor's entire aim. For these activities, these interests, compose only the fringe of what is, after all, the magnet which draws all these readers together. I mean the employing organization, the work in which they are united—in short, the common job.

To assume that people today are interested in the personal relationships and associations which the job permits but not at all in the job itself—this, I say, is little short of wicked. When an editor talks constantly about all these secondary activities and then keeps silent about the work itself, the omission follows, I believe, from a complete misunderstanding of the attitude of the worker himself. It is a hang-over from that day when it was supposed by everybody that the only reason men

or women do any work in the world is because they need the money—that the moment the desired dollars are earned they want instantly to get away from the hateful thing that pays them—and that they can be lured into thinking about the job itself only by means of sugar-coated allusions to their companions, their families, and their after-hours' recreations.

The primary function of the plant magazine is, in my opinion, to help the worker to know his work, and so, by knowing his work, to know himself.

It is supposed, of course, that his foreman will tell him all he needs to know about his job—that these steel sheets must be put through those rolls, or this sand into that oiled mold. But I contend that the foreman cannot tell him fully about this job simply because the foreman himself really does not know; it may be years since this foreman went across the yard into the galvanizing department or the foundry to learn exactly why the steel is put through those rolls or exactly why the sand must go into those molds in this or that particular way. Even the superintendent of the department—yes, even the manager of the plant itself—may be little better equipped to tell the worker fully what his job is, properly explaining what his work means in terms of usefulness and service to other human beings. Perhaps in the whole history of the company, this particular "super" or plant manager has never sat down beside either a salesman or a customer. In that case, he can't tell his workers fully about their work for the simple reason that he himself has never taken the time to learn exactly what that work is *for*.

Well then, who is equipped to help everybody in the plant to know the part he plays in the world as the result of, and by means, of his work?

If you'll listen carefully, I'll tell you.

The Editor Must Fight Off Plant Pessimism

It's the plant editor!

The editor, he's the chap equipped to fight off the pessimism which has been created by the modern subdivision of work and its resultant tendency to monotony!

The trouble today in our great factories is not so much that a man gives his whole time to tightening bolt number 8006. The larger difficulty arises from the fact that it is enormously harder for the tightener of that bolt to get the proper picture of his job's contribution and, therefore, of his own contribution to other human beings, than in the days when three or four men built a wagon. For in those days those builders probably knew the man who was going to use it. They expected to keep permanently in contact with both their handiwork and its new owner. As they tightened each bolt, they carried always the picture of that particular operation's meaning and value to that particular friend and neighbor.

Today, it is not so much the change in the nature of the mechanical operation as in the nature of the market—the wideness of the gap between maker and user—that makes men discouraged; they find it hard, unaided, to think highly of their work because they are not properly helped to know the men and women customers whom they are serving. These, instead of neighbors, may be far beyond the Seven Seas.

But these Seven Seas can be bridged—these distant users can be made neighbors of the makers—if only the editor will conjure properly with his pen and paper!

Thus the steel plant where we ran 20 to 30 tons of steel sheets through the cold-rolls every day, we generally had the satisfaction of knowing we were making "automobile iron." Every car we saw made us wonder whether *we* had happened, a few weeks or months before, to handle the sheets that now were doing their bit as sides or fenders.

But there were certain days in the plant when all of us were excited.

"On your marks there, Charley!" my buddy would say, "today it's 'electric iron'!"

What is "electric iron"? What were we making?

Well, I never learned—at least not there in the plant. The best answer I could get was:

"Nope, you can search me—except that it's blamed important. If you make the lightest mistake with it, they sure raise hell with you!"

When I asked a foreman, "Where does this stuff go to?", he looked surprised and answered, "W'y, over to the inspection department. Can't you see?"

It was years before I really learned what I had done in that steel plant. Visiting a factory at Pittsfield—where, by the way, my friend Mr. Ashe of this group wields his pen—I was shown a great warehouse full of thin steel sheets, with the explanation that "All the good motors must use these: electricity doesn't work properly on solid steel blocks."

It was a thrilling instant.

"Wait a moment," I asked my guide, Mr. Chesney, the manager. "Do you mean to tell me that this is 'electric iron'?"

When he assured me that it was, I felt as if a long delayed reunion had finally been staged.

Every Man Wants to Know the Reason Why

"Show me to it!" I exclaimed in my delight. "I've been looking for this for years. Me, I'm the father of this stuff!"

Incidentally, it is worth mentioning that the particular plant where I helped make good motors by helping make "electric iron," has no employees' publication. I can't help wondering whether one reason for this lack may not be that so many plant magazines fail to consider the meaning—and hence the joy—of the job as the veritable "bull's eye" of their aim.

It was an inefficient foreman who directed a group of illiterate foreign-born laborers to "Dig a hole six feet deep here," and then a half-hour later ordered them to close it up and "Dig another there!"—with, still later, a further order to "Close up that second hole and dig a third one over here!"

With that, these lowliest of workers, men who we think are interested in the money and nothing else, showed their mettle. Taking their shovels calmly and leaning them against the wall, they retorted:

"No! alla time deeg here—deeg dere—for not'ing—like dam' fool! We quit!"

Then the foreman did what he should have done in the first place—explained that blueprints had been lost and that until the pipe could be discovered and the obstruction removed, their sweating friends in the hot sheet-mill inside would get no cool water at their work. With that the men took up their shovels.

"Oh, sure," they said; "we help find-'em damn-fool pipe!"

Today, entirely too many thousands of men are unhappy because they do not know their job—do not know what they are doing—simply because they have, for instance, never seen the completed machine for which they have been making parts for years. I say it is impossible for such men to think properly of their work unless they know how it "cogs in" with the wheels of other operations throughout the plant, the industry, or the country for the rendering of a worth-while human service.

In all the world there is nothing which for a moment compares with a man's job for helping him to understand his importance to other people and other people's importance to him.

Along, therefore, with the personals, the safety hints, the thrift suggestions, the athletic notes, and all the others, there should go on a constant explanation of the work to the worker, constant effort by the editor and his reporters to interpret to the individual his connection with the processes of his own hands, then of these processes with those of his department, and those with the whole plant, and the whole company—its history, ideals, past tribulations, present objectives, past and

present leaders, etc. After that, the whole great industry, and the whole great industry's contribution to the country and the world.

Mind you, I do not say that such interpretation is easy, for unless it really "gets over" it does not interpret. But I do say that without constant effort at such interpretation the plant magazine fails to live up to its complete possibilities.

Without taking time to speak fully of the "how" of all this, I want to mention the best method of helping workers to see the human service and hence the human nobility, hidden in their ordinary, everyday jobs. I mean the editorial policy of mentioning every exceptional happening in connection with the actual work of the man, the department, the plant, or the company—every meeting of such an emergency as arises when, for instance, floods wash away a telephone central and hence call upon production and shipping departments to work long extra hours to supply a new one.

Such crises—and the loyal meeting of them—are common throughout industry. Everywhere, too, the big boss boasts to his companions at the club of his ability to handle them. But in too many places, the workers, who have shared in the crucial effort, wonder why they are not given more chance to share the common thrill. Surely, every one of these employees has upheld the reputation of the company in just as notable a way as if he had helped to win a pennant on the diamond. Yet scarcely an issue but carries the pictures of the company's crack athletes?

All this holds true when the company makes, for instance, its first shipment of goods to India, Australia or Borneo. The shame is that, too often, the workers—perhaps even the foremen outside the shipping department—are given no opportunity to stick out their chests as far as does their chief. I tell you they are just as anxious to enjoy their work as he is!

His Magazine Tells Him About His Company

Such notice of these exploits is worth while in itself, but it serves also to help the worker to understand the achievements which are constantly contained in the limits of his daily stint of effort. Within the covers of his magazine, thus, the man can find not only a chance to know his work by knowing all those who use his product or his service. He can also find there a grandstand filled with the other members of the company—sembled associates before whom he can feel himself a performer—a performer whose meeting of every daily requirement or critical emergency will by no means fail to be observed.

It is almost impossible, I believe, to over-state the truly spiritual value of the editor's usefulness in all this. From my close-up view of the minds and hearts of this country's and Europe's workers, both as a laborer and as a consultant, I would say that today vast unhappiness and heart-break are caused not only among the workers but also among the officers of American industry, because so many of their executive leaders have asked from them not more but less than they would like to give! Too often an executive assumes that everybody will be happy if only he asks a minimum of service from them! That's bad for the company, but it's worse for the persons concerned. To all these a minimum service means minimum self-respect—minimum satisfaction in the feeling of their meaning and value to their fellows and themselves.

One reason so many young men and women today indulge in crime is because we are not properly developing these exploit possibilities of the daily job. So the thrill—the indispensable thrill—is sought for in the gardens of forbidden fruit. This error, I claim, comes from the willingness of most of us to believe that while our own job possesses these possibilities of achievement, the other fellow, of course, need not even dream of finding them in his!

I should feel, therefore, that I had not lived in vain if I could persuade the plant editors of this country—and their bosses—to engage in a forward movement at

exactly this point. Today, literally millions of our fellows are praying for the chance to enjoy, somehow or other, a measure of that thrill which we know must have been Lindbergh's. With close to 100 per cent of all these millions, however, virtually the only chance for this exists, if anywhere, within the limits of their work. If my studies among laborers mean anything at all, they mean that these workers know all this much better than do we. With all their hearts they themselves want to find these possibilities in their jobs. But they cannot do this today without just such help as the magazine can give.

How can more companies and more editors be persuaded of this truth that men genuinely wish to find spiritual assurance and re-assurance in their work?

The other night at Albany I went forward to talk with the engineer. I found him oiling up his magnificent black beast and keen to discuss with me the probabilities of its continuing its run from Harmon to Buffalo without "heating up." He soon told me that he would shortly celebrate his seventieth birthday!—after looking after engines for forty years—and railways fifty-nine!

St. Peter, Too, Will be Interested in a Man's Job

Now, according to some of the plant magazines, this man would be expected to go up to St. Peter and present his credentials by telling all about his children, his garden, his new car, his savings, his last vacation, etc.—everything except his job. It is to laugh!

Why, it's as certain as anything can be that when that man comes to the Golden Gates, he'll knock on the door and with his chest out, look St. Peter right in the eye and say:

"Pleased to meet you, sir! My name is Jones—Jones of Utica, sir. For the last ten years I've been taking Number 19 from Albany west and Number 29 east. That's the Lake Shore Limited, you know, sir. For 30 years before that, I fired or drove the best 'power' on the same road."

That's all! With that, I tell you, he'll rest his case! Furthermore, he'll be perfectly sure that St. Peter will be man enough not only to let him in but to introduce him to a few of the Twelve Apostles so they can pass the time arguing about the solid satisfaction of running engines in comparison with fishing-boats!

No, we don't take men's jobs seriously enough. It is perfectly proper to say that today the great powers and principalities of this world are the United States, Great Britain, Germany, France, Italy—and U. S. Steel, General Electric, General Motors, Baltimore and Ohio, Swift's, United Fruit, etc. It is not too much to say that the heads of these great organizations touch today the life of their times more deeply and effectively than does, for instance, the King of Spain. The reason is that everywhere men's lives—and, yes, their very souls—are being determined by the hopes, the fears, the hungers, the satisfactions, the thrills—or the disappointments—engendered in the hours not of their leisure but of their labor!

For myself, I want no better calling than the job of helping to make better the conditions of American life by helping to make better the conditions of American work. And just this can be the job—and the joy—of the plant magazine's editor—to help men everywhere to think better of themselves by helping them to think better of the product of their hands.

All this was in the mind of the writer of Ecclesiasticus when he wrote of the smith, the potter and other workers:

"All these put their trust in their hands,
And each becometh wise in his own works.
Yea, though they be not sought for in the council of the people,
Nor be exalted in the assembly;
Though they sit not on the seat of the judge,

Nor understand the covenant of judgment,
And be not found among them that utter dark sayings;
Yet without these shall not a city be inhabited,
Nor shall men sojourn or walk up and down therein.
For these maintain the fabric of the world
And in the handiwork of their craft is their prayer."

In conclusion I can do no better than to quote my old friend, Evan Pugh. It was after the meeting of the "Bolshies" in the Welsh coal mine that he related:

"Yusterday, the under-manager do sye to me, 'Pugh, thot been a good job.' And I do sye to 'em, 'In 43 years in this pit, in 43 years, thot been the first time that any company man do sye to me, 'Pugh, thot been a good job.'"

Then one of his companions took it up.

"Aye," he said, "Aye, thot been it! Every man do know that for a kindly word he'll work 'is bloody 'ead off. But every man do know that no dog be've well for a man with a w'ip. And every man of feelin' and sensibility do know that for 'im, the w'ip o' the tongue and the lash o' the lip be worse nor any w'ip on any dog. Every man *moost* 'ave a chance 'ere *on the job* to show 'imself the man, now moosn't he?"

With all my heart, I say he must. But I say, also, that I know no group of men in better position to help him get the joy of playing the man there in his work than this group of plant magazine editors here today.

The utmost of power, then, to all your editorial elbows!

ADJOURNMENT

SIXTEENTH ANNUAL SAFETY CONGRESS NATIONAL SAFETY COUNCIL

Food Section

New Section Officers

Chairman, F. A. HASSE, Corn Products Refining Company, Chicago, Ill.
Vice-Chairman, H. T. EGGERT, National Biscuit Company, New York City.
Secretary and News-Letter Editor, W. P. PENTY, Kellogg Company, Battle Creek, Mich.
Poster, Lantern Slide and Safety Kinks Committee Chairman, J. T. DOOLIN, Casualty Reciprocal Exchange, Kansas City, Mo.
Membership Committee Chairman, W. H. CUNNINGHAM, Pillsbury Flour Mills Company, Minneapolis, Minn.
Engineering Representative and Publicity Committee Chairman, THOMAS S. STROBHAR, Wagner-Taylor Company, Philadelphia, Pa.
Program Committee Chairman, FRANK T. COLEMAN, Continental Bakeries, New York City.
Statistics Committee Chairman, R. E. PROUTY, Aetna Life Insurance Company, New York City.
Executive Committee, THE OFFICERS AND—
G. A. NOXON, Ralston Purina Company, St. Louis, Mo.
R. B. ROBINSON, Washburn Crosby Company, Buffalo, N. Y.

Retiring Officers

Chairman, VERN D. SUTTON, Postum Cereal Co., Inc., Battle Creek, Mich.; *Vice Chairman*, F. A. HASSE, Corn Products Refining Co., Chicago, Ill.; *Secretary and Chairman Membership Committee*, A. H. WEIDENMANN, Casualty Reciprocal Exchange, Kansas City, Mo. *Committee Chairmen: Program*, F. A. HASSE, Corn Products Refining Co., Chicago, Ill.; *Statistics*, RALPH E. PROUTY, Aetna Life Ins. Co., New York City; *Poster*, A. C. SELMON, M. D., Kellogg Company, Battle Creek, Mich.; *Engineering Representative*, THOS. S. STROBHAR, Wagner-Taylor Co., Philadelphia, Pa.; *Executive Committee*, THE OFFICERS and H. T. EGGERT, National Biscuit Co., New York City; ALEXANDER DIENST, National Sugar Refining Co. of N. J., Long Island City, N. Y.; STANLEY H. KERSHAW, National Safety Council, Chicago.

Tuesday, September 27, 1927

VERN D. SUTTON, Chairman

Safety Engineer, Postum Company, Inc., Battle Creek, Mich.

The first session of the Food Section of the National Safety Council was called to order at nine-thirty o'clock by the chairman, Vern D. Sutton, safety engineer, Postum Company, Inc., Battle Creek, Mich.

CHAIRMAN SUTTON: I think one of the chief benefits to be gotten out of a conference is in becoming acquainted with the other people who are in attendance, so in order that we may all know each other, I wish you would each rise and give, in turn, your name and your connection.

(Automatic roll call).

CHAIRMAN SUTTON: The National Safety Council wishes our attention called to the posters, not only those in this room, but throughout the hotel. There are about a thousand on display and it is desired that you look them over carefully and if there are any you could use, write down the numbers and headquarters will furnish you with the copies to use in your plant.

Perhaps the first order of business is the appointment of a Nominating Committee, so tomorrow we may hold our election of officers for the coming year. I will appoint as members of that committee, Mr. S. H. Kershaw, Mr. H. T. Eggert, and Mr. F. T. Coleman. They will report tomorrow morning.

Unfortunately, the next thing on the program is some remarks by the chairman, but since I have already made a few remarks, I shall simply continue.

What the Food Section Has Accomplished

Vern D. Sutton, Postum Cereal Company, Inc., Battle Creek, Mich.

It is seldom, I believe, that a year-old baby is asked, unless in playful spirit, "What have you accomplished?" and, impliedly, "What excuse have you for continuing existence?" Yet that question is being asked, and justifiedly, of the year-old Food Section.

Well, we have learned to walk and we've learned to talk, and, with the parental supervision, provision, training and assistance of the National Safety Council, the Food Section can feed itself. This is a metaphor rather than a pun. In other words, it's a healthy child and will probably live.

In reviewing what we have accomplished, giving reason for our existence, and justifying our hope of continuing existence, let us consider what we were supposed to accomplish.

In the first place we were supposed to discover and create, and then improve, every possible opportunity to be mutually helpful to each other as members of the Food Section, to be helpful to other members of the National Safety Council, and to be helpful to the safety movement in general. This the Section has earnestly striven to do with some visible success and we hope also with some success which only the records of Eternity will reveal.

Let us determine if we have met the standards specified in the outline of organization and activities of industrial sections.

We have maintained a staff of competent officers. I presume to say, competent, even though I have been one of them. What I have lacked in qualification I hope to have made up in intense interest and willingness. The vice-chairman, Mr. Hasse, has given me invaluable assistance and wise council. We were so unfortunate during the year as to lose by tragic death our exceptionally capable secretary, membership chairman, and News Letter editor, Mr. Allen Wiedenmann. And here I want to pay tribute to one whose insistence and argument did much to make clear the wisdom of a Food Section, who served energetically on the Steering Committee during its twelve months of operation, and who a year ago willingly accepted three positions in the Section, one of which is about as discouraging and difficult as can be imagined. In his shocking death we lost one of our most interested, energetic, and valuable members and co-workers.

Among the specified desired accomplishments to be attained by committees,

cooperation with the headquarters staff in producing posters especially applicable to the hazards of industries in our Section. There have appeared our specifically food posters during the year and photographs for others are waiting appearance. There have been several general posters as the result of suggestions by Food Section members. Perhaps to some of you this seems exceedingly small, yet I refer to it with some pride, at the same time regretting that more members have not developed a responsibility-assuming, productive interest in the matter. The headquarters staff are earnestly desirous of producing safety posters effective in each of the various kinds of industry represented in the membership of the National Safety Council, but how can they provide those which will be specifically applicable to hazards inherent to our operations unless we aid them?

Another important committee to a section is its Program Committee. "The most important," I hear you say. Yes, if a section exists to provide programs at the Annual Congress, this committee is the all important, but there are so many possibilities for a section that it is difficult to say which is the most important committee.

As to the functioning of our Program Committee, just consult your memory and the proceedings of our meetings held in Detroit last fall and await the delightful experience which is to be yours during the next three forenoons. Our Program Committee has justified the existence of a Food Section.

Membership Committee Activities

The Membership Committee has, I believe, done most of its work individually. Many members of the Section have also, I understand, cooperated in an effort to increase the membership not only of our Section but of the Council at large. Two years ago when interested safety men met in committee at the Cleveland Congress, to discuss the proposed formation of this Section, there were 17 present. A year ago the Section was accredited with 121 members. Today we have 125. That does not mean only four have been added; thirteen have come into the fold during the year, but during the same time nine have failed to make their membership valuable to themselves and therefore cancelled. I wish there were some way to cause members to avail themselves of the benefits of membership, instead of dropping their certificate into a desk drawer and forgetting all about its attendant privileges until receipt of invoice for renewal of membership, to which they respond with a cancellation. There ought never to be a cancellation of membership in the National Safety Council, but while the Council can furnish safety nutriment it cannot make members eat it.

One of the most vital forces to continue the program of activity of our Section throughout the year is the Food Section News Letter. 'Tis true that for the scheduled session of our Section we designate whom we wish to speak and assign a topic, while in the News Letter we call for open discussion. It is wished, however, that you would feel the same constraint to contribute to it as you would to respond to an invitation to speak in our sessions, and the same interest you manifest in participating in our verbal discussions here. The News Letter will never accomplish its real purpose until you all feel it a duty and a privilege to help make it.

During the organization stages of the Section we got out four News Letters. During the past year, or since the last Annual Congress, we have gotten out ten. We are sorry they have not been monthly, but feel some little pride that it was possible to get out as many as we did, containing material which we

feel a portion of our membership read before consigning to the wastebasket, without the aid of more numerous contributions from said membership.

What the News Letter is to the Section, the National Safety News is to the parent organization, the National Safety Council. We have not done what we aspired to do in the way of contributing to the National Safety News. You have no doubt observed the portion of our monthly safety journal devoted to the Plant Publication Section. It is my understanding each and every section in the Council is entitled and urged to avail themselves of this same privilege. Due to the newness of our organization and the disturbance from uncontrollable causes of such organization as we have been able to effect, we have not taken advantage of this opportunity.

One of our members, Mr. C. J. Alger, of the Corn Products Refining Company, contributed a splendid article on "Control of Explosive Dusts," which appeared in the August, 1927, issue. We wish other members would contribute to the National Safety News either direct to the staff or through the officers of the Section.

Cooperation Necessary on Statistics

Our Statistics Committee has done splendid work and would have done even better had they had better cooperation from members. Statistics is our best weapon in fighting accidents.

Our engineering representative has also functioned creditably.

Cooperation with trade associations is another ideal for Sections really wishing to achieve. To just what extent we have been able to do this I am not prepared to state. I do know that the Michigan branch of the Association of Operative Millers have invited our members to speak on safety at their conferences, and as a result of such speeches, safety was for the first time one of the topics discussed in their last national meeting, held at Dallas, Texas, in June of this year. I assume there has been other similar work.

Another ideal is to hold regional meetings of our Section. This, I trust, will come later, but probably not until we are a little older and a little stronger in our organization. However, that is an objective and we have our eyes upon it.

We hope also to some day arrive at that stage of maturity where we shall be one of the Sections employing a field secretary, the benefits of which are immediately apparent to you.

As a Section we are asked to do everything in our power to insure a large attendance of members of our Section and representatives of other industries, at the Annual Safety Congresses. I trust you all respond to that irresistible impulse to talk up the Congress in your community and secure as large a delegation as possible, not only from your plant but from your city or town.

At our Food Section sessions last year we had an attendance of 39 different delegates, many of whom attended both meetings. I trust our three sessions this year will show a large increase in the number to express their interest by meeting with us. While I expectantly anticipate this, if it should not be realized, I am confident that at all events we shall maintain the same splendid interest and receive the same enjoyment and benefit.

CHAIRMAN SUTTON: I am going to throw the meeting open now to general discussion on what the Food Section has accomplished; I am sure that many of you have come here with ideas that you want to express.

F. A. HASSE (Corn Products Refining Co., Chicago, Ill.): There isn't much of a discussion that I believe I can start. However, there is one thing that I wish could be brought out, and that is in regard to the News Letters. Will some of those now here get up and tell us what they really think of the News Letter?

It was discouraging not to have, at times, the cooperation we needed—we published only ten issues—and I hope some of you will give us your opinion of it.

CHAIRMAN SUTTON: Mr. Wiedenmann accepted the editorship of the News Letter, and to the time of his death it was the work of his hands, with what contributions could secure from the members. Upon Mr. Wiedenmann's death I endeavored to carry on that part of the work. But I want you to speak critically, for I feel the News Letter has not been what it should have been. You are at entire liberty to say anything you have in mind.

H. P. WARREN (Minute Tapioca Co., Inc., Orange, Mass.): I noticed you said there are about 125 members in the Food Section, and I am wondering if it would be possible to have a reporting of the accidents, hospital cases, time off for various reasons—each member making a report—and then a summary of these circulated among the members so that the Food Section might have the benefit of it. To me, it doesn't do much good to know there is a certain amount of lost time and accidents when I know that the figures came from industries that have no relation to food. I am wondering if such a thing could be developed in this section.

CHAIRMAN SUTTON: What do the rest of you think of that? It seems to me to have great possibilities. The chairman of the Statistics Committee is earnestly desirous of receiving reports from each one of you, and Mr. Prouty and the News Letter editor could cooperate so you would get those reports monthly in the News Letter. I think Mr. Warren's suggestion—at least in part—could be carried out this year. I think that was about what Mr. Keefer had in mind. He spoke of the possibility of sending out a blank with the News Letter to get this report. Of course, it can be confidential as you desire, so far as names are concerned; you may call your companies, A. B. C. D, and so forth, and still give us the benefit of your experience in exchange for ours.

Interests Duplicated in Other Sections

FRANK T. COLEMAN (Continental Bakeries, New York City): It seems to me that this section is composed of people who are also interested in the Taxicab and Fleet-Owners Section, and, as I wrote you, we seem to have a conflict between the sections; so I have to keep running back and forth in order to get the benefit of both. I am wondering how many of the others here have the same problem, and if they think it would be of interest to cooperate with the Taxicab and Fleet-Owners Section more closely.

H. T. EGGERT (National Biscuit Company, New York City): I think that is a very good suggestion. We have the same problem, for we have a fleet of some 1,200 motor trucks, involving a tremendous expense each year—in fact we run probably 1,500 motor accidents each year. Besides this fleet, we have employees who use their own cars on company business, probably about 1,000 to 1,500 of these cars are in use. I think it a good idea to have some cooperation between the two sections.

FRANK T. COLEMAN (Continental Bakeries, New York City): I wonder how many members there are in the same predicament?

CHAIRMAN SUTTON: I can't tell that; we would have to make a canvass and inquire. If it meets with your pleasure, I think it would be well to appoint a committee to correspond with all members of this section to find out to what extent this is a problem with them. I think we will find that almost all problems of safety are inherent in the Food Section as well as the Taxicab and Fleet-Owners Section, and there are principal ones to which we might give attention later on through cooperation with the other sections. How many of you here have fleets of motor vehicles—say of twenty or more? (Eight).

How many have six or more in a fleet? (One).

MR. EGGERT: How about those concerns that have employees who use cars of their

own for company business? In cases of accident the company is vitally interested in these cars from a legal point of view.

CHAIRMAN SUTTON: How many present have employees who use their cars for company business? (Eight)

C. J. ALGER (Corn Products Refining Co., Chicago, Ill.): It seems to me as though cooperation could be reached by the arrangement of meetings rather than by trying to coordinate the activities of both sections. I would say the Food Section should arrange its meetings so as not to conflict with the Taxicab and Fleet-Owners Section, and those who had an interest in both could attend all sessions without any trouble.

CHAIRMAN SUTTON: That might be, and should be, worked out, but there are problems that are going to come up in the same way with the other sections. I don't know how many of you have plant publications, but we sometimes find that we can't attend both the sessions of the Food Section and those of the Employees' Publication. However, it is to be hoped that some arrangement can be made to enable us to attend the various meetings in which we are interested.

Is it your opinion that perhaps the program committee can make such arrangements as not to interfere with the Taxicab and Fleet-Owners Section meetings in the matter of time, and will that cover the situation, or should there be other efforts toward cooperation? What do you think, Mr. Coleman?

Program Plans Made to Coordinate

FRANK T. COLEMAN (Continental Bakeries, New York City): I think there should be subjects of interest to both sections, but if the membership were split fifty-fifty you would have half the members not interested in one problem while the other half are.

CHAIRMAN SUTTON: I think it is the desire of headquarters that no section place on its program subjects that are natural problems of some other section. For instance, "The Hazards of Motor Vehicles" is a subject that should be discussed in the Taxicab and Fleet-Owners Section. They probably would be very willing to have us attend a session where such a subject, perhaps very vital to us, would be discussed, but it hardly belongs on the program of the Food Section.

I think we should simply try to arrange our meetings so that our members can go also to the Taxicab and Fleet-Owners Section if they wish to get the discussions there and participate in them.

Do the members present who have fleets believe we should appoint a committee to learn what other members of the Section also have fleets, and then recommend whatever method of cooperation they think we should adopt.

MR. COLEMAN: I think it would be better to leave it with the program committee to work out.

CHARLES J. STROBEL (Wagner-Taylor Co., Philadelphia, Pa.): Why not send out a questionnaire and then arrange the replies of the members, similar to the form the American Rating Company used on delivery?

F. A. HASSE (Corn Products Refining Co., Chicago, Ill.): I would suggest that it would be advisable to appoint a committee; we already know how many here have fleet operations, and I would suggest that the committee appointed be asked to determine just how many of the entire membership would actually be interested in cooperating with the Taxicab and Fleet-Owners Section, the membership varies—many of them are ice cream manufacturers, and some might not have the same kind of problems.

C. J. ALGER (Corn Products Refining Co., Chicago, Ill.): It would seem to me that we are all in the same boat, we are all manufacturing food products and dealing with the retail trade, and we all have the same interest in accident prevention. I think it is a question we can settle right here. I venture to say that 90 per cent of us

interested in the problems of the two sections; no matter how small we are, have the same problem of getting orders and of delivering them.

CHAIRMAN SUTTON: Unless someone wants to make a motion that we appoint committee for this work, the program committee will feel it their duty to take this matter up when they prepare their program. Will you express your pleasure in matter of appointing a committee or remain silent?

MR. EGGERT: I make a motion that we appoint a committee.

MR. COLEMAN: I second that motion.

CHAIRMAN SUTTON: It has been moved and seconded that we appoint a committee to determine the methods of cooperation between the Food Section and the Taxicab and Fleet-Owners Section, for the benefit of that section and ours.

Cooperation with the Taxicab and Fleet Owners Section

MR. EGGERT: I would suggest that Mr. Coleman be placed in charge of that committee.

CHAIRMAN SUTTON: I wonder if Mr. Coleman will serve.

MR. COLEMAN: I should like to see the motion voted upon.

MR. EGGERT: I think that committee could work with the program committee, because that committee would be very much more vitally interested than the program committee, so far as the fleet situation is concerned.

CHAIRMAN SUTTON: All those in favor, say aye; opposed, no.

(The result was a tie.)

CHAIRMAN SUTTON: Let's vote the other way; all those in favor raise their right hands.

(The motion was carried.)

CHAIRMAN SUTTON: How will you have that committee chosen?

MR. HASSE: I make the suggestion that the committee be appointed by the chairman.

CHAIRMAN SUTTON: Is there any other suggestion?

Then I shall appoint Mr. H. T. Eggert as chairman, and Mr. C. J. Strobel as a member of that committee. I would appoint Mr. Coleman, but he is opposed to the committee.

MR. EGGERT: I suggest that Mr. Coleman be made a member of the committee because he is located in New York where I am, and we can get together easily. I think he is perfectly willing.

CHAIRMAN SUTTON: Mr. Strobel is located in Philadelphia which is not far from you, so he should be able to meet with you. If there is no other discussion on this subject, we will go on with our program.

C. J. ALGER (Corn Products Refining Co., Chicago, Ill.): I should like to say that, having attended the meetings of the National Safety Congress in the past when anyone in the food manufacturing line seemed to be out of step, I think the officers of this section are to be commended, particularly our worthy chairman, for the progress they have made.

CHAIRMAN SUTTON: I am exceedingly grateful for your kind words. It is my impression, too, that we were out of step in the Food Section; we had no place to go, for one thing, so the improvement has made me very enthusiastic.

The next subject we are to consider is one that may well be considered in any and every section of the Congress, the matter of plant publications. We are very fortunate in having it presented to us by the editor of the best plant publication in the food industry. In saying that I want to remind you that my own company as a plant publication, but it takes its hat off to *The Staley Journal*. We are going to hear from Miss Ruth Cade, editor, *The Staley Journal*, A. E. Staley Company, Decatur, Illinois.

The Employees' Publication Safety Value to Food Workers

Ruth E. Cade, Editor, The Staley Journal, A. E. Staley Manufacturing Company, Decatur, Ill.

While the employees' magazine is not a new institution, it is only in the last few years that its number has increased to any great extent. Also it has been only within a comparatively few years that such publications have taken on the aspects of a real magazine.

Until a few years ago the editor of such a magazine was more likely than not the factory handy man. He helped in the employment office, the personnel, safety and insurance departments, and edited the magazine between times. Everyone, including himself, wondered why the company wasted money having such a thing printed, for it was, quite naturally, a jumble of odds and ends.

Then, a few foresighted employers began to see the good which was buried in these publications and decided to dig for it. First one company and then another turned the editing over to one man whose major duty it was to edit. Some companies were even so possessed of the pioneering spirit that they hired trained editors for the job. But it was several years before that departure was regarded as anything but rank foolishness.

With the management just waking up to the possibilities of an employees' magazine, then, it is not at all surprising that the employees do not yet realize how fully they can use such a publication. In some cases they never will, for there are always cases where things do not work out as they should. But we are considering the more ideal conditions.

There are generally two reasons which are responsible for the publication of an employees' magazine. As a rule such a magazine is published to promote better fellowship among the workers, or to promote safety among them. I believe firmly that the better magazines are not overbalanced either way but devote the proper attention to each. In fact they are so closely interwoven that it seems hard to separate them.

Of course, speaking as an editor, I would say that no magazine can be its best and do its best if it is ruled by a higher-up blue pencil. If a magazine is to do the most good its editor must have as his motto that timeworn bit—"of, for and by the people." I am not a radical in any sense, but observation has shown me that employees' magazines edited to please some one man or group, are missing fire.

We here are all concerned especially with factories which manufacture food products but I cannot see wherein our problems differ greatly from those of an editor in a plant where freight cars or linen sheets are made. We are all working with and for human beings.

And it is just here where you laymen, if I may so call you, have your part. The editor may have all kinds of freedom of tongue and pen, but unless the people whom he serves work with him, his efforts will be so much waste motion.

As has been said before, the magazines which more nearly approach the ideal, seek to promote good fellowship and safety work. Those two things cover a wide field of endeavor. But it is for you as well as the other fellow for whom this work is being carried on, remember, and each one of you must do his part. And this is how—

Primarily a magazine must be read if it accomplishes its purpose. It will be read if it is attractive. To be attractive it must be well printed, well illustrated, well written and newsy. You will say—that's the editor's job—and it is, partly. The editor must see that the type is easy to read and attractive to look at, that the paper is good, that the halftones are clear, that the cartoons are well drawn and really funny, that the articles are well and interestingly written. He must also see that

is newsy, holds the reader's interest and leaves him eager for the next issue. If he can't do all of these things and more, he is a poor editor and should seek other work.

But an editor cannot sit at his desk nor even spend hours each day with the plant people and just absorb interesting news. He, if he is anything of a newspaper man, will get a lot of copy, but the finished product will be just him. It is only when very one concerned gets interested to the point where he comes in with contributions, that an employees' magazine is really "of, for and by the people."

Your magazine is your mouthpiece, and if you have a worthwhile scheme you want to put across, talk it over with your editor and see if he can't help you. For instance, nothing helps along the general good feeling among a group of workers more than organized athletics. And how better can such activities be fostered than through the press? If your town is not too large the local papers will give you some publicity, but your best bet is your own factory publication.

Go to your editor, tell him about your team, help him to get the score after each game, help him to get the players together for a picture. Tell him, above all, little incidents which come up at the games and practice. Everyone likes the feature stories as well as the straight news. Remember how, just before the recent pugilistic battle at Soldiers' Field you read the feature stories in the newspapers? Westbrook Pegler, among others, wrote columns every day of straight feature stuff for one of our big Chicago dailies and I'll wager it was read as eagerly as the straight news stories on the same event.

Practically every factory nowadays has a fellowship organization of some kind, which gives parties or other entertainments during the year. If your work is that of taking charge of those affairs, learn to use your magazine for all it is worth in giving them publicity. Give your editor advance stories on each party and then give him good follow-ups after it is over. You and the editor together should make these parties such a grand success that by the end of the season no hall in town will be big enough to hold your crowd.

Everybody Likes to See His Name in Print

Human beings like to see their names and their pictures in print. Keep this in mind when you are talking to your editor, and tell him bits of news of the people in the plant with whom you come in contact.

If you are the safety director at your plant I hardly know how you can carry on your work unless you use the magazine for all it is worth. Bulletins may be posted about the plant, meetings called and foremen instructed to talk, but the families will not know of this unless they read about it in the magazine. Then it will become generally discussed in the homes and the men will feel that safety is something which carries over after the whistle blows.

There are a great many ways in which safety material can be used in magazines. The best thing for you to do is to get together with your editor and map out your publicity plan for a year in advance. Some editors devote certain pages to safety each month, while others scatter safety material through the magazine. It is a much argued question which is the better, and I am inclined to think it is a purely local matter. Like spats and monacles, what will do for one community will not do in another.

Whether your safety material is used in concentrated or scattered form, however, it must be carefully selected and written. I may bring a storm of protest down upon me when I say it, but I believe safety articles written about local cases, cartoons and pictures which have a local interest, are much more effective than those furnished by a clipping service.

Factory workers are not, as a rule, great readers. Being human, too, they will slide over stuff which they think is put in there for their good, unless there is some

way to catch their attention. If they catch nothing familiar at first glance, probably they will go on to the next feature. But if, on the other hand, you can intrigue their interest by using local names and incidents, they will read the whole thing.

I know the argument put up is that the people publishing the clip sheets are specialists in safety and have a better knowledge and better ideas on the subject than the average editor. I grant that, but while I think these services are excellent, I am convinced that as a regular diet, unmixed with local color, they soon lose their power.

Subscribe to your clipping sheets, read them and see that your editor reads them, but use only those parts which apply to your needs. Mix these well with local stories. This means more work for the editor and the local safety man, but the results, I feel, will be worth it.

In the plant with which I am connected, products from corn are manufactured and two of our greatest hazards are dust explosions and infections. Of course, dust explosions will occur even when workers do not carry matches, but we keep up a war on match carrying just the same. We do this by story, picture and cartoon. And we do the same with our war on nails. Grain doors left carelessly lying on the ground with nails pointing up are a special peeve of ours, and we bring this subject up occasionally in picture and story.

One of our problems has always been to get the man with a small cut or scratch to report to the first aid hospital at once. We have used, in the *Journal*, a great deal of publicity about our hospital, and I believe that has helped greatly in reducing our number of infections and increasing our number of first aid treatments.

I could go on and on telling you my ideas, but I think I have suggested one of the important ones—that your plant magazine should be yours to use, and you owe it to your company and your job to use it. If you are not well acquainted with your editor, make it a point to get to know him. Learn that, although their life work is publicity, newspaper people can keep secrets better than anyone else. To help you best your editor must fully understand your proposition, so do not hesitate to make him your confidant. I am sure he will, in return, work with you for the betterment of your plans for your work.

All of this time I have been going on the assumption that in each of the plants you represent a magazine is published. If you come from a company which has no such publication, suppose you take upon yourself the task of starting one, or seeing that one is started. It need not be elaborate nor expensive at first—just a publication appearing regularly and being “of, for and by the people.” If you do make the effort it will be only a short time, I am sure, until both employer and employee will thank you.

Most Plants Are Interested in an Employee Publication

CHAIRMAN SUTTON: How many here are representatives of companies who have their own plant publications or employees' publications? Will you raise your hands?

Whether you have a plant publication, I know you are interested in this paper and this subject, so we should like some discussion on employees' publications.

Miss Cade, you mentioned something about the handy man sometimes being the editor of the employees' publication. Is it feasible in an ordinary plant to have one person devote his entire time to such a publication?

MISS CADE: Of course that depends entirely upon the plant. My idea was that the best magazine is the one that accomplishes its purpose best, that has for its editor one person whose major duty is the editing of it. Only in the smaller plants is the magazine handled by one whose editing work is a side line.

Our magazine was started about ten years ago by a man who was safety director.

His idea was all right, but he would just throw together a few ideas and his ideas were much better than his results.

MR. ALGER: I think we should call on Mr. Hennessy for the reasons why our publication at Argo fell through. They had a lot of experience.

M. M. HENNESSY (Corn Products Refining Co., Argo, Ill.): I think the reason our publication fell by the wayside was due to the fact that I started it, I being a new editor of the kind that Miss Cade just mentioned. It went along very nicely for a year or two and then we finally discontinued it altogether.

I think Miss Cade's magazine is the best in the starch industry and contains a lot of information for the people.

CHAIRMAN SUTTON: To revert to my question again, as I understand it, the distinction is that a handy man edits the paper in his spare time or just when he gets to it or when his major duties do not interfere, and an editor can devote himself chiefly to the paper, even though he devotes some time to other things?

MISS CADE: Yes. Quite often among our plant publications we find editors whose major duty is editorial work, although they usually have some other work to do also; they are the editors who recognize their responsibility for their publications.

CHAIRMAN SUTTON: In your opinion, can an employees' publication succeed where the editor has other duties, even another occupation which he holds on a par with his magazine work?

MISS CADE: That depends, of course, upon the editor. Like mixing golf with business.

An Excellent Paper in the Home Safety Division

ALBERT H. RICHARDSON (General Electric Co., Erie, Pa.): I don't have any questions to ask Miss Cade, but I should like to supplement a few of her remarks, and possibly at the same time answer your question.

I am very much interested in plant publications. The majority of editors of employees' publications (and I have met over a hundred), edit their publications only on part time. I don't think there are over a half dozen who devote full time to their publication work. In my experience, it is a part time job, yet I am responsible for getting out the paper each month; so for that reason you might classify it as a major job as it must get out on time if it is to be of value.

What Miss Cade said about making it interesting is, of course, fundamental; it has to have a lot of safety items in it, local color, to be of particular interest. If you will fill it up with boiler plate or clip sheet material, it will soon lose its appeal.

I wish that every person here who is interested in plant publications (and even if you are not), would get a copy of the proceedings of the Home Safety Section and read the talk by Mrs. Bertha Winter Mahoney, "As the Home Keeper Sees It," given in that section on Monday afternoon.

She told about safety in the home, and I think you will all agree that a big factor of safety in the plant is the mental attitude which the man brings to work with him, and that attitude is directly related to home conditions. If there are accidents in the home before he leaves for work, he is more or less upset and there is likely to be an accident in the plant; or if there are people at home who are fearful of his getting hurt at the plant, that has a direct relation to his work. There is value in having safety articles in your publications, addressed to the folks at home, if you give those articles interest and local color.

MR. ALGER: I should like to inquire about the method of distribution and whether a fee is charged; if there is a fee, of what particular advantage is it?

MISS CADE: We give ours away, but some companies do charge for them. They say they charge for them so their employees will realize they are getting something worth while for their money and will read them and take them home, but we never have found our employees undervaluing our publication. We do have a price on the

front of it, but that is because two or three news stands have asked for our magazine; they put it on the stands every month and sell perhaps a dozen copies. That is the only reason we put any price on it. The distribution is accomplished through the foremen every month and some are sent by mail.

CHAIRMAN SUTTON: All of this discussion is very interesting. If you find time, I think you would enjoy the meetings of the Employees' Publication Section. The matter of distribution, for instance, has been thoroughly discussed in that section; some insist one way is better while others think another way is better.

C. J. STROBEL (Wagner-Taylor Co., Philadelphia, Pa.): I think when we read in national magazines such articles as "Every Woman Her Own Electrician," "Every Woman Her Own Gas Fitter," and subjects of that kind, and advertisements illustrating a woman washing dresses in gasoline or looking for the gas jet with a match, we should do something toward censorship of those things.

CHAIRMAN SUTTON: Just what do you mean by censorship?

MR. STROBEL: I think they should be gone over by people who know about them before they are sent out for publication.

CHAIRMAN SUTTON: I think we all agree that there is a great deal of danger from that source, but how could we do anything in regard to it?

MR. STROBEL: In connection with one advertisement I remember I wrote to the advertiser and got a nice reply and it was corrected.

CHAIRMAN SUTTON: About the only censorship I know that we could effect is for someone to regulate this through the editors; someone who sees those articles in a popular magazine write a nice little spiel for your plant publication, pointing out the dangers, and in that way protect your own employees. I hope that some time the National Safety Council and other agencies in the safety movement will effect legislation that will place a censorship on just that sort of thing. Returning to the subject of plant publications, Kellogg's have a magazine now, haven't they, Mr. Smoke?

FRANK SMOKE (Kellogg Co., Battle Creek, Mich.): About a year ago we started the idea of a plant publication, then we got in an efficiency man. But we are rid of him now and we hope to get back into it again.

CHAIRMAN SUTTON: In other words, watch our Smoke.

MR. SMOKE: Our plans are all laid and I think it is going through this time.

CHAIRMAN SUTTON: If there is no further discussion, we will pass on to our next subject, an exceedingly interesting one that concerns us all, by Mr. M. M. Hennessy who is safety and employment manager of the Corn Products Refining Company at Argo, Illinois.

Keeping Safety Alive in the World's Largest Starch Plant

M. M. Hennessy, Safety and Employment Manager, Corn Products Refining Company, Argo, Ill.

As Mr. Sutton said, "Keeping Safety Alive in the World's Largest Starch Plant," or the world's smallest pickle factory—it makes no difference—is my subject. We are all out for the one purpose, the saving of life and limb, and I am just going to try to hit the high spots of what we are endeavoring to do at Argo, which happens to be the largest starch plant in the country.

If you will permit, I will just run back a few years to 1911 when we first started. At that time if we had an accident we found out what caused it and then put a guard there. Our only thought at that time was guards; we never thought about personal contact, at least we didn't do much about it. A lot of you fellows were ten years ahead of us. But we finally got our plant well guarded, but with no first aid, no nurses, no examinations—we hired our men at the gate, the foreman

assing on them. There was plenty of labor, immigration was heavy, so all we had to do was to go to the gate for one man or 15 men.

But we soon got away from that condition in 1919 and 1920, years that we all know. The first thing we got into was the shortage of labor; they took all our young men into service and then they cut down on immigration. We didn't pay much attention to safety even then; we got busy on production—"get the men and get out the stuff"—we were not even so particular about the quality in those days. But we had accidents and we had plenty of them. It was not an uncommon occurrence to see ambulances about every day, sometimes a man lost a leg and sometimes one was killed outright. No doubt it was the same in your plant.

Labor turnover was tremendous, and we all know that is a big cause of accidents.

After the war, conditions changed and we all began to take inventory to find out where we were, not only on production, cost and quantity, but on labor. Labor had become pretty scarce in 1921, although there was slight depression in our company and probably in yours.

Checking Up the Causes of the Accidents

And then in the interest of safety we began to check up and find out what were the causes of accidents. Our plants, we found, were well guarded, we had our different insurance inspectors and engineers making monthly inspections, and still we had accidents. We decided then and there that we had to get to the men themselves. It was a big job. How were we going to do it?

We started off by making a few changes. I might say that at that time in our organization we had a good many foreigners, some of them straw bosses, and each of those fellows would bring in his own particular clansmen—forming a separate tribe in each department, a clique of itself, a separate company, you might call it. Of course, we soon decided that was bad, so when the young men returned from the service, we began putting them in positions, wet starch and dry starch, where we never thought we could let young people work, where we had always used foreign labor. These young people soon broke up the Greek and Polish combinations and now we have what we call an American combination. We even have a sprinkling of colored help.

I might mention that colored help has proved of value to us: colored boys work also in our restaurants, our locker rooms, and prove very efficient. I know a little group on the outside of Chicago who say they prefer Mexican help, while others wouldn't have colored help at all; but so far as we are concerned, colored help has been very satisfactory. I might add that they have helped us reduce accidents, too; we can talk to them, while our foreign labor couldn't understand us; we had to talk to them, and print our signs in a foreign language.

As I said, in 1921 we abolished the employment of so much foreign labor, saying, "You speak English, understand us, or we don't want you." I think that change from foreign to American foremen has been a great help to us; they take an interest in their men, get their confidence in many ways that they couldn't in the old days. Now we handle most of our so-called welfare problems by putting them right up to the foremen. If he runs up against a problem too big for him, he takes it up with our legal department, but anything of that nature must come through the foremen.

I might just say a word about the employment department, which is strictly 100 per cent service; we are there to give service to the employees no matter what it might be. We are the first contact with the new employee when he comes in and we give him a physical examination, not a heavy one, only taking about three minutes, just long enough for us to look for such conditions as hernia, bad eyesight, and such things; then we give him a safety talk, telling him what kind of plant he is going into, describe the hazards, warn him against smoking and tell him to be care-

ful around the machines. We give him a short form letter and then send him down to the foreman.

We handle safety matters in the employment department; we have about 200 houses that we sell to our employees; we have a lunch room and a store, and we have a stock selling plan and group insurance. We try to handle everything that we can in the interest of our employees—we even go so far as to make up wills for them sometimes, and we have occasionally arranged with the local undertaker to take care of any trouble of that kind. All those things help us in the safety work, because when we help our men in those things, we get their confidence, and when we go to them with suggestions and hold meetings, they respond readily, and let us know all that we want to know. I believe that personal contact has more to do with the elimination of accidents than anything else we can do.

In our first-aid room we have had doctors and we have had nurses, in time past, who weren't of any great help to us in safety work; for you might have a doctor who is a little uppish or who becomes too disgruntled when a fellow comes in perhaps a little too often for a minor injury. That sort of thing doesn't help, for when we have people like that there, the men won't come in. So we brought the first-aid room right up to the minute, with good doctors, and it is a very satisfactory arrangement. When a man seeks first-aid for any kind of serious injury, we of course follow that up; we send him to one of the best hospitals in Chicago, and we have skilled medical men do all the major work. We have a special list of these doctors.

How the Safety Organization Works

Our safety organization works something like this: We have a committee, composed of a man from each department, which meets monthly, and it works out fairly well—not so well as we should like to see it, however, for we don't seem to have success in getting our men to offer suggestions; but occasionally one of our fellows develops into a real live one and becomes a real worker. At these meetings the investigation of accidents is gone into very thoroughly; we question the foreman on the job and our safety department recommends changes in order to eliminate any possible recurrence of an accident.

We write up every accident on a special form; that is, the form is filled in to show the name of the injured person, his department, the time, how it happened, on what machine, whose fault it was, his, ours, or the company's fault. We of course have to be the judges, so we consult all interested before we make our decision. It is a very satisfactory way. In case of a lost-time accident we hold a meeting in the particular department in which it occurred. We go down and tell them that Tom Jones got hurt, how he got hurt, and then we show the gang how they could eliminate that sort of accident. I think it is a very good thing because everyone is present, and because we run three shifts and try to make all three shifts with our talk, that accident is advertised thoroughly in the department in which it happened. We occasionally hold mass meetings; we take a whole division and have the boys there from the Chicago office and our own manager gives a short talk or brings in some interesting outsider; I think bringing in outsiders has a whole lot of weight.

Not so long ago, Isaiah Hale, of the Santa Fe, talked to a group of our foremen and did more to stimulate them than any speaker we ever had; he had a real message, and talked for a solid hour. You have got to sell your foremen, of course, on your program; you have to put it across to your foremen first.

We have the usual run of National Safety Council posters and we put all those up; we also have a clock at the gate which shows the number of hospital and lost-time accidents, just as all of your probably have a race track or something else. Having the accidents posted means a lot, where you don't have too many, for a lot of the men will know the man who got hurt and will be interested in how it happened.

We have three or four other plants and we have competition between them for the best record from year to year. Last year the Pekin plant made a very good record. That has helped us a whole lot in reducing our accidents, and we have gone into it vigorously this year.

I know we have all had good records in the last year or two; I know our company has reduced its hazards due to our organization work. There is no question about it; if you have good organization you can put it over. Just the general conditions since the war have certainly helped us to put over our good record, which before was cut down because of our labor turnover. When we have brought it down to the very minimum, we can throw out our chests and say we are sitting on top of the moon. But we have to cut down the accidents per month, and I am just going to give you our record because I think it is a fairly good one in spite of general conditions, and while I don't say our safety organization is perfect, it functions better every day, and if you have any suggestions, I certainly will be glad to have them.

In 1919 (of course that was a bad year), we all had bad records: we had 272 lost-time accidents, an average of 22 accidents per month during the year. 12.6 accidents per hundred employees.

In 1920 it ran somewhat better, and in 1921 it was reduced because we slowed up a little. In 1922 we started improving, until in 1926 we made a big reduction—only 32 lost-time accidents during that year, against 272 in 1919. Our average lost-time accidents per month for 1926 was 3.2 per 100 employees and our average lost-time accidents per month was 5. This year we have had 23 lost-time accidents up to September first, against 128 in 1920, 92 in 1921, 95 in 1922, and 89 in 1923, for the same period. We have had some minor lost-time accidents, but we started out this year with a determination to improve, to make a 50 per cent reduction over the year 1919. We went to our departments, talked with the gang, started off right.

I don't think there is any question that your plants are well guarded; these days they all are; so we are working with all our force to get to the man. Our manager has department is accessible at all times, so I think we are working it out successfully.

Getting Out Clever Home Made Posters

CHAIRMAN SUTTON: I might say in connection with the 50 per cent reduction, they are getting out some clever posters, home-made posters.

Miss Cade spoke about the plant publication referring to local injuries, having items on local injuries instead of your clip sheet stuff; and I think that is true of your posters, for notwithstanding the splendid ones the National Safety Council furnishes, you can get out better ones, more effective ones because they apply to your own employees, your individual problems. So keep your eyes open for those opportunities and get out home-made posters. They are wonderful things with which to get results, and those posters you people have been producing are exceedingly impressive, the ones you used in your 50 per cent reduction campaign.

Now let's indulge in some discussion on what Mr. Hennessy has said, or anything that occurs to you in regard to safety.

H. P. WARREN (Minute Tapioca Co., Inc., Orange, Mass.): I should like to ask Mr. Hennessy who is the man who is responsible for safety.

MR. HENNESSY: The general manager is responsible.

MR. WARREN: To whom does the doctor report?

MR. HENNESSY: To me. I think it should be that way, the general manager is a pretty busy man, and anyway the general manager doesn't know a thing about any of the fellows and we should know about every individual, his home life and so forth.

F. T. COLEMAN (Continental Bakeries, New York City): I should like to know, Mr. Hennessy, how you operate your competition; if you have four plants, what reward you make.

MR. HENNESSY: Will you explain it, Mr. Algers?

C. J. ALGER (Corn Products Refining Co., Chicago, Ill.): In all accident competition between plants, the first thing to stay away from is handing each individual a premium, if you want to keep up enthusiasm. We have over a period of 11 years handled accident competitions, and we don't give premiums unless a man saves another man's life, and then we hand him a gold watch.

For this accident competition between the plants, a trophy was selected last year, designed to carry a safety message. For recording the progress we had a clock. Incidentally the trophy cost about \$200. The competition was so keen between Argo and Pekin that we didn't know until the last week who would win. This year we have a similar trophy which will be presented to the plant that has the best accident record based on severity and frequency, and while Hennessy at Argo is in the lead, they haven't won yet. I think we shall make further progress.

MR. COLEMAN: We have a little different proposition, for we have 100 small units all through the country, each in charge of a manager, and I can't see how we could run a competition where there are different hazards in different groups of men; I should have to take the managers' word for the records.

MR. ALGER: I think if we were in that position, we would pick out the larger plants and confine our efforts to the ones having the larger number of employees. You will find two or three of the insurance companies willing to cooperate in accident campaigns. In our plant at Edgewater there are two banners to be awarded.

H. P. WARREN (Minute Tapioca Co., Inc., Orange, Mass.): Let me ask whether you have your costs figured. One concern may spend a great deal for safety and another not so much. Is that taken into consideration?

Few Safety Recommendations Possible Today

MR. ALGER: When we started in on the safety work, it was my job to go around and recommend safety measures, and they were made uniform in all plants. Today I could go through the Argo plant and make less than 10 recommendations whereas once I could have made 300. It required spending in 13 years about \$114,000 on safeguards. We spent a lot of money usefully and perhaps we wasted a little, but today our problem is much easier for it.

H. T. EGGERT (National Biscuit Company, New York City): Can you tell us how most of your accidents occur; that is, are they the result of the operation of machinery or the result of carelessness?

MR. ALGER: Carelessness. A lot of supervision is required. I am speaking of manufacturing accidents; for example, in our plant at Argo, where we handle quantities of dried feed and have a steam dryer, a welding operation was being conducted, causing a flash. That is the fault of the safety department; we should have known the danger of such a condition with dried feed. It is not always the carelessness of the worker. We have had one man go around the shaft in a couple of years, and that accident was our fault. Most of our accidents decrease under careful supervision. Train your foremen and safety man.

MR. EGGERT: What percentage of your total accidents are machine accidents?

F. A. HASSE (Corn Products Refining Co., Chicago, Ill.): They are under 5 per cent, aren't they, Mr. Alger?

MR. ALGER: Yes, from 3 to 5 per cent.

MR. EGGERT: Our experience would about correspond with yours?

MR. HASSE: As I recall it, we had a total of four actual machine accidents in 1926.

MR. ALGER: We have at least 300 punch press operators in all of our plants, punching tin plate.

MR. EGGERT: Do you have many hand trucks in use in your plants?

MR. ALGER: Yes, quite a number.

MR. EGGERT: Do you have many toe accidents? Principally where a man pulls truck, resulting in a fractured toe or some bad foot injury.

MR. ALGER: We do at all our plants, but we have some accidents that are worse in toe injuries; for instance, when a man is caught between a truck and a car door.

MR. EGGERT: We have had some bad experiences with hand trucks.

MR. ALGER: The thing is to keep them in condition and load them properly.

MR. EGGERT: They are supposed to be in splendid condition, and are supposed to be loaded properly, but it seems that our men will continually pull these trucks over their feet, chiefly over the toes. We probably have 30 toe injuries per month. Of course they are not all lost-time accidents; maybe there are five or ten lost-time accidents per month.

MR. ALGER: How much of a load do they carry?

MR. EGGERT: It varies from 500 to 1,500 pounds. We have two types of trucks, one of them with four wheels, one on each corner, and the other has four wheels arranged in a diamond shape which tips when moved and something lands on the man's foot. We have had an idea of moving the wheels back, but that won't work out. I have been working on safety shoes and am interested now in a shoe that is put out by a certain manufacturer, and we have about 15 pairs with which we are experimenting.

Bread Racks a Source of Minor Injuries

F. T. COLEMAN (Continental Bakeries): We have the same proposition as the National Biscuit Company. We have many bread racks and the men jam their fingers and run over their toes. I have tried to get the men to push the trucks rather than pull them on account of this and also get away from back injuries, but I can't get them to do it. Consequently they get their hands jammed against the post or other racks and their toes run over, but I am going to keep at it.

MR. ALGER: You have your poorest class of labor on that, don't you? You start your men on truck jobs?

MR. EGGERT: Yes, our lowest grade of labor.

C. J. STROBEL (Wagner-Taylor Co., Philadelphia): In trucking in the warehouse, our men push all their trucks and the truck handles are extended out.

MR. EGGERT: That is all very well in most cases where there is a man in the front and a man in the back, but when you start pushing, you get those back injuries, the kind that don't get better.

CHAIRMAN SUTTON: You spoke of handles on your trucks. Maybe Mr. Coleman has a problem there.

MR. COLEMAN: If you put handles on them, you can't get so many on the rack. The operating department objects to handles.

MR. STROBEL: Why can't they put handles on the inside of the stays, the same as trolley car handle.

CHAIRMAN SUTTON: It seems to me that such a handle would interfere with the amount of room.

MR. STROBEL: You must have support for the stays; why not put them on the inside?

MR. COLEMAN: There are shelves on these racks.

MR. STROBEL: How wide is the support?

MR. COLEMAN: You couldn't get a substantial handle on it.

MR. C. J. STROBEL (Wagner-Taylor Co., Philadelphia, Pa.): I mean the width of your upright; have your handle there.

MR. COLEMAN: You have the same proposition. They will just reach around the outside and not use the handles.

MR. EGGERT: They slide pans on ours and inside there is no room for a handle.

We have several bread plants, but fortunately we experience very few injuries in our bread plants; most occur in our cracker plants and carton plant.

MR. COLEMAN: In regard to competition, I just had a contest for no accidents, based on the boxing idea, having bantam weights, middleweights, heavyweights: bakeries up to 40 inside employees in the first group, and so on. Lost-time accidents would count as knockout blows, but there were so many bakeries that had no knock-out blows in the six months I can't decide which won, and there is only one prize. Being so widely scattered makes it such a difficult problem.

MR. ALGER: You will have to go through with them; after what they accomplished that ought to be worth the money.

ALEXANDER DIENST (National Sugar Refining Co. of New Jersey, Long Island City, N. Y.): We have electric trucks and all kinds of trucks and very little room, pretty close quarters, but I must say we have very few accidents of this nature. The worst thing is scraping of the hands, and we attribute the solution to education, which is the only thing I believe will overcome it.

MR. COLEMAN: That takes us back to the same problem—personal contact; put it up to the foreman and hold him responsible.

The Foreman Should Be Held Responsible

R. G. STRATTON (Travelers Insurance Co., Philadelphia, Pa): This gentleman has touched upon one of the most important things, the holding of the foreman absolutely responsible for accidents in his department.

Some years ago I had quite a liberal education in Battle Creek, so I feel qualified to speak. I think you are unfortunate in this, because you produce a product having so low a unit value; in other words, the purchase price to the retail trade is in the minority of trade value, and this is all the more reason why it is so important to your work to remember the incidental cost of accidents and all the more reason why the foreman in his department must be held directly responsible for the accidents.

Executive participation is essential. Many times this will be put off because it is thought a foreman will resent being held responsible for accidents although he really is, and he should be shown that an accident is a breach of economy.

If any of you have read the recent brochures put out by the National Safety Council, you will realize how important that is. Just multiply the cost of your accidents by four or more and put that amount directly out of your pocket as loss.

The condition here is one of supervision, for this reason: Any accident that happens in a department of a plant, with the exception of one in a million, is not the first time the condition which caused it has existed. In other words, the bruised hands, the bruised feet, and other accidents are typical of what results from the same condition persisting without correction. A man in charge of a department where such injuries occur frequently, has seen day after day this condition promoting the accidents and probably has done nothing to stop it, and that is why, if he is held responsible, he will, through eagerness for advancement or perhaps through hope of monetary gain or retirement at a later period in his employment, do all he can to promote the interest of safety.

There are a few excuses a foreman will give that he should never give when there is an accident. If you insist that a foreman investigate each and every accident and report on it to the safety man or the general manager or the head of the department, and let him decide in his own mind what the incidental cost of that accident is, it will set him thinking.

Establish an accident court of inquiry and hold periodic meetings in regard to an injured employee, and then you will produce a condition in your plant that will make the foremen realize their responsibility. As soon as they realize that they have a

responsibility not only to the company but to the other employees, particularly those near them, you will have fewer accidents. I have seen the thing happen when every accident absolutely ceased.

M. HENNESSY (Corn Products Refining Co., Argo, Ill.): We once a year send an itemized list of all the accidents occurring in our plant; and we apply the cost of each accident to that?

R. STRATTON: Perhaps I didn't make myself clear, for in speaking of the incidental cost of accidents I meant the incidental cost to the concerns as compared with medical, the cost in loss of production, loss of time in taking him to first-aid station, the time lost by other employees in running to the scene of the accident and talking about it afterwards. Accumulating those facts together gives us the total cost to the manufacturer, of the accident.

CHAIRMAN SUTTON: That brochure you spoke of was gotten out by your company, was it not? How can we as individuals obtain copies of it?

R. STRATTON: Anyone is privileged to write our home office, the engineering division, and it will be glad to furnish any number of them.

RANK SMOKE (Kellogg Co., Battle Creek, Mich.): Referring to Mr. Stratton's remarks about his experience in Battle Creek, I should like to add that the Kellogg Company as a whole has had a lot of experience with Mr. Stratton. Years ago he worked on us monthly and I want to say he is very capable.

T. EGGERT (National Biscuit Co., New York City): You say the ratio runs four times the expense for compensation; but I suppose, however, that that is determined chiefly by the state in which the accident occurs because the rate for compensation varies and also according to the amount of remuneration received—trained mechanics, for instance, receive more per hour than unskilled labor. Under these circumstances don't you think it is rather difficult to arrive at an average for all injuries?

The Incidental Cost Four to One

R. STRATTON: In making our study of this, we took into consideration all of the factors by which the cost would be affected and averaged them, and that average is four or more, so it really matters little what states are concerned, whether the state has a compulsory code—such as Ohio and six other states—or not, whether the minimum and maximum limit. It makes no difference whether it is a high wage earner or a low wage earner, because it is an incidental cost; in other words, a highly paid man is connected with or in a group with other highly paid men, and the comparison is made with his associates. Perhaps in that case we have proved the ratio quite low in estimate, but the original study of some 15,000 accidents led us to the ratio four or more with no classification.

CHAIRMAN SUTTON: I want to say that you will find that brochure not only of great interest, but of value in selling safety to the higher-ups.

D. J. STROBEL (Wagner-Taylor Co., Philadelphia, Pa.): I submitted a question a short time ago to the Travelers on a proposition that came up in regard to the manufacturing costs of accidents—why not charge it up to the injured or to the foreman? The reply came back that that would be a poor policy, but I understand it was put through.

MR. ALGER: I should like to know how some of you go about the inspection of elevator elevators.

MR. EGGERT: We have all our elevators inspected by the Otis Elevator Company, and in addition we have our own inspections.

MR. ALGER: Just what kind of a test do they make?

MR. EGGERT: They thoroughly test everything, in general.

MR. ALGER: Does anyone else inspect that way?

MR. COLEMAN: We are doing the same as Mr. Eggert's company.

MR. ALGER: I am going to tell about an accident we had, for I am wondering whether your experience has been the same. We have had a very serious experience, we had an elevator fall, and it opened our eyes. Now we check up the inspector regardless of who it is.

MR. COLEMAN: That would be a pretty big job for us, with 100 plants. You would need a pretty good man who is technically trained.

MR. ALGER: He could spend a day at each plant.

MR. SMOKE: Regarding your checking, we have a system by which a regular safety inspector goes through the plants regularly, then the Otis Elevator people inspect them, and finally along comes our good friend, the Travelers, checking monthly, so we have a three-way check.

I wonder if you have in mind some careless tricks of employees between inspections. We have an elevator in our corn mill which gets rough usage and lots of it, and the men will get careless in making repairs on it so that in one case it went to the basement, but that was a case where repairs were made temporarily and there was no chance for an official inspection of it.

MR. ALGER: It requires two men from an hour and a half to two hours to properly inspect elevators.

MR. SMOKE: That is true. We also have a millwright in our department who is supposed to have charge of all the elevators, and that millwright goes around with the inspector, so with him, we really have four men to inspect our elevators.

MR. ALGER: Do they trip the safety dogs?

MR. SMOKE: Everything is tried out as to load capacity.

MR. STRATTON: I want to introduce myself in another capacity, as a member of the National Safety Council A. S. M. E. safety code committee on elevators, and I want to say that, frankly, you are treading on dangerous ground when you consider inspection of elevators from the layman's point of view, particularly in the inspection of safeties, unless you are positive you have in mind sound principles and rules of safeties and can trip them without serious injury to the safety cable; but I will guarantee right now they can't be taken out and put back in the proper condition unless it is done correctly.

I can take you to places where brand new installations have dropped out and where old type installations are still giving excellent service, and you wonder how the heck they are doing it; so you have to take a grain of salt perhaps along with it, and trust to the insurance inspector that he is doing his best with the equipment you have under your control.

At present we are conducting in Washington a test through the Bureau of Standards and the A. S. M. E. Committee that will probably prove a revelation in connection with the 210-story building to be constructed in New York for which we have to revise everything.

So what I want to bring home to you is that you have got to trust to men who are active in the elevator inspection game; they are doing their best, and no one can tell when cables will part, when mechanical defects will crop out before a later day inspection is made.

There are sad occurrences after inspection; I had one which concerned one of the men under my supervision. It was not my fault, and he did his duty, and neither of us could foretell that that thing would happen. If you make as careful an examination as you can, then you have to feel you have done your duty to that extent.

ADJOURNMENT.

Wednesday, September 28, 1927

The second session was called to order at nine-thirty o'clock by the chairman, D. Sutton.

CHAIRMAN SUTTON: The first thing is the election of officers: I shall ask the man of the Nominating Committee, Mr. H. T. Eggert, National Biscuit Co., New York, to give his report.

Report of the Nominating Committee

Chairman. F. A. Haase, Corn Products Refining Company, Chicago, Ill.
Vice-Chairman. H. T. Eggert, National Biscuit Company, New York City.
Secretary and News-Letter Editor, W. P. Penty, Kellogg Company, Battle Creek, Mich.

Chairman Poster, Lantern Slide and Safety Kinks Committee, J. T. Doolin, Casualty Reciprocal Exchange, Kansas City, Mo.

Chairman Membership Committee, W. H. Cunningham, Pillsbury Flour Mills Company, Minneapolis, Minn.

Chairman Program Committee, Frank T. Coleman, Continental Bakeries, New York City.

Chairman Engineering and Publicity Committees, Thomas S. Strobhar, Wagner Electric Company, Philadelphia, Pa.

Chairman Statistics Committee, R. E. Prouty, Aetna Life Insurance Company, New York City.

CHAIRMAN SUTTON: You have heard the report of the Nominating Committee. What is your wish?

J. ALGER (Corn Products Refining Co., Chicago, Ill.): I move the nomination be closed.

(The motion was seconded and carried.)

CHAIRMAN SUTTON: I might add that the chairman of the Poster Committee, Doolin, is also to take on work in connection with posters, lantern slides, safety kinks, and so forth. You will hear more about that through the News Letter during the year. Furthermore, you can learn more about what is meant by safety kinks by consulting the Safety Exchange pages of the NATIONAL SAFETY NEWS. FRANK SMOKE (Kellogg Co., Battle Creek, Mich.): Are we going to vote on this separately or collectively?

CHAIRMAN SUTTON: That will be determined later.

FRANK SMOKE: I want to say this in regard to Mr. Penty and the News Letter. Mr. Penty doesn't feel that he has time to carry on this work and therefore to the service we should put someone else in his place.

CHAIRMAN SUTTON: I talked with Mr. Penty and told him that if he didn't do his work effectively he would lose his job with the Kellogg Company.

What shall we do, then, gentlemen, with the nominations?

It was moved and seconded and carried that the nominations be accepted as presented.

CHAIRMAN SUTTON: Although we are asked to follow as nearly as possible the printed program, this morning we have to deviate a little on account of the absence of Mr. Hubbel, who was to give us a paper on dust explosions. In place of that paper, I am going to take the liberty of putting the last speaker

on first so that we may have it to consider and discuss during the remainder of the morning which we shall devote to more or less informal discussion.

We shall hear now from Mr. Ralph C. Prouty, Aetna Life Insurance Company, New York City.

Statistics—An Aid to Accident Prevention

Ralph C. Prouty, Aetna Life Insurance Company, New York City

The value of accident statistics and records is potential rather than intrinsic. They are but a means to an end and not an end in themselves. They are worth while only when the preventionist carefully studies and analyzes them and applies the results in his efforts to promote safety. Then they become valuable working tools for the safety engineer and the time and expense involved in their compilation is justified.

Inasmuch as accident statistics are based upon accident records, it is thought advisable to consider the records necessary for accident prevention purposes. It is very easy, if one is not careful, to become so engrossed in building up an elaborate set of records, that sight is lost of the purpose for which the records are being prepared. The safety engineer should be constantly on his guard to avoid falling into this error, ever remembering that he must make practical deductions from his statistics and apply such remedial measures as the deductions suggest.

A careful survey should be made by every industrial concern to determine what records are needed for accident prevention purposes. When a system has been established, no additions should be made to it unless it can be shown that the additional data will enhance the value of the records and statistics as accident prevention aids. The records suggested represent the requirements of an average concern.

Foreman's Accident Report

The first report of an injury should originate with the immediate superior of the injured person and it should be prepared immediately after the occurrence of an accident and sent to the plant safety engineer or other person in active charge of the safety work. This report should serve a double purpose. It should give prompt notice to the proper person of the occurrence and bring out vividly the conditions responsible for the accident. Moreover, the requirement that each foreman submit a written report will have a salutary effect on the accident situation as no foreman will care to admit in writing that he has permitted unsafe conditions and practices to exist in his department.

It is believed that the following items should appear in the foreman's report:

1. Department.
2. Date of injury.
3. Time of injury.
4. Name of injured.
5. Duties of injured.
6. Extent of injured's experience.
7. Cause and nature of the accident.
8. Condition of machinery or equipment involved.
9. Where the injured was sent for treatment.
10. Foreman's recommendation for prevention of similar accidents.

When the foreman's report is received by the one in charge of the accident prevention work, its accuracy should be checked by an investigation and the data can then be utilized in preparing a permanent card record of the accident.

the card should provide spaces to show the following items in addition to those given on the foreman's report:

- A. Diagnosis of attending physician.
- B. Probable disability.
- C. Date injured returned to work.
- D. Description of any permanent disability.

It will be noted that several items have been suggested for the permanent record card which are of a medical nature. Undoubtedly, such information can be secured readily in most instances from the first aid room, as the nurse or first aid attendant will naturally keep a record of all injuries treated. No attempt will be made in this paper to specify what medical records should be kept. The requirements will be determined by local conditions such as the size of the plant, the nature of the first aid arrangements, whether the workmen's compensation is insured or carried by the employer and various other considerations. It should be remembered, however, that those primarily interested in accident prevention can often secure much helpful information from the first aid department and from the medical records.

Monthly Accident Analysis

Once each month the permanent card records should be subjected to a thorough study and analysis. This should be done, preferably, at the beginning of each calendar month so that the safety engineer will have the results at hand for the regular meeting of the general safety committee, which is customarily held during the first week of each month. A sheet should be prepared with a list of standard accident causes at the extreme left. The names or numbers of the departments of the plant should then be written horizontally across the top of the sheet. The record cards are now sorted by department and under each departmental heading the number of accidents from each cause is placed opposite the appropriate cause designation. By adding the figures horizontally, the total number of accidents from each cause will be secured. Adding the departmental columns will give the total number of accidents in each department.

Some concerns analyse only the tabulatable accidents, that is, those causing loss of time beyond the day, turn, or trick on which they occurred. Others choose to include in their analyses all accidents reported, on the theory that what caused a minor accident might have caused a more serious one. I should refer to make two separate analyses—one of the minor cases and one of the tabulatable accidents. A careful check of each and of one against the other should show the analyst pretty clearly what has transpired during the period under consideration. The value of the analysis sheet will be greatly increased if the amount of lost time in days is shown by causes and departments also.

If card records containing the information suggested are maintained, it will be possible to make special studies from time to time which will probably throw light on many accident prevention problems. For instance, one can easily determine by analysing the data the percentage of accidents that occur during each working hour of the day, the day or days of the week on which accidents occur with the greatest frequency, and the month of the year during which the accident toll is the heaviest. Studies along these lines have shown in some instances that accident peak was reached between 3 o'clock and 4 o'clock in the afternoon. The fatigue element was suspected of being responsible in a measure, at least, and the flattening out of the peak after the inauguration of rest periods apparently confirmed the correctness of the deductions. Again, such studies have shown that accidents occurred more frequently during periods when artificial lighting was necessary and have led

to improvements in illumination, which not only reduced accident frequency, but also contributed toward better production records.

Just how the results of the analyses should be presented to the official staff and to the rank and file is a problem for each safety man to solve. In any event, he should remember that he is essentially a salesman—selling safety. A good salesman, we are told, recognizes three distinct steps in the sales process. The first is securing attention; the second creating a desire for what he has to sell; the third, intensifying that desire to a point where the prospect is ready to act. What better material can you desire to assist you in selling safety to the management and men than the bulletins, charts, graphs, tables and reports you can prepare from the results of your accident analyses?

Accident Rates

Accident frequency and accident severity rates are the yardsticks used by safety engineers to measure the success or failure of their efforts. It does not do one much good to know that fewer accidents occurred or that less lost time was occasioned by accidents during a given period of time than during a like period of time in the past. Many factors such as temporary shut-downs, holidays, increases, or decreases in the working force, and overtime employment may be responsible for apparent changes in the trend of the accidents and lost time. In order to make fair comparisons, the number of accidents and the lost time must be related to an exposure factor. The best exposure factor generally available is the man-hour-exposure.

The statistical plan used by the National Safety Council contemplates accident frequency rates based on the number of tabulatable accidents per one millions hours worked and accident frequency rates based on the lost time in days per one thousand hours worked. For temporary disabilities, the actual days lost are used in the computation. The amount of time to be charged for a death or a permanent disability is determined by reference to a table printed on the back of the Council form. It has been said that the scale of time charges for deaths and permanent injuries is of doubtful value because complete actuarial justification for the amounts is lacking. A committee is now making a study of the subject and probably will have some helpful recommendations to make when its work is completed. In the meanwhile, it is earnestly suggested that members of the Food Section compute rates according to the present plan so as to be able to make periodical comparisons of their own records and to furnish the National Safety Council with comparable records to be utilized in figuring average rates for the entire Section.

The Section is to be congratulated on the showing it has made in submitting statistical data to the Council. The records of 63 plants representing 20,928 employees were available for the staff engineer in computing rates. The grand total and averages for entire Section for 1926 were as follows:

Average number of employees.....	20,928
Total hours worked.....	36,405,803
Deaths	4
Permanent disabilities	48
Temporary disabilities	1,279
Total accidents	1,331
Days lost—deaths	24,000
Days lost—permanent disabilities	36,337
Days lost—temporary disabilities	18,700
Total days lost	79,037
Frequency rate	23.
Severity rate	1.4

The 63 plants reporting were divided for analytical purposes into six groups. The designation and rates of the several groups are:

1. Confectionery manufacturing—			
Frequency rate	21.11	Severity rate	.32
2. Dairies and dairy products—			
Frequency rate	8.62	Severity rate	.85
3. Milling—			
Frequency rate	22.65	Severity rate	.27
4. Food products manufacturing—			
Frequency rate	20.56	Severity rate	2.48
5. Sugar manufacturing—			
Frequency rate	34.41	Severity rate	.81
6. Food miscellaneous—			
Frequency rate	20.83	Severity rate	2.61

Considering the Section as a whole, it shares with the Automotive Section the honor of having the fourth lowest frequency rate of the sixteen Sections as reported to the Council for 1926. The Cement, Chemical and Textile Sections were the only ones to develop better frequency rates. From the standpoint of accident severity, the Food Section ranked fifth among the sixteen reporting. The Automotive, Power Press, Textile and Rubber Sections had lower severity rates. Surely, this is a commendable record.

Deaths and Permanent Disabilities

A study of the grand total figures brings out some interesting facts. Of the total days lost from all causes 76.3 per cent were due to deaths and permanent disabilities. Deaths were responsible for 30.3 per cent of the lost time—permanent disabilities caused 46 per cent. The Sectional frequency rate may be considered favorable and the data seem to indicate that the present severity rate is at its present level, not because of a multiplicity of accidents involving normal time losses, but because a comparatively small percentage of all the accidents resulted fatally or caused permanent injuries.

All of this points to the desirability of focusing the attention of the Food Section members on their serious accidents. It is suggested that each permanent disability and fatal case be reviewed again by the concerns that experienced them and that careful checks be made to learn if their causes have been entirely eliminated. Possibly some of us have taken too seriously the oft repeated statement that not more than one-third of all industrial accidents are due to mechanical conditions. Perhaps we have depended too much on the educational side of accident prevention and have not given enough attention to mechanical safeguarding and engineering revision. A well balanced program includes a place for each of these phases of safety engineering and it is not difficult to believe that well organized accident prevention work of an educational nature, coupled with intensified efforts along engineering lines, will make it possible for the members of the Food Section to review with pride next year a record that is even better than the one just considered.

(Mr. F. A. Hasse, Corn Products Refining Co., Chicago, Ill., incoming Chairman, took the chair.).

CHAIRMAN HASSE: All of you have listened with interest to the paper just submitted regarding statistics as an aid to accident prevention, and perhaps some of you have a few points you would like to bring out.

FRANK T. COLEMAN (Continental Bakeries, New York City): I should like to ask Mr. Prouty why the insurance companies do not furnish data when you ask for it. I find that any time I try to put an extra burden on them, I run into

all sorts of objections on their part. It seems they are reluctant to give the information which they have in their files.

MR. PROUTY: The question is just a little from the point of the paper.

I want to make this clear, the severity rates and the frequency rates have nothing whatever to do with insurance. I am not familiar with insurance arrangements of the members of the Food Section, but I believe a good many of you are self-insured. The National Safety Council asks for us to arrange with all the members the basic data from which these rates can be figured, with the idea of enabling the members to cooperate with each other.

I presume most of you know this, that when those figures are sent through the National Safety Council, the source is not made known to anyone; no one knows where these permanent disabilities occurred except the National Safety Council staff.

To answer more directly your question (I can't speak for any other company but my own). I assure you my company would be glad to furnish you or anyone else who is a policy-holder a list of accidents, lost-time, man hours, etc.

Make the Records and Statistics Simple

VERN D. SUTTON (Postum Company, Inc., Battle Creek, Mich.): I should like especially to emphasize Mr. Prouty's assertion that records and statistics should be as simple as possible, just so far as they contribute as an accident prevention measure or enable you to do your accident prevention work.

Speaking of the reports to be made by foremen to the accident prevention department or safety engineer, he recommended that the foreman report among other things the condition of the machinery or the equipment involved, and that he recommend a means for prevention of similar accidents.

I should like to ask not only Mr. Prouty but other members what their experience has been when the foreman in charge of the equipment involved in the accident asserts that it is all right and upon investigation it is shown that it is not—that is, have you found any tendency on his part to lie to protect his reputation or to keep his job or for any other reason?

CHAIRMAN HASSE: From the Corn Products Company's standpoint, as soon as an accident happens in our plant, we see that the injured man is taken to the first-aid room and given proper attention; then the foreman investigates just how the accident occurred, and just as soon as his report comes in it is checked up and we soon find out if the foreman is telling the truth. So far, I do not recall where the foreman ever stated the machinery was guarded when it wasn't, or that it was in good condition when it wasn't. I think our equipment is guarded as well as it can be. Sometimes an inspection is made and we find things that we didn't know about; but when brought to our attention, we immediately take care of them.

MR. PROUTY: I happened to find in my file a couple of reports prepared by two different concerns, one a member of this section and the other a manufacturer of artificial leather. You might be interested in how those questions are phrased. One on machinery accidents was, "Was machine properly guarded? Were guards in use at the time of the accident?" Then in small letters, "Answer yes or no. If questions 13 or 14 are answered 'No,' describe fully at the bottom. What recommendation can you make to prevent similar accidents?" There is a space for the name of the machine on which accident occurred.

"Was the accident preventable; if so, what caused it?"

Try to get the information from the foreman, have him tell all he knows for after all he is the key man in your plant.

CHAIRMAN HASSE: As your program will show, and as Mr. Sutton already announced, we have deviated because, I am sorry to state, Mr. Hubbel will not

able to be with us. We have decided to allow an open discussion on matters relating to the problem of preventing dust explosions.

To begin it, I am going to take the liberty of calling on Mr. Alger, of the Corn Products Company, who has been associated with Mr. Price in the Bureau of Agriculture in Washington on the Committee to Prevent Dust Explosions.

C. J. ALGER (Corn Products Refining Company, Chicago, Ill.): I haven't a whole lot to say, but to begin with, being well acquainted with Mr. Hubbel, I want to say that we have a real loss in not having him with us this morning. There is no doubt that his experience and ability in handling and attacking this problem is about as great as any that I know outside of that of Mr. Price's in Washington.

In our industry about three years ago we experienced a decided catastrophe. It was a dust explosion, but the cause is not definitely known. After that trouble in Pekin, we started shaking ourselves up in order to enforce a new standard of housekeeping conditions, the first problem to be attacked being to make things dust-tight.

We were behind the procession at that time, but our engineering department started out to do the job and without any definite data to guide them as to friction losses and that sort of thing, they accomplished considerable. Then after we made our equipment dust-tight, and established a new standard of housekeeping conditions, it was a question of seeing everything was properly enforced. Fortunately our company has always enjoyed the greatest cooperation with insurance carriers, and so we have not only our own inspectors, but the inspectors of the insurance carriers call any time of day or night, to see that housekeeping rules are enforced. Of course, the cleaning and sweeping costs have amounted to considerable.

Circumstances of a Near Accident

We had a flash at Argo about a year ago. That morning we had a breakdown, and one of our representatives found conditions pretty dusty. He didn't waste any time, but went right to the foreman and saw that he cleaned up.

The flash was caused by a trunnion roll dropping out of place, permitting a drum revolving very slowly to heat up by friction, but the workmen escaped. The overhead transmission was thoroughly cleaned; there was some dust, but there wasn't sufficient dust so that the flame propagated to the floor. It started around the ceiling, and the force of it was enough to force outward steel constructed windows five or ten inches. It caused little damage, but nevertheless it proved that the enforcement of good housekeeping conditions is a necessity. Occasionally we may have little flashes here and there, but the extent of their damage is limited.

I don't want to take up a lot of your time, for I know you have had experiences of this kind. We came here to get information about what the other fellow is doing, and I should be glad to answer any questions you might care to ask me.

CHAIRMAN HASSE: So long as Mr. Alger has indicated his willingness to answer questions, I suggest you ask him some.

Many of you handle grain from which we all know dust originates and causes a hazard, so kindly proceed to ask him questions.

W. H. SEWARD (National Carbon Co., Inc., Cleveland, Ohio): Have you ever had any experience with fire starting from dust accumulated on electric light bulbs?

MR. ALGER: We have not, but that could happen, at least so I have been told. We use a vapor-proof globe, a double globe, and have had no trouble.

Getting into the cause of dust explosions, you have a discussion there that will last a hundred years. It can be attacked from almost any angle, but people are correcting the condition today; they have their shoulders to the wheel, and

next week at Boston tests will be made of dust, starch dust and aluminum dust particularly.

C. J. STROBEL (Wagner-Taylor Co., Philadelphia, Pa.): Do you use a vacuum system?

MR. ALGER: In our sweeping and cleaning, we have at times used a vacuum system which I believe in time will be made efficient, although you must admit that a man climbing up a ladder, with a lot of hose, to sweep the ceiling beams, is a difficult task. We use lamb's wool brushes, anything that will get the dust.

MR. STROBEL: I might say the structural members of the buildings sometimes deflect 60 or 75 degrees.

MR. ALGER: Yes, and we have sometimes gone to the extent of filling in all I-beams and making them flush, and our newly designed windows at Pekin have no sills.

FRANK SMOKE (Kellogg Company, Battle Creek, Mich.): At your unloading docks where you unload your cars, what arrangement have you for dust collection, with reference to the health of your men?

Respirators Used in Unloading Corn

MR. ALGER: In unloading corn, we furnish the men with respirators, and we have had no great trouble. The respirators are wetted down before they are used. As you know, kiln-dried corn gives off a lot of dust, so of course, you have a dust hazard where that is being unloaded.

In the plant at Argo, we are finishing a very extensive dust-collecting system; it has been in operation only ten days, but we can already see an improvement.

MR. SMOKE: No oscillating fans to catch your dust and carry it away from your car doors?

MR. ALGER: By all means; we have a duct system over the belt which carries the dust off by suction.

MR. SMOKE: Does it carry the dust off above level, above ground?

MR. ALGER: As we unload, it goes through a steel grating. Of course, with the wind blowing, that is difficult in an outside operation; but as soon as we can we get it down underneath we start picking up the dust.

MR. SMOKE: We have that same arrangement in our new grain elevator tanks. We have over the track under the grain shed, something to take care of that dust, for sometimes we can't see a man for it.

MR. ALGER: Underneath. We don't allow any locomotives to go over that corn; now and then they will drop a spark or two. We have gone after the railroads and we always have received their full cooperation. They put something under the boiler to prevent this escape of hot cinders.

Starch dust would probably ignite at a temperature of 1,200 degrees Fahrenheit.

CHAIRMAN HASSE: I might mention that the locomotives when switching are all equipped with what we call a screen, over the smoke stack; it catches any sparks, and underneath the furnace we have an additional pan which is to catch all hot coals falling from the boiler.

I see we have with us several insurance men who no doubt go through some of these plants, especially where there is a dust hazard, and we should be glad to hear from them.

H. L. BURRILL (Maryland Casualty Co., St. Louis, Mo.): I make the surveys at the Corn Products Company's plant at Pekin, and I will say that that firm is doing all it possibly can to keep down the dust. It looks to me as though the secret of the whole thing is: no dust, no hazard.

I have another plant where we make surveys. They have called upon the safety department to make a weekly test of every single belt in the dust area. This includes not only starch but grain, and a report has to be sent in showing

what is the status of the humidity in that building on every single belt. I keep in that way a very close check on things, and copies are sent in to insurance company, and the inspector goes with the man who makes the test; even though that man has made a test but three or four days before, the insurance inspector has the equipment to make a test of his own.

Do you see a very rigid test and check is kept on everything, so I don't believe there is a possible chance of sparks from smoke stacks causing damage.

W. CHAPIN (Chapin & Company, Chicago, Ill.): We have a feed plant at Almond, and use an explosion valve. We have something like the hotel doors are used in winter, so at no time is there a continuous movement, and that if a tank starts an explosion it won't follow through. That runs vertical instead of horizontal, like a hotel door.

We grind a lot of cotton seed cake which contains a lot of metal; so we run through magnets, but even then a lot of the stuff gets through.

Besides that, we erected a special building for grinding with corrugated iron sides, we have dust drawn off into a cyclone. Since we have taken those precautions, no accidents have occurred.

MR. ALGER: I should like to ask how many wings there are on those valves?

MR. CHAPIN: Four

MR. ALGER: I wouldn't place too much value on those. We have used the butterfly valves and have had flashes through them.

MR. CHAPIN: I will add to that we don't run a continuous conveyor, only about 30 or 40 feet, and then drop it into a tank, so it doesn't run all the way across; if the conveyor is outside, it is covered.

Experiments on the Value of Explosion Dampers

I. L. BURRILL (Maryland Casualty Co., St. Louis, Mo.): What do you think the value of explosion dampers on elevators, extending through the elevators to the roof, with the dampers so arranged that the explosion will take the line of least resistance?

MR. ALGER: We have been trying to run such an experiment. Opinions are divided on that, however. A damper might offer some relief, but the dust committee is divided as to its value. There might be enough force and violence to tear the elevator to pieces before it went through the vent. There have been cases where vents to the outside where just a piece of paper over the vent was not damaged in an explosion when everything else was torn to pieces.

CHAIRMAN HASSE: This topic is of much interest. In looking over the registration cards, I notice there are several men representing the flour industry. As we have heard several times, the flour industry is well up in the prevention of dust explosions by various means and methods. I am sure, then, we should like to hear from the gentlemen.

Do you have anything to say about it, Mr. Cunningham?

W. H. CUNNINGHAM (Pillsbury Flour Mills Co., Minneapolis, Minn.): I really don't think I have a thing to offer, but I should like to ask if you have had any experience where your corn is heated, giving off carbon dioxide?

MR. ALGER: We have had corn heat, but not to the extent of really firing. It will do that once in a while.

MR. CHAPIN: It is very dangerous to go into bins where there is a high moisture content. We have rigid instructions not to go alone without a life belt and a man above.

MR. ALGER: Two men are the thing to have; tie a rope around one with some one above.

CHAIRMAN HASSE: At our Edgewater plant when it was shut down for a period of months, some of our men went into a tank, an open steep water tank which

was partially filled with water and had been standing there for months. They wanted to drain this water out, and one of the foremen went in there and tried to take out a plug and was overcome by an existing gas. The other foreman pulled him out immediately, fortunately, and then that foreman who rescued the first one tried to pull out the plug and was also overcome. When we received the reports we took it up with our laboratory. We had used chlorinated lime, which has some effect on steep water, and we thought it might be that which caused it; but it was found that the gas was due to the stagnant water in the tank. When the men went in there they stirred up the gas which, being heavier than air, overcame them.

That is the first experience we had, and we issued warnings that no men are to go into any tank unless another man is with him, so that if he is overcome the other man can help him out. The same rule applies to our men who go into feed hoppers, and so forth.

ALEXANDER DIENST (National Sugar Refining Company of New Jersey, Long Island City, N. Y.): In your experience; are dust explosions always caused by a spark, or sometimes spontaneously?

MR. ALGER: I have never heard of a dust explosion being caused by spontaneous combustion.

The Department of Agriculture is checking up on spontaneous combustion, but at present no one seems to know whether it is a germ, some chemical action or what. I was told a short time ago the farm fires throughout the country are caused in this way and that the fires occur more often in cow barns than in places where horses are kept.

Dust Hazards in the Handling of Coal

H. P. REID (Universal Portland Cement Co., Chicago, Ill.): We are interested in this dust hazard from the standpoint of pulverized coal and coal dust. Answering the question of the gentleman here, it has been our experience where we have pulverized coal and the coal has gone off and the dust collected in a vent, that with moisture present at a certain temperature the dust will collect on the duct walls, due to the condensation in your vent. This dust, after it has once been dried and then re-moistened is extremely dangerous from the standpoint of spontaneous combustion.

We can take our coal and dry it to four per cent moisture, let it lay, take the same coal and dry it to zero moisture; but take that coal and let it collect on the inside of a hopper, or on the shell of the ducts where condensation has taken place, and you have moisture, and it is hazardous; it is sometimes so moist that you could wring it out by hand, and if a little of that coal is put on the floor, it is glowing. When a collection of coal dust has come to a glow, if a little breeze strikes it, it will burst into flame.

The question I wished to ask was whether any of you have had any experience with an explosive mixture; we can get a mixture too rich to explode and too lean to propagate. Have you had in your experience where you first started with a dusty condition and collected 85 per cent of the dust and then left 15 per cent of it, a greater hazard than if you had left too rich a mix?

MR. ALGER: There is a whole lot to that. Every time you shut down your machine you have a dust explosion hazard, confined to the equipment under cover; but back that up with good housekeeping and if you do have a flash in your room it won't amount to anything.

If you have an explosion it will go through the ducts and tear them to pieces, but if your room is dust-free, there is no fuel.

There is something to what you say in regard to the explosive mixture. I understand eight ounces of starch dust per thousand feet of air is an explosive

ure, and—I can't speak with authority—maybe three times that amount you ignite at all.

ost of our explosions have occurred during shutdowns, when the men were to lunch. The fire at Pekin occurred right after the lunch period when equipment was not carrying a load. Don't operate your equipment, if you help it, without carrying a full load; running the conveyors and bucket ator empty is extremely dangerous, because you have an ideal condition there an explosion.

ESTER S. JOHNSON (Quaker Oats Co., Cedar Rapids, Iowa): What is your ion of this method of experimenting with the use of inert gases to prevent explosions?

R. ALGER: I think it is the coming thing. As to whether this gas has any : on food products is something else. We are studying it some; a few concerns : tried it, and I understand it works fine in pulverizing sulphur, for there is trouble at all. Of course, an important thing in such an operation, is to be you are maintaining a proper oxygen content.

think this is to be demonstrated in the tests at Boston next week, and I under- d the Quaker Oats people are putting equipment of this kind in their plant Cedar Rapids.

The Massachusetts Mutual Conducting Tests

MR. JOHNSON: That of course is in an experimental stage. The Massachusetts tual is conducting tests of these explosions. Mr. Hoxie was at our plant for a siderable time. In their experiments with explosions chambers outside of Boston, r found they could absolutely prevent any explosion by the introduction of inary flue gas. Their experiments showed also that the perecentage of this in air need not be to the extent of inconveniencing any of the men.

his gentleman suggested a damper to prevent the carrying of the explosion ig. We equipped all of our elevator heads with dust preventive, percussion heads. They operate by percussion and are absolutely foolproof. When the ussion reaches that chamber it turns the quartz.

at Cedar Rapids we have just started a big grain house and we believe that it has very finest equipment to take care of this dust disposal and dust explosion ard there is. The windows are of the explosion type; for an explosion at ntreal in a big elevator there, it was shown that the section of the factory ipped with ordinary window lights and regular sashes was damaged a great l and the fire damage was quite bad; on the other hand, the newer installations, ipped with explosion-proof windows, were undamaged for the windows simply ned with the percussion, and it was found that while the fire had its origin that section, the windows opened and let the explosion go outside. Even the inary window glass withstood considerable of a horizontal thrust.

ERN D. SUTTON (Postum Co., Battle Creek, Mich.): I wonder what the policy he safety engineers present is in regard to securing good housekeeping conditions the dusty departments. Do you simply have an order that they must keep departments clean or do you attempt to impress on the men the importance doing so for their own protection?

MR. ALGER: After the flash occurred at the Pekin plant, we came back to Argo l showed moving pictures of it. They said we were crazy, that we would ghten the men to death, but there is convincing evidence that we were right. e don't have any trouble with our foremen, although occasionally one comes ck with a statement that he doesn't have enough help. We impress them that an housekeeping must prevail, and there is no limit to it. The foreman is held ictly responsible.

CHAIRMAN HASSE: There is another thing, gentlemen, that I should like to add, and that is that sometimes you will find that a workman who is delegated the task of sweeping down the overhead will miss places, and we have had to discharge men for that reason and get men that we have trained so that they do sweep down all beams and overhead equipment so they will be clean.

There is an inspection made regularly to see that the overhead is kept clean; the foreman should take that responsibility and see that his men are trained properly in cleaning.

A. J. T. BROWN (Union Carbide Company, Sault Ste. Marie, Mich.): We are active in pulverizing coal, but the gentlemen here from the cement company said something in regard to the moisture coming back into coal after it was once dried. We have a practice of wetting down our floors. You couldn't do that, though, in a starch factory. I am wondering if you have had any trouble from wetting down, mixtures getting back into your ventilating flues.

Perhaps I should have asked what is the advantage or disadvantage resultant from wetting down, we will say, pulverized coal? Perhaps you have had some experience that will enable you to answer.

Essential to Keep the Housing Tight

H. P. REID (Universal Portland Cement Co., Chicago, Ill.): I believe that wetting down is only adding to your trouble in housekeeping. I think we can eliminate this hazard considerably by keeping the housings tight so that the dust doesn't get out.

In the first place, I am a great adherent to the rule not to make dust rather than to clean it up; but of course on certain conveyances and machines I don't think we can stop it. I don't think we can get spontaneous combustion from wetting down that way, but it could apply to other dusts beside coal. The fine particles of dust separating as they are and getting into the vents become impregnated in such a way that they have a chemical action and you get an evolution due to gases more than from moisture, which is extremely dangerous to that vent.

The trouble we have in the collecting of dust from our housings, machines, elevators, conveyors, and so forth, is that the moisture content in this material has pulverized and the further condensation of moisture due to the heat condenses on the ducts, which seems to have developed a condition that is extremely sensitive to spontaneous combustion.

We have overcome that by buying heavy vents for the collectors. We find heavy insulations necessary to protect against condensation.

Answering directly, I don't think you can get anything worse by wetting down except a muddy condition.

FRANK T. COLEMAN (Continental Bakeries, New York City): I started a discussion on two different propositions in this section here, the Fleet and the Food Section conflict, and I wanted to say that I have just been upstairs at the Taxicab and Fleet session and asked for cooperation in the matter of arranging a program to take care of our common problems.

Another thing. I should like to ask if any one has had much experience with foreign substances in the safety field. We have some trouble that way, and I shall never feel I have done my work successfully until I eliminate any chance of contamination of our product by foreign substances. I thought it might be interesting to see how many here would be interested in that problem of foreign substances to the extent of guarding open electric light bulbs, watching our nails, splinters, and so forth, and watching our outside containers. I know one of our flour companies sent us some whole wheat flour not long ago, and we found two big pieces of steel in it. If that had gone through it would have wrecked the

ler, an expensive proposition, and if it had gone through into the bread and found by a consumer, it would have meant a lawsuit perhaps.

should like to know what you people are doing in connection with guarding against the entrance of foreign substances. In the East, it seems to be right at the peak, especially where we have many newly graduated lawyers with nothing to do but file claims, a lot of them alleged, a lot of them real. It is a serious position. Maybe you fellows out in the West don't get the claims and are so much interested, but you fellows who distribute in the East should consider it.

Do you think it would be advisable for us next year to have a session on this subject?

BANK SMOKE (Kellogg Company, Battle Creek, Mich.): That is getting to be a strictly a manufacturing proposition, which all manufacturers are fighting to get away from. We have had those things happen. One particular instance I recall of a girl who found a diamond ring in a package of corn flakes; she wrote to ask if we were giving one in each package. The inside of your factory should be kept in order.

Foreign Substances in the Foods

ALPH C. PROUTY (Aetna Life Insurance Co., New York City): A good many of these things that cause you to have damage also may cause you to have personal injury, and it would seem to be entirely proper for us to consider some of the ways of eliminating the introduction of foreign substances into food products, with thought in mind of saving human life.

J. ALGER (Corn Products Refining Co., Chicago, Ill.): I think it is a subject we can all well afford to spend considerable time upon. We sell corn syrup to the candy manufacturers, so we have to watch out.

CHAIRMAN HASSE: Mr. Coleman, that proposition you brought up was discussed last year's Congress, Mr. Strothbar delivering at that time a very fine paper that I am sure you would be interested in reading. The subject seems to warrant the permanent committee's consideration for our next Congress.

R. COLEMAN: I should like to get a list of members so we will know how many are actual members. It seems to me there is a small representation here; for instance, so far as I can see, there is no one here from our competing lines, and now the Purity is doing safety work. It seems to me that the Corn Products Refining Company have an extra large representation.

CHAIRMAN HASSE: You are right, Mr. Coleman. We were talking about that yesterday. We are going to try to get a 50 per cent representation next year.

R. ALGER: It seems to me you could pick out certain sections of the country, and delegate one individual to call upon the members or prospective members in each section. Have that delegate make a personal call, it wouldn't take over an hour or two, and then you will get these additional representations.

BERN D. SUTTON (Postum Co., Battle Creek, Mich.): This matter of attendance at this Congress was done almost exclusively through the News Letter, so far as I know. It doesn't seem to be sufficient. I wonder if it wouldn't be well to have an especially appointed committee to endeavor to work on it throughout the year, intensifying their efforts next fall as the Seventeenth Annual Congress approaches, to secure a larger delegation of the Food members.

One way to determine the number of members in the Food Section is to take all members of the National Safety Council engaged in a business pertaining to food, human consumption and classify them as members of the Food Section. We will get the list you will receive on request from the N. S. C. headquarters. We will distribute News Letter on that basis, and we urge representatives from that list to consider themselves members of our Section and to attend our sessions.

But I think we ought to urge everyone to help enlarge the attendance.

CHAIRMAN HASSE: I believe that committee would be a very good proposition, Mr. Sutton, and I believe it would be in order to have a motion to appoint such a committee.

FRANK SNOKE (Kellogg Company, Battle Creek, Mich.): I move we appoint such a committee.

(The motion was seconded and carried.)

CHAIRMAN HASSE: I take pleasure in appointing you, Mr. Sutton, as a member of that committee, and Mr. Eggert and Mr. Coleman.

MR. COLEMAN: I think you should have someone from the West; I am in New York.

CHAIRMAN HASSE: The appointment has already been made.

MR. FRANK T. COLEMAN: I think our members are widely scattered, from coast to coast; can't we get someone around Kansas City or in the Middle West?

H. T. EGGERT (National Biscuit Company, New York City): I suggest we further the idea of Mr. Alger's by having everyone here a member of this committee. Each person can call on two or three concerns requesting them to be represented at the next Congress, rather than have two or three persons attend to all of this. It is also better to call personally.

CHAIRMAN HASSE: There is not enough money to spend for travel.

MR. EGGERT: We could reach isolated places by mail.

MR. COLEMAN: Mr. Eggert is in the East, Mr. Sutton is in the Middle West; why couldn't you get someone from the Far West? Make each one a sort of regional head.

MR. SNOKE: Just like we are in a factory—we have to place the responsibility somewhere.

MR. EGGERT: That responsibility can be with the chairman.

CHAIRMAN HASSE: I am willing to accept that responsibility, and do my share.

MR. EGGERT: I suggest then that with Mr. Hasse it be a committee of four.

C. J. ALGER (Corn Products Refining Co., Chicago, Ill.): And give each man a list in his district.

MR. COLEMAN (Continental Bakeries, New York City): I make a motion that it be a sectional committee of five, and follow out Mr. Alger's idea, each man being given a list of members and non-members in his section with which to do his best to bring in more members and a bigger attendance next year, each one reporting to the Food Section their progress.

CHAIRMAN HASSE: In order that we may handle this proposition right, I am going to postpone the appointments at this time, until we get a list of members so we can get the proper representation. You will be advised later, if that meets with your approval.

ADJOURNMENT.

Thursday, September 29, 1927

**F. A. HASSE, Chairman,
Corn Products Refining Company, Chicago, Ill.**

The third session was called to order at nine-thirty o'clock by the chairman, F. A. Hasse.

AIRMAN HASSE: It looks as though we are going to have a very interesting evening. The first subject, I believe, we are all vitally interested in. No doubt one of the members of this section has the machinery hazard to contend with, whether or not we actually have it properly guarded we will be able to tell Mr. Rice gives us his viewpoint.

It gives me great pleasure to introduce Mr. Leslie M. Rice, district chief engineer, Liberty Mutual Insurance Company, Chicago, Illinois.

Machine Hazards in the Food Industry

**Mr. M. Rice, District Chief Engineer, Liberty Mutual Insurance Company,
Chicago, Ill.**

The growing and preparing of food and food products covers a wide and varied range of operations, nearly every phase of processing being done with some sort of machine-driven machinery.

The improving standards of living are making continuous demands upon our machine designers for equipment that will eliminate more labor and for processes that can be operated automatically. The first stage of this development often increases the hazards while the hazard decreases as we become more automatic.

In 1790, at the time of our first census, the work of several rural families was required to supply one townsman. At the present time seven rural families supply one townsperson. In 1820 it required 60 hours of man labor to bring an acre of corn through the crop cycle. Today we carry the crop cycle through in five hours. Our Agricultural Department tells us that we are harvesting our wheat crop this year with some 80,000 or 90,000 less laborers than we did a few years ago. Some of our agricultural research experts have gone so far as to demonstrate that egg production can be increased with the aid of electricity, likewise they have shown us that yields can be multiplied with electric energy and so again increase our machine hazards. However, they have not commercialized it to such an extent that they are of our safety engineer much concern.

Presumably, as a Food Section, we are not directly concerned with the machine hazards arising out of the manufacture of mechanical equipment used in planting, raising, harvesting or processing food and food products or even equipment to manufacture food containers, although many food product plants manufacture their own containers.

Generally speaking we may split our raw food some six or seven ways, as follows: Grains, Meats, Dairy Products, Vegetables, Fruits and Nuts, Salt and Water.

After several years of experience our Workmen's Compensation Casualty Bureaus, according to product and processing operations, divided our food product manufactures into some 50 odd classifications and they have been able to go a step further to show us which of the food products plants have been and still are causing us the most accident concern for our human equipment.

The average cost of our losses, using Illinois figures for comparison, are the highest in the cereal division and lowest in the fruit and nut group, the latter being about 75 per cent of that of the cereal group. Practically all of the groups have farm machinery operation, some more than others, and because the losses are heavy in this operation the average loss cost is raised in the basic groups.

This talk was intended to pave the way for discussion on machine hazards and for your convenience the groups and the group classifications producing the greatest accident losses are given in their order. The most serious coming first.

Group Classifications in Relation to Accidents

Cereals

Cereals and cereal products are divided roughly into eighteen classifications. In their order we have:

- Cotton Seed Oil Mfg.
- Macaroni Mfg.
- Operation of Farm Machinery
- Corn Products Mfg., Glucose and Starch Mfg.
- Carbonic Acid Gas Mfg.
- Cotton Seed Oil Refining
- Milling Grains
- Grain Elevators
- Extracts Mfg.
- Alcohol Mfg.
- Malt Houses
- Baking Powder Mfg.
- Essential Oils
- Bakeries—Bread, Cake and Crackers
- Confectionery

Vegetables

- Eight groups.
- Operation of Farm Machinery
- Beet Sugar Mfg.
- Extracts
- Pickle Mfg.
- Alcohol Mfg.
- Sugar and Molasses
- Canneries

Meat and Meat Products

- Seven groups.
- Operation of Farm Machinery
- Butchering
- Fish Curing
- Cold Storage
- Packers
- Lard and Sausage Mfg.

Milk Products

- Seven groups.
- Operation of Farm Machinery
- Ice Cream Mfg.
- Cold Storage
- Creamery Operations and Milk Depots
- Milk Products
- Dairy Farms

's and Nuts

Nine groups.

Operation of Farm Machinery

Manufacturing of Fruit Juices

Canneries, Fruit Preserving and Fruit Evaporation

Oils

Cocoanut Shredding, Spice Mills, Coffee Grinding and Roasting

or Works Operation

we use the bakery as the basis for comparison, since bakeries are familiar to all of us, we find the accident losses in the manufacture of cotton seed oil are times as serious as those of the ordinary bakery. This is due chiefly to the fact the bakery usually has a better average class of employees; in addition, there has been greater safety revision on the mechanical equipment and perhaps a little of what Casualty Underwriters choose to call "sweetening," giving the advantage to the baker. At any rate, the oil refinery has plenty of room for improvement. The operation of farm machinery is some three and one-half times as hazardous as that of the bakery. In this instance we are up against a weakened supervision over the industry is seasonal and there are such widely scattered operations. With the advent of the more automatic machinery such as the combining of one machine to harvest, thresh and bag grain our hazard to that extent is lessened and the next step is to help further improve the equipment and further educate the operators.

Making Macaroni Also a Dangerous Process

Macaroni manufacturing does not look serious, but this industry contributes a considerable number of saw accidents and dough mixer cases; and to help make things worse, we lose an occasional hand on the noodle machines. Only a short time ago a noodle machine operator lost a hand at the wrist when the dough held him long enough to trap him before he could get away.

In bakeries we always fear the hazards of the dough mixer because it is likely to produce the most serious injuries. Many dough mixer accidents are due to the lack of safety devices, while others are due to a shortage of what the "hard boiled" master calls "pep" to snap into form at the right time. A short time ago we had a case where a man had an arm broken between the elbow and shoulder on a dough mixer. This is an ordinary dough mixer five feet in length, three feet deep and about three feet wide, of the tilting type. Blades are staggered and pass within an inch of an inch of the sides and bottom of the shell. The shaft was geared to a pulley which in turn was driven by a belt from the line shaft. The movement was slow but positive. It appears that the man was short of dough and went over to the mixer for a new supply. The mixer man was filling the second tub and it was necessary to apply power to eject the dough and before applying power the operator had noticed that his customer had his hand on the upper edge of the mixer and he told this fellow to park his hand elsewhere, but after the second warning he applied the power and the blade caught the cotton glove which the fellow was wearing and pulled him into the mixer, breaking his arm before the operator could stop the machine. This simply indicates that "hard boiled" supervision is as necessary as good guards.

Another case somewhat similar so far as supervision goes was on an icing mixer used to grind oranges in a cake plant. The custom is to cut oranges in three or four pieces then to drop them in the machine which has a long built up throat to make it convenient to reach in; and finally to drop a special weight on the product and push it to the machine to grind the oranges. In this case the operator choose to use

his hands and when his fingers slipped it nipped off the tips of two fingers. Again we come back to supervision.

The nougat cutter in the candy factory is a common source of finger amputations just as it is on the meat slicers. The difficulty of cleaning the nougat cutter tempts the operator to remove the guard so that he can clean easier and oftener. He usually does this until he cuts off a finger, then the boss gets "hard boiled" and every one uses the guard until the boss' memory fades again.

A very considerable portion of our troubles in the bakery arise out of cleaning the machines while in motion. Where we have a "hard boiled" safety superintendent they seem to get along just as well on production and have very few cleaning accidents. Eventually we arrive at cleaning machines when quiet—why not before an accident?

Trouble With the Circular Saw

CHAIRMAN HASSE: Are there any questions you would like to ask? Undoubtedly, the machine hazard is quite extensive and perhaps some of the rest of you have something you would like to ask Mr. Rice.

FRANK T. COLEMAN (Continental Bakeries, New York City): I should like to mention some trouble I have with circular saws. We have to pass requirements of the board, but the Surety and others do not prescribe the kind that are of practical use for a plant carpenter, as in end-grooving he has to take the whole guard off. Just let him have one loop-hole and he will take the whole guard off. Then the inspector comes around and gives us no credit; we waste that money and do not protect the man after all. Do you know of a good device of this kind?

MR. RICE: I think the Surety has one that it has developed.

MR. COLEMAN: That is the one that follows the board around, isn't it? It doesn't pass the Rating Boards. We could save a lot of money if we could find a guard that would meet requirements.

MR. RICE: I am not so sure you can get a guard to fit an odd table.

MR. COLEMAN: Well, we don't want to make any new installations.

MR. RICE: The ordinary bakery doesn't use it enough to warrant it.

MR. COLEMAN: Does anyone else have any ideas? How about you, Mr. Sutton? Don't you have saws in your plant?

VERN D. SUTTON (Postum Co., Battle Creek, Michigan): We have saws, yes, but we haven't solved your problem. We have guards and they take them off and hang them up, just the same as they do in the other plants.

FRANK SMOKE (Kellogg Company, Battle Creek, Mich.): Did you ever try to hang a man for three days for the first offense and then lay him off entirely for the second offense?

MR. COLEMAN: I would have a tough job to sell that idea, for I have about 100 managers to deal with.

MR. SMOKE: Well then, you will have to sell your 100 men.

Sell the Men Thoroughly on the Idea

MR. RICE: It usually resolves itself back to the matter of selling your men; if they know they must use it, they will use it.

MR. COLEMAN: But I think it would be better to put on a guard that they would have to use.

CHAIRMAN HASSE: We will pass on to the next subject, "The Value of Physical Examinations in the Food Industry," by Dr. A. C. Selmon, Kellogg Co., Battle Creek, Michigan. Dr. Selmon has had considerable experience in this respect, having been associated in the food industry for a number of years and no doubt his paper will give us valuable information.

The Value of Physical Examinations in the Food Industries

L. Selmon, M. D., Medical Director, Kellogg Company, Battle Creek, Mich.

Manufacturing industries are in the grip of such keen competition that bringing down production costs is an ever present problem. An increasing amount of attention is being given to the elimination of waste. The inventive genius of the best minds is constantly making improvements in machinery and manufacturing processes. The result is that the efficiency of the mechanical side of the industries is far ahead of that of the "human machines," the power side.

It would seem to be the logical thing, therefore, that more attention be given to the quality and upkeep of the "human machine." The average manufacturing plant in a year expends for wages a sum nearly equivalent to one-third of the total invested in buildings, machinery and equipment; in other words, in three and one-third years the wages paid are equal to the value of the entire plant. The human machinery therefore represents the largest part of the business, and it should have care and oversight somewhat in proportion to the value of the investment.

Well made, well adjusted, well cared for machinery does good work over a long period of time. This applies as well to the human body as to an electric motor or an automobile.

Physical examinations when properly done should be and are of great value to both employer and employee. Most employers today are keenly interested in everything that concerns the welfare of their employees, and are not sparing their efforts to make working conditions as healthful as possible.

Men are hired to do certain kinds of work, and to do that work properly requires that they possess certain physical abilities. It is much better to find out by a physical examination at the time an employee is taken on whether or not he is physically fitted for the job, than to take the first applicant that comes along and run the risk of getting some one who may have defective sight, an inguinal hernia, or pulmonary tuberculosis.

Much Responsibility Rests Upon the Employer

Under the present regime of the state compensation laws a large measure of responsibility is laid upon the employer for the welfare of those in his employ. Analysis of the commonest industrial accidents reveals the fact that a large percentage, both of those who met with accidents and of those who are off for protracted periods of sickness, were workers who already had some physical impairment. The plant whose employees are in A-1 condition physically and mentally will easily lead all others in low accident and low sickness records.

Physical examinations make possible the placement of workers in the jobs in which they are best fitted; whereas without the physical examination it is more or less a matter of cut and try. When it comes to transferring a man from one kind of work to another his physical examination record will show whether this can be successfully done or not.

Physical examinations will keep the physically unfit and those with contagious diseases out of the plant. In the food industries this is a matter of greater importance than it is in most other industries. An applicant for employment may seem to the employment manager to be a good specimen, yet he may have one or more of the following impairments:

He may have a mouth full of pyorrhea. He may be a typhoid carrier; or

a diphtheria carrier; or have syphilis or gonorrhea. He may have itch or some other loathsome skin disease. He may have a mild grade of pulmonary tuberculosis. He may be an epileptic, or have severe anemia. He may have a severe grade of flat feet, or have varicose veins with large varicose ulcers, or have a large hernia (rupture). He may have defective vision that cannot be corrected by glasses. He may have a flail joint (the result of a broken arm bone that failed to unite.) He may have a leaky heart, hard arteries, or high blood pressure, or a toxic goitre. This list is taken from the experience of a large food manufacturing company and represents the various conditions found by physical examination and for which applicants were rejected.

Physical examinations bring to light a large number of physical defects in the ordinary factory worker. Fortunately many of these are remediable, and some are of a nature that is not necessarily disabling, but calls for instructions to the employment department as to certain kinds of work and certain environments that should be avoided.

Taking the applicants as they come, it is found that only five to eight per cent are rejected on account of physical disabilities. This is really a very small number, and the fact that so few must be rejected speaks very highly for the good working conditions that exist in most of our up to date manufacturing plants. It means that a considerable number of physically handicapped are able to make good in the plant that is equipped with effective, well guarded machinery, and is well lighted, heated and ventilated.

Physical Examination for the New Employee

Preliminary physical examinations are a part of the program in so many of the industrial concerns throughout the country that it is coming to be looked upon as a matter of course. The examiner must have consideration for the feelings of the one he is examining. The examination must be done with sufficient thoroughness to command the man's respect. Those conditions revealed by the examination which require attention should be reported to the applicant. If the man is employed, he should be given the benefit of a recheck from time to time. By following some such procedure as this the physical examinations given by the physicians connected with the industries will have for the employee all the value of the periodic health examination. Now that the life insurance companies are beginning to show the results actually attributable to the periodic health examinations in the way of decreased sickness and lengthened life, we have further weighty evidence of the value of the physical examination in the industries.

CHAIRMAN HASSE: This subject is of great importance to those in the food industry, so I know we shall have some discussion on it.

J. R. CLAIR (Liberty Mutual Life Insurance Co., Boston, Mass.): I should like to ask the Doctor, in the case of a disease carrier working on raw batches of material, is it true that the baking process will neutralize the ordinary disease germs that may be contained in these raw batches?

DR. SELMON: In the case of a typhoid carrier that would be true; the germs are carried through to the excreta and if he gets some on his hands and then handles things without having first sterilized his hands, that can happen.

MR. CLAIR: Is it true that the baking process will destroy germs?

DR. SELMON: Yes.

MR. CLAIR: Really, then, in processes that are baked, the first danger would be from those who handled them after they are baked.

FRANK T. COLEMAN (Continental Bakeries, New York City): I should like to ask the Doctor if there is legislation country-wide toward forcing the food manufacturers

require a physical examination of food employees by someone outside of the local authorities?

R. SELMON: Not to my knowledge, but there may be some.

R. COLEMAN: Do you advise that employees get physical examination at their expense and furnish a certificate before they actually begin work?

R. SELMON: I don't know that I do. I think most of the manufacturing industry give a physical examination as an expense to the company.

R. COLEMAN: That is quite an expensive proposition, isn't it?

R. SELMON: Yes, it costs several dollars for each individual, if it is done right.

R. COLEMAN: We have so much floating labor that I shouldn't think it would be worth while to spend the money.

R. SELMON: That is where preliminary examinations work in, where you just hit high points, where you catch the gross defects; for permanent employees the examination is much more thorough.

R. COLEMAN: Either kind would require a medical man.

Discussion of the Preliminary Examination

R. SELMON: The first is cheaper because of the small amount of time involved; sometimes it takes about ten minutes.

R. COLEMAN: Why not have our employees do that?

R. SELMON: Could you depend on it?

T. EGGERT (National Biscuit Co., New York City): I should say you couldn't have doctors in New York who give a health card for twenty-five cents.

R. COLEMAN: You could specify your own doctor.

R. EGGERT: In my opinion it would be improper to tell a man where to be examined unless you paid the physician's fee.

R. SUTTON: Isn't the purpose of this preliminary examination, or elimination examination, to determine whether you wish to employ the applicant, and couldn't this examination then be made by a registered nurse who has been trained especially for that?

R. SELMON: I don't think so, Mr. Sutton; to make an examination of value, the examiner must have enough knowledge to see things quickly, size the man up by his physical appearance, tell something about him, whether he has heart disease, a color suggesting anemia or tuberculosis; he must listen intelligently to his heart, to his lungs, and no nurse is trained to hear or to interpret what she hears by the stethoscope over the heart.

R. SUTTON: The reason I asked that question is because I know of a concern (now following the practice, but it did at one time), which had certain questions were asked by the employment manager, questions of a physical nature. They also, to some extent a physical examination to determine conditions like hernia; he passed these examinations he was then subjected to a more thorough one. This employment manager happened to be one whose tendency ran to first aid, and perhaps was more qualified than the ordinary layman, but not a registered nurse.

R. SELMON: I should think it would be hardly practical.

P. WARREN (Minute Tapioca Co., Inc., Orange, Mass.): Suppose you have a man, Dr. Selmon, who is not physically unfit and yet not particularly strong, who might be all right for a fairly light job. Do you hire such a man? Or do you insist he be absolutely o. k.?

R. SELMON: No, I tried to bring that out in the paper.

R. WARREN: I judged so. Supposing you changed that man, or the foreman or superintendent, whoever it is, changed him, to some other job. Do you get a notion of that before the man is changed?

R. SELMON: Yes, that comes around to us. If there is any question on the part of

the employment men, they come to us and look up his history to determine whether he can undertake that work.

MR. WARREN: Are they in a position to determine? Aren't there conditions where, due to an impending layoff, for instance, a man might request that he be transferred because he doesn't want to get laid off? And perhaps the job to which he is being transferred is more than he can handle, but he takes the job.

The point is whether or not that is referred to the medical man before the change is made. How much of the medical statistics are used all of the time in changing men from one job to another? Do you actually use these statistics or are they gathered merely to protect yourself from taking in a man who may have a communicable disease or be ill fit for the work?

DR. SELMON: In our case, the employment manager is informed that he won't be fit for some kinds of work; he knows that the man can do light work, but not heavy work, no strenuous stooping over or anything like that.

J. R. CLAIR (Liberty Mutual Life Insurance Co., Boston, Mass.): I should like to know what your experience has been in the setting up of a system of physical examination in a plant. It is evident it would be a more or less bad procedure for moral purposes to immediately lay off or discharge someone who might be an old employee and yet whom you find to be physically unfit. What has been your experience in setting up a physical examination system in a plant, where no system of that kind has previously been used?

DR. SELMON: I don't believe it can be made compulsory. It would take time.

The Problem of the Old Employee

MR. CLAIR: What would be the procedure supposing your employees were old? Supposing out of a group of 200 you find a half dozen old employees who are evidently unfit for the job they are working on, what do you do with them?

FRANK SMOKE (Kellogg Co., Battle Creek, Mich.): The committee of five passes on them to try to find out what sort of position they can handle. This gives a good check on it, the employment manager's and the doctor's and that of the committee of five.

DR. SELMON: In the instituting of the new employees' examinations we have no trouble; we can require every last one of them to be examined, and the old employees are sold the idea just as fast as possible. But you must go easy on the compulsory part.

FRANK T. COLEMAN (Continental Bakeries, New York City): Is it practical to set an age limit, say sixty?

DR. SELMON: I don't think so; the pension system hasn't been very successful, but I couldn't make a statement on that.

MR. COLEMAN: In reviewing our accident record this year, I find that a number of our serious accidents have happened to men over sixty years of age. I'm getting hard boiled about it, and I'd like to get rid of them. Fortunately, however, my company has a heart, and wishes to take care of these men in view of the fact that at the present time, we have no pension system.

DR. SELMON: There is the difficulty, for one man is old at 40 and another not until 60, depending on the way they have lived. That is the reason for this physical examination. A man may be old in years and not in body. It is very difficult.

M. E. HOUSER (B/G Sandwich Shops, Chicago, Ill.): Referring to the remarks by Mr. Coleman regarding the applicants paying for the examinations, themselves: We operate in 18 cities throughout the country and physical examinations are very important matters with us; we have our own examiner in each city. We send our applicants to these examiners, and we pay for the examinations.

Some time ago the question came up that the applicant should pay the examination fee, but we found it wouldn't work except in one city. The most likely applicant

uld refuse to consider further a position when an examination was required in
; manner.

MR. COLEMAN: Is your labor turnover large?

MR. HOUSER: Yes.

MR. COLEMAN: Then I should think it would be a very expensive proposition.

MR. HOUSER: It is. It runs into several thousands of dollars per year, although I
it recall the exact figures.

We try to use the young folks in our work, a different class. We seek to get the
e of girl known as the home girl, and the boys are clean cut, and our examination
them is very strict. The company pays three dollars for each examination, and
have them re-examined every six months.

MR. COLEMAN: Outside of the increase in good will, do you think it worth while?

MR. HOUSER: Yes. In the majority of cities there are ordinances; the law requires
t restaurant employees be examined, and we are compelled to do it in most cities
we have just gone one step farther and made it universal in our system.

A Position for the Man With One Eye

D. J. STROBEL (Wagner-Taylor Co., Philadelphia, Pa.): Dr. Selmon, supposing
I had an applicant for employment who had an artificial eye, would you employ
n?

DR. SELMON: Yes, if he had another good eye.

MR. STROBEL: Supposing he lost the sight of the good eye, then; wouldn't the
nt be held responsible for both?

DR. SELMON: Yes, I think it would be in some states.

VERN D. SUTTON (Postum Co., Battle Creek, Mich.): I don't think you would
held responsible for total loss of vision, but only for the loss of sight of one eye.

CHARLES PRAHL (Gridley Dairy Co., Milwaukee, Wis.): If a man loses an eye,
insurance company or the self-insured pays for the loss of the eye. In our state,
must pay to the Industrial Commission of Wisconsin a certain set sum, \$3,500 for
e. If he loses the other eye, the company pays for the loss of the eye the same
ount as for the first, but the employee gets from this amount an amount equal to
: amount of total disability.

So you don't assume any more responsibility when you have an employee lose the
ht of the only good eye he has remaining.

CHAIRMAN HASSE: The same applies to Illinois. If a company employs a man
th one eye, if he loses that eye, he is permanently disabled and is supported by a
cial fund created for this purpose.

MR. SUTTON: He must have proof that he had compensation for the first eye, so
pposing he lost the first eye at home or in childhood and received no compensation.

MR. PRAHL: I am not sure what the law is on that.

MR. EGGERT: I should think it would be the same. He would receive compensation
: the second eye and be paid for total disability out of the fund.

CHAIRMAN HASSE: I am afraid we are getting away from the subject.

Are there any other questions? I should like to ask one question of Dr. Selmon:
; you reexamine your employees and how often?

DR. SELMON: That depends on conditions. Some I re-check every three months;
ne of those who have diabetes, sugar in the urine, high blood pressure, I even more
requently re-check. Others about once a year.

CHAIRMAN HASSE: You have no set time?

DR. SELMON: No, it depends on the condition of the employee.

CHARLES PRAHL (Gridley Dairy Co., Milwaukee, Wis.): We have also mutual
nefit associations in our company and we combine the examination with the exam-
ation for the mutual benefit association, and the applicant has to pay a dollar to
in the association. The doctor's fee is split up between the mutual benefit and the

company, and so the cost is low. The company contributes one-half of all the dues to the association and as our labor turnover is rather small, the expense is rather small.

W. H. CUNNINGHAM (Pillsbury Flour Mills Co., Minneapolis, Minn.): Do you have a similar practice with regard to mutual benefit associations, Dr. Selmon?

DR. SELMON: No, our particular mutual benefit association doesn't require a physical examination.

MR. CUNNINGHAM: Is there any difference between the standard for the employment and the standard for the association, Mr. Prael?

MR. PRAEL: No, the physical examination for employment is based on the physical examination for the mutual benefit association: if an applicant can pass the mutual benefit association examination, he can pass the examination for employment. It isn't severe, except in the case of hernia; a man with hernia would be disqualified for the hard work we have.

MR. CUNNINGHAM: Don't you think there is a risk?

MR. PRAEL: Well, all the people we have examined have been healthy.

Discussion of the Convention City Resolution

H. T. EGGERT (National Biscuit Co., New York City): You accept them for employment if you accept them for the mutual benefit association?

MR. PRAEL: Yes, for the men engaged in employment expect the mutual benefit protection as a welfare proposition, even though they shouldn't care to assume the responsibility of it.

CHAIRMAN HASSE: We have just received the following resolution:

"Whereas, The National Safety Congress is more efficiently and economically held in its headquarters city, and

"Whereas, The cost of sending delegates is as low if not lower when the Congress is held in Chicago, and

"Whereas, The city favored by the Congress when moved from point to point gains only at the expense of the delegates and their employers,

"Be It Therefore Resolved, That this Section is in favor of holding the Congress in Chicago regularly during the last week of September in each year."

FRANK T. COLEMAN (Continental Bakeries Co., New York City): That sounds like a chamber of commerce affair, boosting Chicago. I think there is a lot of value in going to other cities to promote interest in safety; we can get much more interest stirred up that way.

I make a motion that resolution be voted down.

(The motion was seconded.)

CHAIRMAN HASSE: It has been moved and seconded that the resolution just read be voted down.

C. J. ALGER (Corn Products Refining Co., Chicago, Ill.): We have all attended conventions before and I think everyone is agreed that this has been the most successful of all the Congresses. Chicago is centrally located, and with our various industries, we have scattered throughout the country and it seems to me that Chicago could bring more people in than would be true of New York. The convention in New York seven or eight years ago was the smallest in point of attendance of any I ever attended.

I think the resolution should be adopted.

MR. COLEMAN: The motion was made and seconded. I call for a vote.

CHAIRMAN HASSE: Gentlemen, we will hold that vote off for a few minutes.

VERN D. SUTTON (Postum Co., Battle Creek, Mich.): Mr. Smoke has gone down to headquarters to see if they fostered this resolution and if they will send someone

to explain why we should support them in that. After we get their viewpoint, they may change or confirm ours.

CHAIRMAN HASSE: At least we will be better able to discuss it, although in the meantime we might be giving our views on it.

MR. EGGERT: I haven't any thoughts either way and am willing to let the majority decide.

MR. ALGER: I should like to inquire in regard to that resolution, is it the opinion of the boys here who have attended previous Congresses that any one city is best suited to have the Congress?

MR. EGGERT: I think the arrangement in Detroit was very unsatisfactory, as the meetings were held in so many places.

CHAIRMAN HASSE: I believe that is the reason it was held in Chicago this year; it is the only city where we can meet together under one roof.

Few Cities Capable of Handling the Congress

G. A. NOXON (Ralston-Purina Co., St. Louis, Mo.): It seems to me that with a convention the size it is, with the exception of the three largest cities, no other city could hold it. We would just have a repetition of what occurred last year in Detroit, with members running all over the city to their meetings. This is the first time we have ever held the meeting so smoothly.

MR. SUTTON: May I ask Mr. Noxon what are the cities he has in mind as being able to handle this convention?

MR. NOXON: I am from St. Louis, but I have in mind New York, Chicago and San Francisco.

MR. SUTTON: The reason I asked for the names of the cities was so we might consider the geographical location of them. The last time we went away from the geographical center of the country was when we went to Boston. I didn't attend that meeting, but I understand from those who did, the convention was not so well attended because it was so far from the delegates' headquarters. It seems to me that if the convention were confined to one central location it would always have a larger and larger attendance.

CHAIRMAN HASSE: We have a gentleman here from headquarters, Mr. Fish.

CARMAN FISH (National Safety Council): This is the first time I have seen this resolution, and I am really not in a position to state whether it is official or not. It looks as if Mr. Prussing is merely trying to get a straw vote on the opinions of the delegates as to whether to hold the Congress in Chicago or in some other city. Of course that is a matter to be decided by the Executive Committee. I do not believe that anybody at present is in a position to give any definite information, although I do not see any harm in your expressing your preferences.

MR. COLEMAN: I should like to ask the speaker if it doesn't stimulate interest to meet in other places, and if it doesn't arouse more interest in safety in other cities where we might meet.

MR. FISH: There is no doubt that holding a Congress in different sections of the country stimulates the interest in safety there. The only trouble is that the Congress is now so large it is difficult to find accommodations for it, and that is one of the reasons why regional conferences are becoming popular.

Motions and Counter Motions

MR. ALGER: In Kansas City this spring they had a regional conference that was well attended, by about 900 delegates, which helps to prove that Chicago is ideally situated geographically to bring in the largest number of people.

MR. SUTTON: I have a motion I should like to put, although it won't be parlia-

mentary with the one preceding it still before the house: I move we table the motion before the house.

A. COWEN (Union Carbide Co., Sault Ste. Marie, Mich.): I want to speak against that. I think that that resolution asking that the permanent meeting place be Chicago hereafter, denotes the growth of the Congress, that it should come to a size that we can't meet anywhere but in Chicago. I think we should meet here regularly, for the next development will be a sectional development, resulting in sectional conferences, with this meeting in Chicago an annual meeting where representatives of all these various section conferences will gather together to consider the whole safety movement. I am heartily in favor of Chicago.

MR. COLEMAN: A motion is before the house; I call for a vote.

MR. SUTTON: Do I understand that Mr. Coleman maintains that my motion is not in order? It wasn't seconded?

MR. ALGER: There was a motion before the house when your motion was made.

MR. SUTTON: My motion pertained to the one that was made.

MR. COLEMAN: It was not seconded, therefore I call for a vote.

CHAIRMAN HASSE: All those in favor of holding future conventions in Chicago—

MR. COLEMAN: That is not the motion. The motion is that the resolution be voted down.

Closing Moments of the Session

CHAIRMAN HASSE: All right. All those in favor of the motion that the resolution be voted down, kindly raise their hands.

(The motion was not carried.)

The other resolution, then, is still before the house.

(Mr. Sutton's motion that the resolution be tabled was seconded and carried.)

MR. SUTTON: I move this Section express itself as favoring, in case the National Safety Council headquarters decides later to hold the convention each year in any one city, that that city be Chicago.

MR. ALGER: I should like to amend that motion to the effect that this group go on record as recommending Chicago as a permanent location to the Executive Committee.

MR. SUTTON: The reason I didn't include that idea is that in case the communication has not come from the Council headquarters and that they are not fixing upon one city as the permanent place to meet and in case this is just a straw vote, we have merely gone on record as favoring Chicago in case they do fix on one city, leaving it with the National Safety Council to determine whether it is advisable to hold it in one city. If they do determine to hold it in one city, then this section would favor Chicago.

MR. ALGER: Then I withdraw my amendment.

CHAIRMAN HASSE: Is there a second to this motion?

(The motion was seconded, put to a vote, and carried.)

CHAIRMAN HASSE: Well, that disposes of that.

We are to have a series of lantern slides which have been furnished us by courtesy of the Kellogg Company.

(The slides were shown and described by Mr. Frank Smoke of the Kellogg Company.)

CHAIRMAN HASSE: Are there any questions? If not, then, our program for the Sixteenth Annual Safety Congress has come to a close. I believe, however, I speak for all when I say the sessions have been of real benefit to us, and in behalf of the officers of the Food Section, I want to thank all the speakers and those who have participated in the discussions.

Although we are closing our sessions for the year 1927, they will still be conducted

Food Section

ough the News Letter, and any problems or anything you may wish to suggest
t will be of help, will be welcomed by Mr. Penty of the Kellogg Company, Battle
ck, Michigan.

ADJOURNMENT.

INDEX

Volume I.

- C Session, Minutes, 289-331.
 Accident Statistics: "Accident situation in the chemical industry", (Whittemore), 567-569.

SIXTEENTH ANNUAL SAFETY CONGRESS NATIONAL SAFETY COUNCIL

Marine Section

New Section Officers

Chairman, A. R. BUSH, The Barber Asphalt Company, Maurer, N. J.
Vice-Chairman, (In Charge of Membership and Publicity), ARTHUR M. TODE, The Texas Company, New York City.
Vice-Chairman, (In Charge of Posters and Slides), ROBERT F. HAND, Standard Oil Company, (N. J.), New York City.
Vice-Chairman, (In Charge of Information and Service), CAPT. R. C. BRENNAN, Pacific Steamship Company, Seattle, Wash.
Vice-Chairman (In charge of Stevedoring), F. P. FOISIE, Waterfront Employers Association, Seattle, Wash.
Secretary and News-Letter Editor, W. S. WELCH, The Travelers Insurance Company, New York City.
Program Committee Chairman, JOHN S. HUNTER, The Atlantic Refining Company, Philadelphia, Pa.

Retiring Officers

Chairman, CAPT. WM. P. KAIN, American Steamship Owners' Mutual P. & I. Assn., New York City; *First Vice-Chairman*, C. H. POTTER, Potter Transportation Co., New York City; *Second Vice-Chairman*, ROBERT F. HAND, Standard Oil Co. (N. J.), New York City; *Third Vice-Chairman*, CAPT. R. C. BRENNAN, Pacific Steamship Co., Seattle, Wash.; *Fourth Vice-Chairman*, F. P. FOISIE, Waterfront Employers' Assn., South Seattle, Wash.; *Secretary*, A. R. BUSH, The Barber Asphalt Co., Maurer, N. J. *Committee Chairmen*: *Poster*, CAPT. G. BARTLETT, Cosmopolitan Shipping Co., Hoboken, N. J.; *Program*, R. E. PROUTY, Aetna Life Ins. Co., New York City; *Membership*, ARTHUR M. TODE, The Texas Company, New York City; *Stevedoring*, F. H. WEEKS, Weeks Stevedoring Co., New York City; *Research*, CAPT. IRVING L. EVANS, Chairman, United States P. & I. Agency, Inc., New York City; *Publicity*, ARTHUR M. TODE, The Texas Company, New York City; *Information and Service*, MILTON D. MCINTYRE, Pickands, Mather & Co., Cleveland, Ohio; *Engineering Representative*, W. E. WELCH, The Travelers Ins. Co., New York City.

Tuesday, September 27, 1927

CAPTAIN WM. P. KAIN, Chairman.

Manager, American Steamship Owners' Mutual P. & I. Association, New York City

The first session of the Marine Section of the National Safety Council was called to order at nine-forty o'clock by the chairman, Capt. Wm. P. Kain, manager, American Steamship Owners' Mutual P. & I. Association, New York City.

CHAIRMAN KAIN: The section has devoted a great deal of time and attention to the matter of posters. I don't believe at the present time that the poster situation, so far as the Marine Section is concerned, is entirely satisfactory. We have had some difficulty in getting the kind of photographs and material we desire. I believe that during the coming year, we will probably make a much better showing in that respect than we have during the present year.

Capt. Evans will you give us just a short summary of what you have been doing with the statistical records?

CAPT. I. L. EVANS (U. S. P. & I. Agency, Inc., New York, N. Y.): A committee has been called upon, whose principal object is to account for how gauge glasses are manufactured and by whom and why, and also to give the reasons why they break. As a result, I made quite an exhaustive study of the subject and prepared an article which I submitted to the chief engineer of the Council for distribution.

In the matter of statistics, no particular progress has been made by the committee, because they have had no ground upon which to work. The Department of Labor has been working upon the subject of statistics through the cooperation of the steamship owners and other sources, to obtain information for the U. S. Compensation Commission. That, I might say, I propose to refer to more specifically and in detail later in my paper, so it will be a matter of record. I think there is nothing else to be said on behalf of the committee at this time.

A. M. TODE (Texas Company, New York, N. Y.): The substance of the report which I have delivered to your chairman shows that during the past year, we admitted 70 new members to the section. It is quite interesting to see how they are classified.

Annual Report of Membership Committee

At the 1926 Annual Safety Congress held in Detroit, there were enrolled with the Marine Section a total of sixty (60) members. The Membership Committee appointed at that time set as its goal the increasing of the Marine Section membership 100 per cent, a feat never before accomplished by any section of the National Safety Council during the space of one year. Due to the efforts of the several members of your committee, and through the assistance accorded the committee by other members, the Membership Committee now reports that the goal has been achieved. There are now on the rolls of the Marine Section 127 members, an increase of 70 members, equivalent to an increase for the year of 117 per cent.

Number of members in Marine Section as of October 1, 1926.....	60
Cancellations of members received from October 1, 1926, to September 26, 1927	3
	57
Number of new members admitted to Marine Section from October 1, 1926, to September 26, 1927.....	41
Subsidiaries and affiliations of members admitted to Marine Section from October 1, 1926, to September 26, 1927.....	29
Total for year 1927.....	70
Total membership of Marine Section as of September 26, 1927.....	127

The 70 members admitted to the Marine Section during the past year are classified respectively:

Petroleum corporations operating steamships.....	16
General freight and passenger steamship companies.....	14

Marine Section

5

Shipyards and repair yards.....	5
Stevedoring companies.....	6
Industrial companies and equipment manufacturers.....	12
Railroads operating floating equipment.....	2
Insurance companies.....	2
Maritime associations.....	3
Personal membership.....	4
Nautical schools.....	1
Miscellaneous	5
Total.....	<u>70</u>

Summary of Section Memberships

Among our 127 members are included the majority of the great American petroleum corporations, some of the largest and most influential American passenger and freight steamship companies, the largest railroads operating floating equipment, important shipyards, repair yards, stevedoring companies, industrial organizations, etc. A summary of our membership, the large majority of whom are actively and consistently prosecuting accident prevention work in their respective organizations reveals:

Petroleum corporations operating steamships.....	26
General freight and passenger steamship companies.....	24
Shipyards and repair yards.....	8
Stevedoring companies.....	12
Industrial companies and equipment manufacturers.....	13
Railroads operating floating equipment.....	19
Insurance companies.....	5
Maritime associations.....	6
Personal memberships	4
Miscellaneous	10
Total.....	<u>127</u>

Respectfully submitted,

Captain R. C. Brennan, Pacific Steamship Company,
 Wm. L. Bunker, California Petroleum Corporation,
 Alexander Hynd, Garland Steamship Company,
 C. D. Kennedy, Waterfront Employers' Association of Portland,
 Fern Wood, Williams Steamship Company,
 G. D. Zeh, Associated Oil Company,
 Arthur M. Tode, chairman, The Texas Company.

CHAIRMAN KAIN: I believe, Mr. Tode, you are the only representative of the nominating committee present and I ask you to report tomorrow.

We will now devote our time to the papers and discussions that are on the program. The first paper is entitled "The Maritime Safety Movement and Its Relation to America's Merchant Marine Problem," by Mr. Norman F. Titus, chief, Transportation Division, Bureau of Foreign & Domestic Commerce, U. S. Department of Commerce, Washington, D. C. Unfortunately, Mr. Titus has been in Europe during the greater part of the summer and he was not able to get back in time to attend the Congress. Mr. Roberts of the Department of Commerce will read Mr. Titus' paper.

The Maritime Safety Movement and Its Relation to America's Merchant Marine Problem

Norman F. Titus, Chief, Transportation Division, Bureau of Foreign and Domestic Commerce, U. S. Department of Commerce, Washington, D. C.

Americans, generally, are beginning to realize quite definitely that their country can no longer pursue a policy of isolation and self-sufficiency. Irresistible economic forces, largely due to the World War, have brought about new conditions which are presenting problems demanding early recognition and settlement.

As a result of its economic evolution, the United States is now a creditor nation; this is a new role, for hitherto it has been a debtor nation. This new development inevitably will produce profound changes in our economic status and force upon us new lines of action and new responsibilities. It is possible that, very shortly, we shall be importing more than we export and thus shall have an unfavorable trade balance. Such a change, however, will be accompanied by a great development of other functions of service, the payments for which are classified as invisible items on the international balance sheet. In other words, America may buy more than she sells, but she will equalize matters by acting as banker, ship-owner, insurance underwriter and investor for other nations. In this way other nations will pay invisible tribute to her. The study of economic history reveals the operation of these principles with great clearness.

However, it does not take a student of economics to recognize the growing importance of the necessity for an American merchant marine; the mere fact that the United States has a foreign trade of ten billion dollars a year, and that the freight bill for transporting this great quantity of goods is six hundred million dollars a year, is proof enough that our merchant marine is an imperative necessity. Obviously, as good merchants, Americans should do as much of their own delivering as possible.

Nevertheless, it does not require any evangelist to expound the doctrine of an American merchant marine as the American public is already strongly on record concerning this matter. Ever since the World War taught us the supreme importance of shipping, we have been clamorous for a merchant marine. Only last year this fact was evidenced in a most emphatic manner. The Shipping Board had been called upon by the United States Senate to prepare and submit to it comprehensive and concrete plans for building up and maintaining an adequate merchant marine, either publicly or privately owned and operated, for commerce and national security. The Board supplemented its own study and investigation by conducting public hearings in thirty-three cities, and also by addressing nine thousand questionnaires to representative organizations and individuals throughout the country.

The result of these inquiries was summarized in three statements:

- No. 1. It was unanimously held that the United States should have an adequate merchant marine for national defense and commerce.
- No. 2. With almost equal unanimity it was held that the merchant marine should be privately owned.
- No. 3. With equal unanimity it was held that until it is made possible for private interests to successfully own and operate the American merchant marine, the Federal Government must continue to do so.

Thus we have a clear and definite public affirmation of our merchant marine policy in favor of private ownership and operation as enunciated in the Mer-

chant Marine Act of 1920. This is as it should be, for one of the fundamental principles of our democracy is the preservation of the vital initiative and enterprise of our people. This statement of principle may be clear, but the actual putting it into practice constitutes our American merchant marine problem.

It has been pointed out repeatedly that the prerequisite of any successful operation of American merchant vessels in the foreign trade by private initiative is equality of opportunity with our principal foreign competitors. All that American shipowners have ever asked is an even start with their competitors; with this even start they guarantee profits. If they cannot guarantee profits, the investor will turn elsewhere, and without a supply of funds an American merchant marine would be an impossibility.

Three Issues to Be Met by Ship Owners

At the present time there are three issues that have to be met in order to achieve the necessary equality of opportunity for American shipowners. They are:

(1) The capital charges of our shipping must equalize those of our foreign competitors.

(2) Operating costs must approximate those of our competitors.

(3) Investors must be definitely assured of freedom of private owners from government competition; in fact, the menace of the great government fleet must be removed once and for all.

These various factors are too well known to require elucidation, for they have been debated in and out of Congress for years and there is a very extensive literature on the subject. Suffice it to say, however, that these disadvantages arise both from legislative requirements and restrictions and also industrial charges, all of which, in the main, have their genesis in commendable causes—better wages and better conditions for American labor.

Many solutions have been offered for these difficulties; but, while it is obvious that some form of governmental aid must be extended to maintain a merchant marine adequate for commerce and national security, nevertheless, the public and shipowners generally have looked with disfavor on any subsidy based on the tonnage or speed of the ship or upon the size or organization of the crew. Out of the continuous discussion, however, has been evolved a plan which is now meeting with such favor. It calls for a vigorous adherence to the spirit and letter of the Merchant Marine Act of 1920, quickly reducing government operations and placing ships in private hands under what is known as the trade route contract system.

This plan first calls for a committee of inquiry composed of representatives of shippers, ship owners and government departments to determine exactly which trade routes are vitally necessary.

The next step is a study of each individual route and an evaluation of its physical operation. In this study the committee will consider all factors of physical operations, cargo offerings, competition, etc.; it will determine what it should cost to maintain a service of a certain definite number of sailings per year. If the route can, in the judgment of the committee, be operated under normal conditions at a profit, then no governmental aid would be recommended. If, however, aid is necessary, the committee will determine the amount. After all this investigation has been completed, the plan proposed is that the government shall contract with private owners to render service in each route, the government paying a bonus of such a sum as the committee determines.

There are many details connected with this scheme. For instance, the Chamber of Commerce of the United States holds that the routes should be put up

for competitive bidding. Others hold the view that the government shipping organization should be revamped. At any rate, this trade route contract plan seems to offer a feasible solution of this merchant marine problem that has vexed us so sorely. Such a solution would guarantee equality of opportunity and enable our shipowners to get an even start in maritime competition.

However, this theory of trade route contracts is only half the story; for once we place our shipowners on even basis with foreign shipowners, American genius will be called upon to produce and maintain that refinement of operation that will give the same supremacy in maritime affairs that America possesses in industry. If this supremacy is to be attained it must be acquired by the same methods; the shipping executive must display the same capacity for efficiency, economy and scientific management that his brother industrial executive displays.

A Successful Battle with Rising Costs

For over a generation American industry has been battling with the question of higher costs and has been conspicuously successful in its efforts. So striking have been the results that, during the last two or three years, delegations and commissions from Europe have arrived in this country to study our industrial methods. Their purpose has been to ascertain how we could pay the highest real wages in the world and still compete with other nations in the world's markets. These visits were a frank recognition of our industrial supremacy; this supremacy being based upon original methods, most of which are distinctively American.

The shelves of every library are weighted with books dealing with the subject of American industrial methods. In these volumes we find our educational and social systems analyzed as to their effects upon our industrial progress; there are books without number upon mass production, refinements of methods and machinery, discussions of the human element in business, elimination of waste, scientific management, employee representation, safety engineering, cost accounting and many allied subjects.

Although industry has made such a remarkable record in the solving of its problems, apparently it has never occurred to shipping executives to profit by this experience. Railroad executives have been more alert, however, for during the last five years they have adopted many of the principles found in industry with the result that a veritable revolution has been wrought in railroading. The developments in railroading, through more scientific management and speeding up of service, have been such as to have produced remarkable effects upon business generally. The reduction of stocks in merchandising and similar changes, have been largely due to the improvement in rail transportation.

Herein lies a tremendous opportunity for shipping. By concerted and militant effort on the part of shipowners, the government aid program based upon trade route contracts can be consummated. With this achieved, shipping would have the equality of opportunity that has long been its dream. With this dream realized, adoption of the same intelligent and scientific methods as prevail in industry would make our merchant marine an outstanding success.

In launching such a new program the maritime safety movement is, undoubtedly, one of the most obvious and promising methods of attack. For several years, especially the last two, shipping has been laboring under excessive costs for personal injury insurance; this has been due to the increasing severity and number of accidents. As the increase in rate has been caused by excessive accidents, the remedy is to reduce the number of accidents. Industry has faced

this same issue for twenty-five years and has successfully met it with safety engineering.

Thus shipping has a great evil, but a remedy lies ready at hand. Wherever tried, safety engineering has been remarkably successful. Its general adoption by American shipping would be a first step in a program of efficiency, economy and scientific management that would put shipping on the same plane as industry and make possible real American maritime supremacy.

CHAIRMAN KAIN: Gentlemen, you have heard the paper which Mr. Roberts has just read. We are open for discussion.

CAPT. I. L. EVANS (U. S. P. & I. Agency, Inc., New York City, N. Y.): From my view of the situation, the conditions and problems and the possibilities which Mr. Titus has described in the paper are so obvious they are hardly open for discussion. I don't believe there is anyone to take issue—we all agree with them. The only problem to be answered is how to get them put into effect.

MR. ROBERTS: I presume your educational campaign would have something to do with that—posters and so on.

CHAIRMAN KAIN: The next paper is entitled "Marine Statistics and Their Relation to Seamen's Compensation," by Capt. Irving L. Evans, U. S. P. & I. Agency, Inc., New York City.

CAPT. EVANS: The title of my paper is a little more narrow in fact than I have treated the subject. In a way, it fits in with the paper by Mr. Titus. Here, again, we have the problem of trying to make the ship owners see the advantage of taking up and following some of the suggestions which have been and are being made.

Marine Statistics and Their Relation to Seamen's Compensation

Irving L. Evans, Vice-President, United States P. & I. Agency, New York City

There are many excellent reasons why every American ship owner should be deeply interested in marine accident statistics.

The use of the word "statistics" seems to have the same effect upon many marine men that a rough sea ordinarily has upon a landsman. Statistics, as here used, means only complete information about a particular and important phase of the ship owner's business, to which he now pays but slight attention, because usually he is relieved by insurance from financial responsibility for accidents occurring on the ships.

The ship owner has complete information, or "statistics," as to the methods and sources of obtaining cargo and passengers to carry and thereby earn revenue. If American ship owners are to compete successfully with foreign flag vessels, they must look not only to increasing the tonnage to be carried in American bottoms, but also to the reduction of overhead and operating expenses. This can be done, to some extent, at least, by wise and intelligent handling of the information constantly passing through the office of every ship owner. It is in the form of reports of accidents, damage and loss, also the payment of many claims. This applies not only to claims for personal injuries, illness and deaths, but to cargo damage, shortage and other claims.

Complete information, or statistics, covering marine accidents and claims will not only enable ship owners to reduce the number of accidents and claims, and thereby save, through a reduction in the total amount paid for claims, insurance premiums, or assessments under compensation laws, but will place them

in a position to deal intelligently and successfully with proposed Federal legislation, whether favorable or adverse.

At the annual meeting of the Marine Section of the National Safety Council at Cleveland, Ohio, on October 1, 1925, I stated that, in my opinion, there would soon be a Federal Compensation law covering the marine industry. Just twenty-one months later such a law, covering a large part of the industry, went into effect. It needs no stretch of imagination to foresee the presentation to Congress, in the very near future, of a proposed Compensation Law for the entire marine industry. This will come, I believe, either as an amendment to the present act, which became effective on July 1, 1927, to modify and change that law and include the men on seagoing ships, or as a separate act to cover seamen. I am reliably informed that steps will be taken, by the organization representing the men covered by the existing law, to increase the maximum allowances and to make other changes for their benefit. The consensus of opinion seems to be that there is room for improvements in the law, which should benefit the ship owners as well as their employees.

A Safety Code for the Marine Industry

The ship owner should not only have complete information to insure the passage of fair and reasonable amendments to the existing compensation law, when, and if made, but also to inaugurate the presentation and adoption of a safety code for the marine industry. Such a code is bound to come, and, in my opinion, will be introduced in Congress in a comparatively short time. It will undoubtedly cover the marine industry as a whole, when it comes, because the United States Compensation Commission has already been authorized and directed, by Section 41 of the present Federal Compensation Act, covering longshoremen and harbor workers, to investigate and study safety provisions and causes of injuries in employments covered by the act; also from time to time to make to Congress, and to employers, such recommendations as it may deem proper, as to the best means of preventing accidents.

American ship owners are already over-regulated to a point where they are hampered in competition with ships of other nations. The only way they will get relief through helpful and favorable legislation is, in my opinion, by being prepared to inaugurate and work for the repeal of certain laws and parts of laws, together with the modification and passage of others.

Our ship owners are found fighting before Congressional committees, trying to have proposed adverse legislation, initiated by others, modified, far more often than they are found working for the passage of something favorable which they have themselves initiated. In order to inspire confidence in Congress and to secure the support of the public in favor of improved legislation in aid of the American Merchant Marine, ship owners must be prepared to present facts to Congress in statistical form to justify and substantiate their recommendations. This can and will be done only when the ship owners, working through some central body or organization, place their combined knowledge and experience, in statistical form, where it can be used for their mutual interest and benefit. This principle applies whether they are working for the prevention of accidents, the adoption of a safety code, or the passage of a ship subsidy bill.

Before attempting to fight for the passage of favorable laws or to defeat those that are unfavorable, complete information, or statistics are necessary. Every ship owner recognizes and appreciates the value of statistics, or exact information, when he has to appear before a Congressional committee.

Statistics, as such, have little, if any, intrinsic value, but they are highly

valuable as beacon lights to guide the actions of those seeking to accomplish a definite purpose. No compensation law can be prepared, enacted and administered intelligently without statistics, to be utilized as rules and guides for those dealing with the subject.

We often hear statements made to the effect that statistics cannot be kept of accidents in the marine industry, and particularly those occurring on board ships, because the hours of labor are too irregular and uncertain. We know, from the splendid work done at Seattle, Washington, by the Waterfront Employers, and others elsewhere, in compiling, classifying and recording exact statistical information covering injuries to longshoremen at that port, and the causes thereof, that that branch of the industry can be properly handled.

There seems to be some doubt and confusion as to what information should be kept and recorded to be of value. There are some principles followed in compiling standard accident statistics which are applicable to the marine industry, in my opinion, based upon my knowledge and experience in that industry, with particular reference to the men afloat.

The marine industry is seriously handicapped in that there is no central source of information, reliable or otherwise, showing even approximately the number of deaths and permanent personal injuries, to say nothing of accidents of a less serious nature occurring on board ships.

Three Factors in Standard Accident Statistics

The record in standard accident statistics consists of three factors, which are used in practically all branches of industry. They are:

1. The exposure factor, determined by the total hours worked.
2. The frequency factor, shown by the number of accidents.
3. The severity factor represented by the time lost by reason of accidents.

In the standard plan accident severity rates are figured upon the days lost per each thousand hours worked; and accident frequency rates are based upon the number of lost time accidents for each million hours worked.

Accident severity rates and frequency rates can be determined from the above basic data, in the marine as well as in other branches of industry.

The accidents may be divided into three groups. First, those causing only temporary disability; second, those causing permanent disability, either partial or total, and, third, those resulting in death. The next important steps are: (a), to record the number of accidents causing loss of time beyond the shift or watch on which the men are injured; (b), the number of days lost on account of such accidents, and, (c), the total number of hours worked by all employees during the period under consideration. For temporary disability, the actual number of days lost, exclusive of Sundays, is employed in standard accident statistics. In cases of permanent partial or total disability and deaths, the time lost is determined by consulting a table which forms a part of the standard accident statistical plan. Standard accident statistics may, therefore, be used in the marine industry as a whole, in my opinion, for the following reasons and with the following slight modifications and exceptions:

Section 2 of the Act of March 15, 1915, commonly called the Seamen's Act, provides that "the sailors shall, when at sea, be divided into at least two watches and the firemen, oilers, and water tenders into at least three watches, which shall be kept on duty successively for the periods of ordinary work incident to the sailing and management of the vessel."

The Supreme Court of the United States in the case of *William O'Hara et al vs. Luckenbach S. S. Co.*, 1926, A. M. C. 149, decided in effect, on January 4, 1926, that it was unlawful to divide crews of ships into watches or to work them

while at sea other than as required or permitted by Section 2 of the Seamen's Act, except, of course, in the event of an emergency.

This makes it clear that deck crew, the sailors, may be worked for twelve hours out of twenty-four and the engine and fire room crews worked only eight hours out of twenty-four while at sea. The hours of work of the licensed deck and engine room officers, the mates and engineers, while at sea are also limited by law to eight hours in twenty-four, except in cases of emergency.

The law does not fix the hours of the men in the steward's department, those preparing and serving meals, shall work while at sea. Their hours are long and irregular, but it will be fair, for statistical purposes, to adopt twelve hours in twenty-four, the same as may be lawfully required of sailors.

Necessary Work Must Be Done on All Days

It is apparent that while at sea ship's crews must work Sundays and holidays, watch and watch. Section 2 of the Seaman's Act also provides that while such vessels are in a safe harbor, no seamen shall be required to do any unnecessary work on Sundays and certain specified regular holidays, but this does not prevent the performance of work by the whole or any part of the crew, necessary for the safety of the vessel or her cargo and for several other specified purposes, nor does such provision prevent the dispatch of a vessel on her regular schedule or when ready to proceed on her voyage. The work that may be and is required at any time during the voyage, even when the ship is in a safe harbor, is, therefore, so varied and extensive that no change from the watch and watch basis of computing hours of labor would seem to be necessary or advisable.

Crews are usually signed on within twenty-four hours of sailing time and frequently start to stand watch and watch from that time. They at least start on sailing day. It would be fair, therefore, to take as the basis, for statistical purposes, the number of hours per day which men may be worked lawfully and apply that for each day from the beginning until the end of the voyage, starting the day the crew signs articles and continuing until they are paid off, which must be within forty-eight hours after the ship is entered at the Custom House. Whether the sailing and arriving days should be used, or the days articles are signed and the crew paid off is unimportant so long as a uniform policy is adopted. This latter is important and the coastwise voyages would have to be arranged on the same basis as those in foreign trade. It is not only necessary that a uniform basis for keeping statistics be adopted, but that uniform reports and other forms be used.

Section 2 of the Seamen's Act provides that "at all times while such vessel is in a safe harbor, nine hours, including the anchor watch, shall constitute a day's work." Nine hours work per day, therefore, is the proper basis to use for all members of a ship's crew between the end of one voyage and the commencement of the next. Since the hours of labor in port and at sea are fixed by law, that requirement furnishes the best basis for statistics.

The increase in the membership of the Marine Section from sixty one year ago to more than twice that number at the present time is excellent proof that broad interest has been aroused in accident prevention work. Another proof of increasing interest is the fact that during the past three months the U. S. Department of Labor has had a corp of experts checking over the records of steamship companies and other sources of information, to obtain data about actual injury and death cases which have been handled, in order that these facts may be used before Congress, by the United States Employees' Compensation Commission, to demonstrate whether or not a compensation law for

seamen would be better than the present unsatisfactory and economically unsound plan of compensating them for their injuries.

The ship owners, without exception, have shown keen interest in the compilation of the desired information and have either made their records available to the Department of Labor or volunteered to themselves obtain the information from their files, at their own expense, and place it at the disposal of the Government. No better proof of their interest in the subject could be desired or obtained.

I am advised, however, by the representatives of the Department of Labor that of all the many files examined by them personally, estimated to me at more than two thousand, only about 10 per cent contained complete information which would enable them to determine, for statistical purposes, the number of days lost by the man as a result of an accident, the amount of money, if any, paid for injuries, whether he had been paid wages to the end of the voyage, period of hospitalization, etc. This information had to be obtained by the representatives of the Department of Labor from independent sources, although it was easily obtainable and should have been in the files in practically every case.

It would appear, therefore, to be of vital interest and importance to ship owners to collect, classify and distribute such information through their respective associations, or otherwise. Acquiring knowledge is of little consequence unless one applies the knowledge acquired.

The ship owners have demonstrated their interest in the safety movement and if they would know the value of the idea, they should try it out.

A More Minute Study of Statistics

CHAIRMAN KAIN: Gentlemen, we are now open for discussion on Capt. Evans' paper.

R. E. PROUTY (Aetna Life Insurance Co., New York City): I think most of those present are familiar with the fact that I wrote an article on the general subject of accident statistics in the marine industry, which appeared in the NATIONAL SAFETY NEWS. The basis which I suggested for the securing of exposure figures was somewhat different from that suggested by Capt. Evans. I am not attempting to show that my plan is better than the other. I know, however, that we have a gentleman here who arrives at his exposure in a slightly different manner, and I wonder if Mr. Arkills won't say something.

M. E. ARKILLS (Waterfront Employers of Seattle, Seattle, Wash.): Since Capt. Evans' paper was presented in Cleveland two years ago, I have looked back upon that as one of the fundamentals of statistical gathering. It gives the whole general plan for such work. What we need to do now, I think, is to go more minutely into the different branches outlined in that paper. To answer the question on exposure, we are arriving at our exposure through well formed statistics that are available in our office as to the actual earnings of the men working on the waterfront. We have their average daily wage, their average hourly wage, including time and overtime and penalty time, which in our port for last year amounted to \$1.08½ per hour worked. Now, if you take the payroll of any employer operating in those ports on Puget Sound where these men serve, if you divide that payroll by one dollar three and one-half cents, it gives you the main hours of exposure, which to us is a rather simple way of arriving at the amount of exposure.

I would like to mention a couple of other items in connection with Capt. Evans' paper of today. He mentioned something about the causes of accidents. It is my candid opinion, that if we would go to the very cause of each accident and group those accidents of similar nature, show the actual cause, we would find some very willing engineers when it comes to making certain deck equipment changes. For

instance, on some ships, I am sure that winches would be thrown in the bay and new winches installed, and they would be paid for in three or four trips on just the cargo broken through faulty winches and faulty gear.

Now, to go to another subject that Capt. Evans touched on today, this matter of a safety code which the commission is to suggest to Congress and to the employers. One of our employers takes the attitude that when that is suggested to him he can turn it down. I tried to disabuse his mind of that idea. I would like an expression from this group as to whether or not it is possible for the employer to have very much to say when the code is suggested. Going on the thought that it will not amount to much, the employer's viewpoint on this, we have gone ahead and drafted a tentative safety code. I have given out a few copies to those present, and I certainly want to see the blue pencil stuck through that in every place there is a possible chance to make a hole. If we adopt a safety code, I think we should have one that spells safety and not bureaucracy, and it should be a minimum safety code in every regard and not the maximum requirement.

CHAIRMAN KAIN: Mr. Arkills, I would like to ask you how that code is being prepared. Is it by one or two men.

Safety Committee Helped in Formulating Rules

MR. ARKILLS: Our safety committee over a period of three years covered 50 items that were suitable to be worked over into rules of action. That formed the nucleus about which we started to build this code. The English laws on maritime shipping and safety laid down a few more. We have revamped some of those, or Americanized them, and we then took up everything else that we could get from industry that would in any way fit the marine industry, and have worked them into this code. I imagine there are about 200 items in it now. There are at least 50 more that I shall want to put in it myself when I return to Seattle, together with those that are coming in daily from the mimeograph copies that I have sent out for blue pencilling by more of our employers and safety engineers around the town.

CHAIRMAN KAIN: Do I understand this code is to cover the entire operation of ships?

MR. ARKILLS: Owing to the fact that the compensation act, as it is now written, does not cover ship operation, we haven't gone into that; excepting where it does say "ships," we have covered some items. I think they will all be cut out.

CHAIRMAN KAIN: Is it your intention to submit that to all the ship owners on the Atlantic coast, for instance, before adopting it?

MR. ARKILLS: I haven't copies enough at present, but I should be glad if you thought possibly you could have mimeograph copies made in New York.

CHAIRMAN KAIN: It would be very helpful to do that.

CAPT. EVANS: In answer to Mr. Arkills' statement about the employer at Seattle who felt inclined to turn down the suggestion of the Compensation Commission if made, I think legally and technically he is entitled within his rights, because the act merely provides that the commission has power to suggest to Congress or to employers. If they have power only to suggest to Congress, we would certainly not say that the suggestion was law. If, therefore, we suggest to the employer, it has no more effect than the suggestion to Congress and there is no provision for any penalty in the act or elsewhere for his failure to follow the suggestion.

Now as to the basis for getting statistics, while I have read the article prepared by the chairman of our program committee, I feel that the basis for getting a thing of this kind on board ships, the basis for hours of labor, must be that which is fixed by law and which is actually followed. I don't see how you can take any other basis in the ship personnel, because that is the one which is followed.

I should like to suggest to this section that the chairman be authorized to take up with the steamship owners, who are members of the association, the question of appointing a committee to work with the Marine Section and its officers and committees, on a plan to suggest to the Steamship Owners Association a basis for getting at statistics for the marine industry. I offer that as a motion.

(The motion was seconded, was put to a vote and carried.)

CHAIRMAN KAIN: In that connection, I might read an article from the Council which deals in a general way with what is known as safe practices pamphlets or semi-technical papers on subjects which are of specific interest to the various industries represented in the National Safety Council.

A Plan for Sectional Safe Practices Pamphlets

Suggestion. It has been suggested that next year each industrial section should complete three safe practices pamphlets on semi-technical subjects which are of specific interest to the industry represented by that section.

What Has Already Been Done. Several sections have already done some work of this kind so well that other sections should be encouraged to undertake similar projects. For instance, the Construction Section has one sectional pamphlet on "Construction Work"; the Paper and Pulp Section has one pamphlet on "Paper and Pulp Mills"; the Metals Section two pamphlets, one on "Cleaning and Finishing Room in Foundries," the other on "Blast Furnaces"; the Mining Section has two pamphlets, one on "Underground Mine Cars and Haulage," the other on "Mine Rescue Training and Operation"; The Textile Section one on "Cotton Mills"; and the Public Utilities Section one pamphlet on "Protection of the Public in Public Utilities Operations." Sample copies of several of these pamphlets are attached to this letter.

How to Get Started. If this general suggestion is approved by your section, the chairman of your Engineering Committee might be given responsibility for working out the detailed plans. His plans and recommendations would be submitted to your Executive Committee; if approved, he would be asked to do everything necessary to put the plan into effect.

Suggested Plan. Attached is a list of all subjects which have been discussed at Congress meetings of your section. After each subject are listed the names of those men who spoke on that subject.

It is the suggestion that the chairman of your Engineering Committee study this list of subjects, making such additions as may be necessary to secure a complete list of all of the major accident problems in your industry. Then from this list select at least the three best subjects which could be developed into three Safe Practices Pamphlets.

A special committee of five to ten members of the section should be selected to handle each subject. In selecting a committee, it might be advisable to give special consideration to the men who spoke on the given subjects at the Congress. If a certain man presented a formal paper on that subject, perhaps he might be made chairman of the committee.

As soon as a committee is appointed, the Council's staff will send the chairman of that committee a copy of the congress paper which was presented on that subject, together with all other related data that is available. The committee will use this paper and data in preparing its pamphlet report.

Work of Committee. Members of the committee may be asked to meet from time to time, but the majority of the work can undoubtedly be done through correspondence. The work may be divided through the appointment of subcommittees, or the

chairman of the committee may find it necessary to prepare the first draft of the report single-handed. Copies of this draft can be given to each member of the committee for review. The committee chairman should take the criticisms and suggestions for improvement which come to him from his committee members, correcting his first draft accordingly, and then send out copies of a second draft for further review. He will go through this process until one draft (it may be the second, third, fourth or fifth draft) is approved by the majority of the committee. This draft should then be presented to the sectional executive committee for final approval and publication by the National Safety Council.

Reasons for Adopting This Plan. (1) This will bring out into the open much good data that is now "buried" in the congress proceedings.

(2) It will bring up to date and summarize all existing data on a given subject.

(3) Each pamphlet will present the cumulative experience of a group of members. As it is now, each congress paper presents the viewpoint of but one man.

(4) It will multiply the number of active workers in each section. It would be ideal to have every member of the section actively working on one or more committees.

Won't you please see that the contents of this letter are discussed and understood by the members of your section? Then notify this office what action is to be taken.

Sincerely yours,

W. Dean Keefer, Chief Engineer and Director,
Industrial Division, National Safety Council.

A List of Subjects and Authors

<i>Year</i>	<i>Subject</i>	<i>Author</i>
1923	Marine Fire Hazards	F. S. Titsworth, Attorney, New York City.
	Ship Stevedoring Hazards	W. E. Welch, Travelers Insurance Co., Hartford, Conn.
	Uses of the All-Purpose Canister Gas Masks Aboard Ships.	Capt. S. M. McBride, Chemical Warfare Service, Washington, D. C.
	Need and Functions of Ship Safety Committees.	George A. Marr, Secretary, Lake Carriers Assn., Cleveland.
	Carbon Dioxide in Marine Fires.	Chas. L. Jones, Institute of Ind. Service, Pittsburgh, Pa.
	Ship Personnel Hazards	Capt. Irving L. Evans, U. S. P. & I. Agency, New York City.
1924	Maritime Casualties	R. F. Edwards, Prudential Insurance Co., Newark, N. J.
	Reducing Accident Costs in Water-front Work—the Conflict Between Compensation and Admiralty Laws.	J. F. Fouhy, Manager, Smith Insurance Service, Inc., New York, N. Y.
1925	Fuel Oil—the Elimination of All Hazards Incidental to Its Handling.	J. H. Welter, Manager, Barber Asphalt Co., Maurer, N. J.
	Organizing for Safety on Board Ship.	A. R. Bush, Barber Asphalt Co., Maurer, N. J.
	Marine Statistics—Their Value and Compilation.	R. F. Edwards, Prudential Insurance Co., Newark, N. J.

Marine Safety of Personnel.	Capt. Irving L. Evans, U. S. P. & I. Agency Emergency Fleet Corp., New York, N. Y.
A Year's Attack of Stevedoring Accidents on Puget Sound.	M. E. Arkills, Waterfront Employers of Seattle, Seattle, Wash.
1926 Accident Prevention on Tank Steamships.	A. M. Tode, Marine Department. Texas Co., New York, N. Y.
Safety Engineering as Applied to Shipbuilding.	R. E. Prouty, Aetna Life Insurance Co., New York, N. Y.
Protection and Indemnity Insurance in the United States.	A. J. Smith, Marine Office of America, New York, N. Y.
Inventive Genius Developed by Ship Safety Committee Work.	George A. Marr, Secretary, Lake Carriers Assn., Cleveland, Ohio.
Accident Prevention Work in Passenger, Automobile and Freight Ferry Service.	W. S. Wollner, Northwest Pacific R. R. Co., San Francisco, Calif.
Safe Practices in Steamship Terminal Operations.	A. C. Warfel, Hartford Accident & Indemnity Co., St. Louis, Mo.

Valuable Data That Should Be Utilized

CHAIRMAN KAIN: There is attached to this letter a list of the subjects which have been discussed before the Marine Section of the Council from its inception. I think there is a great deal of valuable data in many of those papers, in fact I am sure there is, and that data together with the valuable papers that are being presented at this session of the Congress, will undoubtedly be of considerable help in the work of preparing a pamphlet for the coming year.

I think some of the steamship companies are represented here. I would like to have an expression of opinion on the advisability or inadvisability of drafting a code of safe practices in connection with steamship operation.

M. D. McINTYRE (Pickands, Mather & Co.): I think the code would cause a lot of trouble.

CHAIRMAN KAIN: I think the various industries represented in the Council have had that very point in mind. We all know, for instance, that state legislatures and the federal Congress are very much inclined to grab anything that is labelled a code and introduce it into the various legislatures to become law. Of course, once that is done, it is more or less an inflexible proposition and there is always danger that there will be features introduced which, while they might do in one section of the country or in one branch of industry, would work hardship in another section of the country or in some other branch of industry.

We, of course, know there are a great many types of ships in service and that they are operating under various conditions; so it seems to me that it would be rather dangerous to bring out a code unless it had first been criticized and examined by practically everyone in the industry and had met with their approval.

R. E. PROUTY (Aetna Life Insurance Co., New York City): Mr. Arkills evidently has a code in mind and it would be wise, if it could be so arranged, that the material which the Waterfront Employers of Seattle and the West Coast are working on could be used not for code purposes, but rather as a contribution toward a safe practice pamphlet which could be gotten out merely as a suggestion by the National Safety Council.

MR. McINTYRE: Perhaps that would be of much more interest to the industry than to have a code.

CHAIRMAN KAIN: I think that point is well taken. Anything that is labelled a code is much more apt to be adopted in law.

CAPT. EVANS: I might say in that connection that the Lake Carriers' Association, of which Mr. McIntyre's company is a member, has a pamphlet containing a long list of safety suggestions or recommendations submitted by the association to its members. It contains many very excellent suggestions and some of those pamphlets were circulated among this section when its membership was not nearly the size that it now is. Many of the suggestions are applicable to the operation of coastwise ships equally with ships on the Great Lakes. They do not call that a code. It is unnecessary to call it a code. If they don't adopt a code of some kind or a practice pamphlet of some kind and attempt to do something, they will find themselves regulated upon this as they have upon most every other subject by some law from Congress. It is only that suggestion that I have been trying to emphasize—that unless those in the industry themselves take some action, they will find that something will come either from the seamen or their representatives, or from some member of Congress who has been interested in the subject through some other source.

Minimum Requirements Outlined in the Code

ELMER B. TOLSTED (Fonda-Tolsted, Inc., New York and Chicago): It seems to me that it may be desirable to bring out your code before you bring out your safe practices pamphlet. That sounds like getting the cart before the horse, but when you look at it practically, I don't think it is doing so. Your safe practices pamphlet is very likely to be taken as a standard and everything that is found to be in the safe practices pamphlet is likely to be put into the code, whereas if you start on the code, get that out first, you can add a lot of things in the safe practices pamphlet. The things in the code are requirements, those in the safe practices pamphlet are merely recommendations. Therefore, I believe that it would be desirable to bring out your code first and have it as harmless as possible, and the safe practices pamphlet can have all the recommendations you please. That is a practical recommendation, I believe, for the saving of considerable money in the industry.

CHAIRMAN KAIN: Is your idea to make that code as simple as possible? Would you adopt minimum requirements for the code?

MR. TOLSTED: That is what your code is likely to be. It is most likely to be absolute requirements, things that must be done and as such should be as simple as it can possibly be made.

CAPT. EVANS: The problem to my mind is not as difficult of solution as it might seem. The United States Steamboat Inspection Service has authority by statute from Congress to make such rules and regulations for the safety of life on shipboard as they may consider necessary and advisable. Such rules and regulations, when approved by the Secretary of Commerce, have the force and effect of law. They can be changed on 30 days' notice by merely calling a meeting of the Board of Supervising Inspectors. That is the kind of code I have in mind, but I suggest and I would recommend that the ship owners prepare themselves with such a code and go, not to Congress, but to the Steamboat Inspection Service of the Department of Commerce and suggest what should be done; get the advice, aid and assistance of that body and then put something into effect. Congress will not interfere because it will already have the force and effect of law.

If they find that it is a hardship, that it is not workable, they can go back with the suggestion that certain modifications and changes be made and in that way place themselves within the control of the proper department of the government. There will be authority back of the code, but it will not be placed where it needs an act of Congress to change it.

CHAIRMAN KAIN: Do you believe, Captain, that if that were done it would pre-empt any legislation?

CAPT. EVANS: I do because it has the same effect.

CHAIRMAN KAIN: Of course, at the present time, the steamboat inspectors are largely devoting their activities to passenger craft.

CAPT. EVANS: That is true. There is no question about their authority under the law.

CHAIRMAN KAIN: No, that is very true. Of course, there is an advantage in that they have an organization all set up to handle such matters.

CAPT. EVANS: Yes, and their men would know whether or not the different phases and suggestions were practicable or not, whereas, with all due respect to the members of Congress, they would be guided by such advice and suggestions as they would get from outside sources without practical knowledge of the subject.

CHAIRMAN KAIN: There is a feeling today, I believe, in the steamship world, that the steamboat inspectors should be curtailed rather than given more authority to impose restrictions or limitations on the operation of ships.

CAPT. EVANS: Well, I can only point to the beacons that are staring the ship owners in the face, that is, Section 41 of the present compensation law covering longshoremen and harbor workers. That has already authorized the Compensation Commission to make suggestions to Congress and to employers relative to safety provisions and cause of injury; it certainly points to future action by the commission. It points to the intention of Congress to act because it calls for suggestions upon the subject.

CHAIRMAN KAIN: Are there any other comments? I think we have covered the situation pretty thoroughly. We can go on to the next paper.

Building Safety Into Ships

H. E. Parker, Fore River Plant, Bethlehem Shipbuilding Corporation,
Quincy, Mass.

The subject upon which I have been requested to address you is one that has claimed and received the undivided attention and best efforts of naval architects, marine engineers and shipbuilders for generations past.

The hazard of travel by sea has furnished an endless subject for song and story, and the mere sight of the ocean in its immensity awes the beholder and impresses him at once with the sense of its resistless power and of his own insignificance.

Mankind has built vessels, of varied forms of construction, for centuries, and in them has used all the navigable seas and streams of the globe for travel and trade routes, braving the hazards of storms, rocks and reefs, collisions, fire and other causes of shipwreck through which the sea has collected its enormous toll of human lives and property.

The same hazards confront us today, but we have made some progress in our endeavor to minimize these hazards and their effects, through improvement in hull construction, the use of radio-telegraphy, provision of life-saving apparatus and appliances, signalling and communication systems, fire detection and extinguishing systems, etc.

The subject is so vast that we must confine ourselves to brief mention of a few of the outstanding developments tending toward the production of safer ships and increasing the factor of safety for those who travel upon the seas.

The main factor in the development of hull construction, tending toward the greater safety and strength of ships, is the watertight subdivision of hulls.

It is obvious that the equipment of a ship with life-saving apparatus and appliances is secondary to the construction of internal bulkheads, dividing the ship

into watertight compartments which will secure such a reserve of buoyancy as will enable the ship to remain afloat for a reasonable period of time after a serious accident, and thereby insure, with the aid of proper and efficient arrangements, that all the units of the life-saving apparatus can be safely launched into the water with their quota of passengers.

About the middle of the last century some of the ships were being built of wood, some of iron, and a smaller proportion were of composite construction. Iron, as a material for ships, had definitely established itself; but many ship-builders and shipowners preferred wood, and others preferred the structural advantages arising from the use of iron framing partially plated, with the advantages of a wooden skin to receive copper sheathing and thereby avoid the fouling of bottom which was experienced by iron vessels sailing on long voyages.

The service records of iron ships built during that period prove conclusively that, despite the limitations then imposed by the comparatively primitive rolled iron industry, the foremost builders of iron ships could, and did, design and build good ships.

The evolutionary changes in the forms of construction, as rolled iron manufacture reached more advanced stages, would be interesting to dwell upon, but, unfortunately, the limits of this paper forbid more than a mere mention of the subject.

The Old Iron Ships Had Wooden Decks

For several years following the first appearance of iron ships, they were fitted with wooden decks, which covered only stringers and tie plates, iron decks being unthought of. As ships increased in size the necessity for providing greater strength than that obtained through the use of stringers and tie plates finally resulted in the fitting of iron decks, but, at first they were covered with wooden deck plates. Later the wooden sheathing was discarded, except on passenger ships and those ships built for some special trades, and unsheathed steel decks became the usual thing on cargo steamers.

Various preparations have been placed upon the market, and used somewhat extensively, for the purpose of protecting iron and steel decks from corrosion, and, in addition, affording the other advantages associated with wood sheathing.

Now, to return to the subject of watertight subdivision. In Great Britain's Merchant Shipping Act of 1854, it was enacted that "every steamship built of iron, of 100 tons and upwards, shall be subdivided by substantial, transverse, watertight partitions, so that the fore part of the ship shall be separated from the engine room by one of such partitions, and so that the after part of such ship shall be separated from the engine room by another of such partitions; also, that every screw ship built of iron shall, in addition to the aforesaid partitions, be fitted with a small, watertight compartment inclosing the after extremity of the shaft."

These partitions, or bulkheads, were to be provided in addition to the collision bulkheads which were required to be fitted forward on all vessels of that period.

This law was repealed in July, 1862, and the reason given for the repeal was: "not because of any doubts as to the necessity for proper and sufficient watertight partitions, but because these enactments, which required only two of such partitions for all sizes and classes of ships, had become practically useless or mischievous."

It was found that in large vessels more partitions were necessary to insure

the safety of the ship, than the number required by the law in question; and it was thought better to leave builders and designers unrestricted in providing extra strength and security for the various types and sizes of ships, rather than to pin them down by statutory regulations, which could not be drawn up in such form as to cover the constantly changing needs and circumstances of the shipbuilding trade.

The loss of 233 persons in the passenger ship "London" in 1866, together with the foundering of the "Amalia," led to a meeting of the Council of the Institution of Naval Architects to consider the general question of safety of life at sea. It was considered that one of the things far from satisfactory at that time was the number, position and construction of bulkheads in passenger and other ocean steamers. Recommendations were formulated by the Council in 1867, the fifth of the list reading as follows:

"It would add much to the strength and security of steamships if transverse and longitudinal bulkheads, coal bunkers, iron lower decks and screw alleys were all so connected with the hull of the ship and each other, as to form independent cellular compartments, watertight and having all their communications with the decks and each other by watertight doors, worked from the deck. In proportioning the compartments (especially in ships devoted to passengers), it is desirable to so arrange them, that if any two adjacent compartments be filled with water, or placed in free communication with sea, the remaining compartments will float the ship. It is considered that no iron passenger ship is well constructed unless her compartments be so proportioned that she would float safely were any one of them to be filled with water, or placed in free communication with the sea. Double bottoms are to be regarded as a great element both of safety and strength in the structure of a large iron ship."

The British Admiralty Investigation of 1875

The matter of double bottoms will be considered later on in this paper, but now it is desired to call attention to the fact that the foregoing recommendations to shipowners and shipbuilders had but little effect, as was shown by the results of an investigation made by the British Admiralty in 1875, for the purpose of determining the suitability of mercantile vessels for certain government purposes. It was found that only about thirty vessels complied with the minimum requirements deemed necessary by the Council in 1867, while over 4,000 vessels failed to meet the minimum requirements.

Following this investigation there was a decided improvement in ship construction, conforming to the requirements mentioned, for in 1883 some 400 vessels were found that complied with the minimum requirements as formulated by the Council.

Many of the vessels of that period had bulkheads fitted that ended at the height of the load waterline and were therefore useless, in so far as the safety of the ship after damage was concerned; as a matter of fact such bulkheads were primarily fitted for the purpose of adding strength.

In reference to the matter of double bottoms, it was about 1860 that water ballast tanks began to form a part of the bottom structure of steam colliers. The cellular double bottom is to a large extent an evolutionary development of the "McIntyre" tank, so the early steam colliers were to that extent the progenitors of the typical mercantile steamer of today.

In 1876 a system of double bottom, bracket framing was introduced; but it was not until about 1880 that the cellular double bottom appeared in mercantile ships in a form at all resembling the present form: although an arrangement somewhat like it had been adopted some years previous in armored warships, but without the characteristic feature of the margin plates at each

bilge, with its frame attachments, which up to the present time, with some modification, is peculiar to the mercantile steamer.

In 1887 cellular double bottoms had become quite general in both cargo and passenger ships, but up to a couple of years later some of the largest and fastest ships were constructed without double bottoms, and with ordinary floors and shaped keelsons standing upon them. A few years later only vessels built for carrying petroleum in bulk, and some of the smallest cargo steamers in the coasting trade, were being built in that way.

Results shown in the cases of collision of large steel ships fitted with double bottoms have demonstrated quite conclusively the great protective value of the double bottom.

It might prove of interest to note here that ships carrying cattle from this country to England were fitted with bilge keels for the purpose of reducing rolling long before the practice became general upon passenger ships. Cattle carried by the ships were injured by heavy rolling, therefore the ships were fitted with bilge keels.

The shipping classification organizations have played an important part in obtaining increased subdivision construction in ships, particularly since 1882. Their requirements insisted upon more bulkheads for the larger vessels than were demanded by the repeal law of 1854, the increased number of the bulkheads being determined by the length of the ship, and the requirements specified the approximate positions of the bulkheads.

In 1887 a committee of the House of Commons of England, appointed to consider the laws relating to boats and other life-saving apparatus, stated in its report: "The proper placing of bulkheads so as to enable a ship to keep afloat for some length of time after an accident has occurred, is most important for saving life at sea, and a thing upon which the full efficiency of life-saving apparatus largely depends."

Bulkheads Become Established in Ship Construction

An advisory committee appointed shortly afterward by the British Board of Trade, expressed the same opinion; and in March, 1890, a special committee was appointed by that body to consider and report upon "the manner in which ships shall be sub-divided so that they may float in moderate weather with any two compartments in free communication with the sea," and further "what precautions are necessary as to openings in longitudinal bulkheads to enable the water to pass freely, or under control, from one side to the other in case of the ship showing signs of instability, as might readily be the case should she be struck on a transverse bulkhead and two compartments, both on one side, be in free communication with the sea."

The committee recommended that the suggested standard should apply to all seagoing steam vessels, not less than 47½ feet in length, which held passenger certificates under the Merchant Shipping Act and also to passenger channel steamers, irrespective of their length, whose principal employment was the carriage of passengers and mail.

Somewhat less rigid requirements were proposed for smaller types of seagoing vessels. The committee further recommended "that a compartment subdivided by one or more longitudinal bulkheads should be treated as one compartment only, unless the owners notify the Board of Trade, that the vessel will not have her stability seriously reduced, or lost, — that any part of the bulkhead deck at the side is underwater, in the event of a space between a longitudinal bulkhead and the vessel's side, or of two such adjoining spaces on the same side of the vessel being open to the sea. If the Board of Trade

is not satisfied in this respect, trimming valves should be fitted at such longitudinal bulkheads."

The report of this special committee exerted a beneficial influence tending toward a further improvement of watertight subdivision of ships and a consequent increase of safety.

The "Titanic" which sank with a loss of 1,498 lives, following her collision with an iceberg in 1912, and whose loss shocked the civilized world, had only a single skin on her sides above the double bottom. It was the general opinion that if the ship had been fitted with an inner skin carried up the sides of the ship from the inner bottom skin she would not have been lost.

After the loss of the "Titanic" her sister ship, the "Olympic," was withdrawn from service for a number of months while having an inner skin fitted.

Longitudinal bulkheads are fitted in the best and fastest ships crossing the ocean today. The additional protection afforded in the case of a collision where the outer skin of a ship is penetrated is quite obvious.

Methods of Stiffening Watertight Bulkheads

The stiffening of watertight bulkheads has been greatly improved upon. In 1860 the only stiffening provided, beyond what was afforded by the several decks, consisted of angle bars of reverse frame size spaced about 30 inches apart. The steamer of small tonnage built at that time usually had more decks than would be the case today, but the bulkhead stiffenings were, as a rule, inadequate to the task of resisting the pressure of a hold being filled with water. Lloyd's Register increased the stiffening requirements by insisting upon vertical stiffeners, of frame angle size, and the addition of horizontal stiffeners spaced four feet apart. Later on deep vertical webs at the middle line and on each side were added, their number being determined by the breadth of the vessel, and these were supplemented by semi-box stiffeners in cases where decks were not laid on the beams and by fitting brackets to the heels of the vertical stiffeners and to the extremities of the horizontal stiffeners. Subsequent developments resulted in the general practice of using vertical stiffeners only, frequently formed by flanging the edges of the bulkhead plates, which for this purpose are arranged vertically. The stiffening of the bulkheads in the way of each "tween deck" and in the holds, being governed by both the depth from the top of the bulkheads and by the height of "tween decks" or depth of holds, as the case may be. The stiffening of transverse watertight bulkheads of today is a decided contrast to that of the past.

The loss of the "Titanic," already mentioned, brought about the great International Conference on Safety of Life at Sea, held at London, England, from November 12, 1913, until January 20, 1914, with official commissioners representing the Governments of the United States (where commissioners were sent to represent the President of the United States), Great Britain and Possessions, France, Italy, Russia, Germany, Spain, Austria, Belgium, Netherlands, Norway, Sweden and Denmark, having at their disposal the knowledge, skill and experience of the world's foremost naval architects, marine engineers, shipbuilders, shipowners and navigators, united for the purpose of making a world-wide effort to minimize, so far as human skill and effort might contribute, the hazards confronting lives and ships at sea. The conference resulted in the promulgation of Articles and Regulations prescribing the standards and structures to be used for minimizing every known form of hazard to life at sea. The Articles and Regulations cover the greatest range, providing for the patrol and destruction of derelicts, navigation safety, communication of distress signals, code provisions of life saving apparatus and equipment, anti-fogging equipment, training of ship's crews in boat and fire drills, etc.

Senate Document No. 462, Sixty-Third Congress, Second Session, published by the Government Printing Office in April, 1914, defines the types of vessels in the United States to which the Convention Articles and Regulations apply.

That the modern ship, constructed in accordance with the requirements demanded by the rules and regulations adopted by the International Conference on Safety of Life at Sea, is a safer ship than any constructed in the past was convincingly demonstrated on May 23, 1927, when the steamship "Malolo," while on her trial trip, was rammed by the freighter "Jacob Christensen" while proceeding through a fog about 15 miles southwest of Nantucket Shoal lightship. Distress calls radioed by the "Malolo" after the crash brought ships to her side from every point of the compass, but they resumed their voyages later when told that the injured ship was not in need of assistance. The "Malolo" was towed to New York for repairs. A few brief extracts from an account of the accident, which appeared in the May 29 issue of the *New York Times* gives us the following information: "Her two fire-room compartments were flooded with more than 6,000 tons of water, which had poured through a great gash below the waterline, yet the ship floated on a comparatively even keel, although drawing more than her normal draught."

The Wonderful Efficiency of the "Malolo"

"An enemy ship seeking to disable her could not have selected a more vital spot," is the opinion of Rear Admiral David W. Taylor, U. S. N., retired (who was on board as an observer), "yet she remained afloat. It is unprecedented," he said, "to see a ship rammed square amidships and still float. The 'Empress of Ireland' went down in a few minutes, in the St. Lawrence River from a similar injury. You can judge how hard she ('Jacob Christensen') hit us ('Malolo') by the fact that she struck on the port side and cracked a plate on the opposite side of the boat. It hit just at the bulkhead partition. We owe our escape to the lessons learned in the 'Titanic' disaster. At the International Convention for Saving Life at Sea, in London, after that accident, the question of water-tight bulkheads, height of bulkheads and such matters were discussed and regulations recommended. This boat is built in accordance with those regulations although such construction is not a law in this country."

From the same newspaper account we learn that "after the 'Malolo' had been tied up to the Hoboken pier about one hour, divers for the Merritt, Chatman and Scott Companies went down to see the actual amount of damage done. They reported that 24 feet below the waterline there is a gash ten feet long and four feet wide, reaching for about ten feet into the hull. The divers also found four other breaks about eight inches long."

The "Malolo" carries 20 non-sinkable lifeboats, with a varying capacity of 1,016 people; 54 more than her total list of passengers and crew. Two of these lifeboats are heavy duty motor boats, each equipped with "wireless" sending and receiving apparatus and capable of towing all the other lifeboats.

The circumstances attendant upon the accident and the nature of the injury received by the "Malolo" furnish a complete illustration, requiring no elaboration, of the value of the subdivision of the hulls of ships into water-tight compartments. It is well worth the expenditure of considerable thought and money, and the effecting of compromises where necessary, if it leads to the designing and building of hulls which will not lose their buoyancy and stability when subjected to hazards of the sea and at the same time are not open to any serious commercial or financial objections.

We might note a few more points regarding the structure and equipment of ships, tending toward greater safety, before bringing this paper to a close. Ships

ships are required to steam through ice are protected by means of special framing and plating forward near the water-line. Suitable steering gear is a matter of great importance and is given special attention in the design of all ships. Submarine hull signals are of great importance. These signals travel faster and farther than in the air and have the added advantage that at the depth where the signal is being transmitted the successful transmission of signals is not prevented by the heaviest gale. Ships equipped with the receiving instruments are enabled to pick up these signals from lightships when all other means fail.

Radio-telegraphy plays such a tremendous part in the safety of lives at sea and the fact is so well recognized that the mere mention of it suffices. Lifeboats, life rafts, and other buoyant apparatus and appliances are a necessary part of every ship's equipment and are following the general trend of improvement in design and construction. For the prevention of fire on ships, the elimination of wood and other combustible material, as far as possible, will reduce the fire hazard. In addition to the usual means of extinguishing fire by the use of water and steam jets, there are several fire detection and fire extinguishing systems; some of these operate in conjunction with each other, the pipe line through which the detector indicates the presence of fire in any compartment serving also to carry the extinguishing fluid for distribution throughout that compartment, the same being operated by the turning of a valve.

The ships built today have greater strength of structure, provide greater security against the hazards of the sea and maintain a greater regularity of schedule than the ships of the past.

Some of this development and improvement can be credited to the substitution of mild steel for iron and the use of high tenacity steel for those parts of the ship's structure subjected to the principal tensile stresses. Some of the development is due to the improvements made in marine steam engines, to the application of the steam turbine and to the further advancement furnished by the diesel engine and electric propulsion.

Progress in the processes of steel manufacturing, in the rolling of steel plates and sectional material, have been conducive to more efficient structural combination and therefore to stronger and safer ships.

Judging by past performance we can look forward with great hope to the future. We cannot tell what tomorrow will bring forth, but progress ever moves forward and we have every right to believe that the ships to be built in the future will be the best and safest that the world has ever known.

Possibilities in the Use of Stainless Steel

CHAIRMAN KAIN: That is a very interesting paper, Mr. Parker, and I thank you on behalf of the section.

Gentlemen, have you any questions you would like to ask Mr. Parker in connection with his paper?

M. E. ARKILLS (Waterfront Employers of Seattle, Seattle, Wash.): We have some winches now that are equipped with stainless steel. I wonder if it would be possible to use stainless steel in the hulls of ships to overcome the rust.

MR. PARKER: It is quite possible to use stainless steel at the present time, though they haven't developed it to the point where it can be used commercially for that purpose. I understand it has been considered for hulls for some time but up to the present time, the engineers say "no." That is the only reply I can make. In regard to its use around winches, that is getting to be a very general practice and I think the engineers practically recommend it.

MR. ARKILLS: Isn't that on account of the cost, perhaps?

MR. PARKER: That is what I mean, that it is not commercially used now for that reason.

CHAIRMAN KAIN: Are there any other questions, gentlemen?

A. M. TODE (The Texas Co., New York City). On the subject of stainless steel, we have used that to quite an extent on our oil tankers in the piston rods, valve stem, etc., on our oil pumps and we found it very desirable. It is true that the first cost is higher, but I think the majority of steamship owners will be glad to pay the additional price for that material when they realize how much better it works out afterwards. In the oil tanker trade, we would like to have a greater use for stainless steel, that is, we would like to have it adapted to more of our work. It is unfortunate that up to the present time, it has not come into such common use. We also use on our oil tankers what is called a vent or vacuum valve. These valves are put on the tanks in order to relieve any pressure due to expansion and contraction of the oil. For many years these valves have been made of regular steel and fitted with springs. Gasoline has a very harmful effect on steel, not only in the tanks themselves, but especially on these valves. The tankers must have these valves in good condition at all times, because if they should stick and the pressure in the tanks should increase to an appreciable extent, the tanks will be ruptured. This has happened on numerous occasions. We are now going to have these valves manufactured for us of stainless steel so that corrosion will be eliminated and the sticking of these valves will practically be eliminated.

Stainless Steel of Advantage to Oil Companies

The construction of stainless steel hulls, of course, is a very large subject. Speaking for the oil tanker trade, I think that if stainless steel could be manufactured at a reasonable price, it would meet with a great deal of approval with the oil companies, because we have a great deal of trouble in having the tanks rust. In fact, it is commonly known that oil tankers when first built are put in what is called the light oil trade—that is gasoline trade—because of the tendency to corrode rapidly. After ships have been in the light oil trade anywhere from seven to ten years they are taken out and used for carrying crude petroleum, because that has a preservative effect. We have tried any number of paints and various concoctions which have been offered us, in order to prevent them from rusting. We have never yet been able to find anything which will withstand the action of the gasoline and save our plates.

There is another manufactured process which has come into prominence in the last few years that is known as chromium steel plate. We have tried that in various parts of our ships and found it very successful. Of course, that is quite high in price, too. There is a method of merely covering the surface of the steel with palladium or chromium, a very light coating, of course. That coating is also being used by automobile manufacturers now for the nickelware on the automobiles to prevent rusting.

MR. ARKILLS: I believe the cost of paint in five or ten years, just painting the hulls, which is unnecessary with stainless steel, would pretty nearly in itself absorb that first cost that would be additional to the ordinary steel. At any rate, any replacement of plates would eat it up very rapidly.

CHAIRMAN KAIN: One of the most common causes of accidents, at least on freighters, has been the falling of men through the hatches. The present type of hatch, used on general cargo ships, appears to be unsafe under certain conditions. I think shipowners would certainly welcome a different type which would help reduce accidents.

MR. PARKER: Of course, your accidents are controlled pretty much by the regulations set up by the American Bureau of Shipping, which states that you must have a hatch of such a nature which is a water-tight hatch. Now there have been quite a number of discussions relative to the very thing you speak of. One answer to it is a non-slipping floor material around these hatches, the impression being that the reason men are falling into the hatches is that they stoop over and their feet go out from under them. That seems to be getting a good deal of attention and I think that it is really coming. Take naval vessels, for instance, they are using non-slippable gratings, ladders and things like that of a special make, just for that purpose.

The slipping on ships seems to be the biggest hazard in connection with the ordinary run of ships, although not the biggest hazard in connection with oil tankers.

MR. TODE: I would like to correct you, to say our accidents are mostly due to falls on oil tankers.

The Wooden Hatch a Source of Accidents

CHAIRMAN KAIN: We have had some very serious accidents with the wooden hatch which is quite generally used. The hatch covers are not always kept up as thoroughly as they should be, but even when they are, we occasionally find that the shipbuilders have turned out an arrangement of hatches which in itself contributes to the accident. I am referring particularly now to the dimensions of the hatches. You will often find, for instance, in any given hold that the dimensions of the hatches on the weather deck are different from those on the 'tween deck. As you know, in handling cargo those wooden hatches are shuffled around more or less and are put on very carelessly, often fitting too loosely, so that there is not sufficient bearing surface under the hatch covers. The longshoremen often fall into the holds with the hatch covers, a drop of possibly 20 or 30 feet. It seems that in taking precautions to prevent these accidents, they could begin by standardizing the hatches on any given ship.

MR. PARKER: There is no question but that could be done. I do know this, that shipbuilders are absolutely wide open for any kind of suggestion that will minimize accidents. To shipbuilders, accidents have gotten to be a very serious thing. It seems that some of the ships that have been turned out by shipbuilders have a Jonah attached to them, having had several accidents, and that has quite a reflection on the builders themselves. They are, as I say, very wide open now to receive anything in the way of recommendations which will minimize accidents on any ship they build.

CHAIRMAN KAIN: Do you know whether they are making any effort to design a different type of hatch, one which would be less liable to cause accident?

MR. PARKER: No I don't think they are because that is a peculiar thing about shipbuilding. You have to take into consideration that there are no two ships alike. You may build, say, two or four ships which you say are alike. But there were no two ships ever built alike. The government, today, is trying out a scheme on naval vessels to build six scout cruisers supposedly alike, but it is one whale of a job to bring that about.

CAPT. EVANS: You see no reason do you, Mr. Parker, why they should not have hatchways of the same size in ships of general class and why the sections of hatches for those standard hatchways should not be made the same dimensions, so that if they should get misplaced or one substituted for another as is now frequently done, they will make a fair fit?

MR. PARKER: There is no reason why they couldn't standardize that as far as I can see, excepting it would have to be standardized according to types.

CAPT. EVANS: The importance of it is emphasized by the experience of the past summer. There occurred ten or a dozen deaths in as many days, as a result of men going through hatches.

MR. PARKER: Was that through the main hatches?

CAPT. EVANS: Through the 'tween and main deck hatches, the regular cargo hatches 'tween decks or bridge deck or main deck, or whatever it might be.

MR. PARKER: In most of the modern ships the cargo hatches are built up approximately 30 inches with a protective flange all the way around, which is the first step that helps the condition that you speak of. Practically every ship being built today carries that flange on each deck.

The Chief Difficulty May Lie 'tween Decks

CHAIRMAN KAIN: I think the chief difficulty is on the 'tween decks. They put on those wooden hatches and use them as a platform while loading the cargo in the 'tween deck compartments. I think by far most of the accidents occur in that way, although there are a few happening at the weather deck hatches.

MR. PARKER: Most of them are coming out with that flange on at every deck. If you pass through three decks you have three flanges. On some of the ships that were put out during the war, so-called shipping board vessels, a great many of them are perfectly flush, you can step right off.

M. E. ARKILLS (Waterfront Employers of Seattle, Seattle, Wash.): Mr. Chairman, would it not be possible to make up all hatches in multiples of certain figures, like even-feet and half feet, and no hatch be made any other dimension? If you go on board a ship now and measure the hatches, you will find them four feet, one and three-eighths and some eight feet, one and three-quarters. Those are things for which there is no excuse in the construction of a vessel. In the making of a 40-foot hatch, you can make it a few inches longer or shorter to reach that multiple. They could easily be established. They would come in regular dimensions, then your hatches would always fit all they way through the whole ship.

MR. PARKER: The principle of hatches is entirely the other way. When you build a ship, you build the hatches as large as you can between certain points. That is where you get your unusual dimensions.

MR. ARKILLS: That isn't the only thing that is done backwards on ships.

There is one other thing I don't think comes up in the paper you have read. That is the location of the gooseneck, with reference to the side of the ship. You will find the gooseneck or the heel of the boom located away out near the rail on one ship with a great long boom. There is no way of getting any drift on your guy. The next ship will have a short boom and single mast and the heel will be near the center line.

The Engine That Wouldn't Fit

MR. PARKER: Of course, when a man wants a ship built, he gives you the design and you merely work out the details in construction. That reminds me of a contract we took a short time ago. A man wanted us to build a ship and he wanted a certain type of engine which he was going to purchase, himself. We took the contract under that basis and when we commenced to go over the plans, found no way possible to get the engine into the ship at all.

In another case a man wanted us to build a ship for him and he was going to furnish the power equipment, the engine and boiler, etc. When we checked the thing up, we found when we put the engine and boiler in, it couldn't carry a pound of cargo.

But I do feel this way, that shipbuilding today is growing by leaps and bounds to a much safer ship in all ways.

MR. ARKILLS: The principal point that I wanted to bring up was that we find lots of ships with the mast amidship and two short booms that will scarcely reach over the side of the ship, which means that in trimming your booms and handling cargo, you often have to lower them so much in order to get out; that you don't drift enough in your falls which makes your falls pull very much against each other and causes failure of guys or booms or other gear. That is one thing we might recommend that our American Marine Standards Committee look into and make recommendations on.

The other item is an engineering proposition. When we made those boom tests in Seattle at the University of Washington, among other things, we found that one man went so far as to say that the boom could be considered as a column. If you will go aboard any cargo ship with any length of boom at all and hold up a straight edge when the cargo boom is lowered in the position of work and sight over the top of your straight edge and boom, you will find many times the boom is below the straight edge in the center at the belly of the boom which means it is not in center. Yet if you consider that as a column, you are considering it under its wrong engineering elements and there is the first engineering mistake in the treatment of booms. We should treat them under a different engineering principle, and that being true, I think we should do something to get more engineering into the construction of booms, into the maintenance of them and into the setting of the masts.

I think those are two very important things. I have seen many failures that seem to point right back to those two simple things that have just come up from present practice, rather than engineering requirement.

No Two Ships Have the Same Arrangement of Parts

CHAIRMAN KAIN: I think what you said is quite true. The matter of booms, in fact all the cargo handling equipment on ships, does not come under the supervision of the steamboat inspectors. The classification societies practically pay no attention to it, so that in the final analysis, the design and arrangement of that gear, whether it be a moving part or a fixed part, is left largely to the discretion of the shipyard or to the personal views of the owner, and the result is that we have a great many different rigs. In hardly any two ships will you find the same arrangement. Some of them are very good, others are fair, some really dangerous and the ships operate possibly for the entire period of their lives with the particular arrangement put on them when built. If something carries away, it is renewed, but it is very improbable that any alteration is made in the design or structural arrangement of the gear. One thing you mentioned this morning, the matter of goosenecks on cargo booms. Often they are very poorly designed or fitted. There is considerable corrosion of the metal at that particular location because it is exposed to the weather. The boom gooseneck is often more or less neglected by ships' crews, becomes frozen and the first time it is used carries away and you have a serious accident. I think that the Marine Section could very well afford to work with the Marine Standards Committee and also with the naval architects and the Classification Society, to try to work out some better general arrangements for the cargo handling gear on ships.

MR. ARKILLS: I came across a proposition recently that might be of interest from an engineering standpoint. That was along the line of a ship that had broken or bent down two steel booms. An examination of the booms showed they were full strength five-ton booms, according to American Marine standards and to standard practice of the day, but the winch was a foreign one with a heavy rotor and very

small solenoid brake; the result being that when they came up against anything solid, the rotor continued to operate, even after the power had been shut off, on account of the small solenoid brake which did not stop the rotor soon enough to save the booms. As a result, in five months seven booms had been bent down on that vessel. There is no doubt in my mind but that it was just engineering unbalance that caused it.

CHAIRMAN KAIN: That was really an electrical problem rather than a mechanical one.

MR. ARKILLS: It is a balance of design that was not attained in that particular instance.

Placing a Prohibitive Load on the Wooden Boom

CAPT. T. W. SHERIDAN (New York State Nautical School, New York City): I have quite a number of times seen wooden booms broken that were supposedly up to full strength, probably due to the load being swung out, and lowered away too fast, permitting it to bring up with a sharp turn. You get a much greater stress than the mere weight of the load because of the fact that you are actually stopping a falling body with its momentum. That puts a sudden stress on the boom or sometimes buckles the boom and breaks it in the middle, especially if it is away out.

MR. ARKILLS: We have that same difficulty on two different lines of ships. They have very fast winches and they hold well on stopping or reversing double winches and the operators quite often like to drop the load away down, almost to the bottom of the hold and then stop it suddenly. The whole gear is just flopping in the air when they do it. I have made quite a campaign against that very thing with our hatch tenders and foremen and the result has been that you see very little of it any more. It is absolutely foolish because there is plenty of time to take that load down slowly and stop without that sudden impact.

R. E. PROUTY (Aetna Life Insurance Co., New York City): I have been greatly impressed while listening to the discussion this morning, with the possibility of having a generation of men at sea who will have a greater knowledge of the ways and means of preventing accidents. By accidents I mean both personal injuries and property damage. It seems to me that the finest field in which work can be done is among the young men attending the nautical schools. They will be the men who will carry on and I have wondered as I have been sitting here, if it would be possible to arrange with the several schools to have a half-day or day session, perhaps once a year—perhaps a joint session of the students and the members of the Marine Section—who might happen to be in that particular vicinity—and stir up as much enthusiasm as can be stirred up by providing through the section, competent speakers for such meetings. I understand, of course, that the educational activities pertaining to safety are carried on through the entire curriculum, but they would, perhaps, put a little more emphasis on it. As to the practicability of the plan, I would have to refer to gentlemen who are more familiar with the school conditions. I would like to put that on the table and hear what you think of the subject.

Safe Practices to Be Studied in the School Ship

7

CAPT. SHERIDAN: I think they have lecturers on all kinds of subjects. I think it could be very easily arranged.

MR. TODE: In fact, I can say that Capt. Tomb, whom I saw just before the school ship sailed, intended to have in the curriculum for the coming winter, something on safe practices and desired to have someone from the Marine Section come aboard the ship and deliver a talk on modern steamship safe practices to the cadets.

E. B. TOLSTED (Fonda-Tolsted, Inc., New York City): Mr. Parker has spoken of building the hatches 30 inches above the deck. How high would it be practical to build those up? Could you go up to 42 inches or 48 inches? How high would be practical to go?

MR. PARKER: I don't know that it would make much difference whether it is 30 inches or 60 inches in that particular respect, except that I don't think it would be practicable to build them beyond the point where a man could look over.

MR. TOLSTED: The reason I ask that question is that safety engineers in other fields have found 42 inches the minimum height a railing should be built. A railing 30 inches high is low enough to sit upon and is low enough to fall over. A railing 42 inches high is not low enough to fall over and can't be easily sat upon, although you can climb on it. If hatches were built 42 inches high, they would be railings in the proper sense of the word.

Accidents Due to the Hatch Cover

CAPT. EVANS: The answer to that would be that now, with the hatch coamings the way they are built, the men perform a great deal of their work without getting up on them. The number of accidents might be increased in proportion to the height you increase hatch coamings. A great deal of the difficulty now comes in the men putting on one or two sections of hatches and then getting up on those to put on the remainder; and in putting sections in the wrong place and then walking over them. Those sections slip and fall and that is exactly what happens now causing many injuries. Others step on the hatch coamings to make short cuts.

MR. PARKER: I have a suggestion to make here to shipowners to adopt a practice we have in a shipyard. Whenever putting on hatch covers, start from the bottom and come up and if a man falls he can't fall more than six or eight feet. That is a strict rule. You have to start from the bottom of the ship and come up, putting in each deck as you come through. We have two or three things in that line relative to hatch covers. We have never had a man fall yet.

CAPT. EVANS: That is a perfectly good rule where you are putting on all hatches where a ship is in port. It is well recognized that it is general practice for ships merely to put on the weather deck hatches, leave the rest open in order for the holds to air out, "sweeten" as they refer to them, while the ship is in port. That is one of the reasons that the weather deck hatch is closed and the rest remain open most of the time in port.

MR. ARKILLS: There is still another feature there. On a day when it looks rainy and they knock off at noon, or for dinner at night, they put on the top cover so as not to have to cover all the way down—go away for the hour and come back to take that cover off. It is too much unnecessary work to cover all the way up and down.

CHAIRMAN KAIN: In so far as these 'tween decks are concerned, you mentioned the fact that most of the ships built immediately after the war had no coamings on the 'tween-deck hatches.

Deficiencies of the War Time Built Vessel

MR. PARKER: Yes, a lot of the shipping board vessels were built during the war period under great stress and they left off a lot of things they didn't think necessary. Among them hatch coamings on the 'tween decks.

CHAIRMAN KAIN: That has worked out to the ship owner's advantage in another way in connection with the handling of cargo. Most of the cargo is dragged out of the 'tween decks to the hatch. We have found that where they had the hatch

coamings, the sacks were inclined to catch and tear and that did a great deal of damage to the cargo.

MR. PARKER: I think your answer to that particular question is in having the hatch larger on the 'tween deck.

MR. ARKILLS: Even at that, a large load will tear and break against the edge. It doesn't make enough difference. They do not make them more than eighteen inches, which isn't sufficient.

Then, to answer Mr. Tolsted's question from another angle, if the hatch coaming were made 42 inches high, it would be found that the hatch tender or signal man would be leaning over there and would endanger himself from the cargo hitting him. If he has to watch out, he stays back enough so he is on his feet and alert, he isn't in a reclining position or in a state of mind where he lets go his thought of care. Another thing, every bit you raise the hatch coaming, you raise the load in coming out of the ship. The lower that side is, the less liable you are to hit that with your tray and slingboard and spill the draft down on the men working below.

Possible to Design a Different Type of Hatch

CHAIRMAN KAIN: Do you think it would be possible, Mr. Parker, to design hatch covers entirely different in type, which would be safer, for instance some sort of a suitable steel hatch?

MR. PARKER: Well, of course, they do have various types now, which from that standpoint, I should say, are perfectly safe. As I gather it, it is a question of raising or lowering the hatch covers.

I think the problem can be easily solved in that connection by a recommendation from this body to two sources—one, the naval architects and the other the American Bureau.

MR. ARKILLS: How about the American Marine Standards Committee?

MR. PARKER: Yes, that is all right. There is continual talk on this question of what they can do in designing to improve the safety of ships while in operation. That is a big question. The trouble is that they, perhaps, don't have enough information at this time. As a matter of fact, a good deal of this is news to me in connection with men actually falling through these hatches.

CAPT. EVANS: The most frequent source of serious injuries is putting on, taking off and crossing hatches.

MR. PARKER: I should say that would be rather startling news to naval architects.

MR. ARKILLS: I would like to ask Mr. Parker what his opinion is of sectionalizing hatches such as the Pacific Steamship Co. have done on all their coastwise vessels? They have sectionalized them to the point where they handle them with the gear instead of by hand. This saves considerable time, does away with the breakage, makes them stronger and they don't have that danger of men falling through 'tween deck hatches.

Further Details of the Discussion

MR. PARKER: I think that is really the best answer to the whole question and that is coming quite rapidly. There was considerable objection to that from the owners.

MR. ARKILLS: I can easily see why a complete hatch that is hinged and lifts up, opening the entire hatch at once is very objectionable when it comes to handling deck rods, long rails and long pieces of lumber down the hatch, because it is in the way.

MR. PARKER: It can't be a hinged type. We have built some on the east coast.

our sections to the hatch. They are much safer in that respect without any question. There is no man-handling to that. It seems the only objection is the fact that it is too much trouble for them to open a hatch for ventilation, by taking off a section of the hatch. In this case they would have to lift it up. In the other case they can send a seaman up there to lift three or four sections and let it go. Whether that objection would hold water if it were put up to the naval architects and people like that, I don't know.

MR. ARKILLS: I can see where it would be a drawback in fumigation.

MR. PARKER: Fumigation on some of the ships is pretty necessary.

DR. F. X. CRAWFORD (United Fruit Co., Boston, Mass.): I might say, Mr. Chairman, that we have ships with four sections and if there is no leakage—or if the leakage is small it makes little difference in the engineroom and fireroom—we can do fumigation in the summertime easily in thirty minutes.

MR. ARKILLS: The point I was trying to make on this fumigation is that when you open the ship for fumigation, or after the fumigant has been left aboard a certain prescribed length of time, then you send men above to open up to allow it to freely air itself out. You have no equipment there to open that up until you get up steam in the boiler.

DR. CRAWFORD: You could take one of the deck officers and one man, it can be done with those two men, or you could take an officer and let him do it alone, put on two clips into the hatch cover and go back to the winch and lift it.

CHAIRMAN KAIN: Are there any further questions? If not, we will go on to the next paper.

Unfortunately, Mr. Hand is on a trip to Panama and is unable to be with us. Mr. Prouty will read Mr. Hand's paper.

Practical Benefits From The Physical Examination of Seamen

Robert F. Hand, Standard Oil Company of New Jersey, New York City

When Mr. Ralph E. Prouty, chairman of the Program Committee of the Marine Section, spoke to me about preparing a paper on the Physical Examination of Seamen the matter didn't cause me any great concern. In our own company we make a regular practice of examining seamen before signing them on, and it wasn't until I began to jot down a few notes on the subject that the thought struck me how relatively few steamship companies follow this line. It was this thought that led me into a broader field, namely, the attitude of the shipowner toward accident prevention.

Happily, as a result of the untiring work of our own and other organizations engaged in the promotion of safety afloat, I think that the average ship operator is beginning to realize that accidents enter every definitely into the debit side of his voyage accounts. It was not only the consistent hammering of safety talks, articles and posters—the psychology of advertising, so to speak—which brought about this condition, but cold statistics showing the actual monetary loss from an accident, the meaning of which could not be overlooked. The notable reduction in the number of accidents at sea each year is the fruit by which the work of the National Safety Council may be shown.

Mr. Arthur M. Tode, chairman of our Membership Committee, Captain J. P. Kain, chairman of the Marine Section, as well as Mr. W. E. Welch, our former chairman, can probably tell us just how hard it is in some instances to convince shipowners of the practical benefits of accident preven-

tion. The answer in so many cases is "We are members of this and that organization and do not feel that it is advisable for us to add to our list at the present time." The trouble is that even in companies which are members of the National Safety Council the attitude of the management is inclined to be more or less passive, and you know as well as I that before the rank and file can be "sold" on the safety idea you have got to sell the executive officers and keep them sold.

A Lack of Cooperation Handicaps Safe Practices

If the manager of a department walks in at ten o'clock every morning and is inclined to be lenient on punctuality, you won't find many of the clerks in a hurry to reach their desks before nine. Exactly the same is true of accident prevention and there are few places where this is more strikingly exemplified than on the dock. The pier superintendent or boss stevedore may have his own ideas on the safe type of equipment for handling a particular kind of cargo but if his suggestions are ignored or receive little encouragement from the management his attitude will be one of "what's the use?" When a sling breaks due to a defective rope, when obsolete clamps slip on a load of steel plates and the mass goes crashing to the bottom of the hold, or when a winch fails to hold under the weight of a draft because it is too worn or of insufficient power to handle the loads being swung into the ship, the responsibility too often lies not with the stevedore, not with the pier superintendent, but at the door of the owner himself. There is a moral power in the attitude of the management on any subject connected with the business which is invariably reflected in the work of minor executives and employees.

Men in the shipping business as a rule are a pretty hard-headed crowd—they are natural skeptics. They have to be. With constantly fluctuating freight rates, close competition and the general uncertainty of the industry, the shipowner cannot afford to gamble on any plan, the benefits of which are theoretical or at least indirect. This might be said to be one of the reasons why the physical examination of seamen has not become more general, were it not for the fact that experience covering a period of several years has demonstrated beyond the shadow of a doubt that the saving from this practice is real and definite.

An Argument for Physical Examination

The other objection seems to come from those who are opposed to "mixing sentiment with business." They point out, and not entirely without reason, that seamen as a class are pampered too much, that well-meaning but impractical legislation has restricted the power of the master and undermined discipline on shipboard, that the activities of shyster "sea lawyers" have resulted in a claim for damages against the company every time a man slips on deck or hits his finger with a hammer. Here again the objection is but another argument for physical examination. It is true that the treatment of bad teeth, removal of tonsils, operation for hernia, correction of varicose veins, hydroceles and hemorrhoids, and the encouragement among members of the crew of corrective, curative and hygienic measures do afford the man a valuable protection against future diseases and injury, but the economic saving to the owners is a direct one. Let's get down to a few concrete cases.

The requirements of the doctrine of "Maintenance and Cure" and the liability of heavy damages for accident and sickness, under which a ship operates

when faced with the possibilities contained within the provisions of the Jones Act, leave the shipowner wide open to all kinds of fraud. If a man should slip going over the rail, for example, it would be very hard to prove that a hernia did not occur or become greatly aggravated by that simple mishap. The strong possibility that cheap lawyers who thrive on such cases will try to fake a damage claim against the shipowner shows the wisdom of insuring that a man has a sound physique before he places a foot on deck. It is much cheaper to know in the first place that he has no physical defects before leaving the employment office. Experience in handling the disabilities of seamen shows that any physical defect of chronic disease, no matter of how long a duration or whether or not it is known or suspected by the man himself, becomes a liability of the ship.

The Rate of Rejections for Physical Causes

The rate of rejections for physical causes varies from month to month but the average is between three and four per cent—depending, of course, on the turnover, most of the rejections occurring among new applicants. Hernia and tuberculosis rank highest among the causes of rejection; then come chronic heart diseases, acute infections, such as syphilis or gonorrhea, contagious skin diseases, hydrocele, serious varicose veins and other hazardous infirmities. If the applicant has joint or other minor defects it is wise to make a note of such in case the claim is made later that the disability in question is due to some accident which occurred while the man was employed on the vessel.

The liability of the ship for damages is obvious in the case of hernia and chronic diseases. To force a man to correct his defect, take proper treatment or to find a suitable employment which is free from the dangers of the sea and long absences from medical attention, is a direct economical saving to all parties, and the elimination of infections or contagious diseases from the ship's personnel is not only beneficial to the man himself but is a protection to the rest of the crew.

In selling any idea or service the first question asked, naturally, is "What is it going to cost me?" And the second, "What return will I get for my money?" Let us see what physical examination amounts to in dollars and cents and how it can best be carried out.

In steamship companies operating vessels on regular trade routes between fixed ports, it will probably pay, at least at the home port, to employ a physician on a salary basis. The doctor not only can carry out the physical examination of seamen but may also see to it that the company's vessels are maintained in a sanitary condition.

There Are Five Definite Benefits

At some of the outports, of course, this will not be practicable and the same is true in smaller companies with only a very few ships. In such cases, however, a local doctor can be engaged to examine seamen before they are signed on. The cost of his service varies between \$2 and \$5 per man, depending upon the port.

The actual monetary return from the physical examination of seamen, while a very real one, is difficult to estimate. However, against this comparatively small cost you have the following definite benefits:

1. Rejection of men unfit for service.
2. Correction of minor defects which may later become aggravated. If the

examination of applicants is carried out properly and in the right spirit, men with minor defects are able to give full and competent service.

3. Consequent protection of the shipowner against possible fraudulent claims for damages.

4. Protection of the crew against infections or contagious diseases, which insures healthier, more efficient workers.

5. A steadier group of seamen which reduces labor turnover, thus ultimately cutting down the operating cost of the ship.

The Government Now Provides a Physical Examination

As a matter of fact the benefits of physical examination have already been recognized by the United States Shipping Board which completed arrangements not long ago in all ports of the United States whereby American seamen will receive thorough physical examination prior to shipping on vessels of the Government Merchant Marine. Medical departments have been installed in the different Sea Service Bureaus; and in ports where the Shipping Board does not have its own physicians, the physical examinations will be given by regular medical officers of the United States Public Health Service, acting in conjunction with Local Officials of the Shipping Board. In a few ports where these medical examinations have already been tried out, gratifying results have been obtained. Not only have the examinations been of value to the crews, but they have also proven of great economic benefit to the American merchant marine by assuring at all times a supply of seamen who are known to be in the best physical condition.

In the last analysis, however, you can't blame the general reluctance to adopt this plan entirely on the shipowner. Human beings are all more or less selfish and while the safety of the workers themselves is naturally the prime consideration in accident prevention, you won't find the average owner showing much concern over the fact of a seaman slipping on deck a few hundred miles out at sea. When you can show him, though, that even a minor accident is affecting the operating cost of his vessel you've got him interested and when, furthermore, you can prove to him that such accidents have been and can be prevented you'll convince even the hardest skeptic that, here at least, a little "sentiment with business" has its economic value.

CHAIRMAN KAIN: Dr. Crawford, I think you have had considerable experience in this matter of physical examinations of seamen.

Thorough Examination Is Approved

DR. F. X. CRAWFORD (United Fruit Co., Boston, Mass.): Well, I might say that we examine every man every trip. The first examination is not quite as extensive as the paper would suggest. I think I rather agree with the paper, we should go through a more thorough examination. The first examination is principally for physical defects that might prevent a man from being a seaman; second, hernia; third, venereal disease. A man going out on the next trip is merely examined as to venereal disease. We are operating in Boston five British ships and, under the law, bringing in an alien seaman with a contagious disease makes a costly proposition to us. It costs anywhere from \$50 to \$500 to cure him and we are compelled by the United States laws to pay that bill. I don't hesitate to forbid shipment of any man whom I consider not fit for sea duty, and in consequence we have reduced our expenses. So I believe it is a very important thing and I think every ship owner who doesn't have a medical examination of his crew is very foolish. For instance, a man might slip on the deck and say he had a hernia as a result. He might have

hernia all the time, but simply went on board ship as a means of forcing the pany to pay for his operation and give him compensation while in the hospital. an example of that, before we had a physical examination on shore, we had a work one hour. When I arrived in the afternoon he said he was sore. He at nine the next morning and came to my office. He claimed he got it there it cost us \$300 for that man. He came there with the direct intention of making pay the bill. That is just as true on the ships. I think it is a very, very ortant thing to have a physical examination and it would pay for itself many s. It has with us.

HAIRMAN KAIN: You have no doubt it will pay, even where it is necessary to the doctor on fee basis?

The Physical Examination Will Pay Many Times Over

R. CRAWFORD: It will pay for itself many, many times over in the course of a ; and eliminate cases that would surely cost money later. Take, for instance, an with defective sight or some physical defect like a weak heart or poor legs would allow him to fall and break one leg or do some other injury to himself ; ould cost you a great many hundreds of dollars and I am sure that doctor would for his salary many, many times over every year you have him.

HAIRMAN KAIN: Your examinations are not confined to men serving on ships or foreign flags?

R. CRAWFORD: Even on American ships, just simply for cleanliness. I imagine ie course of a year, I turn down 20 or 30 cases of hernia and probably 50 to 60 s of venereal disease. You can see how easily that would amount to a large of money. Take for instance 50 cases of venereal disease that we have kept the ships, they would average at least \$100 apiece a year, or \$5,000.

APT. EVANS: I might add that I was reliably informed during the past few ks that an effort will be made to have the law amended so as to include the ig of all seamen at the expense of ship owners. Of course, originally the intent he law was to prevent ship owners from bringing men suffering from loathsome contagious diseases into this country. It was interpreted first that the man must on in a foreign country, but later was interpreted again to mean signing on in country. Therefore, in the case of a man signing on in the port of Boston, g to Panama and coming back to Boston again, we were liable for that man's lition, even though he may have had it before he signed on the ship at Boston even though he may have been sailing out of an American port for three years.

R. CRAWFORD: It makes no difference and it is unfair as it is. A ship coming this country, or an American ship bringing in an alien suffering that way ought ay his bill, but I think it is unfair to pick up that man in a port of the United es, take him out and then bring him back and be forced to pay his bill. Not .that, but if they can prove that you took that man out without proper exam- on, they will fine you \$1,000 as well.

Accident Costs No Small Portion of the Voyage Costs.

HAIRMAN KAIN: They can even go farther, in the cases that are incurable; can compel you to deport the man.

APT. EVANS: That applies also even though he had been in the country three s.

R. ARKILLS: Mr. Chairman, there was an assertion made in the paper some- g to this effect—that the accident costs are no small portion of the voyage costs. onder if anyone has ever compiled the accident costs against the voyage costs

to show the actual percentage. I believe they would be very convincing figures to ship owners and would probably help to sell your safety program to such owners.

CAPT. EVANS: I might say that our company makes to the Shipping Board each month a report which analyzes each claim, takes up the nature of the claim, the amount demanded, the cause of the accident, the time lost, money expended and the amount paid finally, so that if that were taken and segregated from the other costs, you could get a very convincing picture as to just what the situation is. We have not, however, attempted to take that and apply it against the other costs of the voyage to get at the picture mentioned.

A Medical Club Plan in Seattle

MR. ARKILLS: While we are on this medical proposition, I would like to say just one word in connection with a medical club in Seattle. The men came to the safety committee, composed of four members from among the men and four members of the employers, and asked if it would be possible to get medical attention off the job: and after the passage of this compensation act we felt that if they were covered for all their accidents and sickness off the job, it would practically do away with the passing of the hat in the Hall. We encouraged it and looked up three or four different places where such medical clubs had been formed; and they have gone ahead and contracted for seventy-five cents a month now, and I dare say that over three-quarters of them have availed themselves of this voluntary proposition. For that seventy-five cents a month they get, off the job, all accident and health medical attention.

On the first day of August a man who was intoxicated and trying to negotiate the street at a crossing, was knocked down by an automobile. He happened to be in this medical club and it cost the bridge clinic something around \$600 to take care of that one case before they had ever gotten a cent from the contract. They are carrying on very faithfully and the thing is spreading and will, I imagine, take in better than 95 percent of the men inside of six months.

MR. PARKER: Is the company a contributor?

MR. ARKILLS: No, the companies have nothing to do with it excepting that they have loaned their paymaster to the men to act as a clearing house for that seventy-five cents per month out of their pay. We have a central pay office that pays most of the payroll right at the Hall.

MR. PARKER: Do you operate a relief department in the plant?

MR. ARKILLS: No.

Only the Unlicensed Personnel Is Examined

CAPT. EVANS: Doctor, in your examinations on the ships of the United Fruit Line, do you include in the examinations the officers of the ships?

DR. CRAWFORD: No, just the so-called unlicensed personnel.

J. S. HUNTER (Atlantic Refining Co., Philadelphia, Pa.): We include our licensed personnel. We had a case of that kind and three were turned out for hernia.

DR. CRAWFORD: Everybody is examined. The examination they go through is similar to that which an insurance company will put a man through. The examination of the crew that I spoke of is just a superficial examination, but the officer personnel of the entire company must go through the thorough physical examination. Everybody on salary entering the company must pass this examination—everybody, no matter in which branch they enter.

Ships—Personal Injuries

Milton D. McIntyre, Pickands, Mather & Company, Cleveland, O.

In the development and study of accident prevention, I think it is generally agreed that any organization which expects to secure satisfactory results in having its employees conduct operations with a minimum of personal injuries and loss of life, must realize that safety work, both ashore and on shipboard, occupies a distinct and important place in its affairs.

It is essential that the chief executive be sincere and in entire sympathy with accident prevention, and interested in having his officials devote time and vigorous effort to that work. He should know that the real and directing influence must come down from his office, and his attitude and safety policies be well known to all of the employees. He should be interested in learning the where;

when, how and why of at least each serious or fatal accident that occurs to his employees. Mere authorization of expenditure for proper mechanical guards to make the operations safe, without active and earnest effort, is not alone sufficient. An unusual number of accidents, as shown by the record, should be viewed with as much concern as a rising cost statement, for it is pretty certain to indicate that somewhere down the line inefficiency exists in that organization. While his officials, and the employees under them, may do much on their own initiative, we can quite safely say that much more could and would be accomplished with active encouragement and genuine support from the chief executive.

Included in the various operations of our company, we have a fleet of 44 ships engaged in the carrying of bulk freight, ore, coal, limestone and grain, on the Great Lakes. Once a year all masters and chief engineers are called to headquarters of the company in Cleveland, Ohio, for a conference, during

which considerable time is given to the discussion of accident prevention. This conference closes with a banquet and snappy program which promotes mutual acquaintance and cooperation. We have the same plan of ship's safety committees which was presented before our Congress several years ago by Mr. Marr, of the Lake Carriers' Association, which, briefly outlined, is as follows:

Six men, three from forward and three from after end, compose this committee, which always includes the lowest licensed men from the forward end and the engineer's department. (Boatswain and handy men are included if carried.) The balance of the committee is selected by the master and chief engineer, from each end of the ship, no two to be of any one grade. One of the licensed men is appointed by the master to act as chairman, the other licensed man serving as secretary. Meetings are called by the master some time between the fifteenth and the last of each month. Both he and the chief engineer, however, attend only in an advisory capacity. They, as well as the members of the committee, sign the minutes indicating their attendance. Copies of the minutes are sent to the manager of the fleet and to the association.

Special Duties of the Committee Members

Duties of the committee members are: Consideration of safety, instructions to new men, discussion of injuries occurring on other ships and, where they have authority to act, the carrying out through their respective departments of such steps as the committee finds advisable. Members who have not authority to act recommend that their superior officer give the matter necessary attention. Each member of the committee receives two dollars from the master at the end of the season for each meeting attended, and if no accident to any of the ship's crew requiring absence from the ship, has occurred during the season, a bonus of \$10 is paid from the office to each member of the committee who is still a member of the crew, and who has attended at least six meetings. Ship owners in this association report to it the nature of injury and description of accidents occurring on their ships, and brief resumes are sent monthly to all members so that there is excellent opportunity for keeping posted on the accidents and safety recommendations on the other fellows' ships.

In addition, the Lake Carriers Association furnishes a Code of Recommendations prepared from the experience of all the vessels, covering the following points: Lights, hatches, hand rails and gratings, ladders, rigging, tackle, gear and stagings, machinery, valves, boilers, pipe lines, etc.; fire, cables, loading and unloading, life preservers, warnings, boat and fire drills and first aid.

We have found that safety meetings held by the men on shipboard are most effective in getting the safety idea over to the rank and file, and in keeping it alive. The number of ships in our fleet receiving the bonus has increased each year. In 1923, 22 per cent; in 1924, 30 per cent; in 1925, 47 per cent; in 1926, 70 per cent.

Meetings That Offer a Basis of Contact

These monthly meetings create a certain contact between the management and the entire crew and tend to make the committee members feel a responsibility in keeping the ship's accident record clear. Soon after these meetings have been held, the crew inquire and hear what matters were discussed, and know that the company is interested in safety. I would like to read a few excerpts from the minutes of some of our vessels, as they are typical of the way in which our committees accept their responsibility.

"When back oiling coal bunker, see that all coal is off angle irons and shelf pieces so that there will be no danger of accident."

"This ship has the distinction of not having a man leave on account of personal injury from accident since the fall of 1920. Let this committee watch their step and watch the action of others and advise new members of our crew when they ship, as to any danger that may confront them. Always bear in mind that it is the duty of this committee to advise and try to enforce the safety rules."

"Captain reminded us to keep people off the ship that have no business aboard, telling each member he has authority to keep strangers off boat, and it is his duty to find out a visitor's business and report to one of the officers, and he would handle the case as he saw fit."

"Captain attended meeting and required each member to relate some act he has done since last meeting, toward the promotion of safety."

"Warned shipmates to use ladder in coming aboard instead of walking up the mooring cable."

The Fleet Superintendent Goes Over Accident Reports

Our office deals directly with employees in handling all claims for injuries. All accident reports are carefully gone over by our fleet superintendent, and any accidents involving laxity in the enforcement of safety rules, lack of proper supervision or bad practices, are promptly discussed with the ship's officers, who know that a full explanation is going to be required.

While the committee system is helpful, it is not a complete panacea in preventing all injuries. Some men seem to be slow to know when they are in danger themselves or doing something that may injure others. We have found that injuries occur frequently when handling lines and cables. The men apparently misunderstand signals or neglect to use the becket, and fingers are caught between the spile and cable when the engine takes up on the cable. Quite a number of accidents happen when men run along the deck. Recently one of our sailors who was in a hurry to get back to supper, while running down the deck, slipped and severely injured his knee. The fire hold and engine room contribute to the shipboard injuries; clinkers get on firemen's ankles while cleaning fires; coal passer neglects to have a blister taken care of and finally has infection set in; fingers damaged when oiling or feeling engine. We have been very insistent in keeping strangers and newsboys off our ships. Some time ago a newsboy, attempting to board one of the ships, fell from the ladder to the dock, quite severely injuring his hip. As a result, we have had to be very careful in keeping everybody off the ship who has no business aboard. Injuries have been quite frequent also on account of falls, such as slipping on an oily hatch cover, and slipping on the deck during a storm. Men have attempted to go aboard while intoxicated, and have fallen off the gangplank. We have also had instances where men in the same condition attempt to get aboard on the mooring line, which has not proven to be a very safe means of getting aboard. Accidents happen because material has been left where it should not have been, causing injury when it fell from some upper place on the ship. Ladder accidents have been caused by slipping, barking shins, by not having a sure hold, or going down the ladder the wrong way. Not long ago a sailor was going ashore and went down and off a ladder which was about four feet from the dock; he did not notice that it was not on the dock, and that the vessel was shifting along the dock.

As we all know, the United States Longshoremen's and Harbor Workers'

Compensation Act, effective since July 1, 1927, applies to employees, excepting seamen, injured on shipboard, and this will do away with the litigations which have heretofore been possible between employee and employer. The principle of compensation has now been well established and it is to be hoped that in the near future our Congress will enact a fair compensation law which will include seamen and provide an equitable remedy to assure injured seamen and their dependents certain and sure relief. While they do receive medical service now, their injuries and misfortunes still expose them to a certain class of attorney who perhaps would not welcome a law which would take away a large source of income. When the State Compensation Acts began to operate, many employers seemed to show considerably more interest in accident prevention, but many industries always had given that work the attention it deserved. It is pleasant to realize that many ship owners have accepted their responsibility to their employees in seeing that anything possible and reasonable is done for their safety and freedom from accidents.

ADJOURNMENT.

Wednesday, September 28, 1927

The second session of the Marine Section was called to order at nine-thirty o'clock by the chairman, Capt. Wm. P. Kain.

CHAIRMAN KAIN: The first business before the meeting is the annual election of officers of the section. Mr. Tode, I believe you have the report of the nominating committee.

Report of the Nominating Committee

Chairman, A. R. Bush, The Barber Asphalt Company, Maurer, N. J.

Vice-Chairman (In Charge of Membership and Publicity), Arthur M. Tode, The Texas Company, New York City.

Vice-Chairman (In Charge of Posters and Slides), Robert F. Hand, Standard Oil Company (N. J.), New York City.

Vice-Chairman (In Charge of Information and Service), Capt. R. C. Brennan, Pacific Steamship Company, Seattle, Wash.

Vice-Chairman (In Charge of Stevedoring), F. P. Foisie, Waterfront Employers' Association, Seattle, Wash.

Secretary and News-Letter Editor, W. E. Welch, The Travelers' Insurance Company, New York City.

Program Committee Chairman, John S. Hunter, The Atlantic Refining Company, Philadelphia, Pa.

Research and Statistics Committee Chairman, Capt. Irving L. Evans, United States P. & I. Agency, Inc., New York City.

Engineering Committee Chairman, R. E. Prouty, Aetna Life Insurance Company, New York City.

Executive Committee, the officers and Capt. G. Bartlett, Cosmopolitan Shipping Company, Hoboken, N. J.; R. F. Edwards, The Prudential Insurance Company, Newark, N. J.; Capt. Reginald Fay, The New York Central Railroad Company, New York City; W. A. Kiggins, Jr., A. H. Bull & Company, Inc., New York City; Capt. W. P. Kain, Shipowners' Claims Bureau, Inc., New York City; Ellis Knowles, C. D. Mallory & Company, Inc., New York City; Eugene F. Moran, Jr., Moran Towing & Transportation Company, New York City; Capt. C. H. Potter, Potter Transportation Company, New York City; C. Story, Jr., Cities Service Transportation Company, New York City; Fern Wood, Williams Steamship Company, Inc., New York City; J. Wright, Export Steamship Corporation, New York City; D. J. Murphy, Murphy Cook & Company, Philadelphia, Pa.

CHAIRMAN KAIN: Gentlemen, you have heard the names of the officers as reported by the nominating committee. What is your pleasure?

CAPT. I. L. EVANS (United States P. & I. Agency, New York City): I move the nominations be closed and the Secretary be instructed to cast a unanimous ballot.

(The motion was seconded and carried and the Secretary cast the unanimous vote of the meeting for the men nominated.)

CHAIRMAN KAIN: The first paper this morning is by Mr. A. M. Tode of the Texas Company.

Observations on Safety Precautions Aboard Tank Steamships

Arthur M. Tode, Superintendent, Technical Division, Marine Department, The Texas Company, New York City.

Maritime nations have always been interested in the question of safety of life at sea, although, probably, early sea regulations were at first more concerned with property than life. As geometry teaches us, "the greater includes the less," and as the safety of life is largely dependent on the staunchness and experienced operation of ships, it follows that the improved seaworthiness of vessels, together with modern safeguards against collision, fire and other accidents, tend more and more for security of life.

The subject of safety of life at sea cannot be solved from any particular point of view. Many angles must be considered concerning the safety of tank ships and of their personnel, the prevention of accidents, fires and explosions and other hazards peculiar to this type of water transportation. It will be of interest to review some experiences of the past, point out possible dangers and focus attention where consideration is required.

Property of enormous value in the maritime industry is destroyed and many lives are lost every year by fire. The prevention of such tragedies and of accidents to sea-faring personnel and property on board ship is, therefore, one of utmost importance. The maritime industries have come to recognize that conservation of resources in this direction is an essential factor in present day ship operation, and deserving of most careful consideration and study.

Considering the types of vessels engaged in carrying the world's commerce, practicable safety in their operation, and accident prevention afloat, may roughly be divided into three groups: passenger liners, general merchant and freight vessels, and tank ships. Whereas experience shows many similar marine accidents occur on all types of vessels, there are some safety precautions necessary to be observed which are peculiar to each of the three classes defined. Such safety precautions are also dependent upon the particular type, as well as trade and service of the ships, and individuality must be exercised in the adoption of means and methods best suited to their needs.

Fire on board any vessel at sea is undoubtedly the worst of catastrophes. Every officer and member of a ship's crew must exercise eternal vigilance to guard against its dread occurrence. In spite of all the precautions which are taken, however, numerous cases of fire at sea and on vessels while in port or undergoing repairs have taken place. Unfortunately, some fires have been due to carelessness on the part of shipyard workers or members of the ship's complement, others to defective electrical or mechanical equipment, some, probably, to "an act of God," while the origin of many fires has never been satisfactorily explained. Often of a spectacular nature, the destruction of ships by fire at sea during the last few years has resulted in the publication of many important reports and papers pertaining to these losses. Of the several kinds of vessels mentioned heretofore, the operation of tank ships, from the standpoints of both safety and economy, is one of prime importance.

Tank Ships and Their Cargoes

The use of petroleum products increased rapidly some years ago and, augmented by the urgent requirements of the world war, necessitated the building of many tank ships.

Depending upon the service in which they are engaged the vessels of an

oil company's fleet are designated as refined oil ships or as dark oil ships. The cargoes carried are classified as highly flammable products (i. e., naphtha, naphtha distillates, all grades of gasoline, benzine and similar highly volatile products), flammable products (i. e., light Mexican, South American, and all domestic crudes), and less flammable products (i. e. Panuco crude, fuel oils, gas oil, water white, lubricating oils and similar products which are but slightly volatile). Molasses, asphalt, cocoanut oil, and creosote are included among other bulk cargoes transported in tankers.

Since the building of the first tank ship about the year 1872, fires and explosions have occurred at various times due to the accidental ignition of mixtures

Mar. 18

FIRE!

What Would Fire at Sea Mean to YOU?

Don't smoke in your berth or in other unauthorized places. (Use only safety matches.)	Keep the coal bunkers ventilated.
Don't throw oily rags about the decks.	Don't tamper with electrical equipment.
Don't use gasoline for cleaning purposes.	Observe safety and fire prevention rules strictly.
	If you find a dangerous condition, report it at once.

Every Man in the Crew Must Help to Prevent Fires

of air with vapors of the more volatile hydrocarbons. Accidents resulting from this cause have frequently involved serious loss of life and destruction of property. The observance of stringent rules on tankers to minimize such accidents is therefore of utmost importance.

Oil cargoes as carried in tank ships are generally considered a hazardous commodity regardless of the nature of the oil. A cargo of high flash oil is, however, no more hazardous than carrying oil as fuel, except that there is more of it. Additional precautions are necessary when transporting low flash and volatile oils as cargoes, but it is a fact that even fuel oil is volatile when heated, irrespective of the cargoes carried, therefore, certain precautions must be observed which may vary, depending on the grades and characteristics of the oil.

The real danger aboard tank ships is the fact that a fire starting anywhere in the ship may possibly ignite the entire fuel and cargo. The important function in safeguarding any ship from fire is a strict observance by all per-

sons of the necessary regulations and the providing of the most up-to-date methods of extinguishing any fire before it has an opportunity to spread.

General Characteristics of Petroleum Vapors

Certain characteristics of petroleum vapors have been established through scientific research, as well as the investigation of fires and explosions which have occurred on board ship. In this way the oil companies have been able to minimize the occurrence of accidents due to the ignition of these vapors. It has been found that certain crude oils and refined oils evaporate freely at ordinary temperatures. The vapors which result are heavier than air, and when mixed in certain proportions with air become highly flammable.

Due to their greater density, the vapors arising from the surface of oil in a tank will not become diffused in uniform proportion with the adjacent air. Such vapor will tend to form a very rich mixture immediately above the surface and a leaner one at the top of the container. It has also been observed that such vapors, which in reality are fluids, may remain for a considerable length of time in the generating receptacle, or may flow unperceived for some distance in stream lines.

Investigations made by petroleum corporations have also proven that vapors given off from a petroleum product and diffused with air in a confined space result in a mixture which at first is merely flammable, burning rapidly when ignited but without audible explosion. Combustion takes place with greater rapidity, together with increasing volume of sound, as the proportion of vapor to air increases. If this is continued the proportions conducive of violent explosions are finally reached. Thereafter, any further increase in vapor content will result in a reduction in the energy of combustion and flame of longer duration. From a flammable but non-explosive state such mixtures become explosive, followed by a flammable condition as at first.

Oil will not ignite except in the presence of air. The vapor or gas from the oil is, however, highly explosive when mixed with certain proportions of air. Oil or its vapors will not ignite of its own accord but only by the application of heat of a higher temperature than its flash or fire points. However, the vapor will be readily ignited if brought in contact with a spark or flame. Oil vapor, being heavier than air, tends to collect in pockets in the lower part of the ship's tanks, double bottoms and adjacent spaces. Investigations have shown that oil upon ignition may tend to flare back to its source, in this way igniting an open tank from whence it came.

Flash Point and Fire Point

As the hazards of transporting oil are in proportion to the flash and fire points of the product, a more detailed explanation of these two characteristics will be of interest. If oil fuel is heated in an open vessel vapor comes away in increasing quantities as the temperature rises, but this vapor will have no tendency whatever to light itself, i. e., there is no danger of spontaneous combustion. The vapor will not take fire unless a light is applied to it. If a light is applied at intervals to the surface of the oil, a condition is reached at which the vapor will give a sudden flame or flash of fire. This is called the flash test and the temperature at which this occurs is called the open cup flash point. If the oil is raised to still higher temperatures, a condition will presently be reached when the vapor takes fire, upon a light being applied, and burns continuously. This is called the fire test, and the temperature of the oil is then known as the fire point.

In order to obtain more accurate measurements, the close flash test has

ders and gangways securely.
Also, look before you step.

been developed. This is a more precise method and has practically superseded the open flash test. In the close test, oil is gradually heated in a closed vessel, the mixture of vapor and air above the oil being well stirred up to make it uniform. A light is applied at intervals until at a definite temperature a flash is obtained, which is considerably below that of the open test. The open flashpoint is generally 30 to 35 degrees, Fahr., above the close test, and the fire test 45 to 55 degrees, Fahr., higher still.

Vapor is given off from oil in somewhat the same way as from water, until the air above the surface is "saturated," but it is not given off in considerable quantities until the temperature is within about 3 or 4 degrees of the close flash point.

General Safety Rules and Regulations

The operation of tank steamers and the repairs which must be made at periodic intervals is governed by features peculiar to this type of vessel. Quick turn arounds are absolutely necessary to the economical operation of tankers. Oil cargoes are rapidly loaded and discharged and a tank ship is apt to be in port only 24 hours for such purposes each trip. Another feature relates to the peculiar repairs which must be effected on oil tanks, oil pumps, oil piping, heater coils, etc., involving a large amount of oil-tight work. Any gassy condition must be eliminated before repair work is started on deck, in the tanks, or in adjacent spaces. The combination of all these features makes the management of tank ships an exacting one.

Rules and regulations covering every possible hazard from fire and explosion have been promulgated by the several petroleum corporations. These regulations include every phase covering the safe loading and discharging of the vessels, precautions to be observed in the cleaning of cargo and fuel tanks preparatory to executing repair work, defects to be guarded against in electrical and mechanical equipment, rigid instructions against smoking, carrying of naked lights, etc. Such regulations may vary slightly with the different companies, depending upon the particular conditions, yet similar general safety rules are strictly observed on all tank ships.

Prevention of Boiler Room Oil Fires

The chief risks of fires on board all ships burning oil as fuel, whether passenger, freight or tank ships, are in the boiler room. These risks arise by leaks from valves or pipe joints, by faulty burners, or by incorrect manipulation of the burners. There are risks of fire and explosion due to percolation of oil and vapor through joints of the steel plating and by loosening of rust enabling leakage to occur, hence the fitting of cofferdams for safety. The vapor, and the oil itself, are liable to leak through riveted and caulked joints of steel work, even though these have passed a good watertight test. The pipes for filling and emptying oil fuel, and the vent pipes, should be as short and direct as possible, and be so arranged that if any leakage occurs, dripping or any fine spray arising will not reach hot surfaces of the boilers, steam pipes, etc. The pipes for supplying oil to the furnaces should be carefully led in the same way, and all joints made metal to metal on these delivery pipes, in which considerable pressures exist.

In lighting up the boilers skill is required to avoid the formation of volumes of an explosive mixture in the furnaces and uptakes. Every precaution should be taken to prevent unburned oil from collecting in the furnace, as the hot brick gasifies it and there is serious danger of a flareback and a violent explosion. Proper precautions will eliminate such dangers. No matter how hot

the furnace may be, if all burners are temporarily secured, no attempt should be made to relight from the incandescent brickwork. Very serious accidents have resulted from this practice.

The oil must be quite free from water or from sediment of any kind, as these may cause the flames of the burners in one furnace to be momentarily extinguished while spraying will still continue, and immediately afterwards the mixture may be fired by explosion. The burners must be maintained in a clean, efficient condition to avoid stoppage by carbon deposit, and also to prevent dripping, both of which lead to difficulties involving fire risk. The fire rooms should be kept scrupulously clean, and no old clothes, rags or pieces of wood which would absorb oil should be allowed to remain, in case of a burst of flame from any cause. Drip pans should be provided in front of the boiler furnace and under the fuel pumps and should be kept in clean condition. Where boiler room bulkheads are covered with insulation, an inspection should be made from time to time to ascertain that no fuel oil has leaked through into the insulating material, thus constituting a fire menace. The bilges in the boiler room and pump rooms should be thoroughly hosed out frequently and all oily bilge water should be immediately and completely removed.

Excessive temperature of oil to the burners is another source of danger because the tendency of oil to leak increases with rising temperature. In most mechanical atomizing systems the oil is heated above its fire point, the only factor of safety being that it is not in contact with air until it reaches the burner tips. Excessive oil pressure is also dangerous, due to possibility of some part of the system bursting. The relief valve which is provided for safety in this system should be adjusted for the desired pressure and together with the thermometer and gauges in the oil discharge lines, should be checked for accuracy at regular intervals. Another important factor in fire prevention is avoidance of soot accumulation in the uptakes and stacks. Proper regulation of burners and frequent use of mechanical soot blowers will minimize such accumulations. Cooperation should exist between the deck and engine departments regarding the best time to blow tubes. This operation often results in burning masses of soot flying from the stack and landing on the decks, and ships are frequently headed into the wind when tubes are being blown.

Safety Precautions When Loading or Discharging

Oil cargoes are pumped into and out of tankers through flexible hose connections. For the purpose of grounding static electricity generated in a vessel and thereby eliminate sparking at the cargo connections when connecting or disconnecting the hose an electric short circuiting device is usually provided. All scuppers from which a spill might flow are plugged oil-tight with wooden plugs. While vessels are loading or discharging flammable products, the tank tops are kept closed and the tank top dogs slacked off and thrown back. The ullage plug holes on the cargo tank tops are covered with a fine mesh wire gauze or wet gunnysacks until the ullage plugs are permanently secured in place. Loading certain petroleum products "overall" (that is, with an open end of hose inserted in an open hatch or manhole), is a dangerous procedure on account of the gas generated. Lubricating oils, having a high flash point, are commonly loaded in this fashion with entire safety.

The overflowing of a tank when loading cargo is a very serious occurrence and a matter which is carefully guarded against. Some serious accidents in the past can be directly attributed to neglect in this respect. Besides danger of explosions and aside from the fact that the presence of floating oil in the

vicinity of a ship is a direct menace to the vessel, tank overflows frequently cause undesirable and injurious pollution of adjacent waters, and is a direct violation of harbor ordinances.

When loading a vessel the several tanks are carefully watched and frequently gauged. When the cargo enters the expansion trunk, the purpose of which is to provide a confined space at the top of a tank to limit the free surface, the rate of loading is reduced and every precaution taken to prevent an overflow. When loading tanks, allowance is made, of course, for the expansion and contraction of the oil due to changes in temperature. Valves in ship's filling lines must not be closed while pumping, to avoid overflowing, as this is likely to burst the hose.

The bursting of a hose when loading or discharging is another serious matter. This is guarded against by maintaining the proper pressure on the cargo

pumps, as well as by visual inspection and pressure tests of the hoses at regular intervals. The hose connections to the ship's manifolds must be solidly made to prevent leakage while pumping cargoes. The loading finished, care should be exercised, in disconnecting, to drain the hose, preferably by hoisting its middle portion, to avoid danger incident to spilling oil on deck. Cargo hose when not in use should be securely stowed in some protected place, in order that deterioration as a result of exposure to weather or moisture may be avoided.

In some instances the loading of highly flammable products after dark or during severe electrical storms is prohibited. During such times all fires on board are extinguished and shore steam is used for the operation of auxiliary machinery and for the heating system. Depending upon terminal and local regulations, flammable and less flammable products are usually allowed to be discharged after dark and vessels permitted to use their own steam.

On some ships gas-freeing pipes are fitted to each tank and carried up masts

in order to allow gas to escape or air to enter should changes in pressure occur while at sea, due to changes in temperature; also when loading or discharging cargoes with the hatches closed. This arrangement permits the evacuation of dangerous gases in an elevated zone where cause for fire is but rarely found. It is usual to fit valves on these pipes, which are spring or deadweight loaded, and open either to vacuum or pressure; these avoid the unnecessary loss of vapor and do not open until a definitely arranged pressure accumulates.

Most tank ships have automatic vent and vacuum valves fitted directly on the cargo tank hatch covers; these valves are deserving of careful periodic inspection to insure their being in good operative condition at all times. The openings of these vents or valves are covered with fine mesh copper wire gauze. It is a common failing which should be guarded against, to paint over this gauze, clogging it up completely and practically sealing the vent. The important function of the gauze is to prevent a fire on deck from flashing back into the tank, it having been found that a flame cannot penetrate a finely divided screen. Instances have been reported of tankers afire on deck, where gas emitted from the tank vents, due to the heat, burned as enormous gas jets without igniting the tanks. To minimize the danger of fire due to open ullage covers when loading or discharging cargoes, these openings are often fitted with fine mesh copper wire gauze screens serving as a protection against fire penetrating into a tank, similar to the vent screens.

Cleaning and Gas-Freeing Tanks for Cargo or Repairs

In order to prevent fires and injury to persons and property which may result when tanks are being cleaned or repaired, it is necessary to be assured that tanks about to undergo repairs or cleaning, and under certain circumstances their adjacent compartments, are free from sediment and dangerous or explosive gases. The real danger exists when oil has been pumped from the tanks. After finishing what can be done to clear a tank by the pumps there remains a quantity of oil, or oily sediment, which must be removed by hand. The tank may be thoroughly steamed out and then washed out by filling with water and pumping it out several times and every effort made to thoroughly ventilate it by means of windsails and portable fans, and yet oil vapor will remain.

This vapor is so much heavier than air that it hangs about in every recess of the framing. It is at times necessary to drive the air supply in with considerable turbulence, to stir up and wash out the vapor from these dead corners. Oil has a remarkable capacity for penetrating between the laps and joints of plating and framing, and is held there by rust and scale acting as a sponge. Oil so held when the tank has been emptied and cleaned, is a source of danger for some time and the utmost care must be exercised in cleaning and ventilating the tanks.

As a rule tank vessels are not delivered to a shipyard for repairs until all tanks are steamed, smothered and sealed, or until a gas-free certificate covering all tanks in the ship has been issued. When emergency dry-docking is necessary and no tanks or pumproom repairs are contemplated, the tanks are smothered with steam and sealed prior to the vessel's arrival at the yard, and so maintained until her departure therefrom.

Before a vessel proceeds to a shipyard when repairs are necessary in and/or around cargo tanks, and/or fuel tanks, the several tanks are cleaned by steaming, ventilating, washing down, pumping dry and wiping up, followed by a final inspection to assure that all oil and sediment are removed. The necessary intensity and duration of each process varies according to the con-

dition of the tanks and the nature of the previous cargo carried therein and rests upon the judgment of the officers in charge.

The discharge of washings from cargo and fuel tanks of tank vessels as well as passenger or freight ships is usually done while the vessels are at least 50 miles from the nearest headland. This is in accordance with an agreement reached by delegates from 13 countries at the Preliminary International Conference on Oil Pollution of Navigable Waters held at Washington, D. C., during June, 1926. One of the important provisions of the draft adopted at this conference was to the effect that the discharge of oil or oily mixtures be prohibited within such areas if the oil content exceeds .05 of one per cent:

that is, if it is sufficient to constitute a film on the surface of the sea visible to the naked eye in daylight in clear weather.

American, as well as foreign companies operating tankers are observing this provision. When the ships are en route to loading ports or repair yards the various tanks which have been ballasted are drained into one tank and the mixture there retained until arrival at the port of destination, where facilities are provided for its disposal. In this manner a vessel can refrain from discharging oil within the 50-mile zone and still arrive in port with all tanks clean with the exception of the one tank in which the oily mixture from the ballasted tanks has been collected. Oil separating devices for cleaning the discharge from cargo and fuel tanks have, within recent years, been installed on a number of ships and may assist materially in the future to overcome the objectionable features relative to the oil pollution of inland and navigable waters.

When tanks are prepared for steaming the cover and ullage holes are closed, but left unfastened, and steam at a line pressure of about 75 pounds

is allowed to enter the tank through the smothering line for as long a period as considered necessary. Upon completion of steaming, the hatch covers are thrown open and a windsail rigged into the tank to create air circulation within, thus expelling gases and steam. In cases where the gas content of the air in the tanks is usually high, additional air is forced into the tanks by a portable blower and a canvas duct. Another system employs compressed air which is forced through suction and discharge manifolds on deck, into the tanks; this method has the additional advantage of clearing the cargo lines of vapor and creating good turbulence at the bottom of the tanks. The cargo pumps are also used at times to assist in the expulsion of the gases.

When windsails and blowers have been rigged, the process of washing down is carried on by means of hose connected to a hot water line, the main condenser overboard discharge being commonly employed for this purpose. The washing operation is extended from the top of the tank to the sides and beams, and finally the bottom is thoroughly flushed. Frequently, after the foregoing has been accomplished, sediment still remains clinging to the bulkheads or structural members in the tank and a second steaming period and washing operation must be carried out. When the tanks have been properly washed they are wiped thoroughly dry by means of buckets, brushes, scoops and rags. Special care is exercised to flush adjacent pipe lines, and all suction and discharge valves are kept open up to the master valve on each side of the tank in question.

From what has been briefly reviewed regarding cleaning and gas freeing of cargo tanks, the precautions which are taken to safeguard life and property become apparent. After this work has been carried out to the satisfaction of the officer in charge and the vessel proceeds to a shipyard, no repair work in the tanks or in their vicinity is permitted until the tank or tanks have been certified to be gas free by an outside chemist. In some ports a gas-free certificate may be required to be issued in the near future before a vessel may proceed to a repair yard.

In order that no misunderstanding can occur when describing the gaseous contents of tanks on the certificate the only notations which appear are: "Safe for men," "Not safe for fire," "Safe for men and fire," and "Not safe."

"Not safe" is used when oil or dangerous sediment is present in the tanks or leakage from adjacent compartments may occur, or when the gas content of the air is greater than two-tenths of one per cent. At such times men entering tanks must be equipped with life lines and gas masks and a constant watch maintained on deck for their safety.

Precautions While at Shipyard

In addition to ordinary repairs to hull and machinery periodically made in shipyards on all types of steamships, the tank ship requires repairs of a more or less special nature. This, as has been previously mentioned, is due to her peculiar construction involving much oil-tight work on tanks, bulkheads, pumps, oil piping, heater coils, etc. The precautions taken to insure delivery of a tank vessel to the yard in a gas-free condition have been reviewed.

When it is necessary to drain a tank in drydock, precaution should be taken to catch any mixture of oil and water to prevent it from spreading to the drydock. When renewals of rivets are necessary, care must be observed to mark plainly dangerous compartments from the outside and to otherwise warn workers engaged on the repairs. Before any contemplated work to the cargo lines is undertaken, it is important to ascertain that these have

been thoroughly drained and blown out, so that when lines are broken, compartments will not be flooded, whereby great risk may be incurred, especially if men are at work with torches of fire.

Ventilation of certain tanks is often necessary during the progress of work in the yard. There is always danger of oil vapor from oil seepings in the tanks, under rivet heads, etc., and it frequently happens that when a rivet is renewed flames burst forth around it. Instructions against smoking, carrying of naked lights, permitting strangers on board, etc., are just as important to be observed while the vessel is undergoing repairs as when it is in service.

A number of fires aboard vessels have occurred while the ships were on drydock or undergoing repairs. It must be conceded that where acetylene burners, portable forges and hot rivets are being handled, there is much

greater possibility of fire coming in contact with flammable material whether or not the ship happens to be a tanker.

The danger of fire due to spontaneous combustion must be guarded against on all ships. Waste material, particularly if wet with oil, must not be permitted to accumulate in confined spaces where oxidation of the flammable material may proceed with such rapidity that its temperature is brought up to the point of ignition. With the view toward removing every possible fire hazard, the paint lockers, lamp lockers, closets and store rooms should be cleaned out at frequent intervals in order to assure that no oil rags or other flammable material has been left aboard.

Defective ship's wiring has been the cause of many fires. Whenever insulation is damaged by heavy weather or other causes, particularly where there is immediate danger of a short circuit, repairs should be immediately effected.

There are just two ways to extinguish fire. One is to cool the material below its burning point. This is usually accomplished with water, or chemi-

cal solution consisting chiefly of water. The other method is to smother the fire by cutting off the supply of oxygen, without which fire cannot exist. Water is not very effective for the purpose of extinguishing oil fires because the burning oil floating on the surface of the water spreads as more water is applied. In the case of ordinary fire, such as burning wood, water derives its efficacy mainly from its cooling effect, which is useless when dealing with a light-oil fire; in such a case the oil floating on the water and having an ample supply of oxygen, continues to burn.

It has been recognized that to deal effectively with an oil fire the air must be excluded by means of a "blanket" of steam, sand, non-combustible gas, or

Accidents Don't "Happen" They Are CAUSED!

Replace floor plates and gratings
promptly or rope off the opening.
It always pays to be careful.

some substance that will stand up to and not be broken down or destroyed by the heat; the smothering effect must continue till the temperature has been reduced, otherwise the fire will again break out. The efficacy of the various fire-extinguishing agencies mentioned is dependent upon the particular location and dimension of a fire. Small fires have been quickly overcome by sand; water is reported to have been successfully used in extinguishing fuel oil fires in some cases; steam is a valuable agency on account of its capacity to displace the air, while a most effective method is a system for discharging non-combustible gas into compartments where fires may threaten.

The fire-fighting apparatus with which tankers are equipped, besides axes, water buckets, hoses, hand or portable extinguishers conveniently located about the ship, includes a steam smothering system in the boiler rooms and tanks, while on many modern tank ships an elaborate system for the discharge of inert smothering gas into the various compartments is installed. Carbon dioxide gas (CO_2), which is commonly employed for this purpose, is

stored in a number of steel cylinders manifolded together in batteries, each cylinder containing about fifty pounds of gas, located in a convenient and protected place such as the compartment under the midship house. The engine room, pump rooms, cargo tanks and spaces protected are provided with leads through distributing valves from the common supply. The remote control release handles are located in a place accessible in case of emergency, such as the pilot house or flying bridge. In case of a fire in any one or more of the cargo oil tanks or fuel tanks, it is only necessary to pull the proper control handle in order to release a bank of cylinders, thereby discharging a large volume of high velocity gas into the compartment to extinguish the fire.

Fires in cargo oil and fuel tanks usually occur when the hatch covers over the expansion trunks are open. Experiments have shown that by the use of carbon dioxide it was only the expansion trunk openings which needed

to be protected. Projecting of blankets of carbon dioxide gas across the opening cuts off the oxygen supply completely and causes entire extinction of a fire in a few seconds, the time depending upon the volume of air space between the blankets of gas and the burning oil level.

Importance of Education and Supervision

Fire prevention aboard ship being of most vital importance in every phase of a vessel's operation it is absolutely necessary that every possible precaution should be taken to insure all fire-detecting apparatus and fire-fighting gear being always ready for immediate and efficient service. The elimination of all accidents in the transportation of petroleum products will probably never be realized, but the elimination of hazards incident to its handling is within the bounds of possibility if accomplished with competent and trained personnel, proper methods and equipment.

Safety measures can be formulated, modern fire-fighting apparatus may be

installed, and rules and regulations can be laid down, but they will be productive of little good unless every member of a ship's complement accepts his part of the responsibility and does his share toward the prevention of fires and accidents.

Portable resuscitation apparatus and gas masks are indispensable aboard every tanker. Of equal importance is the necessity for the ship's officers and members of the crew to be familiar with the operation of the equipment for administering artificial respiration. It is also desirable that the men be instructed in manual artificial respiration, preferably the prone-pressure method which has saved the lives of many persons threatened with asphyxiation.

In the training and educational programs fostered by the petroleum corporations, there must be included a counteraction to the human tendency to become careless when "it's all in a day's work"; this tendency to become careless can be lessened by constantly reminding the personnel of potential dangers and pointing out to them the serious consequences which may follow any let-down in accident prevention work. If the minds of the working men be trained against carelessness and chance taking, there will be eliminated a large percentage of the accidents which occur on board ship. Education, therefore, is the prime factor in the successful accomplishment of any safety program.

Most Knowledge Comes Through the Eye

It is claimed that 85 per cent of all human knowledge comes through the eyes. Good safety posters are especially effective where foreign crews may be employed whose members do not, perhaps, speak or read the English language. In such cases safety pictures will convey their messages in a language for which the eyes alone are necessary. Safety posters depicting the correct and incorrect methods of performing certain tasks can, by the universal language of the eyes be imposed upon the most illiterate persons.

Properly instituted safety work is a proved economic asset in any steamship company. The applying of safety education has its reward not merely in a saving in the cost of accidents but also in a better relationship between the company and its employees. A study of the best methods and machinery to be employed to handle their products with safety is continually being made by the petroleum corporations. More than ever the human factor which enters into the safety movement is receiving consideration.

Safety work on tank ships, as in any other line of industry, necessitates a program of education and supervision. The problem of eliminating the hazards incident to handling petroleum products demands that the persons engaged in this work be acquainted with its inherent dangers, and taught the necessary precautions which must be followed in avoiding these dangers.

Proper supervision must include the men, the ship and the machinery. The licensed personnel on the vessels, who frequently complain of the inexperience of the men in their charge, must be taught to realize their own responsibility in this condition and make serious efforts to train and instruct their subordinates. The Marine Department management, in turn, must inaugurate methods which will arouse an interest among the officers on the ships so that the principles of safety will, through them, be indelibly impressed upon the men. The importance of this is apparent when the large turnover of the unlicensed personnel in comparison with the officer replacement is considered, and the fact that a careful analysis of accidents on ships reveals that from 75 to 85 per cent of the injuries are sustained by unlicensed personnel. Inexperience, ignorance and carelessness are the reasons often assigned by engineers in charge of marine safety work for the continual recurrence of accidents

among unlicensed members of the crew and are undoubtedly best overcome by the close supervision and, above all, the personal example of safe and competent superior officers.

There are approximately 1,100 oil tankers afloat of over 1,000 gross tons each, of which over 700 fly the American or the British flag. Considering the nature and volume of the cargoes carried in oil tank ships, the comparative freedom from loss and damage by fire and explosion is a tribute to the skill and care exercised by those sailing in these vessels.

CHAIRMAN KAIN: I think that is a very important and timely paper. During the past year we have had some very disastrous explosions on tank steamers. There has been very large loss of life and a great many serious injuries and unusually heavy property loss not only on the ship, but to other property belonging to third parties. Generally speaking, these tank steamers are owned by oil or petroleum companies or by companies solely engaged in transportation. I think most—in fact, all—of the people operating those steamers are thoroughly familiar with the precautions to be taken in avoiding these explosions and accidents. However, there is considerable difficulty in getting the people on the ships and some of the supervising officers to observe the precautions. I don't know how we are going to overcome this, unless we undertake a campaign of education for the personnel on the ships.

Have any of you gentlemen any questions you would like to ask Mr. Tode? He has covered the subject very thoroughly.

Problem of the Oil Cut Off Valve

CAPT. T. W. SHERIDAN (New York State Nautical School, New York City): I would like to ask Mr. Tode a question. On every merchant vessel not only oil, but cargo vessels burning fuel oil, the local inspectors' regulations require a valve be fitted from the upper deck, generally around the engine room, reaching down. This valve cuts off the supply of oil from the settling tank to the fuel oil pump. It has been my observation in some dozen vessels at different times that with one or two exceptions these valves are absolutely neglected. Either the personnel don't know where they are, or they are disconnected. Is that due to the fact that the personnel do not consider these valves necessary for the safety of the vessel, or is it just due to ignorance and the usual human neglect to take precaution?

MR. TODE: I would say that is due to neglect. I am not answering you directly. I don't recall just the paragraph you refer to, but I have also noticed that the safety valves or steam stop valves which should have reach rods going to the upper deck so boilers can be disconnected in case of a blowout or if for any cause the engine has to be stopped and you can't get to them, are neglected, notwithstanding there is a stringent order that they be connected up; so I would say it is probably due to neglect.

CAPT. SHERIDAN: I think that an investigation or search for safety precautions of this nature should be stressed, not only with the personnel, but with the marine superintendents. I think an additional valve should be fitted to shut off steam from the pumps which pump oil from the settling tank into the heater.

MR. TODE: That is done in some cases.

M. E. ARKILLS (Waterfront Employers of Seattle, Seattle, Wash.): A lot of this paper applies to the ordinary cargo ship that burns oil, and I believe there ought to be some way of getting this knowledge over to them, so that they could profit by this paper. They sometimes clean those tanks and put molasses into a tank that has had oil in it. I am speaking now of ships running between the islands and the west coast, and I am sure these same precautions apply to a great extent in those ordinary cargo ships that burn oil and carry oil.

CHAIRMAN KAIN: I think you are quite right. I know that steamship companies,

both on the Atlantic and Pacific, have the same difficulty and most of the serious fires we have had on oil-burning ships have been caused by failure to observe these well-known practices.

CAPT. I. L. EVANS (United States P. & I. Agency, New York City): I would say the article contains a liberal education for most marine engineers on subjects they have little knowledge of. It would be a valuable paper to have distributed among engineering personnel especially.

CHAIRMAN KAIN: It will, of course, appear in the transactions of this Congress, but we will also have articles printed separately for distribution to members of the section.

O. D. MOORE (Pennsylvania Railroad, Philadelphia, Pa.): I think this paper is of general interest on account of the increasing use of oil in the propulsion of vessels. The Diesel engine burns a lighter grade of oil, as a rule, than is used in oil burning equipment and at the present time, the United States Steamboat Inspection Service has formulated no specific requirements for Diesel propelled ships. We are interested in the fire hazard in a fleet of about seven boats and while the amount of oil carried is comparatively small, there is nothing to go by in the way of experience with relation to the fire hazard.

O. D. MOORE (Pennsylvania Railroad, Philadelphia, Pa.): I might mention that there is a pamphlet prepared by the Marine Hazards Committee of the National Fire Protection Association, which covers these general features in a rather thorough way with specific reference to marine operation.

CHAIRMAN KAIN: If there is no further comment, we will go on to the next paper on the program.

Mr. Foisie unfortunately cannot be here and I am going to ask Mr. Bush to read the paper.

Safety and Productivity in 'Port Cargo Handling

F. P. FOISIE, Waterfront Employers' Association, Seattle, Wash.

Relatively little is known of either safety or productivity in port cargo handling—except that the costs of handling cargo are exorbitant and the accident rate is fearful.

Some conception of stevedoring accidents can be gained from the fact that the insurance premium approximates 20 per cent on the pay roll; in other words, of six men employed stowing cargo the work of one pays the insurance on the other five. There seems no other way at present for measuring the accident rate because there is little accumulation of accident experience in port cargo handling; what little there is remains unstandardized; and the need of exchanging experience is not yet realized.

Some conception of the cost of handling cargo may be gleaned from these facts. Manchester Liners, Ltd., report in their annual meeting of 1925 that 115 days' freight earnings out of 365 days (nearly a third) have been absorbed by the cost of stevedoring alone. The United States Shipping Board furnishes corroborative facts: the stevedoring, wharfage and other cargo expense taken from a considerable number of completed ventures for 1927 in the United Kingdom, South American and Asiatic service cost from one-quarter to more than one-third of the operating revenue.

Fortunately shipping will soon know something of the costs of both accidents and tonnage handled. The Longshoremen's and Harbor Workers' Compensation Act will no doubt lead soon to a compulsory uniform system of reporting accidents, and therefore costs. The United States Department of Labor has inaugurated a study based on the standard unit of man-hour-tons of productivity in cargo-handling in all of the large ports of the country by a competent

research man, Dr. Boris Stern. There is reason to believe that the results in both fields will startle attention and impel action.

Exponents of safety recognize that material handling is prolific of accidents. Of course, cargo handling is devoted solely to material handling. In most ports the labor is casual and therefore fertile of accidents. Moreover, the plant (the ship) is constantly changing, and there are the variables of time, tide, weather, etc., always encountered. These and other factors may be offered in explanation of an inherent high hazard but the fact remains that they are insufficient excuse for the inertia generally to be found in shipping management on the subject of accident prevention.

"The Relationship of Industrial Safety and Production," as developed by the American Engineering Council, goes unrecognized in most ports of the country. Although the Council was not able to extend its studies on this question of relationship of safety and productivity to stevedoring because of lack of the necessary available records, I have no hesitation in stating from personal experience that the conclusions reached by the Council as applied to industrial safety and production apply with equal validity to port cargo handling. Here are the major conclusions reached by Mr. J. E. Hannum, director for the Engineering Council of a study of five thousand plants; ("stevedoring" has been substituted for "industry" and "stevedore" for "factory.") (From NATIONAL SAFETY NEWS for August, 1927.)

Findings That May Apply Also to the Marine Industry

"Maximum productivity in stevedoring is dependent upon the reduction of accidents to an irreducible minimum.

"The initiation of accident prevention is as much a responsibility of the major executives in stevedoring as is the initiation of improvements in productivity.

"Many stevedoring executives have not given to accident prevention that degree of attention and direction that its economic and humanitarian significance warrants.

"The accident and production performances of the best stevedores clearly show that tremendous improvements can be achieved by the remaining stevedores.

"Organized safety work which is effective in reducing the frequency and severity of accidents is being carried on only in a relatively small percentage of stevedoring companies.

"A large number of companies keep no accident records, and make no attempt to analyze such records for determining ways and means of decreasing accidents.

"The weight of evidence supports the common belief that the safe stevedore is the efficient stevedore, and the efficient stevedore is the safe stevedore."

Mr. H. W. Heinrich, of the Travelers Insurance Company, in the study of five thousand accidents summarized in his article, "The Incidental Cost of Accidents," in the NATIONAL SAFETY NEWS for February, 1927, states that the cost of accidents—lost time of other employees, damage to materials and machines, interference with production, etc.—is four times the cost of compensation, medical aid, etc. The "incidental" costs are four times the direct costs. If we may accept that conclusion, then this interesting calculation follows: if the insurance premium for stevedoring operations is 20 per cent on the pay roll, and the "incidental" cost of accidents is four times the cost of the accidents themselves, then the direct and indirect cost of stevedoring accidents amounts to as much again as the full stevedoring pay roll. Moreover, if this stevedoring pay roll approximates one-quarter to one-third of the operating expenses then steve-

doring with its accidents rolls up a most formidable expense and, unquestionably, waste.

This sort of statistical generalization has been resorted to before with shipping interests by many persons for years past—with little result except irritation. Fortunately shipping will be compelled to pay attention to both safety and productivity in the near future. The new Federal Compensation Act calls for a stevedoring safety code by Congress in the near future. We appear to be in a fair way to have legislative intervention in stevedoring management, the inevitable result of failure of the industry to prevent its own accident wastage. Perhaps an even more effective factor compelling attention to the relationship of safety and productivity in port cargo handling is the increasingly severe competition steadily at work, resulting in ever closer scrutiny of costs, and leading toward their sharp reduction.

Factors Making for Safety and Productivity

Although there is little that is known concerning accident prevention and productivity in port cargo handling certain factors making for both safety and high productivity are exceedingly well known, including:

- (1) The necessity of knowing production costs and accident rates.
- (2) Regularization of employment; the decasualization of longshore labor.
- (3) A port safety program, including a safety engineer in each large port, with a joint safety organization of men and employers, working in a common effort and toward a common interest.
- (4) Steady experimentation in designing and operating improved mechanical means of port cargo handling. The presence of surplus labor in most ports of the country has and will inevitably continue to interject severe labor restrictions on the introduction of labor saving machinery in port cargo handling.
- (5) Experience rating for every risk, with premiums accordingly, should furnish a sharp prod to bad experience and continued encouragement to good experience.

The writer's experience leads him to the conclusion that in shipping as in inland industries, personnel problems and production problems are interdependent; whatever makes for competent personnel direction helps toward production; and vice versa, that which represents studied management attention to production cannot fail to take into consideration accident prevention.

A common observation on board ship in port is that where you have cheap casual labor and hectic conditions of supervision and operations, accidents are frequent and severe, and tonnage low. Although the evidence is not available in tangible form to present to shipping management in support of the following statement, shipping concerns doing business in the several ports of the country no doubt can produce the evidence from their own records—namely, that in the three sections of the country where safety engineering is under way on a port basis you will also find progress in production. Galveston is just employing a safety engineer; San Francisco is well under way; Puget Sound has been at work in this field for three years. It has been noted in the port of Seattle that in the last several years while port tonnage has increased, and payrolls too, the number of longshoremen remains approximately the same. More of the time of the men is spent at the job, less in the hospital. The accident statistics confirm this.

In these several sections of the country the relationship of safety and productivity in port cargo handling is recognized. The safe way is the efficient way.

CHAIRMAN KAIN: Gentlemen, we are open for discussion.

CAPT. EVANS: He is too near right to take much issue.

CAPT. SHERIDAN: Mr. Chairman, would the safety engineers' duties come under a government or a private or an insurance jurisdiction?

A. R. BUSH (Barber Asphalt Co., Maurer, N. J.): Entirely private.

MR. ARKILLS: Out west we have what is known as the Waterfront Employers. We were originally organized to fight the Unions and then they afterward got to dealing with the Unions through Mr. Foisie's plans and now have joint representation.

One of the greatest factors to help out in our safety work in the ports of Seattle and Puget Sound, is the fact that all the ports of Puget Sound are copying to a great extent our means of operation in Seattle and the machinery was well set for safety program there when I was employed. Very little credit is due me for the work that has been done. If there is anything, it is just cooperation in what I might have suggested.

Mr. Foisie's paper deals very largely in generalities and with the studies he has made in connection with the foundation research he has just about completed. In any cases he is shooting over my head to answer questions on his paper, but anything in connection with Seattle's operations, I believe, I could describe. There are about 45 companies, I judge, now in that association. They maintain the Hall; they even have a large room there where they can gather without any expense to themselves and they operate this Hall at an expense somewhere approximating \$25,000 a year. I believe it is all paid back to them in many ways each year through the operation and the increased tonnage we get per man over other ports. I hope that will be shown in Dr. Boris Stern's report. At any rate, I do know that with less men today than we had three years ago, there is more cargo through the port of Seattle. That is borne out by our records and the records of the port.

An Increase in the Productivity of Men

CHAIRMAN KAIN: You made the point that there was more cargo handled with fewer men. Does that mean that the men were handling more cargo per hour or that there are actually fewer men employed and that they work longer each day?

MR. ARKILLS: There are fewer men employed, but more hours worked by the same number of men. Three years ago, if I remember correctly, the average wage in the port was somewhere around \$156 a month for the regular gangs. It has gotten up now for those same regular gangs with an increased number in gang formation, to a point around \$176, which shows that the same men are actually putting in more hours, but not excessive hours. At the time I went to Seattle down on the beach, if you had 44 men working, there were about 10 men standing by to fill the breaches caused by those injured or who lost time incident to accidents. We have reduced that at the last compilation of statistics, to a point where only one man to eleven is necessary to stand by to fill the breaches caused by those injured. So I feel that it is undoubtedly a fact that we have fewer men in the hospitals, fewer men injured and crippled, and they actually have an opportunity to work a reasonable number of hours.

CAPT. EVANS: Will you explain just a little, please, what the Central Hall is used for and how labor is distributed?

MR. ARKILLS: We have, as I said, gangs. We had about 10 regular gangs of 10 men each three years ago. I think we have about 26 now. Those men who are in regular gangs don't need to come to the Hall, unless ordered to come by phone. They call up every noon, and whenever they are told to call next. They are despatched from the Hall and they sometimes are despatched right from their homes. All the stevedores are handled that way, excepting the extra board men who must come to the Hall to get their jobs, and they hang around the Hall in the morning, at noon or

any part of the day they think the ship may start. Instead of lining up at the gate for shaping into gangs, they line up at the Hall and are despatched from the Hall. The truckers are on an entirely different basis. They must all come to the Hall to be despatched. The next man out is the next man under the peg where the last man was despatched from. We have pool tables in the Hall where the men can play for five cents a game, a cigar stand in the corner and a fountain where they can buy soft drinks. The men make it a club room as well as a waiting place for their despatching.

CAPT. EVANS: Do all employers maintain the Hall.

Additional Men Are Available in the Hall

MR. ARKILLS: No, they do not. The Pacific Steamship Co., Admiral Mail, the Alaska Steamship Co. and others of less size have a nucleus of their own men and only procure the added men that are necessary in emergencies. Now, for instance, when the "H. F. Alexander" comes in on Monday morning, it is always necessary to call the Hall for additional truckers, because that ship is running on very fast dispatch and they truck through side ports and handle cargo over the side—a tremendous amount of cargo in a very short space of time. In cases of that sort, they must have their additional men over the 250 they would have at their docks all the time. Other stevedores have no men of their own at all. In that case, they must get all their men from the Hall if they are members of the organization. In fact, that is about the only place in Seattle where they can get men. The I. L. A. headquarters have a small handful of men. Most of those men have at some time or other worked on the waterfront and have either eliminated themselves or have been eliminated for cause.

MR. BUSH: You made the statement that they were working longer hours than previously, but not excessive. What do you mean by that?

MR. ARKILLS: We have an eight-hour shift in Seattle and seldom exceed it, except in emergencies; and if you are working an eight-hour shift, I don't believe you are overworking them in most cases, because we have a full hour at noon and a full hour at dinnertime in the evening. Few of the ships work on Sunday, but in some cases, of course, where quick dispatch is required, they do.

MR. BUSH: Do eight hours constitute your working day?

MR. ARKILLS: It is the unwritten law. We do try to work an eight-hour day as far as possible and we dispatch fresh men in many cases to take the places of those who have been working, because fatigue is one of the causes of accidents.

CHAIRMAN KAIN: Is the port of San Francisco organized along the same lines as Seattle?

Such an Organization in Eastern Ports Will Be Modified

MR. ARKILLS: I believe Mr. Pickard has set up a little different organization there. He of necessity has had to work very strongly through the employers. They haven't a joint organization down there, but I believe they have one representative of the men on their committee. A man who is in a position to know what they are doing in San Francisco said they are doing a very nice piece of work and I believe that Mr. Pickard is entitled to a lot of credit for the work they are doing there. I will say this, that they have not been selfish in the use of printer's ink and their educational program is carried on very vigorously. The accidents have noticeably decreased to the operators, that is, as the operators see them, which to me is a very wholesome condition.

CHAIRMAN KAIN: Do you think it would be possible to organize in the Eastern ports and Great Lakes ports on the Seattle plan?

MR. ARKILLS: I don't believe it would be possible to organize New York City on the Seattle basis. You would have to adopt something more on the order of San Francisco; and I believe if you brought a man in from the labor organization into such an organization, you wouldn't want to bring one in that you had to sell entirely on the safety idea to start with. You would have to find some man to represent them who would know the language you are trying to talk, to start with; so it wouldn't be given a black eye before it got started. I do believe that if you were to organize the port of New York, reaching the heads of the companies operating there by means of a few general meetings—get them sold on what is and what can be done, and then work down through their foremen, which is the real way of reaching stevedoring accidents, and in some way or other create more of an organized form of operation in the way of the gang system—give more authority to your hatch tender or let him form his own gangs; hold him responsible—I believe you could go a long way toward a safe port right in a big city like New York. That is my candid opinion and what I would attempt if I were to go there. I may be all wrong.

CHAIRMAN KAIN: I think this is a very important question because there is a tendency, of course, to say "they can do that in Seattle, but conditions are different in New York and we can't do it that way." Possibly, they couldn't do it the same way, but I think they can get sufficient material and ideas so that something can be done in that port.

MR. ARKILLS: I believe it could be done on the San Francisco plan with some modifications and could be carried on very splendidly.

CHAIRMAN KAIN: Of course, in New York, the men to a large extent do work only in sections of the city. There are certain men who work only on certain steamship piers, so that although it is a large port, it might be possible to organize the port into districts and handle each somewhat as you do the port of Seattle.

MR. ARKILLS: I believe that would be entirely possible.

CHAIRMAN KAIN: I have here in front of me three copies of a rough draft of a code by Mr. Arkills. As was pointed out in this paper by Mr. Foisie, it is quite possible there will be a code formulated in a short time at the instigation of the Federal Compensation Commission. There is obvious danger in that plan as was pointed out yesterday, and I think some of you men probably have had considerable experience in shipping and stevedoring, I would like to have you take one of these copies and go through it for the purpose of making constructive criticism. Mr. Arkills will be very glad to have it and that is the only way these codes can be drafted and made serviceable. When completed they should contain the best opinion and practice of the entire business.

Mr. Bush has just reminded me that we are planning to mimeograph this code as it is now drafted and we have all your names here, I think.

The next paper is by Col. Simmons.

The American Marine Standards Committee—The Relation of Its Work to Accident Prevention

Col. Edward A. Simmons, Chairman of the Executive Board, The American Marine Standards Committee, New York City.

The American Marine Standards Committee was formed November 10, 1922, under the auspices of the American Marine Association, for the purpose of paralleling, in the marine field, the kind of standardization work that has been going on in the railway field in this country for more than half a century. Like railway standardization, the primary object of the American Marine Standards Committee is to attain increased economy and efficiency in building, repairing and operating ships by promulgating uniform, simplified standards applicable

alike, in so far as practicable, to both merchant and naval vessels. On the surface, it would appear that commercial gain only is involved; but as a matter of fact, we have considerable in common with the aim of the National Safety Council, since prevention of accidents is ever present as a factor in solving many of our problems, whether they include the design of ship fittings, equipment or machinery, or the formulation of rules of practice.

The Committee Functioning for Four Years

While the American Marine Standards Committee has been functioning steadily for some four years, the results when measured by quantity alone are not large. However, as Rear Admiral Rock in his paper on "Better Ships for Less Money," read at a recent meeting of the Washington Section of the American Society of Mechanical Engineers, has said: "We must guard against mushroom tendencies, superficial studies and perfunctory action. If my advice were requested, I would say that emphasis should be placed on quality rather than quantity."

For record purposes, I am appending a list of 23 publications issued by the American Marine Standards Committee up to June 1, 1927. You will note that some of the standards, for example the group of fittings for deck and rigging, cargo handling gear, specifications for hose, instructions for operation, care and upkeep of boilers, distinctive markings for piping, list of machinery spare parts, recommended equipment and methods for safety on ships, and specifications for pressure and vacuum gauges, are of interest to this Council, as prevention of accidents is an essential factor in each instance.

Aside from the direct relation between standards and safety, there is an indirect tie which is more than superficial—the immediate understanding of standardized equipment and methods by new personnel on a ship. This would be materially emphasized in the event of war, when the Navy, with which the American Marine Standards Committee in cooperating closely, might be called upon to operate merchant ships. This was recognized by Admiral Rock in the paper to which I have already referred when he cited as an example our standard O No. 19—1926, "Distinctive Markings for Pipe," which show at a glance whether a pipe carries live steam, exhaust steam, salt water or compressed air. The advantage of similar markings on all ships is obvious.

By far the greatest single effort toward increased safety at sea so far made by the American Marine Standards Committee has to do with the stability of ships.

Lack of Stability in Vessels Discussed

Lack of stability in vessels may be either the primary or a contributing cause of more losses than appear on the surface; because a capsizing is a relatively rapid process, so that complete information about just what happened is often lacking. Disasters, such as the capsizing of the "Eastland" at a pier in Chicago, on July 24, 1915, and the recent, but fortunately less disastrous turning over of the small steamer "Favorite" on Lake Michigan on July 28, with the loss of 27 lives, led by evolution to the promulgation of certain rules by the Steamboat Inspection service of the Department of Commerce, now in force, which require a so-called "inclining experiment," or stability test, for any vessel under its jurisdiction, the stability of which the inspectors have any reason to question—which rules, since July 1, 1924, have been applied to all passenger vessels intended to carry over 50 passengers, or one of 500 or more gross tons.

The rules in question, however, are both weak and unjust because of lack

of definiteness. They simply say that "a vessel shall have sufficient stability." Thus the factor of safety is left to individual opinion, which is unsound and sometimes proves onerous and unfair to builder and owner alike, because both are compelled to work in the dark and afterwards stand the light of varying opinions. The situation is analogous to one wherein a man decides to build a structure in a large city, employs a competent architect and contractor and after the building is finished is refused a permit of occupancy without material structural changes or a reduction in rated capacity because of a decision by the Building Department that the stress should have been no more than 5,000 pounds per square inch, whereas the architect had determined 10,000 pounds as ample for safety—the actual difference being that with the city the plans would have been filed and approved in advance and, if complied with, a certificate would follow as a matter of routine.

Special Committee on Loading and Stability

Realizing the gravity of the situation and following an investigation by a special committee made at the suggestion of Rear Admiral John D. Beuret, Chief Constructor of the United States Navy, the chairman of the Executive Board, by authority of the Board given November 15, 1924, designated the following to act as a Special Committee on Loading and Stability:

George H. Uhler—representing the Department of Commerce;
David Arnott—representing the American Bureau of Shipping;
J. R. Gordon—representing the American Steamship Owners' Association;
S. D. McComb—representing the Board of Underwriters of New York;
E. H. Rigg—representing the Atlantic Coast Shipbuilders' Association;
Captain J. F. Milliken—representing the Neptune Association;
James Swan, Secretary—representing the Society of Naval Architects and Marine Engineers;
W. F. Gibbs, Chairman—representing the American Marine Standards Committee.

The result was a very comprehensive report which was tentatively approved by the Executive Board on April 5, 1926, put in type and sent to all naval architects, ship builders, ship owners and others here and abroad for constructive criticism.

A summary of the comments reveals some strenuous opposition to the adoption of the report, due in a large measure to fear of the possible far-reaching effects of more rigid governmental regulation, although the reason given by the opponents is that it is not possible to prescribe a stability formula for use in designing ships that can be followed without unnecessary hardship to the owner. In any event, the Executive Board has expressed its confidence in the very able committee engaged in arriving at a solution and it is believed that the outcome will be a report that can be used as a basis for stabilizing and loading vessels that can be followed by all having to do with designing, building and operating ships, including governmental agencies, and contribute much toward the reduction of loss of life and property due to capsizing.

The Aim of the Committee Has Been Attained

The aim of the committee, which was to provide a means of comparing one vessel with another and to create a standard which could be applied to ships of various types and trades, has been attained in the report. If and when it is adopted as standard by the Executive Board, steps will be taken to insure application to all new vessels only, since it would not be practical to include ships already built.

Right here it might be in order to insert, parenthetically, that the American Marine Standards Committee has no leaning whatever toward compulsory regulation. Like Mr. Hoover, it believes in "more business in government and less government in business"; and, again like him, aims to prove it by example rather than precept. However, when it is plain that only governmental intervention will accomplish a desired end, it is my personal belief that the committee would not hesitate to recommend such a course.

A Part of the National Program, Department of Commerce

While the American Marine Standards Committee was initiated by the American Marine Association, it soon became a part of the national program of the Department of Commerce for elimination of waste in industry and commerce; and the work is being carried on in conjunction with the activities of the Division of Simplified Practice of that department, with the very hearty personal support of Mr. Hoover. The development of standards is, however, in no way directed by the Government; but is accomplished, with full freedom of action, by numerous subject and technical committees, the memberships of which are composed of highly qualified representatives of the various branches of the industry. The marine departments or bureaus of the Government participate in the work as units of the marine industry.

Some of the items, perhaps many of them, in the ultimate program of the committee are of special interest to the National Safety Council; and in their development for the purpose of standardization there will be an ever growing need for close cooperation between the two bodies. Unless and until such cooperation exists, there is an inherent possibility of duplication of effort by reason of the mutuality of interests. This has been guarded against by the committee through contacts made with members of the Council on specific safety problems; but it is believed that a more positive interlocking of the two organizations would be advisable to properly correlate their respective efforts.

The chief functions of the Council are assumed to be the determination of causes of accidents and the issuance of recommendations for their prevention; whereas the aim of the American Marine Standards Committee is to develop projects into standards of practice. From this premise it would seem that there is a fairly well defined line of demarcation between the respective motives of the two bodies; and that on subjects of mutual interest good collective results can best be attained by collaboration along that line.

Protection to Life and Property an Economic Factor

It is being more and more recognized in industry that protection to life and property is an important factor in practical economy; that moderate investments for protection result on the average in appreciable savings in operating costs. It is, in fact, one of the elements of any formula for elimination of waste. The factor of safety is especially important in ship operation because of the many hazards inherent to the industry. It therefore follows that almost any project of standardization for ship construction or operation deserves consideration from the standpoint of accident prevention and that the committee's solution of the problems of economy must involve the factor of safety. It is recognized as a fundamental, that true economy overlaps mere cheapness of unit output.

A number of organizations which have interests in common with the committee have appointed representatives to serve as advisory members of the committee's Executive Board. The latter would welcome the appointment of a representative of the Council in the same capacity. It is believed that such an arrangement would be conducive to a mutual understanding on matters affecting both bodies and the unification of their mutual aims.

APPENDIX

Serial Number	Title of Subject	Standards Number
1.	Glass for Air Ports and Fixed lights.....	H No. 1—1925
2.	Mooring Bitts—Cast Iron	H No. 2—1925
3.	Fixed Lights for Ships.	
	Type A—Pressed Steel Frame.....	H No. 3—1925
	Type B—Cast Brass Frame	H No. 4—1925
	Type C—Cast Brass Finished Frame.....	H No. 5—1925
4.	Rigging Screws for Ships.	
	Rigging Screws with Spliced Rope.....	H No. 6—1926
	Rigging Screws with Sockets.....	H No. 7—1926
5.	Ship Fittings for Decks and Rigging.	
	Chain Plates	H No. 8—1926
	Wire Rope Sockets	H No. 9—1926
	Solid Thimbles for Wire Rope.....	H No. 10—1926
	Open Thimbles for Wire Rope	H No. 11—1926
	Thimbles for Manila Rope	H No. 12—1926
	Pad Eyes and Links	H No. 13—1926
6.	Cargo Handling Gear for Ships.	
	Railroad Iron Sling	H No. 14—1926
	Chain Sling	H No. 15—1926
7.	Kinds and Sizes of Hose for Ship Equipment.....	O No. 1—1926
8.	Specification for $\frac{3}{4}$ " and 2" Flexible Metallic Hose.....	O No. 2—1926
9.	Specifications for 2½" Double-Jacketed Cotton Rubber-Lined Fire Hose	O No. 3—1926
10.	Specifications for 2½" Unlined Linen Fire Hose	O No. 4—1926
11.	Instructions for Care and Maintenance of Steel Hulls.....	O No. 5—1926
12.	General Instructions for Operation, Care and Upkeep of Scotch Type Marine Boilers	O No. 6—1926
13.	Kinds and Sizes of Mattresses and Pillows and Woolen, Linen and Cotton Articles for Ship Equipment.....	O No. 7—1926
14.	Kinds and Sizes of Glassware for Ship Equipment.....	O No. 8—1926
15.	Kinds and Sizes of Silverware for Ship Equipment.....	O No. 9—1926
16.	Distinctive Markings for Piping	O No. 10—1926
17.	Specification for 2½" Single-Jacketed Cotton Rubber-lined Fire Hose	O No. 11—1926
18.	Essential Machinery Spare Parts, Accessories and Supplies for Sea-Going Ships	O No. 12—1926

20.	General Instructions for Operation, Care and Upkeep of Water Tube Marine Boilers	O No. 14—1927
21.	Condenser Tube Ferrules and Tube Sheets.....	E No. 1—1926
22.	Specifications for Pressure and Vacuum Gauges for Ships.....	E No. 2—1926
23.	Mooring Bitts—Cast Steel	H No. 17—1926

Close Cooperation With All Maritime Nations

COL. SIMMONS: It is my pleasure to deposit with the Council a set of the standards that have already been promulgated and it is our aim to follow this same plan in connection with the numerous other standards now being developed. While this is primarily a national movement, that is, one designed first for America, nevertheless,

we are cooperating very closely with all the maritime nations, for example, with Great Britain, who started the same kind of work four years before we began. Where they have evolved, or had evolved, standards, for instance, for tail shafts, we have almost paralleled their standards, so that ultimately, it is believed, at least hoped, that a ship in need of repairs can be turned around far more quickly when in any of the large ports of the world. In other words, many of these fittings can, you might say, be taken off the shelf and applied to the various vessels. Of course, this is going to be a work of many years, but had we had some such set of standards prior to the Great War, there would have been a very different story in the ship-building industry.

CHAIRMAN KAIN: On behalf of the Marine Section, I want to thank you for your very interesting paper and for the pamphlets.

I might say that yesterday we discussed one of the hazards causing a great many accidents on board ship; namely, the hatches on cargo ships. One of the things which was developed as a result of that discussion was the necessity for some kind of standardization of hatches, their construction and equipment. They are a very fertile source of personal injury and death. There isn't a day when we do not have an accident, and a serious one, and I think the Council could very well cooperate with the Marine Standards Committee.

COL. SIMMONS: I would suggest the Council name someone in New York or Washington. The executive board which finally passes on anything, meets four times a year and it would be gratifying if the council would designate someone who could sit in on our deliberations and help us, and hatches will undoubtedly be taken up. At the last meeting we passed on life-boats. We adopted a standard for life-boats and it is our intention to cover every part of a ship where the factor of safety is involved.

CAPT. EVANS: It is my understanding you have not thus far covered the question of hatches, Colonel.

COL. SIMMONS: No, we have not. The next great question will be bulkheads.

CHAIRMAN KAIN: Are there any further questions? We will go on with the next paper. Mr. Edwards will not be here today and I am going to ask Mr. Bush to read the paper.

"Health Conditions Among Seafaring Men"

R. F. Edwards, The Prudential Insurance Company, Newark, N. J.

One of the most vital problems in the shipping industry is the desirability and the necessity of hiring physically fit seamen. During the last few years considerable attention has been given, particularly in foreign countries, to welfare work among this class. In this country since 1875 seamen have received treatment at reasonable charges in the U. S. Marine hospitals. Prior to the extension of these services, which took place subsequent to the war, there had been an annual average of more than 55,000 seamen treated in these hospitals or in the out-patient departments.

In addition to this, foreign seamen, averaging about 500 per annum, have also taken advantage of these privileges. For American seamen the average number of days of hospital treatment had been 30 while for foreign seamen two or three weeks terminated the length of stay. With the extension of the services the duration of treatment for both American and foreign seamen has increased practically one week.

The Oslo Conference, held during 1926 under the auspices of the League of Red Cross Societies, constituted a distinct advance and promises to be the beginning of a new era for seamen. The conference dealt particularly with the health problems of seamen. Venereal disease prevention and prophylactic treat-

ment were particularly stressed. The League of Nations International Labour Organization, probably the most important of its kind, recently appointed a joint maritime commission which considered not only the question of regulation of hours, wages and other features, but the health of the seamen as well. A number of very important articles pertaining to this subject have recently appeared in the *"World's Health,"* a publication of the League of Red Cross Societies.

Realizing the necessity for a reasonably accurate knowledge of first aid procedure the officers of the United States Public Health Services have instructed candidates for licenses as masters, mates, pilots, or engineers, the intention being to furnish adequate first aid treatment at sea on vessels having no medical officers. In the past many permanent injuries and deaths among seamen have resulted through the lack of medical knowledge on the part of the officers in charge. At the present time there are very few countries having a sea board which do not offer some facilities for the medical treatment of seamen while ashore. In other words, the health of seamen is receiving more consideration at present than at any time during the past.

While the Shipping Act of 1915 has caused much controversy as to its merit, it has proven beneficial to the steamship owners in that it provides that 65 percent of all seamen shipping on American vessels must be able bodied men. This has a decided tendency to decrease the number of compensation cases contracted under Admiralty law. Some of the findings due to medical examinations, will be set forth in the following sections of this article.

Physical Examinations of Seamen by the U. S. Public Health Service.

During a period of 16 years 48,786 pilots had been examined, of whom 1,542 were rejected, or at the ratio of 31.6 per thousand examined. By far the greatest number of defects found were eye conditions, accounting for a ratio of 30.5 per thousand examined. Of these eye rejections, 680 were attributed to color blindness and 795 to defective vision. There were 3 cases of tuberculosis, 7 of deafness, and 16 of heart disease. There were 4 rejections because of poor physique and 7 because of previous injuries.

During the same period, 56,066 seamen of the merchant marine were examined and 5,663, or a ratio of 101 per one thousand examined, were rejected. Among this class we find a much higher ratio of eye defects than among pilots, 3,623 cases or 64.6 per thousand examined. Defective vision was responsible for 2,407 rejections, a ratio of 42.9 and color blindness for 1,118 or 19.9 per thousand. In addition to this 71 were blind in one eye. A total of 633 cases of hernia were rejected, or 11.3 per thousand. Venereal disease was found in 266 examinations; a ratio of 4.8 per one thousand examined. Malaria was comparatively rare, there were, however, 22 cases of rheumatic fever and 41 of tuberculosis; 24 were rejected because of alcoholism, 15 because of kidney disease and 72 or 1.3 per thousand because of previous injury. Of these 72 defects, 26 were of the upper or lower extremities. Poor physique, skin diseases and diseases of the teeth and tonsils were quite prevalent. In addition, 111 rejections, or a ratio of 2.0 per thousand, were made because of arterial diseases, and 212 or 3.8 per thousand for heart conditions. Hemorrhoids were frequently found.

In addition to the foregoing, 5,259 foreign seamen were examined of whom 494 were rejected, representing a ratio of 93.9 per one thousand examined. These require very little comment as health conditions were found to be very similar to those among the American merchant marine. Eye diseases were not quite as prevalent; however, infective diseases, particularly venereal, were twice as frequent among foreign seamen as among American. Tuberculosis was

another condition found to be more frequent among the foreign seamen. Bearing in mind the close relationship between physical debility and the liability to accident, it need scarcely be pointed out that the cost of physical examinations among seamen desiring employment is well worth the expenditure involved.

Disease Incidence Among Seamen

It has been possible to obtain a record of 411,234 cases of diseases or injuries treated within the last decade. Of these 171,217 were treated in the hospital of whom 6,067 died. It is therefore evident that a rather clear conception of the liability of seamen to particular diseases can be obtained. While it is true that some duplication of cases has taken place, due to a seaman reporting more than once during the year for treatment, generally this need not seriously affect the results and conclusions can be safely drawn from these findings.

The largest single group was that of the infective diseases. A total of 218,294 cases were reported, representing a ratio of 257 per one thousand cases.

As has been pointed out before, venereal disease forms the most important problem with which seamen are confronted. In the series at hand 113,627 cases of venereal disease were reported, representing a ratio of 185.8 per one thousand cases treated. Of these, 24,811 were due to syphilis. The far-reaching affect of these diseases upon the health of seamen cannot be too emphatically stressed. There is considerable evidence that, aside from the active cases of venereal disease reported, at least 2 per cent of other conditions can be attributed to the after affects of these diseases.

There seems to be an excessive number of cases of carbuncles and boils.

Typhoid fever was reported in 3,888 cases, or a ratio of 6.4 per one thousand. Of these 3,510 were treated in the hospital and 301 deaths resulted. While the steamship owners are liable for a poor water supply on the ships it must be borne in mind, however, that many of the seamen visit tropical and semi-tropical ports in which the water supplies are far from acceptable. Anti-Typhoid vaccination of seamen is to be commended.

Tuberculosis was responsible for 13,586 cases, or a ratio of 22.2 per thousand. Over 10,000 of these cases received hospital treatment with an immediate mortality of more than 2,000. While in some cases seamen are subject to poorly ventilated living quarters, generally speaking, their exposure to the action of the sun and invigorating winds should tend to build up a bodily resistance. It would therefore seem reasonable to assume that the seaman's duties themselves are not responsible for this high incidence of tuberculosis.

Other Diseases From Infection

Rheumatic fever was responsible for 30,000 cases or a rate of 49.1 per one thousand. Here we have a condition which to a great extent could be attributable to the duties of seamen. It must be borne in mind that rheumatic fever is a very serious condition in that the after affects upon the heart are very far-reaching. The germs causing this condition have an affinity for the valves of the heart. Disability due to rheumatic fever is likely to be of considerable duration. When a seaman contracts this condition he should immediately go to bed and remain there until condition has cleared, otherwise serious heart lesions may result.

Dysentery was present in 1,528 cases. Here again we have a very serious affection. This is contracted from a contaminated water supply not only in tropical countries but also in some of the southern ports of this country. The fatality ratio from amebic dysentery is particularly high due to the fact that

the ameba travel from the intestinal tract to the liver, causing an abscessed condition which usually requires operation.

Aside from the prevalence of tuberculosis there were 45,715 cases of non-tuberculous respiratory diseases with a ratio of 74.6 per thousand. Bronchitis formed by far the greater proportion of these conditions. Pneumonia was not particularly frequent, on the other hand, pleurisy seems to be a rather common condition among seamen.

Diseases of the skin and hair were next in importance with a ratio of 46.3 per thousand cases. Acne seems to be somewhat prevalent, particularly among employees in the engine room and stoke-hold. Abscess and ulcers of the skin were also quite frequently found.

Diseases of the stomach were reported in 19,483 cases—11,000 of which were due to indigestion—7,000 to gastritis and 500 to ulcer. In view of the large number of cases of indigestion and stomach disturbances reported it is very evident that seamen should exercise greater care in the selection of foods. The effect of alcohol upon the stomach should also be borne in mind as the number of cases of gastritis is particularly high.

Nervous conditions were responsible for 18,252 or 29.8 per one thousand.

Diseased conditions of the mind were responsible for 5,334 cases. While this does not represent a very large number in the aggregate, it has particular significance as far as accident liability is concerned.

Neuralgia and neuritis are also found to a considerable extent among seamen.

Diseases of the muscles and fascia were reported in 15,896 cases—15,571 of these were muscular rheumatism. If we combine these with the cases of rheumatic fever we find a large proportion of seamen reported as having had rheumatism in some form. The debilitating effects need not be enlarged upon at this time but they form a serious reason for rejecting the services of seamen.

Diseases of the urinary system were not particularly prevalent, 12,874 cases being reported. There were, however, a large number of bladder and urethral affections indicating the probable after effect of venereal infection.

Diseased tonsils are apparently very frequently found.

Circulatory disease was reported in 10,240 cases of which 6,683 were heart conditions and 3,557 arterial. The large number of cases in which the valves were involved may indicate a previous history of rheumatic fever. Myocarditis and cardiac neuroses are comparatively rare. Aneurism, while not particularly prevalent is very significant in view of the large proportion of cases of syphilis reported.

Hernia was reported in 8,823 cases, representing a ratio of 14.4 per thousand.

Many cases of diseased teeth and gums were reported. A sailor with poor teeth can not properly masticate the food and the effects of this may be reflected somewhat in the large number of stomach conditions found.

Cancer does not seem to be particularly prevalent.

In the foregoing remarks it has only been possible to point out some of the more prevalent conditions affecting the health of seamen. Many other important features are presented by the data which can not be stressed at this time, however, it is felt that sufficient details have been presented to show the desirability of physical examination of seamen before they are shipped.

Principle Causes of Injuries

Injuries were reported in 102,477 cases representing a ratio of 167.7 per thousand cases treated. The organs or parts affected are given in detail. It has also been possible to ascertain, with a fair degree of accuracy, the nature of the injury in all but 29,000 of the cases. As was to be expected, by far the greater

number of injuries, or 41,106 were to the lower extremities and in 23,935 cases the upper extremities were involved. The back was injured in 3,941 cases, chest, ribs or sternum in 4,871, eyes in 2,396, face in 3,667, muscles or ligaments in 1,914, scalp in 3,855 and skin in 4,503. Contusions were responsible for 22,955 cases, sprains or dislocations for 11,698, fractures for 10,971, lacerations for 7,574, burns for 7,326, gunshot wounds for 465 and stabs for 248.

It is significant that fractures, sprains, dislocations, contusions, lacerations, incised wounds and burns were twice as frequent to the upper extremities as to the lower. More than half of the injuries to the chest and ribs were due to fractures. This condition is particularly suggestive because of the probability of a considerable period of disability. Sprains and dislocations are also significant in that they naturally will cause a considerable loss of time. It is very significant that of 336 injuries to the skull, 249 were fractures and of 274 to the spinal cord, 211 were fractures. The seriousness of a fractured skull or spine need scarcely be enlarged upon at this time. Cases of compound fracture of the skull may cause a total disability lasting from 6 to 12 weeks. While in the case of simple fracture the disability may be somewhat shorter. Fractures to the spine are a very serious condition. Disability due to this condition may be permanent. Death frequently intervenes in many of these cases. The number of gunshot and stab wounds indicate somewhat definitely the likelihood of seamen becoming injured in brawls.

The Mortality of Seamen

For a number of years the British Board of Trade has reported the deaths of seamen in considerable detail. While these details are reasonably complete, it is estimated that a number of deaths occurring among seamen are not reported. For practical purposes, however, these form a fairly accurate basis for estimating the mortality among seamen. It should be borne in mind that British vessels visit every port in the world and that there is much more likelihood of British seamen contracting tropical diseases than there is among American crews.

Referring to deaths from diseases only, we find that 14 per cent of the deaths were due to pneumonia; 13.9 per cent to circulatory disease; 8.3 per cent to tuberculosis; 5.7 per cent to malaria, and 5.3 per cent to typhoid fever.

Among other conditions of special significance are the large number of deaths from sun stroke and heat stroke or 3.3 per cent of the deaths from disease.

Alcoholism, while forming a very small proportion of the mortality was directly responsible for a large number of deaths. Forty-five per cent of the deaths for which alcoholism was responsible were among engine room and stoke hold hands; 21 per cent deck hands, and 13 per cent in the stewards department. Of 315 deaths due to alcoholism, 101 were killed or drowned going aboard, 59 drowned in the docks, 28 either fell overboard or through a hatchway and 14 committed suicide. Comparing the mortality of seamen in the merchant services with all occupied males it was shown that seamen were 88 per cent in excess. In view of the admitted inaccuracy of the records it seems safe to assume that the mortality among seamen is twice as high as among occupied males as a whole.

Further Analysis of British Statistics

Analyzing further the statistics provided by the British Board of Trade as pertaining to the causes of death we find that only 7 per cent of the deaths at sea on sailing vessels were due to disease, the balance being attributed to accidents either to the vessels or to the persons, while on steam vessels 48

per cent of the deaths at sea were due to disease. It is therefore very evident that the liability to accident on sailing vessels is much greater than on steam vessels.

Reviewing briefly the experience of the various departments on vessels it is found that among masters and mates, missing vessels were responsible for 26 per cent of the deaths, and suicide for 5.2 per cent among this class. Nineteen per cent fell overboard or were drowned in the docks ashore. This high proportion of deaths from these causes would seemingly indicate that alcoholism played an important part. Practically the same conditions hold true among petty officers. Deck hands, while indicating a large porportion of deaths from the aforementioned causes also show a large number of falls down hatchways and an excess number of deaths from homicide and suicide. Among engine room and stoke hold hands, 8 per cent of the mortality was due to suicide. The proportion of deaths probably connected with the use of alcohol are extremely high in this department. In the stewards department there were also indications of a large number of deaths due to alcoholism and its ultimate effect.

Compensation Statistics

Primarily this Council is interested in accident prevention. The statistics available as a result of the Workmen's Compensation and Employees' Liability Acts of Great Britain are enlightening. Comparing the shipping experience with other branches of industry it is significant to note that the fatality ratio from accident is somewhat higher than that reported for other industries. This ratio per 1,000 employed has remained somewhat constant during the last two decades, varying from 1.1 in 1923 to 2.1 in 1919 and to 1.5 in 1925. The disability ratios show a somewhat uniform increase reaching 33.4 in 1925 or the highest on record. The fatal accident ratio of sailing vessels is generally three times as high as on steam vessels while the disability ratio shows a decided inclination to increase. That for steam vessels, however, remained practically constant during the entire period.

The average claim payments for fatalities on steam vessels during the last five years was \$1,179, as against \$904 for sailing vessels. The disability payments averaged \$118 on steam vessels as against \$111 on sailing. The entire expenditure was \$1,476,959 for fatalities on steam vessels as against \$103,906 on sailing vessels. In addition to this there was over \$3,000,000 paid for disability on steam vessels and \$137,000 for disability on sailing vessels. It should be borne in mind that these amounts do not include legal, medical, administrative and other expenses.

While it has not been possible for the writer to obtain data relative to the duration of compensation payments in this country, the British experience set forth below is significant.

Duration of compensation for accident, exclusive of Lump Sum Payments, Great Britain, 1921-1925

STEAM VESSELS		Per cent Distribution
Under 2 weeks	2554	13.5
2 weeks	3181	16.8
3 weeks	2649	14.0
4-12 weeks	8165	43.2
13-25 weeks	1711	9.1

26 weeks or over	634	3.4
Total	18894	100.0

SAILING VESSELS

Under 2 weeks	107	12.5
2 weeks	159	18.5
3 weeks	132	15.3
4-12 weeks	384	44.7
13-25 weeks	52	6.0
26 weeks or over	26	3.0
Total	860	100.0

SHIPPING

Under 2 weeks	2661	13.5
2 weeks	3340	16.9
3 weeks	2781	14.1
4-12 weeks	8549	43.3
13-25 weeks	1763	8.9
26 weeks or over	660	3.3
Total	19754	100.0

Active Accident Prevention Campaigns Necessary

It will be noticed in the above table that there is in reality very little difference in the duration of disability occurring on sailing or steam vessels. The large numbers of disabilities lasting 4 weeks or more indicate the desirability of active accident prevention campaigns in the maritime industry. It is to be regretted that not more of our shipping interests are members of the National Safety Council and avail themselves of the privileges made accessible by the Council. Very favorable results are being obtained by steamship companies who have instigated extensive accident prevention campaigns.

It does seem that the time has come when all steamship companies should take an active part in this program. In addition to this statistics should be kept which will enable the steamship owners to estimate the value of their accident prevention work as compared to the results obtained by other companies.

CHAIRMAN KAIN: Gentlemen, you have heard the very interesting paper by Mr. Edwards. Is there any comment or criticism?

Particular Value in a Wealth of Statistics

R. E. PROUTY (Aetna Life Insurance Co., New York City): The principal value of Mr. Edwards' paper lies in the fact that he is quoting from very extensive statistics and, naturally, the value of any deduction made will be increased because of the volume of exposure which he has to deal with. His paper is of a character that makes it difficult for us to carry away from here a great deal of what he has had to say and I know you will all be pleased to learn that Mr. Edwards is planning to have his paper multigraphed with a few additional facts in it and distributed to the members at large.

M. E. ARKILLS (Waterfront Employers of Seattle, Seattle, Wash.): Mr. Chairman, there is one item that appeals to me as being something easily corrected. For instance, when I think of the water on a ship, I think of the storage battery. There

is a battery made on the West Coast now into which you can put any water you will drink and it won't injure the battery. The ordinary storage battery required distilled water. It seems to me that the present seaman must come under the classification of that battery made on the West Coast. He can go on and take water we can't stand at all. We sent some men out to work in the stream the other day. They had to drink the water from the ship. Four out of 86 of them were taken sick just drinking water from the ship. This is not an isolated case, but I believe all too often, water that seems pure isn't up to what it should be, and that is something that could easily be corrected with our present methods of distilling sea water, or purifying and cooling water by mechanical and electrical means.

The Marine Hospital Treats Men for Any Disease

CAPT. T. S. SHERIDAN (New York State Nautical School, New York City): In my experience very few seamen have become sick from over-indulgence in water. In that paper, there is one point that might have a little light thrown upon it. He said that at small cost the Marine Hospital Service treats seamen. They are treated free if they present what is known as a master's certificate. If they get a certificate stating they have served on the vessel, the Marine Hospital Service will treat them for any disease.

CHAIRMAN KAIN: I think he referred to the foreign seamen.

CAPT. EVANS: Another point of interest—he referred to seamen having stomach trouble due to food eaten. According to my experience, a seaman has little choice in food.

CAPT. SHERIDAN: I think when the food was much coarser they had very little stomach trouble. Today they overeat, too much rich food and meat and they don't get sufficient physical exercise. I think that has more to do with their trouble than anything else.

CHAIRMAN KAIN: I think that is a pretty safe conclusion. Most people on ships can verify it.

A. M. TODE (Texas Co., New York City): Mr. Chairman, I think that Mr. Edwards' paper is very interesting and it certainly covers a great scope of investigation and research. I think it will be especially interesting for the various companies, to compare their illness experience on the percentage basis in comparison with the large number of cases which Mr. Edwards has compiled. We have done that for some time in the Texas Company and I know that it will be of great interest to me to see how our individual organization of perhaps 1,400 seagoing men compares with the several hundred thousand cases, and therefore, get some basis for us to continue our work.

CHAIRMAN KAIN: Are you keeping records of illness?

MR. TODE: Yes, we do.

An Argument for Physical Examination of Seaman

CAPT. EVANS: Mr. Edwards' paper, I believe, makes a substantial contribution toward the argument for physical examination of seamen which has been stressed at this meeting of the Marine Section.

CHAIRMAN KAIN: I believe that is its outstanding value.

CAPT. EVANS: I think the importance of the paper for distribution among the members to drive home the necessity for such examination is inestimable.

CHAIRMAN KAIN: It even goes farther than that. As you know, there are a great many serious accidents, such as collision between steamers, where there are a large number of passengers and seamen whose lives are endangered. I think there

is no doubt that a great many of those accidents can be attributed to some physical defect of the men on watch while under way at sea. Most of the serious accidents do occur at night, or in fog and at those times usually the number of men on deck is small.

ADJOURNMENT.

Thursday, September 29, 1927

The third session of the Marine Section was called to order at nine-forty o'clock by the chairman, Capt. Wm. P. Kain.

CHAIRMAN KAIN: The meeting will come to order. Our first paper this morning will be read by Capt. Sheridan (New York State Nautical School, New York City) for Commodore C. Williamson (New York State Nautical School, New York City). The Commodore, unfortunately, couldn't get here.

Safety Education in State Nautical Schools

Charles Williamson, Secretary, New York State Nautical School, New York City

Many years before there was a National Safety Council or any concerted effort made to prevent accidents or conserve life in the various activities, the mariner had adopted a safety slogan which was in use wherever men "went down to the sea in ships." This was "One hand for the ship and one for yourself." In the days of sailing ships this was very necessary, as the foot rope of a yard-arm, with the sail slashing around in a gale of wind, was not a very safe place to work, and it required one good hand with which to hold on. Then, as now, men took chances, using both hands for the sail, instead of holding on with one hand, and sometimes they paid for it with their lives.

Since the days of steamships this condition has changed and seamen now do most of their work with both feet on something more substantial than a swaying foot rope, and seldom go aloft. An exception, however, is the case of the State Schoolships, which, while having auxiliary steam power, make most of their annual cruises under sail. The cadets must, therefore, be taught the old slogan for use when aloft. An engineering, as well as deck, course is taught in the Nautical Schools and "Safety" has an important part in the curriculum. As the cadets are being educated as officers for the Merchant Marine, it is very important that they should be trained in the prevention of accidents and the conservation of life, in order that they in turn, when officers, will be qualified to train and instruct men under their charge.

Unfortunately, some accidents and injuries cannot be classified as "preventable." When they do occur it becomes necessary to minimize the effect or allay suffering. Freight ships do not carry doctors as part of their personnel, therefore, one of the officers, usually the Chief Mate, must have the necessary knowledge and skill to care for such injuries as may occur while at sea. Lack of such knowledge on the part of the officer personnel might result in the loss of life or limb, through the inability to check a hemorrhage, or possibly the permanent crippling of a man through lack of intelligent treatment and care. First aid and hygiene, therefore, are included in the curriculum of the State Schoolships, the ship's surgeon carrying on the instruction, and practical demonstrations being given in bandaging, the use of the tourniquet, sutures and splints.

Instruction in practical work, both on deck and below, is closely affiliated with accident prevention at all times. One method of performing a task correctly and safely is always to be preferred to haphazard methods and unsafe practices. When handling boat falls, anchor gear, feeling eccentric straps, lighting up boilers, and the hundreds of other daily tasks on board ship, there is generally one correct and safe way to do the work. The right way and wrong way of doing these various operations is what constitutes practical

shipboard work and is the type of knowledge imparted to the young men on the schoolships.

In consideration of these facts, it is readily appreciated that the young men graduated from one of the State Schoolships become far better equipped Merchant Marine officers than were their predecessors. These men did not have the advantages available to the young man today, but gained their experience in the school of "hard knocks." Properly trained, careful officers undoubtedly have the fewest accidents to their crews, and are instrumental by personal example in preventing many avoidable accidents and injuries.

The Nautical Schools are educating just such types of officers, and, therefore, should receive the support and encouragement of all who are interested in safety and accident prevention, regardless of whether they are affiliated with the Marine Section, or belong a thousand miles from salt water. The instruction which the cadets receive on board the schoolships will undoubtedly mean fewer accidents on shipboard in future; fewer accidents mean reduced operating expense; reduced operating expense means reduced freight rates, which means reduced costs, the desideratum in these days of high cost of living.

A word concerning our State Schoolships. These exist by virtue of an act of Congress passed in 1874, which provided that the Navy Department would loan to any State establishing and maintaining a Marine School a suitable vessel and her apparel. The States of New York, Massachusetts and Pennsylvania took advantage of this legislation, and established schools, which have been graduating young men as officers in the Merchant Marine for many years; in the case of the New York School for 50 years. These young men are the "leaven" that is to "leaven the whole lump" and they have already brought about many changes in conditions on shipboard and will continue to do so in future.

Instruction in Cargo Work

CHAIRMAN KAIN: Are there any questions?

MR. E. ARKILLS (Waterfront Employers of Seattle, Seattle, Wash.): I would like to ask a couple of questions in connection with the instruction there. I wonder if there is any instruction on the setting up of a cargo boom to take care of the proper drift of the guy lines and preventers?

CAPT. SHERIDAN: Yes, they get considerable instruction in cargo work and particularly that part which touches on the rigging of the cargo gear. Unfortunately, due to the fact that the only vessels they have for state school ships are antiquated gun boats, they cannot do it on the ship, but they do it by frequent visits to all types of ships in port while working cargo, and, I am sorry to say, the cadets are instructed by observing the wrong way as well as the right way. It is not unusual to go aboard ships and see things rigged in a careless and dangerous manner and it is often quite possible to point out the possibility of accident in the way gear is rigged on board ship in New York harbor or any harbor.

MR. ARKILLS: I wonder if you teach them drafting at all?

CAPT. SHERIDAN: No, it is only touched on because the course is two years; you get boys of three years or more in high school and if they haven't had it there, it is almost impossible to give them any intensive drafting course.

MR. ARKILLS: What I had in mind is that if you do teach drafting you can illustrate by an ideal set-up. I have seen no less than 50 failures of guys, just through their being set up too close to the heel of the boom, which makes an undue column load on the boom and also doubles the stress very rapidly on the guy, and naturally causes them to carry away under what seems to be a very moderate load.

CAPT. SHERIDAN: They have a course of instruction which is an adaptation of physics and mechanics—they, more or less, call it steammanship. In this they illus-

trate the parallelogram of forces. They show the proper and improper way of rigging slings, guys, stays, etc., and how the multiplication of loads through improper guying and leading of supports, can cause greatly increased loads to come upon a weak member. That is all dealt with in the instruction. While it is the best way we have of training officer personnel for the mercantile marine, they labor under several disadvantages. One is, they have to take naval ships. They get antiquated naval gun boats with old-fashioned machinery, quite unsuitable for the purpose. On top of that, the Navy, in lending the ships, enforces the rule that they must now have naval officers in command—retired officers. This makes it difficult to inspire the cadets with any idea of mercantile marine practices. Unfortunately they have to unlearn a good deal due to the fact that a good many of the practices there are of Navy origin.

MR. ARKILLS: I have noticed failures of booms have been brought about by freezing of the gooseneck, as we call it, rusting of the bolt or lower end of the boom fastening where it goes through the pad that goes on to the mast. When that is rusted to a point where you pull the guy strong against it, or you stay it where it is and then get a load that turns it the other way under stress, you put a double bending in that boom which causes its failure, due to the fact that it doesn't oscillate properly on the gooseneck bearing. I am sure there are two failures that can be traced to that one fault. It would be such a simple thing if the proper lubrication of a heavy grease that wouldn't be absorbed by salt water, like a cup grease, were used and forced in. That would take care of that situation entirely.

CAPT. SHERIDAN: I have seen a number of cases of that particular accident you describe. When I was superintendent of the school in the seamanship and steamanship, I very strongly emphasized the necessity for those precautions, frequent inspection—especially lifting the boom, not only oiling it, because sometimes in a cold trade you will find crystallization, and an apparently safe boom will all of a sudden crack. When you put a comparatively small load on and she cracks, it is possibly due to the fact that she freezes up due to sudden snap of cold weather. That part, unfortunately, they can only get theoretically and they have the disadvantage of too much naval technique, in what should be civilian employment.

O. D. MOORE (Pennsylvania Railroad, Philadelphia, Pa.) Captain, is there any other standardization of instruction as between the schoolships of Pennsylvania and New York?

CAPT. SHERIDAN: The only attempted standardization is a more or less informal exchange of views as to curriculum. Of course, education to a certain extent has to be standardized because you have to prepare them to take examinations as deck and engineering officers. In that respect the education is standardized by the results they have to obtain, but in other respects there is no formal standardization at the present time.

CHAIRMAN KAIN: Thank you, Captain, for the very interesting talk. Are there any other questions? We will go ahead with the next paper.

Life and Property Conservation in Railroad Marine Operation

**O. D. Moore, Supervisor Marine Risks,
Insurance Department, The Pennsylvania Railroad**

In presenting this paper, it is appreciated that my audience is composed mainly of those interested in the operation of large ships. However, as the fundamentals of safety and conservation are universally applicable, it is hoped that a review of the efforts of a railroad may prove to be of general interest.

Obviously, railroad marine operation forges but a few links in the chain of an extensive system of rail transportation where it touches the waterfront.

Nevertheless, there is a surprising variety and amount of equipment engaged in this service, as illustrated by the following tables showing the classes of equipment and the geographical distribution of boats in which the Pennsylvania Railroad and subsidiaries have a vital interest in the conservation of life and property.

Distribution by Class

Type	No. Units
Carfloats	114
Barges and Lighters	196
Tugs and Steam Lighters.....	58
Ferryboats	15
Steamers	20
Car Ferries	3
Miscellaneous	12

408

Distribution by Port

Place	No. Units
New York, N. Y.	322
Philadelphia, Pa.	32
Baltimore, Md.	22
Norfolk, Va.	25
Chincoteague, Va.	4
Ashtabula, Ohio	1
St. Ignace, Mich.	2

408

My subject has been divided into two parts, first—personal injury safety; and second—marine property conservation. While these arbitrary divisions of activity overlap somewhat in actual practice, an effort has been made to separate them, and the two topics will be treated in the order named.

The Pennsylvania Railroad, through its operating and insurance departments, has been active in the field of organized safety for many years; recently a special department for the further supervision and encouragement of safety on the railroad has been formed in charge of a superintendent of safety who has long been prominently identified with the Railroad Section of the National Safety Council. The various marine departments have naturally come within the influence of these carefully directed safety programs, and it is possible to allocate definitely those activities which have affected marine operations.

There is first of all a ground-work of statistical data upon which to build. Reports of all fatalities and injuries are forwarded to the insurance department where a card record is prepared and filed. The record contains such pertinent details as cause, nature of injury, occupation, length of disability. From the cards, effective statistical information is quickly secured by means of sorting and tabulating machines, and this data is furnished interested officials to point out the major sources of loss in order that remedies may be applied.

While there has been no very serious personal injury problem in the boat operations, it is, of course, desirable that accidents be further reduced. Since January 1, 1925, a separate record has been kept of all maritime personal injuries occurring to employees of the various fleets, and the accompanying statement indicates the proportion in which the major causes of accidents contributed to the total number of injuries and disability days during the period from January 1, 1925, to June 30, 1927.

During 1926 there was a decrease in the number of injuries as compared with 1925, notwithstanding that the year 1926 required the lighterage of a larger volume of freight. The above outline illustrates the hazards against which preventive activities must be directed. So much for statistics.

Each division superintendent and several other interested officers of the railroad receive a copy of the National Safety News every month. Each division has a general safety committee supplemented by local committees, the members of which are constantly changed. It might prove interesting at this point to describe a typical safety committee meeting.

The particular committee selected as an example functions in an essentially maritime atmosphere; it is composed of men from the forces at Norfolk, Va., which is connected with the railroad only by means of vessels sailing from Cape

Charles to Norfolk across the Chesapeake Bay entrance. Here is a well-rounded marine operation consisting of huge sea-going car-floats, powerful tugboats, and passenger steamers constantly plying the waters between Cape Charles and Cape Henry; there is also harbor transfer equipment.

The local freight agent is chairman, and the entire pier, yard and marine operation is represented, about 15 delegates in all. The committee opens the meeting with discussion of a letter prepared by the insurance department calling attention to the personal injury accidents on various divisions of the System during the year 1926. Then comes a statement from the same source showing the standing of the divisions in a current competition for the award of gold and silver safety banners.

Next on the program is a valuable feature. Each representative presents a detailed report of injuries sustained in his branch of the work since the last

Major Causes of Personal Injuries in Railroad Marine Operation from January 1, 1925, to June 30, 1927

Cause of Injuries	Percentage of Total No. Injured	Percentage of Total Days Disability	Percentage of
Deckmen or Shore Attendants:			
Handling freight	1.5%	3.3%	
Handling lines	7.3%	9.3%	
Handling gangway, closing doors or hatches	5.3%	5.6%	
Slipping or falling	38.5%	27.4%	
Miscellaneous	15.0%	14.4%	
Engine Room Employees:			
Burns or scalds	6.3%	8.4%	
Caught in machinery	7.5%	5.6%	
Slipping or falling	7.1%	12.1%	
Tools slipping	8.6%	7.4%	
Miscellaneous	2.9%	6.5%	
Total	100.0%	100.0%	

meeting; the hazards illustrated by these accidents are carefully considered as well as the steps that might be taken to minimize them. The meeting concludes with the presentation of safety suggestions by members of the committee. Action is generally taken on approved recommendations of a minor character and others of value involving administrative action are referred to the proper authority.

This gives a general idea of the safety committee system. Then there are other activities which place the message forcefully before the employees. Special bulletins are prepared and distributed or posted. National Safety Council posters are generously utilized. A supply of the special Marine Section posters has been secured and furnished to the marine supervisors for appropriate use. In doing this, attention has been given to the character of accidents sustained at various ports, as indicated by the special marine record, and subjects selected which might emphasize the hazards suggested by these accidents.

Another feature is the safety banner. To illustrate its use, every Monday morning a banner is raised high in the air at two points on the Jersey City waterfront where it is readily discernible to railroad equipment operating in the harbor. These banners bear the simple word "Safety." Upon the occurrence of an injury to an employee in the ferry or lightering work resulting in lost time, down comes the banner until the following week when a new start is made.

The main reliance of the marine management, however, is upon personal persuasion through individual warnings and instruction, particularly where a lack of caution is demonstrated. This influence passes on down the line through captains and engineers to the deckmen, bargemen, and firemen. Personal interest in the subject is no idle boast; some 380 men out of a total of 1,000 employed in one marine department signed a testimonial to the effect that during the month of March alone they had been individually addressed on some phase of safety by supervisors, safety committeemen, or others.

Precautions Are Taken in Employment of New Men

Then too, precautions are taken in the employment of new men in marine work which are believed to be advantageous to safety. Certain classes of applicants must pass a medical examination, with special attention to eyesight, hearing and the existence of dangerous disease. In New York, where the greatest number of men are employed in a single marine department, each recruit before going on duty is handed a paper prepared by the toastmaster containing specific precautions in order to avoid injury in his work. First aid instruction is given at convenient opportunities, and railroad doctors are readily accessible to the marine operations.

The management is sympathetic toward any reasonable improvement in physical conditions designed to discourage personal injury accidents. It is apparent, however, that these happenings cannot be eliminated by physical changes, and it is for this reason emphasis is laid upon publicity efforts and personal leadership in the building of the safety policy.

Passing now to a consideration of maritime property conservation in railroad operation, it is obvious that efforts in this direction should also have a favorable influence upon the personal injury situation. Careful attention is given to the causes of marine losses and their prevention. Such accidents are reported to the insurance department, and in case of serious or unusual losses, such as fires, sinkings or strandings, a representative is dispatched to the vessel in trouble in order to determine that effective salvage efforts are in progress, or to make arrangements for the employment of wrecking equipment; also to investigate the circumstances. The salvage and disposition of damaged cargoes is given special attention. Likewise, when reports of losses or investigations of the marine inspectors develop possible means to minimize or prevent similar occurrences in the future, the matter is given special consideration.

In addition to specific comment on individual cases, statements are compiled annually from the marine insurance loss records analyzing the major causes of the marine damages that have occurred in each fleet during the year. This information frequently reveals consistent sources of loss and is forwarded to the interested officials with appropriate comment.

New York Has a Marine Accident Investigator

In New York, there is a marine accident investigator—a practical marine man—who devotes his entire time to the development of facts regarding marine losses arising in the harbor. Another unique feature is the marine diver and wreckmaster who has been a regular employee of the railroad at New York for several years; a special crew has been trained to tend the air pumps and do other marine wrecking work, and these men are diverted from their regular employment immediately an accident occurs. Railroad derrick barges are utilized in this work whenever possible. Much property has been saved in this way. The diver also has other duties such as the removal of obstructions from propellers, slips and outlets.

A general inspection of the self-propelled vessels from an insurance standpoint is made annually. Owing to limitations of time and operating convenience no attempt is made to go into this feature so exhaustively as the United States Steamboat Inspection Service which thoroughly covers the technical requirements; nevertheless, fire equipment is tested, life saving equipment is examined, and special attention is given to general order and cleanliness, sub-standard electrical installations, personal injury hazards, and possible improvements in equipment. Reports covering these inspections are prepared and advice regarding the action taken is furnished the insurance department.

These inspections afford an opportunity to discuss the causes of recent accidents with the supervisory forces and boat crews; in fact, that some central agency, in addition to the local personnel, displays an interest in such matters, has a certain valuable moral effect. Then, too, much information pertaining to physical and operating conditions is obtained that would not be available if the work was conducted solely from an office, and a more intelligent handling of marine loss problems results.

A Periodical Report on Fire and Life Boat Drills

A form prepared by the insurance department covering a periodical report of fire and lifeboat drills and inspection of equipment, and containing some 50 questions on the drills and also such matters as condition of steering gear, bulkheads, and alarm systems, is in general use.

Another item affecting property conservation is the equipment of 47 of the 58 tugs and steam lighters with powerful fire and wrecking pumps; these boats have rendered service of incalculable value in fighting wharf and vessel fires, and in saving craft from sinking. They furnish this protection in the harbors of New York, Philadelphia and Norfolk.

There are naval architects, marine engineers and surveyors who plan and supervise the construction of new vessels and the maintenance and repair of the equipment in service. There is a well appointed marine shop at Hoboken, N. J., where all forms of marine work is done excepting that which requires dry docking. There are also small marine repair shops at Camden, Long Island City, Baltimore and Cape Charles.

Up to this point no conclusions have been drawn and no moral cited; the treatise has been a recital of those general activities in railroad marine operation that are calculated to have a favorable influence upon the prevention of marine accidents. Owing to the breadth and diversification of the field, it has been necessary to confine the discussion to general factors. It has been impracticable to relate interesting details encountered in the work, or to analyze the important psychological differences that exist between the rail and marine worker. It is obvious, however, that when a man prepares to step aboard floating equipment he sacrifices a certain degree of safety and places himself at the mercy of the elements; whether this exposure tends to make him more reckless or more careful depends in large measure upon the individual.

Two Fundamental Factors in the Program

It would seem that there are two fundamental factors to the establishment of a life and property conservation program in a marine organization.

In the first place, a definite responsibility should be placed upon some individual, department or agency to record, investigate and publish information regarding accidents and to consider ways and means to reduce or prevent them. In a small organization this might readily be a part-time duty. The effort should not be one of isolated "campaigns," but should constitute a steady and consistent check. Personnel engaged in such work should, of course, be familiar with the nomenclature of the waterfront, and have a practical appre-

ciation of the difficulties faced by the marine worker in the discharge of duty.

The second requirement is a sympathetic attitude toward the activities of the safety agency, demonstrated by a practical interest in its efforts on the part of the supervisory personnel.

The railroad welcomes the assistance and cooperation of the Marine Section of the National Safety Council in its very helpful deliberations and activities, and it is hoped that the efforts toward life and property conservation in Pennsylvania Railroad marine operation may aid the general maritime safety movement.

Accidents Differ Little as to Size of the Vessel

CHAIRMAN KAIN: That is a very interesting paper, Mr. Moore. Are there any comments?

A. M. TODE (Texas Company, New York City): I feel that Mr. Moore's paper is a very valuable contribution to the articles of the Marine Section, especially so as about 15 per cent of the membership of the Marine Section is composed of railroads operating floating equipment. I think that, sometimes, steamship companies and men engaged in steamship affairs, who operate only larger ships, lose sight of the great amount of floating equipment which the railroads do handle in the harbors and the large amount of accident prevention work which some of these railroads do.

I hope that Mr. Moore will contribute some further definite facts regarding the floating equipment in accident prevention work in the future, as I feel that a large number of our members would welcome that.

There was one other point which I was interested to observe which showed that as far as the accidents occurring on their small fleet are concerned, they differ very little from large ships and that the most prevalent type of accident is falls. I believe Mr. Moore's figure is something like 38 per cent of the accidents for falls. Combining our accident statistics of the Marine Department of the Texas Company over a period of six years, the largest number of accidents was also due to falls, both in the engine room and in the deck department, considering the small fleet and the large fleet.

R. E. PROUTY (Aetna Life Insurance Co., New York City): I should like to ask Mr. Moore what he uses for an exposure factor in making his comparative accident statistics, the number of men employed, or the day's work or hour's work?

MR. MOORE: The usual basis for ratios in railroad employment accident statistics, is the rate per one thousand in service. There has been some discussion here regarding the correct exposure upon which to base the ratio of marine accidents. One contention was that it should be based upon the legal provisions and complicated records kept of the exact number of hours that each man worked, which may or may not be practicable. It occurred to me that seamen in ocean and coastwise vessels have constant exposure to certain hazards of the profession for twenty-four hours of the day and that if it would be found statistically correct, it certainly would be theoretically correct, I would think, to use the man-days as the basis for such statistics and it would be a great deal more simple than an attempt to calculate the number of hours.

Question of Deck Pads for the Barges

M. E. ARKILLS (Waterfront Employers of Seattle, Seattle, Wash.): I would like to ask the speaker how he equips his barges with deck pads, or whether they do equip them with deck pads. We have had one or two accidents and barring these, there is tremendous time lost by trying to make fast the lines that secure the barge to the ship while they try to lash them around posts and stanchions that are permanently attached to the barges. This happens mostly in connection with handling lumber. I would say there ought to be some sort of a deck pad on account of the height. There should be something that would hold up and down lines as well as

horizontal ones. The height is so great, it will unwind, come loose and be adrift and the man will think he is close to the ship. When he turns around, he isn't close to the ship at all.

MR. MOORE: I know of no special equipment to increase the height of the posts.

J. S. HUNTER (Atlantic Refining Co., Philadelphia, Pa.): Your barges are equipped with cleats?

MR. MOORE: Yes, I wasn't quite clear about what he meant by pads.

MR. ARKILLS: We find in the Washington Tug and Barge Co. many of the barges have no available cleats, they are either loaded and covered or something of that sort.

Unsecured Hatch Covers Cause Accidents

MR. MOORE: These barges all have cleats.

MR. ARKILLS: Then there is another point. We have had four hatch cover accidents on barges. We find that the hatch covers are not properly secured with chains and in transit they wash overboard and are lost and the men working on the barge temporarily forgetting the hatch is open, will fall in and be injured. It isn't a great fall, but at least they break a leg or an arm. Have you had any accidents of that nature?

MR. MOORE: Practically all of our barge work in New York is handled on deck, either on an open or house barge. Such hatchways as it may be necessary to open are only small ones to get down into the hold.

MR. ARKILLS: They are the ones I have reference to.

MR. MOORE: On the house barges they are located outside of the cargo house and the instructions are very strict that the covers are to be kept on at all times. Of course, it doesn't work out 100 per cent in actual practice.

CAPT. SHERIDAN: Some time ago in discussing the question of accidents with the superintendent of railway marine property, he told me it cost something like \$30,000 in accidents before one of their tugboat captains attained the rating of normal competency. Have you any figures on that?

MR. MOORE: No, sir; I couldn't offer any comments. I should think that would be a very difficult calculation to arrive at, due to the constant shifting of men that occurs and the fact that each tug in our service has three different crews every day.

DR. F. X. CRAWFORD (United Fruit Co., Boston, Mass.): I think it is interesting to note that of the fatalities five were due to gross carelessness on the part of the individual. Another one was due to an error of judgment. I think a big proportion of the deaths are due to errors of the men, errors of gross carelessness and are not attributable to the working plant.

MR. MOORE: That was my object in reviewing them, to get any comments there might be.

Most Maritime Accidents May Be Avoided

MR. TODE: It is an old saying, "Dead men tell no tales," but that percentage of about 87½, being avoidable, merely corroborates what statistics have proven in the maritime industry generally, that from 75 to 85 per cent of all maritime accidents are avoidable. I think we could have no better concrete example than that one here. Our figures confirm that also.

W. P. MOUNTFORD (Pennsylvania Railroad, Philadelphia, Pa.): I would like to stress the thought that in directing your safety committees, you direct your members to bring in practices rather than conditions. In railroad work, 85 per cent of our accidents are attributable to practices and not conditions. This gentleman makes a

similar statement here, I believe; six fatalities could be traced to the same cause. In directing our work on the Pennsylvania Railroad as straight railroad work, we emphasize the necessity for men going out during the course of a month, observing practices and taking remediable measures to correct them rather than bringing in conditions. I believe that is a big factor of marine accident work.

CHAIRMAN KAIN: I think we could learn a great deal from the operation of the railroads.

CAPT. SHERIDAN: Along that line, I might invite attention to the fact that sometimes your additional accident prevention material is ineffective, because on account of the peculiar psychology of the men who follow the sea, it only means that if you put more safety devices there, they take more chances. In the same way, many ships have all kinds of accident prevention devices, and because they have those devices, the people on them take more chances, and cut down their factor of safety just that much.

CHAIRMAN KAIN: If there are no further comments, we will go on with the next paper.

Radio's Contribution to Safety of Life at Sea

Geo. E. Cole, Superintendent, Great Lakes Division, Radio Corporation of America, Cleveland, Ohio

It is particularly appropriate that marine radio should receive a moment's consideration in this Safety Congress, as probably no single agency has served, as it has, to make water travel everywhere safer for lives and property. Radio as a means of communication, education and entertainment is doing a big and growing job, but its service in widening the factor of safety wherever water travel is concerned is fundamental and the primary excuse for its existence.

Radio's contribution to safety at sea began with the first commercial marine station erected by Marconi, in 1897, at the Needles, Isle of Wight, England, and this station had a working radius of about 14 miles. Prior to that, for 70 years back to 1827, we find scientists making vague references to the possibility of "electric conduction" and the vision of radio as we know it today was constantly in the minds of these early workers. In 1882 one applicant for a United States patent made so bold as to say, "Electrical communication, using this apparatus, might be established between points certainly more than one half mile apart."

It remained for Marconi, however, to evolve a system of wireless telegraphy which was at once commercially practical and capable of reliable communication, and naturally its application to marine use claimed first attention. By 1903 a sufficient number of ship and shore stations were in operation to make some sort of regulation necessary; and as a result, the first International Radiotelegraph Conference was held in Berlin. In 1906 the second International Convention was held in the same city, with a majority of the principal countries of the world signatory.

In January, 1909, the practical value of marine radio was probably first brought home forcibly to the world when the "S. S. Republic" collided with the "S. S. Florida" off Nantucket and, through assistance called by wireless, all passengers and crew were removed and saved before the vessel sank. Largely as a result, an Act was approved by the United States Government in June, 1910, requiring radio telegraph equipment and operators on certain vessels, which Act was amended and extended in 1912 and remained in effect until February of this year, when the Federal Radio Commission was enacted into office. Also in 1912 the Third International Radiotelegraph Convention was concluded in Lon-

don with the United States one of the 42 signatory countries. This convention is effective today, but a conference has been called for this year in Washington, to formulate new regulations and standards covering the requirements of present practice and almost wholly changed conditions in every phase of the art.

Just as the "Republic" disaster brought to marine radio recognition and proper regulation; so it is true that the tragedy of the "Titanic," in April, 1912, taught lessons in the use of radio for safety purposes which were given appropriate consideration in the International Conference on Safety of Life at Sea concluded in London in 1914. The importance of these international understandings should not be underestimated as bearing directly on the primary function and duty of radio—the safety of life and property at sea by giving warning of approaching danger and bringing assistance when it may be most needed. Regardless of nationality, type of apparatus or location in the seven seas, the marine radio speaks a universal language and functions its operating methods and procedure on the same fundamental rules, all conceived on and protecting its primary use as an agent of safety.

Marine Radio Equipment Has Developed Rapidly

The development of marine radio equipment has moved rapidly in the last few years as a result of continued research in vacuum tube construction and operation and the commercial application of radio devices more or less perfected under the stress of war-time necessity. Today it is not unusual for vessels in the English Channel to communicate direct with the American coast and for ships in the China Sea to work direct to San Francisco. The record long distance ship exchange by radio was effected January 14, 1926, when the "S. S. Carinthia" of the Cunard Line, on a world cruise, worked direct with the Radio Corporation station at Riverhead, L. I., about 100 miles east of New York City. The vessel reported her position as 10,600 nautical miles distant, off Cape Leeuwin—the southwestern extremity of Australia—or almost exactly opposite on the globe. This distance can hardly be exceeded for surface ships.

This effective development and use of vacuum tube high frequency transmitters in marine service has worked a silent revolution in radio communication practice. Spark type transmitters are no longer manufactured and those remaining in Government and private service are being replaced as rapidly as economically feasible. The entire fleet of the United Fruit Company, among others, recently refitted with tube equipment, and the Radio Corporation is now completing the change from spark to tube on the hundreds of vessels under its radio operating control. The practical value of this large job is radio's contribution to safer sea travel in exactly the same sense as the automobile of today provides more reliable, safer and longer distance transportation than the car of 15 years ago.

The net result is that because of this constant effort to widen the field of radio's service to the mariner, it is impossible for a ship with modern radio telegraph equipment to be out of touch with shore or another vessel. The resources of governments in their military establishments have combined with those of commercial organizations to this end and there is no let-up in the effort to apply every proven principle to make marine work and travel safer or better.

Forgetting, for a moment, the necessity of being ever ready to transmit the universal call for help—S O S—with, as the United States Law phrases it, "a maximum of radiation with a maximum of interference," let us review briefly (for time will not permit more) some other ways in which radio is being utilized to promote safety at sea and as an aid to the navigator.

As a means for personal and business communication thousands of messages

are handled every day to and from ships at sea with the regularity and dispatch of land-line telegraphs. The "Leviathan," for example, on a single five day voyage will handle hundreds of private radiograms in addition to thousands of words of press, weather, hydrographic and service messages. The humble tramp with three or four messages to shore on a two weeks' trip receives the same attention at the coast stations which are generally duplexed, such as in the case of the Radio Corporation's station at Chatham, Mass., which is able to communicate simultaneously with seven vessels without mutual interference. A few of the larger liners are fitted with automatic high speed transmitters and recorders, permitting the movement of radio traffic at 100 words or more a minute as compared to not more than 30 words a minute by manual operation; and few

Modern Radio telegraph installation aboard the "S. S. Gulfpride"

operators can maintain that speed with accuracy. Radiophone broadcast programs are received aboard many ships for entertainment purposes. Four ships of the Grace Line, for instance, have been fitted with unique broadcast receivers, and passengers have danced to music from a New York night club, when steaming through the Caribbean Sea and even off the west coast of South America.

The United States radio law requires that vessels of American registry carrying 50 or more people 200 miles or more, be fitted with radio telegraph equipment with a range of at least 100 miles, and shall carry two or more licensed operators. An auxiliary source of power supply is required, and this, usually storage batteries, is placed on or above the main deck where they will function if the fire rooms or engine rooms become flooded. About 1,950 American vessels, exclusive of naval and Government ships, carry radio telegraph equipment out

of approximately 3,050 of 1,000 gross tons or over, and a large percentage of these are voluntarily equipped as not coming under the Law's requirements. All British vessels of 1,600 tons or over are required to carry radio and most foreign countries base compulsory ship radio equipment on tonnage rather than length of run or number of people aboard.

The dissemination of weather information by radio is world wide and generally standardized by use of universal procedure in observations and codes. These bulletins consist of a weather report and forecast for a given locality, storm, gale

Radio direction finder, control, indicator and receiver

or special warnings when indicated. In order to enable navigators to predict storm movements and weather likely to be experienced, a code known as the Synoptic Data System is available for the transmission by radio of weather observations. This information and system is so complete that the navigator may prepare his own daily weather map at sea on base charts provided free by the Weather Bureau.

The facility with which pictures may now be transmitted by radio, makes possible the radio transmission of weather maps to ships at sea, based on information received ashore from many ships by radio, and experiments on this are under way. Under laboratory conditions it is possible to transmit a picture or printed sheet in less than 30 seconds as compared to 20 or 30 minutes; and, incidentally, as this speed of transmission is stepped up, the possibility of "radio movies" becomes correspondingly greater.

The International Ice Patrol, operated by the United States Coast Guard under provisions of the International Conference on Safety of Life at Sea, is a service of vital importance contributing directly to the safety of shipping in the North Atlantic steamer lanes; and radio alone makes it so effective. In paying a tribute to this service someone has said, "The 'Titanic' disaster would probably never have happened, had the ice patrol been in existence."

Typical American type radio direction finder (external loop structure)

The collection and transmission of hydrographic information and navigational warnings by radio is a service which functions quietly, but effectively and constantly. - Damaged or misplaced aids to navigation, floating derelicts or obstructions, or unusual conditions encountered at sea are reported and retransmitted by high power radio for the benefit of any and all ships concerned. The International radio safety signal—groups of three dashes—is second only to the S O S of distress in commanding instant attention and radio silence whenever heard. This signal precedes warnings of an urgent character sent out by radio

from coast stations with advice such as cyclones, derelicts, sudden changes in fixed obstructions or landmarks. The radio transmission of ice and hydrographic information is obligatory. Weather reports are optional.

Several years ago the Seamen's Church Institute of New York inaugurated a service intended to give medical advice by radio to vessels in New York harbor in cases of physical emergency to seamen. With the cooperation of the large radio operating companies and the United States Public Health Service, these facilities were extended and organized; several foreign countries through their appropriate official departments instituted similar service so that the handling of free medical advice is an established humanitarian function of radio. The so-called "Medico" message has right of way—a surgeon of the Public Health service with a knowledge of available medical facilities aboard ship, indicates procedure for relief based on the nature of the accident or illness and symptoms described, and almost invariably the patient is receiving the benefit of this advice by competent authority within a few minutes. Scores of cases of immediate relief are matters of record and undoubtedly it has been the means of saving many lives.

The transmission of standard time signals by radio under Government supervision, for the adjustment of chronometers is world wide. In most cases the transmission is automatic in connection with a standard chronometer at an observatory and absolute reliance may be placed on the signal; the average lag in the United States signal from Arlington being something less than nine hundredths of a second.

Television Is a Development on the Way

The application of television, or seeing as well as hearing by radio, as it may be applied to the promotion of safety at sea remains to be seen. It is, however, an accomplished fact and who will deny that some day the navigator will be enabled to see his way through fog by radio, as well as get his position and bearing which he now does?

The directional properties of radio waves have lent themselves to several devices designed to give the navigator his position or bearing in thick weather or conditions of low visibility; and this development is of great value when making a land-fall after a prolonged period of sailing by dead reckoning. In a single recent month the radio compass stations operated by the United States Navy gave without charge over 21,000 radio bearings to ships that requested them. In some foreign countries a charge is made for each bearing given by radio.

The radio direction finder aboard ship, operated by the navigating officers themselves and taking bearings on radio beacons established for the purpose—ashore or on lightships—is rapidly becoming a standard item of equipment and is in use on hundreds of vessels with the number rapidly increasing. By use of this instrument the navigator can approach the coast in the thickest fog with an assurance of his position. He can, if necessary keep track of a vessel's movements which may be in his path and the location of a ship in distress is relatively a simple matter. The radio direction finder is purely an instrument to promote safer navigation and is doing it well. Something of a record in connection with the installation of these instruments was set up on the Great Lakes last winter and spring when the Radio Corporation installed and calibrated 135 in 99 working days. Slightly over 200 direction finders are in service on the Great Lakes alone.

The Bureau of Standards in cooperation with the Lighthouse Service have conducted tests with a fixed radio beam for the guidance of vessels through

straight channels or for use in fog to serve the purpose provided by range lights in clear weather. A wireless "lighthouse" has been set up at Inchkeith off the coast of Scotland which transmits radio signals revolving in a concentrated beam and is effective up to 100 miles. A distance finding radio device has shown possibilities; this depending on the difference in time of transmission between a radio signal and sound signal sent simultaneously from a given point. Directional radio has vast possibilities and it is to the credit of the world's merchant marine that radio direction finders and other advanced agencies are being rapidly adopted in spite of the expense in order that life and property at sea may be further safeguarded. It is likewise significant that a large proportion of radio

MARCONI TELEGRAPH COMMUNICATION CHART. DECEMBER 1904.

An early radio communication chart for the North Atlantic

installations are voluntarily made. Of about 175 ships on the Great Lakes carrying radio telegraph apparatus, not more than 10 or 12 are required by law to do so.

Comparatively few passengers on the large liners realize that radio is on duty in some of the life-boats with suitable batteries for power supply. Yet such is the case on several vessels and it is reassuring to know that if the emergency comes the rescue ship can be called by radio, and with her radio direction finder locate the stricken vessel without search; or a single lifeboat if it is afloat, regardless of night or fog.

A striking example of radio's value as an aid and safety agency was demonstrated last spring when the large "S. S. Malolo" was in collision in fog during her trial run off the New England coast. By use of her radio direction finder the ship's exact position was fixed in the fog and broadcast, and by its use five

vessels, in addition to tugs, were given by radio telegraph courses to steer which brought them directly through the fog to the disabled ship. One of the tugs detected by the direction finder was found to be passing the "Malolo" several miles away and was quickly given a new course to steer which brought her alongside. A few minutes after the collision the ship's dynamos were put out of commission and the emergency radio transmitter (as powerful as the average ship's main set) was started up with power supplied by a 25 kw. Diesel driven machine installed on the main deck for such an emergency. This machine was operated continuously for nearly 72 hours, supplying power for the radio and emergency lights, and it was not necessary to use the storage battery reserve which the ship carries in addition.

The Best Engineering Minds Baffled by Static

Static is radio's greatest enemy and the best radio engineering minds are today unable to eliminate or control it and still preserve unimpaired the signal or effect desired. It is known, however, that the strength of static bears a definite relation to the rate of change in barometric pressure, and to quote Commander C. S. Hooper, U. S. N., "It is a known fact that the static emanating from an intense cyclonic area is greatest at or near its center." This means that if static cannot be eliminated it is going to be put to useful work until it can be, and Commander Hooper recently published an interesting article showing how storm areas have been definitely traced by means of static impulses received on a radio direction finder and recorded by a pen on a rotating cylinder. This has not only told the direction from which a storm may be expected to break, but its approximate intensity. The center of disturbance in the Miami hurricane of a year ago was definitely located and followed by a device of this character aboard the "U. S. S. Kittery."

The successful application of marine radio telegraphy is largely dependent on the human element—the radio operator. Although usually without the individual background of tradition and service, we have the word of a Government official that the records show no single failure in an emergency of an operator to stand by his instruments, and the names of 24 on a monument in Battery Park, New York City, who have lost their lives at sea bear eloquent testimony to this fact.

The steering of a ship entirely by radio control from shore or from another ship is more of a stunt, or military maneuver, but it has been and can be done. Radio communication, position and direction finding, is not confined to surface ships, but is equally applicable to submarines and aircraft. With the continued development of vacuum tubes and high frequency radio transmission and a better understanding of their laws and tremendous possibilities it is difficult to draw the line between that which is possible of accomplishment and that which is impossible, and we can easily visualize the navigator of the future more and more dependent on his radio devices for information, control and safety.

The Direction Finder Effective Up to 100 Miles

A. M. TODE (Texas Co., New York City): I should like to ask Mr. Cole, of these 21,000 messages which were given to the radio direction finders, about what was the average distance off shore of the vessels?

MR. COLE: I couldn't tell you about that. I can say that out of 1,400 observations taken on the Great Lakes last summer, the average distance was something like 65 miles. The direction finder, itself, is effective up to 100 or over. The average distance we found to be 65 miles.

MR. TODE: How much error would that give you?

MR. COLE: They have an accuracy of a degree or less. If we find two degrees we look for trouble.

MR. TODE: We had one case where our master reported getting a signal at 265 miles and, I believe, it was between one and one-half at 265 miles.

MR. COLE: On the Lakes the distances are much shorter. That is what I am immediately concerned with now.

CAPT. T. W. SHERIDAN (New York State Nautical School, New York City): Do you find the radio direction finder is affected very materially in a ship with steel booms when the booms are lifted up just before going into port?

MR. COLE: That is all compensated out.

CAPT. SHERIDAN: Can a captain of an ordinary ship himself swing, for instance, off Ambrose Channel and make up a table of errors which would be reliable?

MR. COLE: Of course, when it is done by the radio man, he makes the mechanical adjustment in the machine.

CAPT. SHERIDAN: Do you issue any warning against trusting to the compass when the booms are in a different position?

MR. COLE: Yes, that is all in the books.

CAPT. SHERIDAN: I noticed several instances where inaccuracy was reported on the part of the compass. I thought it was probably due more to the change of the disposition of the rig than otherwise.

MR. COLE: To illustrate that point, I had a case this year on the Lakes where a compass was put on, and it worked fine. All of a sudden, the captain reported two point errors and when he looked around, found he had strung an awning over the so-called observation deck and the awning support wire threw that compass out that way. As a rule, those things occur very seldom and are all compensated.

CAPT. SHERIDAN: Will steel have the same effect?

MR. COLE: It depends on what the relation of that is to the loop.

CAPT. SHERIDAN: Between the two methods, have they both the same effect?

MR. COLE: Yes, but there is no magnetic effect.

CHAIRMAN KAIN: Are there any other questions or discussions? We will go on with the next paper.

The Relation of Gyroscopic Equipment to Maritime Safety

O. B. Whitaker, Sales Division, The Sperry Gyroscope Company Brooklyn, N. Y.

"Come in, Paul, what is it?" called Mr. Charles M. to his secretary who had momentarily appeared at his office door during one of those business hour visits with his old friend John B.

"A cablegram, sir," answered Paul. The friendly atmosphere changed to suspense as Charles opened the envelope and read its contents.

"Thank Heavens they have arrived safely," Charles exclaimed. "You know, the folks sailed on the 18th and—they say they have arrived Southampton safe and sound."

Charles apologized to John for so rudely interrupting his visit, but he could not help being elated over this good news. John, who had not seemed to enter into the spirit of rejoicing, leaned forward in his chair, "Charles" he said "I cannot, for the life of me, see why people rush to the nearest cable office upon arrival in a foreign port and hurry a cable off to the folks back home telling them that they have arrived safe and sound—always sound—just as though they have escaped from the clutches of some terrible plague, when, to be exact, they have completed a trip or voyage by one of the safest modes of transportation on earth.

Now if they would have just told you that they arrived on time after a wonderful voyage, good food, good air and a great time or something to that effect, their cable would have been newsy and interesting to me also."

Charles' "folks" acted upon an impulse that was engendered before the day of the large, fast, ocean liner with its modern construction, strong, reliable engines, greatly improved navigational, fire detecting, fire extinguishing, life boat and radio equipment. To comprehend what this all means, just review the major ocean casualties since say, 1905. The vast improvements which have taken place since that time may be divided into two general classes—those coming under Assurance and those coming under Insurance. The former covers all equipment which assures a safe passage while the latter covers all equipment for the saving of life in the remote case of disaster finding a vital spot in the bulwark of the former. It is in the former that great strides have been made, and rightly so—for if it could be brought to perfection the latter could be forgotten.

The Vessel Captain Is No Longer Isolated

We all realize that it has not been so many years since the captain of a vessel was master of his own destiny, barring the acts of nature. He was provided with a sextant, chronometer and a compass subject to innumerable whims and started on voyages to remote parts of the earth without further assistance from those ashore until land was again sighted.

Science has wrought great changes in these things as well as in our every day existence ashore. The captain of a ship is now not as isolated from the rest of the world as residents of our rural districts. He is also provided with modern equipment for the safe and efficient conduct of his ship from one port to another just as the up-to-date industrial plant provides for the safe and speedy output of its products. His compass has been changed from one responding to almost every thing and condition about it, to one steady and accurate under all conditions; and now his ship is even directed accurately and safely over her course by machinery.

The gyro-compass is responsible for much progress in the safety of ship operation. It has given the navigator an accurate indication of his heading or of bearings based on the true North. It differs widely from the magnetic compass, taking its directive force from the earth's rotation and gravity, both unvarying forces.

Any general statements regarding the many ways in which the gyro-compass increases the safety of ship operation, however, are almost meaningless unless made by comparison. A brief study of the magnetic compass makes us really marvel at the fact that the seas casualty list has not been greater. We must bear in mind that the compass is the ship's guide, on cloudy nights, and especially in fog, it guides the ship blindly. An error of only one degree in heading places a ship one mile off her course for only fifty-seven miles run. With these facts in mind, picture the navigation of a large vessel across the Atlantic with two thousand or more souls on board and with an instrument to guide them that is subject to errors from at least six different causes, every one of which is variable and liable to change without warning.

Idiosyncrasies of the Magnetic Compass

The two principal errors found in the magnetic compass are generally termed "variation" and "deviation." The former is due to the irregularities in the direction of the earth's magnetic field and causes errors up to 50 and more degrees in some parts of the world where there are navigable waters. There is a difference of over 48 degrees in the magnetic meridians within the borders of the United States. The amount of error from this cause is known for different localities and

its rate of change is fairly constant but, on a vessel traversing these lines of varying magnetic variation, corrections have to be frequently made in the course by compass. As an example of this the magnetic error in New York harbor is 11 degrees and this is increasing at the rate of six minutes yearly. In leaving New York and heading down the coast the error is reduced until off the coast of Georgia where it falls to zero and then takes up an increasing error in the opposite direction. If it were possible of accomplishment, a vessel started from New York and headed down along the coast on a proper initial course, but no allowance subsequently made for changes in variation, would, roughly speaking, pass through Atlanta, several hundred miles inland from the coast—not a good place for a sea-going craft to be. Deviation is the effect of the ship's hull on the magnetic compass as it takes up various headings; the ship not being a symmetrical mass, it has greater distracting forces on some headings than on others. The effects of this error are partially compensated for and partly overcome by allowing for whatever value this error may have on a given heading.

Subject Also to the Listing of the Vessel

The earth's magnetic field is also subject to a diurnal change in some localities of over seven minutes. The magnetic compass is also affected by listing of the vessel, as the compass card remains practically level while the horizontal and vertical disturbing elements in the ship's structure change their relation to the card. The compass card is also, and from the same cause, moved backward and forward as the ship rolls. Electrical storms which are not always apparent to the navigator have been known in many cases to affect so seriously the earth's magnetism as to render the magnetic compass almost, if not wholly, useless. Many instances are also on record where vessels have been struck by lightning, completely disabling the compass. Then there is the cargo—rails and other steel or iron products set up such a powerful magnetic field of their own that the earth's field reaching the compass is too feeble to retain any accuracy. Such cargoes, when handled with a magnetic crane often render the magnetic useless.

Now with a picture in our mind of the difficulties faced with the magnetic compass let us turn to the gyro-compass, and study its contributions to the safety of ship operation.

Contributions of the Gyro-Compass

As has been pointed out, the gyro-compass depends upon the unchanging phenomena—stability of the gyro in space, precession of the gyro wheel, gravity and the rotational motion of the earth. With these combined and employed as they are in the gyro-compass and as I shall demonstrate, the result is a true North indicating machine which is undisturbed by magnetic influence and which indicates the true North with a directive force of 160 times that of the magnetic compass and without the application of corrections; thus giving the navigator accurately and directly that which he has had to previously obtain indirectly and then with none too certain results. The safety of navigation is therefore very greatly increased by the introduction of the gyro-compass. This does not mean that the magnetic compass has or ever will be entirely replaced, as it will always prove an excellent emergency compass for it is self contained and does not depend upon any other of the ship's machinery. Navigators tell us that with their gyro-compass they are better able to keep their magnetic compasses in condition for emergency use since they have an accurate and direct check on them all of the time.

The construction of the gyro-compass lends itself readily to the transmittal of its readings to points isolated from the master compass thus making it not only possible, but desirable to mount it in some clean and dry location away from the

bridge. Repeating compasses called "Repeaters" are then mounted wherever a compass indication may be desired. These repeaters are adapted to any kind of a desirable mounting, making it possible to swing them in gimbals for use with an alidade attachment for taking azimuths or bearings, to mount them rigidly as a steering compass or to mount them under the radio direction finder to facilitate the operation of that very useful, modern aid to navigation. The motors used for operating the repeaters are also used for other purposes such as in the course recorder which makes a graphic record of the ship's course and time, and in the gyro-pilot which steers the vessel automatically. The gyro-compass equipment therefore becomes something comparable to a nerve center in the human body, in fact same call it the soul of the modern ship.

A Trip Aboard the Sailing Vessel

With an understanding of the gyro-compass and its principles we will visit a vessel and see for ourselves what this all means. It is about one hour before sailing. We go on board and up to the bridge, and ask the navigating officer to show us about. We are ushered out to the port bridge wing where we find a gyro-compass repeater mounted in a tall stand. "This is called the 'port pelorous,'—we have one in a corresponding location on the starboard wing, as you can see. We use these to obtain bearings," said the officer.

We naturally inquire if the compass is running and are informed that it has been running for several hours and that bearings have been taken to insure its accuracy and that it is ready for sea. We are then told that this is one of the valuable points of the gyro-compass; it can be as readily checked against the dock as at sea, which is not possible with the magnetic, and that this very materially increases the safety of their navigation.

From the bridge wing we are escorted to the wheelhouse where the gyro-pilot, or automatic steering machines, does its work. "A repeater is mounted on top of it for checking while steering automatically and for the use of the wheelman when steering manually," explained our guide who tells us that this machine holds the ship to her course with an accuracy and consistency that are not equalled by any wheelman; some men can equal it for short periods, but sooner or later they tire and lose their alertness, but the machine does not tire or have to be relieved." Our guide further explained that, "because of the accuracy of its steering our dead. Reckoning navigation is very greatly increased."

The Interesting Chart Room

We are then shown into the chart room where our attention is called to the course recorder. "That device," explains our guide, "makes a record of the ship's course, you see we are lying at the dock now and holding a fixed heading so the recorder shows a straight line; as we leave the dock it will show which way we turn, the time we left and, in fact, every turn or course change we make till we reach our destination. These records are valuable for obtaining an accurate check on the course steered, whether or not course changes were made on time, and if necessary to alter course for another vessel or for any other reason, this shows us exactly how long and by what amount we were off our course so that proper allowance can be made for it. Also in case of collision we have a graphic, unbiased record of everything we did to avoid it." We were then shown the engine telegraphs, electric whistle pulls and other equipment about the bridge.

During a subsequent voyage we were permitted to spend some time on the bridge and watch these many things of which this navigating officer had told us, unfold themselves in actual life and we could not help but comment on the marvels of our

time and the fertility of the minds that were so generously contributing to the safety and swiftness of our voyage.

By increasing the accuracy of navigation by decreasing the liability of error, in that all important instrument the compass, by holding the vessel more nearly to her proper course and by making a graph of the ship's heading and time, the gyroscope in the form of the gyro-compass has contributed greatly to the safety of ocean travel.

Example of the Gyro's Resistive Power

A. C. WARFEL (Hartford Accident & Indemnity Co., St. Louis, Mo.): As an example of the resistive power in the gyro, I remember a high school physics demonstration given by a professor who came to lecture us. He had a bicycle wheel so rigged with handles and a little pulley, that by giving the string a pull it would revolve at high speed. He had himself standing on a sort of turntable and after he got that wheel going, he asked some of the students to turn him around. You couldn't do it.

MR. WHITAKER: We had an example of that in our own factory some two or three years ago. One type of compasses we make has a wheel which revolves. We have known them to revolve as long as 18 hours after the current is taken off. In this one instance the compass had to be shipped in a hurry and was put in a shipping crate and sent to the shipping department. One of the men in the shipping department was told to take that crate out and place it on a truck. In doing so, he would necessarily have to make several turns. He picked up the box and all went well until he started to make the turn. The box kept coming up at him. The fellow set it down, said somebody else could have the job, he guessed there was a ghost in there.

CAPT. T. W. SHERIDAN (New York State Nautical School, New York City): Along that line, it might be of interest to everybody to remember that the pendulum has some of the properties of the gyro. Read the account of how Galileo discovered the fact that the earth revolves on its axis, only that was a graphical demonstration of what he saw instead of what he felt, the same way as the man lifting the box. Galileo discovered this accidentally by observing one of those incense containers in a cathedral.

A Single Nail Affected the Course of the Ship

One point, if I may invite attention to it, the disadvantage of having the master compass at a great distance from the repeaters, is the fact that accidents occur to the directional contact wires. In 1913 I had command of a ship. We were going to take President Harding up from South America and they made some alterations in the staterooms to make a presidential suite. Somebody drove a wire nail in through the compass cable and the compass was out for a long time before they could discover what was the cause of the disarrangement. The vibration of the ship would bring the bare wire up against the nail and for some time we had all sorts of investigations. It may be a disadvantage to have the master compass at too great a distance from the repeater.

MR. WHITAKER: That is a very good point. We always point it out to steamship officials. I might say, however, that such a difficulty does not affect the gyro-compass. It affects the indicating instrument on the bridge.

CAPT. SHERIDAN: Another point that I would like to develop; in the nautical school—the cadets just before graduating are sent over to the gyroscope school to

take the course. Now, the question is, is it better to have them go to the gyroscope school or would it be better to offer some sort of a gyroscopic course?

MR. WHITAKER: We have been inclined to offer the latter. We have offered the school the loan of gyroscopic equipment for the summer cruise. I don't believe all year round it would mean a great deal because their time is taken up by other work, but if they could have a machine during the cruise, they would be able to gain valuable information from it.

MR. WARFEL: I might make another suggestion on that particular point. It might not be a bad idea, if the boys, some time during the course were taken through the gyroscope factory.

Students Aboard Ship Visit the Plant

MR. WHITAKER: They are, they spend pretty nearly a week there. The school ship usually comes into the Brooklyn Navy Yard for a few days each year for its annual overhauling and repairs. That is only about ten minutes walk from our factory, so they are given opportunity to go through the plant. I might say in that connection, we maintain a school at our factory from which, in the last three years, we have graduated 1,000 merchant officers, naval officers and men. The naval officers who are assigned to Columbia University always finish their post-graduate work at our plant.

M. E. ARKILLS (Waterfront Employers of Seattle, Seattle, Wash.): I would like to ask the speaker what effect a resisting bearing would have in the mounting of the rotor in the compass, one that would be a bad bearing or dry, or furnish heavy resistance.

MR. WHITAKER: It would slow your rotor down. That would give you difficulty in the compass. It would naturally show itself first as an error in your repeating instruments on the bridge and that is why I say the gyro-compass should be as carefully watched as the magnetic, because the gyro, as we all know, is a piece of machinery and is subject to ailments. Although we believe the present design has gone a long way toward reducing those to a minimum, yet we urge all captains and navigating officers to keep a careful watch on their gyro-compass. We use ball bearings throughout for guide bearings. They are special. They are all annular bearings. Some are of our own manufacture and we really gather those from about five or six different manufacturers because each bearing has certain requirements made on it and different types suit those requirements better.

Compasses Cleaned About Every Two Years

MR. ARKILLS: Naturally, you use very light oil in those.

MR. WHITAKER: We use quite a light oil.

CAPT. SHERIDAN: I think it might be of interest to explain to Mr. Arkills the repeater compasses are not moved by the energy in the gyroscope itself, but the gyroscope directs another electrical motor which does that so that there is comparatively little resistance against the directional force of the gyro, itself. It is known as a phantom ring.

MR. ARKILLS: I wasn't thinking about the remote resources, I was thinking of just the resistance to accuracy in itself.

MR. WHITAKER: It has been worked out so that now we figure every two years, no oftener, a compass should be taken down and the bearings cleaned. That has been reduced to possibly a day's work on the compass once every two years to clean bearings and thoroughly oil them and make it good for another two years. That, we believe, gets the gyro-compass down to a point where it requires less attention

than the magnetic, because most ships must have the magnetic compasses compensated at least once a year.

J. S. HUNTER (Atlantic Refining Co., Philadelphia, Pa.): May I ask about what percentage of our merchant marine are equipped with them?

MR. WHITAKER: I should say, roughly, of the ships on the Great Lakes there are about 30 per cent fitted with the gyro-compass. On deep water, I should judge about 20 percent.

A. M. TODE (The Texas Co., New York City): It has been my understanding that the gyro-compass for many years has been direct current driven and only recently have you been manufacturing alternating current machines.

Closing Moments of the Session

MR. WHITAKER: I might say we started out first with the alternating current machine, the original navy type, in 1920 or 1921. Our reason for going to alternating current was because of the high velocity. We could not get good commutation to drive the gyro wheel by direct current until 1920, and then we found the velocity, very much higher than we required, had been very successfully worked out in industrial work and that encouraged us to go ahead with the direct current wheel, which eliminated the necessity of a motor generator.

Then we brought out our direct current type which we still manufacture and we also manufacture a similar compass for alternating current where it is desired to have an alternating current machine. We find some ship owners don't like a direct current machine.

In most of the salt water work, they are getting alternating current. On the Great Lakes, practically all are direct current. Those few ships which had the alternating current type have been replaced. The alternating current type has a great deal more equipment and naturally requires maintenance and special care during the winter when the ships are laid up. With the direct current type, they simply cover the machine up, lock the room, come back next spring and start it up.

CHAIRMAN KAIN: Are there any more questions?

That concludes our program so far as the papers are concerned.

(After discussion it was)

RESOLVED that the Marine Section does not favor the passing of a recommendation to the Council with reference to the convention city for the coming year, but that we do express our appreciation of the splendidly arranged convention now in session.

CHAIRMAN KAIN: Gentlemen, I think that concludes the program of the Marine Section for the present year. The new officers for the Marine Section have been elected for the coming year. These gentlemen are not new to the affairs of the section. They have had a great deal of experience in safety work and particularly in the work of the Marine Section. I believe that the wonderful record made by the Marine Section last year, both with respect to membership and accident prevention, is largely due to these gentlemen who are going to take over its management for the coming year. I think the Marine Section is most fortunate in having command of their services. They certainly have been very unselfish in giving their time and energy to the work of the National Safety Council.

As chairman of the Marine Section for the past year, I want to express my appreciation on behalf of the section and on my own account for the wonderful support I have received from these gentlemen.

We stand adjourned then for this year. I hope you will all be present next year. We have a very large membership now as compared with last year, and if we do as well this coming year, we will have a very large percentage of the American

Merchant Marine in this section. I don't know of any industry that needs safety more than the shipping business.

MR. TODE: Mr. Bush, unfortunately, was called out of the hotel. He had expected to be here. In his absence, I would like to express my appreciation and, I feel, the appreciation of all our sectional members for the work of our chairman, Capt. Kain, for the past year, and I move that we extend to him a general vote of thanks for his efforts and for the work of the Marine Section during the year 1927.

ADJOURNMENT

SIXTEENTH ANNUAL SAFETY CONGRESS NATIONAL SAFETY COUNCIL

Metals Section

New Section Officers

Chairman, J. A. NORTHWOOD, Bethlehem Steel Company, Johnstown, Pa.
Vice-Chairman, E. G. QUESNEL, Commonwealth Steel Company, Granite City, Ill.
Secretary and News-Letter Editor, JOHN P. EIB, Illinois Steel Company, Joliet, Ill.
Program Committee Chairman, E. F. BLANK, Jones and Laughlin Steel Corporation, Pittsburgh, Pa.
Poster Committee Chairman, C. L. PEAKE, American Radiator Company, Buffalo, N. Y.
Membership Committee Chairman, W. E. MEGRAW, H. H. Robertson Company, Ambridge, Pa.
Publicity Committee Chairman, J. A. VOSS, Central Alloy Steel Corporation, Massillon, Ohio.
Slide Committee Chairman, JOHN A. OARTEL, Carnegie Steel Company, Pittsburgh, Pa.
Engineering Representative, W. H. WINANS, Union Carbide Company, New York City.
Statistics Committee Chairman, H. G. HENSEL, The Youngstown Sheet and Tube Company, Chicago, Ill.
Executive Committee: THE OFFICERS AND—
F. G. BENNETT, The Buckeye Steel Castings Company, Columbus, Ohio.
T. H. MCKENNEY, Illinois Steel Company, South Chicago, Ill.
J. E. CULLINEY, Bethlehem Steel Company, Bethlehem, Pa.
J. M. WOLTZ, The Youngstown Sheet and Tube Company, Youngstown, Ohio.
JOHN P. MUDD, The Midvale Company, Nicetown, Philadelphia, Pa.
E. R. ROSE, Republic Iron and Steel Company, Youngstown, Ohio.

Retiring Officers

Chairman, F. G. BENNETT, The Buckeye Steel Castings Co., Columbus, Ohio; *Vice-Chairman*, J. A. NORTHWOOD, Bethlehem Steel Co., Johnstown, Pa.; *Secretary*, E. G. QUESNEL, Commonwealth Steel Co., Granite City, Ill. *Committee Chairmen: Program*, JOHN P. EIB, Illinois Steel Co., Joliet, Ill.; *Poster*, FRANK H. ROWE, Wheeling Steel Corporation, Portsmouth, Ohio; *Membership*, H. G. HENSEL, The Youngstown Sheet & Tube Co., Chicago, Ill.; *Engineering Representative*, EARL F. BLANK, Jones & Laughlin Steel Corp., Pittsburgh, Pa.; *Executive Committee*, THE OFFICERS and A. C. GIBSON, Spang, Chalfont & Co., Pittsburgh, Pa.; T. H. MCKENNEY, Illinois Steel Co., South Chicago, Ill.; JOHN A. OARTEL, Carnegie Steel Co., Pittsburgh, Pa.; J. M. WOLTZ, The Youngstown Sheet & Tube Co., Youngstown, Ohio.

Tuesday, September 27, 1927

F. G. BENNETT, Chairman

Safety Director, The Buckeye Steel Castings Company, Columbus, Ohio

The first session of the Metals Section of the National Safety Council, was called to order at nine-forty o'clock by the chairman, F. G. Bennett, safety director, The Buckeye Steel Castings Company, Columbus, Ohio.

CHAIRMAN BENNETT: The first order of business of the Metals Section will be the reading of the reports of the officers and in the order of these reports, the present chairman's is to come first.

If I were to go into detail on the activities of the Metals Section during the past year, I know I would steal the ammunition and thunder of the various officers, because, as chairman of the committees, they have really performed the work.

I will say this, however, that we have held three meetings of the executive committee and that each time these meetings have been held, they have been arranged so that we could meet with the executive committee of the national organization. We found that to be quite an advantage because we could take up matters with the various officers and work them out to the advantage of the section.

There is one thing we are quite pleased with this year and that is the interchange of ideas between members. There has been a lot of that, mostly through correspondence, and I think our News Letter has aided materially. I am sure the report of the secretary will not say enough about the News Letter, as Mr. Quesnel is entitled to a lot of credit for the excellent work that he has done in this connection.

I know that has helped our section and there has been a large demand for the News Letters, some of the plants using many copies to distribute among their foremen and men.

I will now call upon the secretary, Mr. Quesnel, for a report and also something about the News Letter.

E. G. QUESNEL (Safety Engineer, Commonwealth Steel Company, Granite City, Illinois): I think the secretary's report could be better left unsaid. The secretary's job is just to interpret the ideas of the various members and pass on information, and I hope I have done that properly this year.

As far as the News Letter is concerned, I don't take any credit at all for that. If that was a success, it was due to the members themselves. I do feel very grateful, though, for the contributions that came in and the prompt response to inquiries sent out. We got in touch with more new industries this year, I believe, than ever before in the history of our section. As a matter of fact, we received inquiries from men in California, Oregon, New Orleans and on the Atlantic Seaboard, writing in to us for information, we referring them to others, which established a means of communication that has been very valuable; and I hope that next year you gentlemen will take advantage of the News Letter and use it as a means of broadening your acquaintanceship, securing information that cannot be secured in any other way, and building up a greater correspondence in your safety organization that will be national.

CHAIRMAN BENNETT: The section's next committee to report will be the chairman of the Membership Committee, Mr. H. G. Hensel. Mr. Hensel is attending another session at this time, so assigned on the program, I will ask Mr. John Eib to read his report.

JOHN EIB (Illinois Steel Co., Joliet, Ill.): I personally regret very much that Harvey Hensel is not here to read his own report because he is entitled to a lot of consideration for his extremely interested and successful work.

Report of the Membership Committee

During the past year, the Membership Committee had a personnel of 34 members, and this personnel was selected from the Members of the Metals Section in as many different states of the United States as possible. I want to take advantage of the opportunity offered at this time to thank each and every member of the committee for the efforts they have put forth during the past year in this membership work. I have had the hearty cooperation of our committee, and I am told that the number of new members for our section, secured during the past year, is greater than that of any other section. It is a fact, however, that cancellations during the past year were rather high, and this especially among the smaller plants in the metals industry.

The record at the National Safety Council headquarters, with reference to the members in this section, is as follows:

From October 6, 1926 to September 13, 1927

Number of members in Metals Section, October 6, 1926.....	745
New memberships during the year.....	90
Memberships cancelled during the year.....	60
Total number of members in Metals Section to date.....	775

I have two suggestions to offer at this time in connection with future membership work in the Metals Section:

First: I am pretty well convinced that the new policy adopted by the National Safety Council of arranging for personal solicitation in districts where a member of the staff of the Council can be sent to call on prospectives with a local safety man, who is well acquainted in the district, is one of the best ways of securing new members. It seems to be easier for a member of the National Safety Council's staff to interest a prospect in membership than it is for someone whose training has not been as extensive in selling memberships as this member of the staff has had. The usual procedure is for a member of the Membership Committee to arrange with a member of the National Safety Council's staff at a time convenient to both and to give up about one day's time to this work in that particular district.

Second: The other suggestion is that the Membership Committee be formed at the Congress or as soon as possible thereafter so that the drive for memberships can be started immediately after this Congress adjourns.

CHAIRMAN BENNETT: If there is a report on the Program Committee, Mr. Eib (that is his real job) have you anything to say on that?

JOHN EIB: Here it is and I hope it goes over good.

CHAIRMAN BENNETT: Thank you very much, John. You did a good job. The suggestions made on this report of the Membership Committee by Mr. Hensel are very good. I have not seen the report prior to its reading, but I imagine that it will be referred to the incoming officers for their consideration. Mr. Hensel has worked hard on this and accomplished a lot of good.

Mr. Frank Rowe has done some very fine work in connection with posters, and I would like to hear the report of the Poster Committee.

FRANK H. ROWE (Safety Director, Wheeling Steel Corp., Portsmouth Works, Portsmouth, Ohio): My report isn't very long this morning. I will read it to you.

Report of the Poster Committee

This report completes another year of service to the membership of the Metals Section and I wish to take this opportunity to thank all those who have helped by submitting posters for use of our Section during the past year. Particularly do I wish to thank the members of the Poster Committee, E. F. Blank of the Jones and Laughlin Steel Corporation, Pittsburgh, and H. P. Shields of the Carnegie Steel Company. The report of the chairman of this committee would not be complete were it not to mention the fine service and help rendered the chairman by Lee H. Gardiner, Director of the Poster Division at the Council Headquarters. His advice and counsel have certainly been of great help to the committee in arranging the posters for the Metals Section. We have furnished two posters every month for the Section.

To the incoming chairman of this committee, we are turning over all correspondence for the past year in hopes that it may be of some assistance in solving the bulletin problem of our section. We have tried to give you the best that we had.

Our experience this year has been the same as in previous years and that is the obtaining of suggestions from the membership on bulletin material. We have tried through correspondence and visits to obtain bulletin material, but without success. We sincerely hope that the membership during the coming year will take a greater interest in bulletins and furnish the Poster Committee with subject material so that they will be able to furnish timely and instructive bulletins to the membership.

Respectfully submitted,

FRANK H. ROWE, Chairman.

MR. ROWE: I thank everyone for their cooperation during the past year.

CHAIRMAN BENNETT: Someone remarked that in looking over the posters there are a lot which show the committee has been doing some good work.

We have one other officer in the section who may have something to say. Mr. Blank is our engineering representative. Do you have any report to make?

E. F. BLANK (Jones & Laughlin Steel Corporation, Pittsburgh, Pa.): You know, Mr. Chairman, I have no formal report, but for the benefit of the members, to show what the engineering representatives is supposed to do, I might state that this job is just short of a day-long job.

Some of the Engineering Section and the Metals Section members might be interested to know, that at the present time, a research is being conducted under the auspices of the S. A. E. Probably most of you are aware of the fact that there has been no research. There is nothing authentic to show at what temperature chains are best annealed. The research is to be conducted for that purpose to find out what the best temperatures are for the different sizes of chains, steel chains and wrought iron chains. This research will probably be conducted by the Carnegie Institute of Technology in Pittsburgh and we hope, for the next Congress, we will have a very complete report on this subject.

You have attended some of the engineering sessions where chain annealing has been discussed and you are aware that one expert will say that 900 degrees is the proper temperature to anneal a chain, another 1,400, and another 1,700. Our research is to determine, through laboratory tests just what the proper temperature of annealing is and this work is about ready to start.

CHAIRMAN BENNETT: Are there any other persons connected with the committees who desire to make a report or have anything to say at this time? If not, I desire to state, as you have all read your News Letters, the Nominating Committee is composed of Mr. J. M. Woltz, Mr. C. L. Peake and Mr. Ed Culliney, and, that, I think, takes care of the reports of committees of this section. So we can now get into the active part of our program which is scheduled for this morning and

entitled "Inspirational." The Program Committee felt it was a good way to start the session off with a good inspirational talk.

It gives me the greatest pleasure, at this time, to present to you, Mr. Charles R. Hook, Vice-President, American Rolling Mill Company, Middletown, Ohio.

Safety in American Industry

**Charles R. Hook, Vice-President, The American Rolling Mill Company
Middletown, Ohio.**

It is my great pleasure, as well as a very decided privilege, to be again with this group who are doing so much to safeguard life and limb. I asked your chairman whether I might have the privilege of just talking to you. I don't believe you want to listen to a speech. I don't think I have one in my portfolio, nor at my command. However, I do think there are a number of things which we can discuss with mutual helpfulness.

Naturally, I would talk to you particularly with respect to those things which interest management; or should interest management; and my tendency would be to talk at very great length, we are so much interested in the subject. We feel that it is such a very vital problem, with respect to production, on which we could talk for hours.

I would like to pause just a moment to pay my respects and to again present my most sincere congratulations to that fine group of fellows, members of the Association of Iron and Steel Electrical Engineers, who at Milwaukee in 1911, gave birth to this great movement for organized accident prevention.

It seems to me that not a session of the National Safety Congress should go by without someone calling attention of those who have later come in to this great movement, to the fact that that group of far-seeing, fine-visioned men, realizing their responsibility, accepted the opportunity to start a very great work. A tremendous amount of work has been done and most wonderful results have been accomplished for the National Safety Council, and I take my hat off to all those men, past president and officers and workers in this movement, who have brought not only happiness to the home through the safeguarding of the wage earner, but also have brought to industry increased efficiency, economy and reductions in the cost sheet.

Just for a moment may we pause to read a few statistics, simply for the purpose of impressing upon ourselves the importance of this program and the extent to which it has grown.

One in Thirteen Was Injured Seriously

In 1926, for instance, the last available figures, there were 1,725 plants reported in which there were employed 1,221,094 men and 3,933,416,031 hours were worked. With what result? One out of every 13 workers suffered a disabling or lost-time accident. Each accident averaged a loss of 78 actual and computed days and an average of six days was lost for every one of the 1,221,094 men employed. To be accurate, the computed days lost for deaths and permanent disabilities, plus the actual days lost, totaled 7,588,852 or 20,791 work years; and for every 140 non-fatal cases there was a fatality.

Is that not a challenge to the industrial manager of today? Does that not give our industrial leaders an opportunity to assist not only in a very great economic problem but a very great humanitarian problem?

While the reduction in lost-time accidents over the past several years has been very remarkable, yet there is much left to be done. I would like to stop for just a second to call your attention to the dollar side of safety. We can't argue with respect to the

humanitarian aspect of this problem. Nobody would dare get up and question the advisability of carrying on this program of accident prevention; but there may be in our group those who are so busy with their every day problems that they may be termed "hard-boiled," and the more "hard-boiled" they are the more they can be appealed to on the dollar side of safety by an actual presentation of the facts.

In looking over some of the things the other day which were in my accident prevention folder, I ran across a few things which we said several years ago and I was very pleased to find that today we don't have to take a thing back that we said ten years ago.

I have before me a statement made six years ago and I am going to read it, in order to show you that we were thinking with respect to the dollar side of safety at that time and that it is just as outstanding a factor in your program today as it was then. It asks this question:

"Is a billion dollars worth saving? Leaving aside considerations of humanity in industrial accident prevention, let us look at the authenticated fact that, in the United States, industrial accidents cause a direct economic loss of more than one billion dollars each year, and besides this, and just as important, an indirect loss through decreased efficiency and production of several billions more.

"Looked at solely from the standpoint of good business economics, accident prevention is of tremendous importance.

"Not so many years ago accidents were 'all in the day's work.' Employers, executives, foremen and workmen alike took this attitude. Men took pride in their scars and boasted of narrow escapes. In shop, mill, factory and shipyard the man who was not willing to take a chance was looked upon as a coward.

Accidents No Longer An Accepted Evil

"But there came a day when the 'all in the day's work' attitude toward accidents came under the cold, calculating scrutiny of a few men—business executives and engineers—who saw a big opportunity not only to save human life but at the same time to wipe out an enormous economic loss. They analyzed the situation and found that, when accidents were considered an unavoidable part of the day's work, a full day's work was never done. They found also that 75 per cent of the accidents could be prevented, and that often as an incidental result efficiency was increased from 10 to 100 per cent. And so for both economic and humanitarian reasons the old attitude toward accidents was discarded and a new era of safety and efficiency dawned in thousands of progressive industrial organizations, large and small. Today the prevention of accidents has become a most important and an inherent part of the day's work in the modern industrial plant. The day's work now means a day's work.

"Any employer or person in an executive position whose company has had to pay compensation or damages to injured workmen will easily realize the heavy, direct monetary cost of accidents. But there are thousands of executives who have as yet failed to see the deepest and most serious economic significance of the accident problem—the indirect loss of efficiency.

"The greatest economic significance of accidents lies in the fact that every accident is a red flag indicating an inefficiency somewhere. When an accident occurs it means not only the direct loss occasioned by that accident, but it points out the fact that there has been a constant leakage of efficiency, a steady loss of time and money."

We said that six years ago. We repeat it today. There is no question about it. In support of that statement, in 1913 we asked our department of accident prevention to present to the management some facts which would conclusively show that the introduction of some safety device or some improvement in methods made a more safe method and could be actually shown to have been reflected in the cost sheet. I have here in my hand that report. You can see the number of pages. All of those inci-

dents are actual cases which were proved and where it was shown that the introduction of a safeguard or a safer method of operation brought with it increased efficiency and a reduction in cost.

Right at the top, let's read one just to show the kind of things that take place. Open-hearth tap holes are burnt out with an oxygen flame. This was in March, 1923. Many explosions have occurred in the use of oxygen. One of the latest reported was in our Columbus plant where a man's hand was fractured.

The safety and maintenance department undertook to make the operation safe and did so. Incidentally, they reduced the amount of oxygen used so that now one bottle does the work of three. As about 125 bottles per month were used, this has been reduced to between 40 and 45. The saving is quite an item.

Safety, Increased Efficiency and Lowered Costs

I could go on and read you case after case showing that with the introduction of accident prevention methods and equipment along with it went increased efficiency and reduction in cost. Just as a matter of illustration, anybody that gets up today and talks about accident prevention and what can be accomplished, must have before him the actual facts. So, if you will pardon a reference to our own records, I will present a few, simply as an illustration of what can be accomplished when those who are interested in the program get behind it wholeheartedly.

At Middletown, in 1916, we had 880 lost-time accidents in the year with 3,500 men employed. In 1920 that had been reduced to 108 with 4,200 men employed; and in 1926 it has been reduced to 75 with 3,830 men employed.

In 1922, on the first of January, we took over a new plant at Ashland, Kentucky. I remember very well that after we had had the plant for some six months, in August of that year, we had 34 lost-time accidents. We had started a program of accident prevention, of course, but it was in full sway; by the following February, with a very large increase in number of men employed and increase in tonnage, the lost-time accidents had been reduced to four.

At our Columbus blast furnace in 1923, we had 50 major accidents or lost-time accidents; in 1925, 20; in 1926, 9, and so far this year they have gone the entire year to date (September 27, 1927) without a lost-time accident in that blast furnace plant.

I don't need the accounting department to bring me a cost sheet to know that money was saved, as well as earnings to those who were employed in that plant. It is self-evident. The very fact that a blast furnace plant can run so far, say over almost nine months, without a lost-time accident is evidence of increased efficiency and of savings in dollars and cents.

Accident Prevention Calls for Intensive Effort

Now, what does it mean? A tremendous amount of work, naturally, has to be done. Everybody from top to bottom must be interested in the program if it is going to be successful. The same thing has happened in all of our other plants and I won't bore you with further details with the exception of calling to your attention a plant which we have just taken over as of August first, at Butler, Pa.

When we got hold of their records, Mr. Adair found that they had 108 major accidents in the first six months, or at the rate of 216 for the year, in a plant employing approximately 1,000 men. Now, they had a safety organization there, supposedly, but what was lacking? There was spirit lacking. But now there is determination from top to bottom to get behind the movement and work constructively all the way along the line and if we don't reduce that frequency rate up there by two-thirds in the year 1928, I'll be very much disappointed indeed and there will be a conference probably in the general management's office some time in January of '29, so we will know why.

Take a situation such as this. Here's an electrical construction gang that for ten years has gone without a lost-time accident. Do you mean to tell me that we are not saving money, as well as wages to those who are employed?

Such examples simply give us courage to go on and to fight for further interest and further accomplishment. And how are we going to do it? It seems to me that we have got to start it off. I don't see how we can expect those who are interested in our program of accident-prevention out in the plant to put forth their best efforts unless they know that their general management is sincerely interested and behind them; and I want to say to you executive officers of companies who are here today, that I don't think you can hold your departments organized for accident prevention responsible for improvement in that program unless you show, by personal interest, that you are backing that program and that you are interested in it—and I don't mean to show that interest second-handed.

The Influence of Executive Interest

You know that you have an entirely different appreciation of an automobile, no matter how new it is, if it is second-hand. If somebody were to hand you a brand new car that had never been run, had never been owned by anybody else, that is one thing. But if the car has been run only four or five miles and then it is brought to you as a second-hand car, you have a different appreciation of it. I think the same thing happens in the plant when the interest of the major executives is handed down through others. I think that an entirely different spirit is engendered when the head of the institution makes his personal appearance at various times and tells the organization personally that he is behind this program. Then they know it. When you meet a man face to face and you look in his eyes and he tells you, "I am behind this thing, I believe in it and I am going to support it," then you know that that is a fact; but if he writes it to you, or if he sends somebody to tell you, there is always just a little doubt about it.

Now, last year our president made a swing around the circle of our various plants, discussing with the organization policy problems of various kinds and at least half of his talk at every one of these sessions was devoted to the subject of accident prevention. I wonder how many of you executives take the opportunity when you hear of some particularly good work in some department to pick up the telephone and call up Bill Jones and say, "Bill, this is Mr. Greene"—and immediately Bill picks up his ears. "Why, the general manager is talking to me; or 'The president is talking to me, I wonder what he has got to say?'" And when he hears on the other end, "Why, Bill, that was a remarkably fine record you made last week; we are tremendously pleased with the action you are taking in the accident prevention program. We want you to know the general management knows about it and we are watching your actions and you are being given proper credit back in the general office." Why, can't you just feel the spirit of enthusiasm warming the whole frame of that individual? I think so.

The Executive Should See the Accident Record

I wonder whether we executives have a program so that the monthly accident record of our plants comes across our desks and if we haven't time ourselves to analyze it carefully to pick out the high spots, do we have somebody perform that job for us and bring it to us boiled down. If we don't, we are losing a great opportunity and are passing up an obligation. At home we take a great deal of interest in this monthly report which shows the standing of the various departments, and our secretaries are instructed to go through that report and if there is some high spot, point it out so that we may have the privilege—I say privilege—and the

opportunity of getting in touch with this, that or the other department, or the head of that department, and let them know that we appreciate that record.

In 1920, it was my privilege to discuss accident prevention work before a conference of the Illinois Manufacturers' Association in this city; and I took as my subject, "Accident Prevention Work and the College Spirit in the Plant." Now, I never went to college; unfortunately I have had to spend a good many hours at night in hard work, trying to accumulate some of the information which I would have otherwise gotten had I had the privilege of going to college; but I have stood on the side lines and I have seen exhibited that thing which we call "college spirit," which we can't describe but which we can feel, that thing which makes fellows go into the game and risk life and limb for the old school. I know that this same spirit can be put into the plant. That same love of the institution can be engendered if we go about it properly. But all those of us who are members of the institution must be playing the game together.

Have we an organization, or have we a team? I can put Babe Ruth and Ty Cobb and Tris Speaker in the outfield and Py Trainor on third and Bancroft at short and somebody else at second and another fellow at first and a star pitcher in the box and the best man behind the bag, and I have got an organization; but I haven't got a team necessarily. Now, what is it with games? It is not only ability but it is the coordination of that ability. It is the spirit possibility and coordination; that is what we have got to have in this program of accident prevention, and it requires that management take advantage of every opportunity it has to show its interest.

Take a Real Personal Interest in Safety

Do we occasionally attend conferences of superintendents and foremen? Maybe they are going to have a banquet. Do we just drop in and say we'd like to attend that meeting to show our interest—not especially invited? Do we take the opportunity to drop in and do those things voluntarily which will impress our interest upon the minds of those who are carrying on this work? If we don't we should. No question about that.

Well, you know there are a lot of men, it seems to me, who go through life with a viewpoint with respect to this movement and are represented somewhat by a mule I heard about one time. A fellow sold a mule to another fellow and the next day the fellow came back with the mule. He said: "I want my money back." The other fellow said: "Why, what do you want your money back for." He said: "Why, you cheated me." The other fellow said: "No, I didn't cheat you." "Yes, you did." "Why I didn't any such thing; that mule is right. I sold you a good mule." "No he isn't. He is blind. I took him home yesterday afternoon, unhitched him, let him loose in the barnyard, and the darn fool walked right over and butted his head into a tree. I want my money back." He said: "My friend that mule is all right, he isn't blind, he just don't give a damn."

Now, there are a good many people just the same way, they are not blind, they just don't give a damn. It is time they were waking up.

I could go on indefinitely pointing out things which the management can do and should do. I am absolutely convinced that the inspiration must come from the top. But in conclusion, may I say a few words to you men who are responsible for the daily carrying out of the work in connection with this program? Are you selling yourself to the boss? What are you doing to make the boss interested in this program? Are you taking advantage of opportunity to send him information about this and the other thing that might awaken a latent interest? If you are not doing it, you are falling down on the job. Are you taking the position that, "Well, darn it, I told him about a particularly fine record in a certain department two months

ago and I didn't get any comeback at all." "Oh, Hell, he isn't interested. What's the use?" Believe me, gentlemen, you men have a job that requires great enthusiasm. I say courage, unusual courage. You have to get into the thick of the fight, with the possibility of getting darn little credit for what you do. You have got to be in love with your work and see a great opportunity; and in order to put the program over, you have got to study the boss just like the boss is supposed to study organization. And you have got to be a darn good salesman. You have got to know how to sell your wares to the boss. Stop and think about it.

Sometimes you will say, "Well, how will I get at that bird?" Have you ever done that? You seem discouraged and don't think there is much chance. Do you give up? Do you quit? If you do, you're not the man for the job. No. You will never get any place that way. You have got to keep at it.

Edgar Guest Put the Thing Forcefully

It seems to me that Eddie Guest (I think it was Eddie), wrote a little poem that rather illustrates the point I would like to make:

When things go wrong, as they sometimes will,
And you want to smile, but you have to sigh;
When the funds are low and the debts are high,
When the road you're trudging seems all uphill;
When care is pressing you down a bit—
Rest if you must, but don't quit.

Life is queer with its twists and turns,
As everyone of us sometime learns;
And many a failure turns about
When he might have won, had he stuck it out.
Don't give up, though the pace seems slow—
You may succeed with another blow.

Often the goal is nearer than
It seems to faint and faltering man;
Often the struggle has been given up,
The runner has lost the Victor's cup,
And he learned too late, when the light was down,
How close he was to the golden crown.

Success is failure turned inside out—
The silver tint of the clouds of doubt,
And you can never tell how close you are;
It may be near when it seems so far.
So stick to the fight when you're hardest hit—
It's when things seem worst that you must not quit.

Do you have an opportunity, in your position as supervisor of this program of "Accident Prevention," to exhibit qualifications? I'll say you do. You have to exhibit real qualities of leadership and executive management if you're going to put your program over. What makes me think so? Let me give you two illustrations that have happened within the last five years in our own organization.

In January, 1922, we took over a plant, the physical assets of which, at the present moment, are valued at about \$25,000,000. It was necessary to appoint a works manager over that particular division. Now, I presume that like a good many others, you may think that we naturally would pick out a department operating

superintendent. You wouldn't think of anybody else. Who got the job? Why, the director of employment, a staff man, back in the general office. Why? Well, he had been a department superintendent at one time before he was appointed a staff director of employment, and in his contact with the departments in trying to find out how and where to get the man who would best fit in this, that and the other job, thereby assisting the general management, he had picked up a tremendous amount of information with respect to the operation of several of the departments. He hadn't been idle. He studied the processes because, in order to fit men to that particular process, he had to show what kind of a man was needed; and how would he know what kind of a man was needed unless he understood the process?

So he was taken out of the personal service division and made works manager of that very important production division.

A Safety Man Is Often a Good Manager

Recently, we acquired properties of three companies, with something over 15 million dollars involved in the plant values alone. It was necessary again to place a man in charge of the works, a vice-president in charge of operations of this new holding. Whom did we pick? Why, we picked Mr. Lewis, who was the director of the personal service division, under which operates our accident prevention staff division, the employment mutual interest, health and so forth. Again a man who by his wide contact with all the departments, knowledge of company policies, company methods, could best represent the general management in general charge of operations.

Is there an opportunity for you men who seem to be at times stuck to some one place? I'll say there is a tremendous opportunity if you make the most of these chances as they come to you. I offer it to you as an encouragement, as an incentive, as safety men, accident prevention men, that while you are studying ways and means of improving your accident prevention record, to be most successful, you must understand the processes of the several departments. What are you trying to accomplish? What are the production problems?

Then you can truly act in an advisory capacity in a way to secure the wholehearted support, not only of the production managers, but of the general management who are back in the general office watching the general results.

I want to call your attention to one characteristic which seems to me tremendously important, and that is the characteristic of diplomacy. May I illustrate that by telling you something that happened several months ago that I happened to know of.

A Gentle Hint to the Company President

The president of a corporation who handled a hundred million dollars, dropped into the plant. His mind was on many things, no doubt, and he was taking some visitors through a mill. He drove rapidly across the track. He didn't know there was an engine approaching, his mind was on a thousand and one things, and I am told that the engine came pretty near hitting him. It didn't miss him very far. It put on the brakes and stopped. The engineer was on his job. Now, he knew it wouldn't do for him to go up and call the president down. In fact, he didn't know the president was in the car until after he stopped his engine and followed that car and they got the description and the license number as the occupants got out and went into the mill, and then they saw who occupied the car. But they made their report just the same and when that report came to the general manager it was very clearly worded. It said that at a certain time and place a car occupied by two gentlemen and three ladies passed over the track and was almost hit by a locomotive. A complete description of the near-accident was contained in the report without reference to the names of the occupants. I say, that was a

rather delicate way of having the information passed on to the chief executive of the company without hurting his feelings particularly, but yet getting the news there.

There are many times when, in order to win the support of those whose support is very greatly needed, you can follow these characteristics of diplomacy. They are very necessary, indeed, and while it is true that an individual ought to be interested in this thing which you are so much interested in, yet you must realize that it takes a long time to sell some men on this ideal. Some of them still think that it is a sort of frill, a sort of welfare work. Gentlemen, I hate that name. It don't like to hear the word "welfare." We never use it in our organization. It isn't welfare work. This is a great economic problem that you are working with and you are cutting the costs and increasing the efficiency of industry as you reduce your lost-time accidents—whether they are lost-time or not, I may add.

The Compensation for the Safety Worker

Now, in conclusion, what is your compensation? Lots of times I assume that you get very discouraged and say, "Oh, well, what's the use? Where am I going? Where am I getting?" and it seems to me that to do your best work you must get your greatest reward from knowledge of the greater service which you are performing. Unless we go about this proposition in that way and then take those financial rewards when they come to us, why we are apt to lose heart. And I say to you very sincerely, that when I think of the work that you men are doing unto the thousands and thousands of children who today are happy and who have the guidance, help and support of a dad who would have been lost to them without your devotion to this great program, I think of Edward Guest's poem, in which he refers to the children as the burden bearers; and I offer it to you as sincere evidence of my feeling that, regardless of what compensation you may receive, you must secure a tremendous amount of comfort in the knowledge that you are contributing so much to the happiness of thousands of children who would otherwise be in sorrow:

The children bring us laughter, and the children bring us tears;
They string our joys, like jewels bright, upon the thread of years;
They bring the bitterest cares we know, their mother's sharpest pain,
Then smile our world to loveliness, like sunshine after rain.

For children are the furnace fires of life kept blazing high;
For children, on the battle fields, are soldiers pleased to die;
In every place where humans toil, in every dream and plan,
The laughter of the children shapes the destiny of man.

Oh, my shoulders grow aweary of the burdens I am bearin',
And I grumble when I'm footsore at the rough road I am farin',
But I strap my knapsack tighter till I feel the leather bind me,
And I'm glad to bear the burdens for the ones who come behind me.
It's for them that I am plodding, for the children coming after;
I would strew their path with roses and would fill their days with laughter.

CHAIRMAN BENNETT: Mr. Hook, we all appreciate very much the excellent inspirational address which you have given us and I am sure that it is going to do a lot of good. We have made no mistakes in calling this session "Inspirational," but at the same time it is quite practical and there is a lot of good we can take home with us.

Mr. Chauncey L. Baker desires to make an announcement.

CHAUNCEY L. BAKER (Association of Iron and Steel Electrical Engineers): I am glad that I have been called on at this minute. The "Inspirational" talk by Mr. Hook was certainly a pleasure to all this morning. I don't know when I have heard anything that was more impressive.

I'm always glad of the opportunity to say just a word of encouragement to the men at the head of the safety work in the iron, steel and metal industries. I do want to bring to you this morning officially from the Association of Iron and Steel Electrical Engineers, their good wishes for a successful meeting. Those fellows back in our engineering association are always greatly interested in the success, particularly of the Metals Section of the National Safety Council; and I want to assure this section that they will, this coming year, as in the past, have the hearty cooperation of the electrical engineers throughout the iron and steel industry of this country.

The steel industry has always been, and I firmly believe always will be, the leader in accident prevention.

CHAIRMAN BENNETT: Thank you very much, Mr. Baker. I am sure that we all appreciate this greeting.

In arranging our program, the thought has been before the section for several years, that it would be beneficial to know the up-to-the-minute news of the metal industry throughout the country in relation to accidents. We do get wonderful reports from the United States Department of Labor, but it has been quite a favor, quite a contribution, to the metals industry throughout the United States to have at our annual meeting each year a person who does get up these statistics and give them to us almost up-to-the-minute. So it gives me great pleasure to bring before this section this morning Dr. Lucian W. Chaney, of the United States Bureau of Labor Statistics, who will give us the record of progress in metal industries practically up-to-date.

The Record of Progress in the Metal Industries

Dr. Lucian W. Chaney, U. S. Bureau of Labor Statistics, Washington, D. C.

The program makers have slightly enlarged the original title of this paper. It is unfortunate that we do not have precise figures regarding all branches of the Metal Industries and so must confine our presentation to that portion comprised under the designation "iron and steel."

There has been much recent discussion regarding the supposed increase in accidents which has apparently occurred in recent years. There can be no doubt that accident *costs* have been rising so far as the insurance companies are concerned. That this rising cost is to be attributed to increasing hazard is by no means clear. There are a number of other factors which may be of importance in bringing about advancing costs.

The assertion in many quarters that "accidents are increasing" makes of particular interest any bit of positive evidence which may be found in the records of accident experience.

Since 1913 the U. S. Bureau of Labor Statistics has been following a selected group of plants in the iron and steel industry which have given serious and vigorous attention to their accident problems. These plants were pioneers in safety activities and have maintained a leading position to the present time.

The records were in such form as to make possible their consideration from two important points of view. First, the accidents could be classified in accordance with the product which the plants produced. Second, the accidents were

classifiable by causes. Each of these classifications is important in forming a judgment regarding the course of accident experience.

Attention will first be given to the changes which have occurred in this group of plants during the years 1925 and 1926.

The frequency rates for the different product groups for these years are as follows: fabricated products change from 27.4 to 24.3; sheets from 11.4 to 9.4; wire products from 4.2 to 3.9; tubes from 4.0 to 3.6; miscellaneous steel products, Group A, from 9.8 to 6.6; Group B from 3.7 to 3.8; the entire group from 8.2 to 6.8.

The Spread of Frequency Rates Over the Years

It will be noted that in only a single instance is the 1926 rate higher than the 1925. The difference is so slight as to be without material significance.

It is desirable to consider this matter from another point of view. Records of accident frequency have been maintained for the plants under consideration since 1913. It will be instructive to consider the spread of the frequency rates over the years from 1913 to 1926. The changes of rate over this period are as follows: fabricated products from 100.3 to 24.3, 75 per cent; sheets from 61.6 to 9.4, 85 per cent; wire products 59.3 to 3.9, 93 per cent; tubes from 27.2 to 3.6, 87 per cent; steel, Group A, from 70.9 to 6.6, 77 per cent; Group B, 41.3 to 3.8, 91 per cent; all plants, 60.3 to 6.8, 89 per cent. These figures are of interest since they represent the results attainable by prolonged and unremitting effort. Since the selected plants constitute between one-third and one-half of the industry and have in 1926 a rate of 6.8 and the rate for the entire industry is 25.3, the other portion of the industry not included in this special group must have a rate not far from 35.

It is now pertinent to consider this body of data from the standpoint of accident causes.

The changes which have occurred from 1913 to 1926 are as follows: machinery from 7.3 to 1.5, power vehicles from 2.3 to .3, hot substances from 5.4 to .5, falls of person from 4.5 to 1.0, falling material 1.2 to .1; handling 26.7 to 2.9, miscellaneous 12.9 to .4.

It must be remembered that these rates represent the experience of plants which have all the different phases of iron and steel manufacture.

It is noticeable that these declines are distributed over the various causes in a very even manner. This indicates that the influences by which the declines have been brought about have been very pervasive. The various causes have been modified to a strikingly uniform degree.

The rates show that machinery is still a considerable factor in accident causation.

Educational Effort Vs. Safeguarding

There has been from the beginning more or less controversy regarding the relative importance of safeguarding and educational effort. This discussion is rather futile. It does not matter very much which form of effort is of greater efficacy since the safety director who neglects either of them will fail to accomplish all that ought to be accomplished.

It remains true that the accidents arising in connection with the operation of machinery average of greater severity than those due to other causes. For this reason such accidents should receive a liberal share of attention.

The above gives an idea of the course of events in those plants which have for the longest time and in the most painstaking manner carried on in accident prevention.

To complete the picture it is necessary to consider the average experience of the industry. Such results as those recorded in the preceding paragraphs are perfectly attainable by all plants which are ready to invest time, effort and money with the same degree of liberality. It cannot be expected that those who have more recently undertaken accident prevention will immediately be able to show such results. It is fair, however, to urge that the average experience of the industry is a reasonable standard of attainment.

A steady effort on the part of all concerned will as steadily advance the standard with a constantly lessened spread until that time which is now fairly in view when the occurrence of industrial accident shall be as surprising as its absence now is.

The Average Experience of Iron and Steel

Beginning with 1910 the Bureau of Labor Statistics has been able, by your cooperation, to maintain a fairly complete record of accident occurrence in iron and steel.

For each of the five-year periods included in this interval the frequency and severity rates have been computed and give a better idea of what has happened than do the annual figures. It is to be understood that these figures are not complete but do represent a sufficiently large majority of the plants to give reliable rates.

The Industry

The industry shows frequency rates 1910-1914, 59.2; 1915-1919, 41.6; 1920-1924, 32.6. Severity rates 1910-1914, 4.1; 1915-1919, 3.6; 1920-1924, 2.8.

The year 1925 registers a slight decline in both frequency and severity, while 1926 showed a further decline in frequency but a slight rise in severity.

Blast Furnaces

Blast furnaces frequency rates 1910-1914, 62.3; 1915-1919, 39.0; 1920-1924, 30.7. Severity rates 1910-1914, 7.8; 1915-1919, 6.1; 1920-1924, 4.5.

In 1925 both rates show further decline while 1926 registers a rise in both rates.

Open Heards

Frequency rates 1910-1914, 73.0; 1915-1919, 50.3; 1920-1924, 32.9. Severity rates 1910-1914, 6.6; 1915-1919, 6.5; 1920-1924, 4.2.

In 1925 there is decline in both rates and in 1926 frequency declines while severity has a rather pronounced rise.

Foundries

Frequency rates 1910-1914, 63.6; 1915-1919, 61.0; 1920-1924, 62.7. Severity rates 1910-1914, 3.6; 1915-1919, 3.4; 1920-1924, 2.8.

In 1925 both rates rise somewhat and in 1926 again decline.

On the whole, foundries are disappointing in that no substantial decline in the rates has occurred since 1907. The frequency rates, which reflect the condition in minor injury, are high as compared with other naturally more hazardous departments. That this is not necessary is demonstrated by the experience of some important foundry organizations which show satisfactory reductions.

Heavy Rolling

Frequency rates 1910-1914, 46.1; 1915-1919, 32.4; 1920-1924, 21.2. Severity rates 1910-1914, 3.6, 1915-1919, 3.9, 1920-1924, 2.8.

In 1925 frequency again declined but severity slightly rose. In 1926 both rates declined.

Tube Mills

Frequency rates 1910-1914, 40.5; 1915-1919, 22.4; 1920-1924, 22.7. Severity rates 1910-1914, 2.2; 1915-1919, 1.8; 1920-1924, 1.9.

In 1925 both rates declined. In 1926 both rates again declined.

The tube mills show somewhat irregular changes but with a pronounced downward trend.

Fabricating Shops

Frequency rates 1910-1914, 79.9; 1915-1919, 55.2; 1920-1924, 52.7. Severity rates 1910-1914, 3.4; 1915-1919, 2.6; 1920-1924, 2.4.

In 1925 both frequency and severity declined while in 1926 a further decline in frequency was accompanied by a rising severity.

These shops deal with large beams and other fabricated structures which require the use of cranes and hoists. There is always a considerable degree of hazard in the operation of such apparatus so that the results which have been attained are distinctly creditable.

Wire Drawing

Frequency rates 1910-1914, 65.7; 1915-1919, 45.8; 1920-1924, 24.0. Severity rates 1910-1914, 3.2; 1915-1919, 2.6; 1920-1924, 2.3.

In 1925 there was a slight rise in frequency but severity declined. In 1926 both rates declined.

Wire Drawing Severity Rates Are High

Wire drawing is peculiar in that its severity rates for permanent disability are and always have been higher than those for death. This is largely due to the hazard of being entangled in the wire as it is drawn toward the block. A hand so caught is exceedingly liable to be taken off. The rates for permanent disability for the three 5-year periods are 1.9, 1.6, 1.5, reflecting undoubtedly an improved condition due to the replacement of older types of apparatus with newer and safer types.

Electrical Department

Frequency rates 1910-1914, 47.1; 1915-1919, 40.3; 1920-1924, 20.5. Severity rates 1910-1914, 6.3; 1915-1919, 7.2; 1920-1924, 3.0.

In 1925 both rates declined and a further decline took place in 1926.

The high but declining severity in this department is related on the one hand to the danger always present in dealing with electricity and on the other to many improvements in method and equipment which have been made in recent years.

Mechanical Department

Frequency rates 1910-1914, 62.7; 1915-1919, 41.3; 1920-1924, 23.7. Severity rates 1910-1914, 4.0; 1915-1919, 3.5; 1920-1924, 2.8.

In the year 1925 both rates declined. In 1926 frequency increased slightly and severity declined.

Yards

Frequency rates 1910-1914, 50.8; 1915-1919, 37.5; 1920-1924, 24.4. Severity rates 1910-1914, 6.0; 1915-1919, 6.1; 1920-1924, 4.1.

In 1925 both rates increased and in 1926 both declined.

Severity rates in this department are almost as serious as in the blast furnace which is readily recognized as a place of danger. The same difficulty is encountered in the internal transportation of plants which is now being met on our streets and highways and in railway service. The power-driven vehicle

is everywhere a menace. The experience of the yards indicates that however difficult the problem of safeguarding the situation it is not entirely hopeless.

Erection of Structural Steel

Frequency rates 1910-1914, 121.7; 1915-1919, 107.2; 1920-1924, 97.5. Severity rates 1910-1914, 31.4; 1915-1919, 22.3; 1920-1924, 19.9.

In 1925 both rates declined and in 1926 both rose.

The group of steel erectors which it has been possible to follow since 1912 is so small that positive conclusions must be drawn with great caution. However, the results are so uniform as to indicate clearly that this is a very hazardous occupation, probably the most hazardous in which man engages. The indications thus far are that the hazard has lessened only slightly in the course of time.

Two Noteworthy Points of Deduction

It has been necessary in presenting this picture to use a somewhat confusing array of figures but there emerges from them a clear demonstration of two points. (1) The iron and steel industry has accomplished noteworthy results in accident prevention. (2) While the rate of progress has slowed down considerably there is still possibility of further progress.

CHAIRMAN BENNETT: I know we have time yet for some discussion on both of these subjects. I think it is quite fortunate that both sort of tie-up, Mr. Hooks' address and also Dr. Chaney's report.

To open this discussion, I am going to ask the gentlemen present just to give their ideas on the general thought that has been brought out and I am going to call on Mr. Morey, general manager, Commonwealth Steel Company, to give a little summary.

A. T. Morey (Commonwealth Steel Co., Granite City, Ill.): I think Mr. Hook presented the right idea from the standpoint of management and also from the standpoint of a safety matter. He brought out the humanitarian side and also the dollar side. When we started safety work at the Commonwealth Steel Company, our compensation rate was two and one-sixteenth per cent. Mr. Quesnel has advised me that our rate for the first six months of this year is one per cent. That is a tremendous difference, and when that is translated into the difference in the happiness of little children and of the home it really means something.

I am mindful of a story I remember reading in my primer at school about Julius Brand. He was an optimist, who was seeking to learn how to transmute base metals into gold, and in the process of experiment he discovered phosphorous and was really the one who gave us the idea of the match. But I don't know of any more wonderful alchemy than the transmutation of accidents into the beautiful activities of this modern industrial program.

The Advantage Went to the Fellowship Department

While we have made a tremendous saving, that hasn't gone to our stockholders, but has gone to take care of the expense of what we call our "fellowship department." I don't like the word "welfare" either, so we thought the word "fellowship" would be warmer and mean more, and we now have a wonderful school. We have had an apprentice school for many years. It commenced with mechanical drawing and by adding history and English and physics and a few other things, we put on an actual high school program in our plant for the boys who had to leave school to go to work; and last year we had over 90 boys taking this high school course. Sixteen graduated and they were given the diploma from the Uptown High School platform along with the others boys and girls from the local high school.

Some of the men had to quit school in the sixth grade and asked if they couldn't have some help to get up to the eighth, so they could take this high school work. So last year we had 16 in the night class and the superintendent of instruction at Granite City, where our plant is part of the St. Louis industrial district, had a little dinner one night and presented eight diplomas to these men who finished the eighth grade course, and this year they can take the high school course.

It has been this transmutation in the loss and waste of industrial accidents that is an alchemy far finer, I think, than old Julius Brand tried to discover.

I am somewhat concerned with Dr. Chaney's figures with regard to ourselves as a steel foundry. I felt some comfort when he said that there were individual plants which had shown progress. I do think we have. However, I hope I am not partial. I like Dr. Chaney's thought that among hazards the steel foundry is not greater than the hazard of the rolling mill.

In our plant we have some 26 overhead cranes. There is a great deal of material moving overhead. A steel foundry is not quite so amenable to the constructive processes that the rolls permit. I really don't know for sure. What do you think, Dr. Chaney? Does this mean less hazard in the foundries or have they a more hazardous problem?

DR. CHANEY: It is probably not more hazardous than the blast furnace. Let me say, if I am permitted, that the Commonwealth Steel Company belongs to the progressive class. Let us admit, however, foundry men, that the problem is greater.

MR. MOREY: Doesn't that call, as Mr. Hook said, for a greater challenge to a greater hazard? Doesn't it simply mean, the finer the organization, the more intensive the study of accident prevention?

We have divided our plant into 35 divisions for safety purposes. It is very evident that the laboratory has less of a problem than the foundry and there was some little feeling that credits were not being given out wisely. Here is a superintendent who has a tremendously hazardous problem, and this other man hasn't; when the figures are read out of the record pattern book, for instance, for a small number of lost-time accidents, he feels it isn't a rightful comparison.

Long Records in Accident Prevention

The pipe fitters' squad has gone over four years without a lost-time accident. During that period they put up 62 miles, placed end to end, of steam pipes and now have the entire plant steam heated.

The wood pattern shop has gone two years without a single lost-time accident; and the whole shop has gone one year without a lost-time accident.

When these instances were read, these men said we were hardly fair, because their problems were greater. So we thought about it and we have come to this conclusion. When the problem is greater it calls for more intelligent supervising, planning, thinking about the problems and taking them by units. We came to the conclusion that there was no difference. Just because a group was smaller, that was no reason why a larger group should have more accidents. The larger groups had to be divided into units; and getting down to the unit idea, we felt the credit should be confined to the units, and I think we have met that condition in that way.

When a man says he has 200 men and another fellow says he has only 20, all right, divide your 200 into so many units of 20 each and then get your organizing ability to work. I think we can meet that problem in that manner.

Isn't it a wonderful movement to be connected with? Can't we be happy? I was one of that number in 1912 in Milwaukee, when the Iron and Steel Electrical Engineers under Mr. Palmer gave us that invitation for a safety section, and we met and organized a council. What a wonderful thing it is and I am surely thankful from the bottom of my heart for all the splendid cooperation and that we have been participants in this marvelous and gratifying work. I congratulate you.

CHAIRMAN BENNETT: The meeting is now open for discussion. We have considerable time left and I know that Dr. Chaney will be glad to answer any questions and also Mr. Hook. I am also glad that Mr. Morey mentioned foundries. I happen to represent a foundry myself. I was rather uncomfortable sitting over here.

JOHN A. OARTEL (Carnegie Steel Co., Pittsburgh, Pa.): I rise in the capacity of an old timer who has worked in the mills and has seen a very remarkable change. I have seen changes in processes, mechanical, electrical and chemical.

Last June it was my privilege and very great pleasure to stand in the motor room in our Homestead Plant in a crowd of a thousand men from the Association of Iron and Steel Electrical Engineers. They stood there expectant and waiting because the late Judge Gary, down in New York City, had been asked to pass his hand over a contrivance that would start that mill, and we saw the motor begin to turn. That was an event in a lifetime, to see a thing like that.

A Bigger and Better Change Came with Safety

That is just one of the changes that have come into our steel mill. Yet there is a bigger and a better change which has come with safety, and safety has helped to bring it—a better feeling, better production, as Mr. Hook says.

Six or eight months ago, it was my privilege to eat lunch at a Rotary Club with the superintendent of a large industrial railroad that brings in the ore, coke and limestone for a large group of steel mills in Pittsburgh, and they had been doing some mighty fine safety work recently. I got the superintendent of this railroad to talk about safety. He said, "Do you know, since this railroad of mine has been doing so much fine safety work, there is a better feeling all around? We are moving more cars since we have been doing such fine safety work."

So, when Mr. Hook says that it is a good thing all around, I want to add my testimony to that.

I want to welcome Mr. Hook and his American Rolling Mills. We need them and we are sure they have this mighty mind and spirit and that we are going to have better safety in Western Pennsylvania, and we are pretty much up to date in safety there now.

The Foundry Superintendent Also Got Busy

N. W. BRADFIELD (Industrial Works, Bay City, Mich.): I don't believe the foundry offers a problem that we can stop. Up at our plant we had the same condition. All other units seemed to be entirely satisfactory but the problem was something that I couldn't handle. I solicited the aid of the plant superintendent and of the managers. The matter of the foundry came up. The foundry superintendent was called to his office and was told, "Every other unit in this plant is entirely satisfactory. The foundry is not. It appears that you lack entirely the ability to take hold of this lost-time accident situation and I want you to do better. I want you to go for a month without a lost-time accident." He went over that month and for several months, and from that time on we haven't had a lost-time accident. I think the foundry problem is just due to lack of interest on the part of the foundry men to take hold of the different parts of the plan.

G. H. McCLAIN (Jones & Laughlin Steel Co., Pittsburgh, Pa.): Since our meeting is turning into a bit of an experience meeting, I want to say that Mr. Hook said something that I have been trying to find expression for for a long time. That is the introduction of that idea of the college spirit in the plant. If he has any doubt about whether or not his little trip up here has been a success, I would like to assure him that it has, because I am one of those safety engineers that he has been talking about and talking to this morning. I received a great inspiration from what he said.

In our jobs, we have a few knock-downs, and we get defeated now and then; and we get into a little narrow place and forget about the other fellow. There is a tendency to go back and lose heart.

You know we have to go to church every now and then in order to keep our religious level up to where our chances will be pretty good on the last great call. It seems to be a sort of habit with us and if we don't go for a long time because we have had too much Sunday work (I'm speaking of the steel men now exclusively), then it is all the easier to keep on staying away from church, and perhaps that is why our morals are not quite up to snuff.

Now, when we come to these meetings and hear such things as Mr. Hook and Mr. Morey have given us this morning, why we go back all rejuvenated; and we are just boiling over and ready to deal with any emergency that arises. I would like to say that I appreciate very much everything which Mr. Hook said and he was talking directly to me. If there had been no one else in the hall but him and me, his speech would have been a success.

CHAIRMAN BENNETT: I remember Mr. Bush, our president, one time saying that there is never a talk or argument but what someone gets good out of it. I know Mr. Hook was talking to me and a lot of us fellows this morning.

The Backbone of Safety Lies with the Executives

J. A. VOSS (Central Alloy Steel Corporation, Massillon, Ohio): We have heard some wonderful expressions this morning from executives along the lines of safety. Every safety man will agree that the backbone of the safety movement starts in the executive offices. We all know that. We know that if our executives back us up, we are going to get real results.

I think that before we adjourn we should pay, as safety men, our tribute to the executives who have made this safety work so successful; and I suggest that we do a rising vote of thanks to all these executives.

(A rising vote of thanks was extended to the executives.)

FRANK LAMB (Industrial Commission of Columbus, Ohio): I think that was a splendid tribute to Mr. Hook and Mr. Morey and these other executives, who have all contributed to better life in our American industry; and I feel that the meeting would not be complete if the same tribute were not rendered to another who has contributed so nobly and so well to advancement of safety in the iron and steel industry. I refer to Dr. Chaney; and I would like to make a motion that this meeting, by a standing vote, approve and thank Dr. Chaney for the wonderful work he has done in building up accident prevention and helping to make a safer iron and steel industry.

(The motion was seconded and a rising vote was extended to Dr. Chaney.)

CHAIRMAN BENNETT: I know we would like to hear just a few words from one of the men who had a lot to do with this success and we are glad to have him here. He is Mr. Tom McKenney.

T. H. MCKENNEY (Illinois Steel Co., Chicago, Ill.): Unfortunately, I was unable to get here early today. That is one of the disadvantages of holding a convention in your home town. Everybody tries to hook you at the time you want to be away.

I didn't hear the address of Mr. Hook and only got the latter part of Dr. Chaney's, but I have had the privilege of listening to them on a few occasions and whatever they said I know was all right.

I don't know that I have a great deal to say, when they call the foundry the most hazardous occupation. When we first started into safety movement, all departments were the most hazardous. The open hearth with its high accidents was the

most hazardous. The blast furnace was the most hazardous. There is no such thing in safety work today as the most hazardous.

I believe one of the speakers brought out the point that if you have a hazardous department you have got to put a little more work in there and bring it out. I don't think we should allow anybody to bring up an excuse and say, "I have the most hazardous work."

CHARLES W. HANKO (Pittsburgh Steel Co., Monessen, Pa.): Before my present connection, I was with the Department of Labor and I used to get into quite a number of the foundries in that district and I found it the same as in every other industry; wherever there wasn't a concentrated effort put onto safety, the records were not so good. I think the trouble with the foundry today is that there are too many men of the old school who are not so interested in safety as they are in production, and the result is that there are more accidents occurring in the foundry.

The Plant With a Bad Accident Record

I recall one plant in particular where their accident record was rather bad, and I talked to their superintendent, who was lukewarm on the subject. I had to go so far as to threaten to have the law onto him. The result was he came along; and I met him after leaving the State Department and he thanked me for making that threat, for he had accomplished what I had asked him to do and the results were wonderful. I think in the foundry a more concentrated effort should be put on safety work.

Another thing is your modern machinery in the foundry, where you have an unskilled man on a machine and then ask him (in some cases, not in all), to rush through the work. I think before an unskilled man is put on a machine he should be given further instructions along the safety line. Foundry lost-time accidents, with concentrated effort, won't be so numerous as they are today.

Mr. H. H. HARRIS, Master Machine Tool Engineer, Erie, Pa., speaking generally as to what both of the speakers had said, said that he did not entirely agree with them, about the same thing with which I do not exactly agree.

There are many activities in the foundry that have to do with safety. But there is a part of it which cannot come under the heading of safety. I happen to have a title a part of which is "welfare."

At almost every safety meeting which I have had the privilege of attending, some gentleman has gotten up and said that he didn't like the word "welfare." Some of these days some bold fellow is going to get up and say he doesn't like the word "safety" and we are going to have to get some other name under which to carry on this great work. In the organization which I have the pleasure of representing we do a great deal of so-called welfare work and I want to say to you that we need no other name for it. It is welfare work, pure and simple, and our men understand it as such; and, I, for one, would like to have them quit picking on that welfare word and leave the name as it is. It is a grand and glorious work and rivals the so-called safety work in which I am also vitally interested.

The Word "Welfare" May Be Misunderstood

MR. MOREY: I would like to apologize, Mr. Harris. I think in the early days the word "welfare" was used in some connections where there was a great deal of paternalism and I think I got a little prejudiced along that line. You have established a beautiful idea, so I graciously apologize.

MR. HOOK: May I likewise accept my spanking graciously and cheerfully? There is undoubtedly a prejudice which arose on the part of a good many of us as a result of the old time so-called "welfare" work when it was very paternal. We feel that

really all this work is what we term "mutual interest work," in other words, we are mutually benefited.

One of the great corporations that we know of originally started "welfare" and I remember with very disastrous results. I remember that the president said that in order for his men to be fit and ready for their jobs they should go to bed early, they should rise early in the morning; they had to do this and they had to do that, and he was giving them this great opportunity. He was doing this for them and he was doing that for them. Well, they were doing a lot for him, too, believe me. There isn't any executive today, especially in the large corporations, who can get very far by himself. We can sit down at our little table and plan and scheme, but after the scheme is passed on, unless we get the wholehearted cooperation of all those down the line, believe me, our scheme is apt to go up in the air; and so it seems to us that this is all mutual interest work. We are mutually interested in it; we are mutually benefited by it. The man on the job is getting no more out of it than the company is getting out of it and that is the thought we had in mind doing away with that word "welfare" because we thought it referred to the old plan, the old scheme.

The Outline of One Plant's Improvement

H. HENRY (The Mansfield Sheet & Tin Plate Co., Mansfield, Ohio): I want to say that both speakers this morning have been of great benefit to me. I heard an inspirational address about ten years ago and this is the first of its kind since that time.

In the face of a rising accident record from a period back in 1921, we engaged in the usual procedure and were spending a vast amount of money on education we found that our accidents were constantly increasing year by year. In 1924 we had an average of 35 lost-time accidents a month and up until October 1, 1925, we had 28 lost-time accidents per month.

Our president came up there and he got up and gave us a little talking to, saying he was very much surprised at us and thought it was a natural thing for any superintendent or foreman to take his men and speak to them of safety and accident prevention.

He wanted me to prove this, so I sent out a questionnaire as to the proper method of instruction and he found that we had approximately the same ratio of lost-time accidents. There were only 26 or 27 reported and they were worse than ourselves, and he wondered what he should do. He got up and told them he was interested in accident prevention work around the plant. He told them he wanted a personal report on every lost-time accident; he was going to hold the foreman responsible; he wanted to know what means were used to prevent a recurrence.

Due to the combined efforts of management and men, lost-time accidents immediately dropped. The average lost-time accidents per month in 1925 had been 28. We had 12 in October, three in November and two in December. In 1926 they were cut to six and one-half, or a decrease of 69 per cent in one year, and in two years, 79 per cent.

CHAIRMAN BENNETT: It is getting close to the time for adjournment, but in conclusion, I think, Dr. Chaney, you have been impressed somewhat with the remarks. They show that the statistics help; that they are using them.

It want to ask this one question, Doctor. Are you getting a better response in your department from the industries in the way of returning your blanks and forms which you have always requested and asked for? Has it been improving? I mean the frequency rate of reports.

DR. CHANEY: It happens that we got in on the game at a very fortunate moment in regard to history, so we have the great majority of the plants in the industry.

We have had over the entire period practically everything that they had. We are managing to add, from year to year, concerns which haven't cooperated with us before so that there is a very definite improvement in the returns.

We could ask, I think, with some earnestness, that they be sent more promptly. As I remarked in the course of my paper, we have just gotten to the point of sending to the press the report for 1926. I think that is about six months late, as we ought to be able to catch up things at least six months earlier than we are. The difficulty lies in the fact that just a few plants fail to respond, which holds the thing back, although all the rest of them may have sent in their responses. We want to get everything in and we feel that it is more important to include everything which is ordinarily being sent to us than it is to hasten the completion of the report. So we do feel that those who are charged with the responsibility of making reports could be a little more prompt than they are and it would help us a great deal.

ADJOURNMENT.

Wednesday, September 28, 1927

The second session was called to order at nine-forty o'clock by the chairman, F. G. Bennett.

CHAIRMAN BENNETT: The first order of business will be to proceed with the election of the officers and get a report of the Nominating Committee. Mr. J. M. Woltz, the chairman, was called home on account of a death in the family and turned the report over to me to read.

Report of the Nominating Committee

At a meeting of your Nominating Committee held at the Hotel Traymore, Atlantic City, July 16th, 1927, the following persons were selected for nomination as officers of the Metals Section of the National Safety Council for 1928:

Chairman, J. A. Northwood, Bethlehem Steel Company, Johnstown, Pa.; Vice Chairman, E. G. Quesnel, Commonwealth Steel Company, Granite City, Ill.; Secretary, John P. Eib, Illinois Steel Company, Joliet, Ill.

In accordance with the resolutions passed by the Executive Committee of the National Safety Council, your committee, and through consultation with the present and proposed officers and executive committee, further recommend the following persons for the positions set forth:

Chairman Membership Committee, Frank H. Rowe, Wheeling Steel Corporation, Portsmouth, Ohio; Chairman Poster Committee, C. L. Peake, American Radiator Company, Buffalo, N. Y.; Chairman Publicity Committee, Jos. A. Voss, Central Alloy Steel Company, Massillon, Ohio; Chairman Statistics Committee, H. G. Hensel, The Youngstown Sheet & Tube Company, Chicago, Ill.; Chairman Slide Committee, John A. Oartel, Carnegie Steel Company, Pittsburgh, Pa.; Chairman Program Committee, E. F. Blank, Jones & Laughlin Steel Corporation, Pittsburgh, Pa.; Editor News Letter, Secretary John P. Eib, Illinois Steel Company, Joliet, Ill.; Engineering Representative, J. T. MacBain, Electro-Metallurgical Co., New York City.

Executive Committee—Retiring Chairman, F. G. Bennett, Buckeye Steel Castings Company, Columbus, Ohio; Ex-officio Chairman, J. A. Northwood, Bethlehem Steel Company, Johnstown, Pa.; Vice Chairman, E. G. Quesnel, Commonwealth Steel Company, Granite City, Ill.; Secretary, John P. Eib, Illinois Steel Company, Joliet, Ill.; Past Chairman, T. H. McKinney, Illinois Steel Company, South Chicago, Ill.; Past Chairman, John A. Oartel, Carnegie Steel Company, Pittsburgh, Pa.; Past Chairman, J. M. Woltz, Youngstown Sheet & Tube Company, Youngstown, Ohio; J. E. Culliney, Bethlehem Steel Corporation, Bethlehem, Pa.; John P. Mudd, Midvale Steel Company, Nicetown, Philadelphia, Pa., and E. R. Rose, Republic Iron and Steel Co., Youngstown, O.

We have interviewed those gentlemen whom we have recommended as your officers and have their consent to serve.

We have been very careful in our recommendations to consult as fully with the membership as our opportunities permitted and herewith submit our report for your consideration.

J. M. Woltz, Chairman.
J. E. Culliney.
C. L. Peake.

CHAIRMAN BENNETT: That is the new committee which was recommended by the National Council Executive Committee.

JOHN A. OARTEL (Carnegie Steel Co., Pittsburgh, Pa.): I move the nominations be adopted unanimously and the secretary cast the ballot.

A. W. BANNER (Carnegie Steel Works, Pittsburgh, Pa.): I second the motion.

CHAIRMAN BENNETT: You have heard the motion duly made and seconded that the report of the Nominating Committee be unanimously accepted and the secretary cast the ballot for the persons nominated. Are there any remarks? If not, the question has been called.

(The motion was voted upon and carried.)

CHAIRMAN BENNETT: It is my plan tomorrow, at a portion of the session to present the incoming officers of the Section and have Mr. Northwood take charge of at least the latter part of the program. I think it is well for the incoming officers to get acquainted with the members of the Section for they need their cooperation for the coming year.

E. G. QUESNEL (Commonwealth Steel Co., Granite City, Ill.): The ballot has been officially cast as ordered.

CHAIRMAN BENNETT: Our first talk this morning will be under the general group of talks direct from the shops. It is quite appropriate and we will now hear from Mr. Al Jaco, foreman, Commonwealth Steel Company, Granite City, Ill.

Safety as a Foreman Sees It

Alvin Jaco, Foreman,
Commonwealth Steel Company, Granite City, Ill.

I have been asked to discuss shop impressions of safety as a foreman sees it. Being a foreman, myself, I hope you will appreciate my position and realize that I am looking out from a situation that most of you are looking in on. Therefore, if we, as foremen, sometimes seem indifferent or apparently non-responsive, please do not criticize us too severely, for we may not have the same perspective of safety.

I am sure we all agree that close, friendly contact must be maintained between the management, safety department and the shop. This contact should be so elastic and practical that it is just as effective during the rush period as when the shop is running normally or even a little slack.

A good approach is essential in presenting safety and generally assures fair consideration. In this connection, let us not forget that things are accepted and done in most shops in a matter-of-fact sort of way. Work is more or less routine and most men have their minds pretty well made up as to what they are going to do and how they think it best to do it. This means that safety suggestions that are intended in any way to change this routine are often received with a certain amount of reservation, unless they in some way appeal to the practical side of the employee. Safety suggestions that succeed are those that are plain, practical and definite. They should carry with them the atmosphere of the shop and never cause resentment. A simple request accompanied by a reason for it goes much farther than an order without an explanation. Poorly thought out instructions often fall short. This is to be avoided. A good foreman will guard against such a situation.

Foremen do not like rules in the shop which are obsolete, impractical, and only effective once in a while. To wink at a safety rule and allow it to be disregarded is a dangerous practice. Besides, it hurts the morale of the shop, causing a certain amount of disrespect in the minds of the men for other rules. If a rule is not operative or practical and is not to be enforced—get rid of it. It is better to have a few rules that are operative than a lot of them that are not. We would like to see our safety rule books revised fre-

quently, and would like to know that when we give them to our men that every rule in the book is to be enforced. This gives us confidence in carrying out instructions, removes the chance for argument, as well as eliminates doubt from the minds of our men as to which rules are to be obeyed and which are to be disregarded.

At the Commonwealth, with our some 3,000 men, we like to think of safety as the right and orderly way of doing things. This makes it a necessary part of our operation and a very material aid to our shop efficiency.

Safety being an operative problem, every foreman must consider accidents in his department as an indication that something has gone wrong. This makes him feel a personal responsibility for the safety of his men. He must also realize that accidents are a heavy burden on shop costs as well as affecting the morals of his force.

If we, as foremen, are to maintain a no-accident record in our department, we surely must have all our men sold on the safety idea and see that they are satisfied, for usually a satisfied workman makes for safe workmen. Our job as foremen, therefore, is to keep in close touch with our men, think with them and work with them, being always ready to give counsel and advice but slow to criticize. In our plant we try to lead our men by practicing fellowship at all times for we have found that most men are splendid fellows when we know and understand them.

Good Housekeeping Pleases the Employee

The average employee today is keenly interested in a good, orderly place to work, modern machinery and a foreman who is not only friendly, but looks out for his interest and gives him a square deal. Let us be sure, however, not to confuse friendliness with familiarity. No foreman can long maintain his prestige if he becomes familiar with his men. He must safeguard the dignity of his position, maintain discipline, be impartial, and demand of even his best friends the best that they can do. In fact, this is the only way he can help his men succeed. No progress was ever made by accepting an indifferent effort. If a foreman discovers that some rule is being violated or work is being carelessly done, he should not make the mistake of correcting his men too strongly in the presence of others. It is much better to call him aside, thus avoiding any chance of humiliating the man. Nine times out of ten, an employee will show his appreciation by correcting the fault.

The safety department should feel that the foreman is one of their representatives in the shop, acting in the capacity of a safety director over his particular group, for safety among his men is usually in proportion to the foreman's ability to interpret it correctly for them. The men interpret the management's sincerity in their behalf through their foreman, for what the workman thinks of the foreman, he also thinks of his company. Is he just or unjust, friendly or unfriendly, interested in safety or indifferent to it? As the foreman, so the workman.

What will make men stop being careless and begin to be careful? My answer would be—a good foreman, one who is sold on the safety idea and knows how to interpret it to his men. He will spare no effort to see that men thoroughly understand their work, their machines, and their company. He will point out the hazards to be avoided, safe ways to do their work, how to wear their clothing, and insist on their reporting to him at once any hazardous conditions discovered.

The greatest asset a foreman has is the men in his department who are careful and efficient. All others are liabilities and it is his job to convert

these liabilities into assets—if he cannot do so, to have such men transferred or replaced. If he makes no effort to do either, is indifferent to the human side of his job, he is not a good foreman, and his department accident and production record will show it.

I was talking to a colored man not long ago about his shoes, as he seemed to be having a hard time getting around, and discovered that he had allowed his heels to wear very badly on one side. I suggested to him that probably if he would keep his heels level he would find walking more comfortable. He had never thought of this and said he would try it. A few weeks later he said to me, "Boss, you shore done me a good turn. Ah got them heels fixed and mah feet are all right now." So we don't know sometimes, just what a little interest in our men will do.

Inefficiency May Be Caused by Defective Sight

At another time, we noted that one of our men was not bringing his work up to standard and after watching him closely for a few days, discovered it was not caused by lack of interest. He seemed to be trying but stopped frequently to rub his hands over his forehead. The thought occurred to us, that perhaps he had headaches, so he was sent to the doctor for examination. It was found that his eyes were weak. He was fitted with proper glasses and from that time on his work has been entirely satisfactory. Without studying this case, this man might have been discharged without being given a fair chance to make good. I mention these two instances to bring out the point of how essential it is to be close enough to your men to understand them.

Men are apt to lose interest and become careless in doing work they do not like, caused generally by lack of necessary qualifications for that particular job. This creates a hazard. A wide awake foreman will be quick to discover the trouble, and use his influence in having such men reclassified and placed on more suitable work. For instance, we place on our heat crane only men who are quick to think and to act, so that if any emergency occurs they may be depended upon to do the right thing at the right time.

When all these things have been done, we find that we have eliminated most of our major accidents; however, we have remaining the things that seem to be the least important which are causing the greatest number of men to lose time. These types of accidents are much the same in the steel foundry, paper mills, or in the merchant marine, and are familiar to every one of us: dropping material on hands and feet, not keeping hands and feet in the clear, taking unnecessary chance with the eyes, etc. The only way we are going to stop this class of accidents is to train our men to keep their minds on what they are doing. Our job as foremen is to interpret the best thoughts that can be secured on safety from our own safety department and other sources, in such a way, that our men will not only understand them, but will carry them out.

I have purposely said little about the inspirational approach of safety, feeling that we are all in accord in reference to the importance of this approach. Also, that this phase of safety will be more ably covered by other speakers at this Congress, they being better qualified than I to present it to you.

My thought, as foreman, is that inspirational appeals should be tactfully made. Most men are very receptive to the human side of life and to reach them effectively, a time must be selected when they are at ease and can safely divert their thoughts from their work. An approach through their home, plant magazine, safety meetings, or personal counsel in private, is the most effective way to reach them, for they at such times have a better perspective, not only of their work, but of other problems of life. I think that is why many

of us fall down in handling men is because we do not pay enough attention to the psychological effect of our remarks. They should be timely made and in the proper place. In other words, put the sugar in your coffee and the salt in your soup; each is fine when properly used, but what a mistake when they are not.

In closing, I leave with you the thought that the foreman has a very important place in the safety organization of any plant. He should consider himself a part of it and, being on the receiving end, should be sure that he correctly understands instructions before passing them on to his men. He should keep the thought constantly before him that human life is a precious thing, and like a flower, needs care, protection and training in order to develop and grow in service.

The foreman who sets his heart and mind to the prevention of accidents and has the humility to be guided by wisdom and truth will not only be a success, but will be honored and respected by both his company and his men.

CHAIRMAN BENNETT: We will hold our discussion until the end of the program so as to get our papers all before you first and then we can take the time that is left for the discussion of all the papers.

Our next paper will be one that should be of interest to a great many of us dealing with one of the specific operations of our metals section, blast furnaces. The subject is "Safe Practices at the Blast Furnace" by Lawrence H. Underwood, superintendent, coke plant and blast furnaces, Youngstown Sheet & Tube Company, East Chicago, Ind.

Accident Prevention at Blast Furnaces

Lawrence H. Underwood, Superintendent, Coke Plant and Blast Furnaces, Youngstown Sheet & Tube Co., East Chicago, Ind.

It is a far cry from the primitive blast furnace—where the native trod a goat skin to produce blast, the semi-molten mass inside a small mound of clay was allowed to cool and the front of the furnace torn out to recover the lump of iron—to the modern blast furnace.

As late a book as John Percy's "Metallurgy of Iron," written in 1864, describes a blast furnace accident of the 1830's, in which a dwelling house and a blast furnace had a common stone wall and an entire family was asphyxiated one night, no doubt by a crack developing in this common wall and allowing gas to enter the house.

A blast furnace plant consisting of even a single stack, offers possibly the largest chance for "mass accidents" of any metallurgical operation. I believe it is quite safe to say that we have passed the high accident peak in blast furnace operation and that this peak is now about fifteen years behind us.

In enumerating possible causes of blast furnace accidents, many weaknesses of design and operation must necessarily be touched upon, which have been remedied in many of our more modern plants, but which still exist in others.

We will first consider accident possibilities resulting from weak or poor design. The hearth, or crucible, of a furnace is that part which lies below the tuyeres. The slag and iron continually being made, accumulate in this part until the proper time for withdrawing them. In furnaces making 800 tons of iron in twenty-four hours and casting at six-hour intervals, the average cast would be approximately 200 tons. The cinder, or slag is tapped generally two or three times between casts, but a large amount is in the furnace just prior to the cast. The danger can readily be realized, if even a part of this accumulation of molten materials fails to be confined until the proper period of withdrawal.

Hearth accidents may occur in a number of ways. First, by the iron working down and coming out underneath the hearth jacket and column base ring. One serious accident of this kind occurred in 1921 with loss of lives, where the explosion resulting from iron working its way down and coming in contact with water, tore a large hole completely under the column base and then up through the cast house floor. I visited this plant shortly after and stood on the top of the wooden piling on the center line of the furnace some thirty feet below the tuyere. It is very general now to put considerably more brickwork between the concrete foundation and the bottom of the hearth and also to put a heavy girdle, either of steel plate, bands or reinforced concrete outside of the column base and down to the concrete foundation. Incidentally warning should be given against using a limestone aggregate in the concrete foundations under the furnace.

The Iron Escaped Through the Furnace Bottom

At another plant, within the past year, a new furnace lost its iron through the bottom for a period of two or three casts. The furnace was shut down for several days and no damage resulted, except the loss of product and the lost iron was never visible at any point. In this connection, it has been thought that, with the advent of large hearth furnaces, it might be wise to eliminate the horizontal joints in brickwork up to the bottom of the hearth, because of the possibility of floating the layers of brick, when laid with horizontal joints. While this idea seems logical, peculiarly enough, this method was employed in the last mentioned case.

The next class of hearth trouble is a breakout through the hearth walls and jacket. This should be remedied generally by the proper type of jacket. One type which has been successful, is very heavy cast iron sections, with steel pipe cast in for the cooling water. Another type, is the same jacket with a lining inside of cooling staves, which are narrow cast iron sections of sufficient thickness to permit steel pipe to be cast in. Another type has a very heavy steel plate jacket with the cast iron cooling staves inside of it. In some localities, where there is a large amount of slag handled per ton of iron produced, they are experimenting with a special very highly refractory fused Alumina brick for hearth lining. It is essential, that whatever hearth protection is used, external bands of heavy steel or reinforced concrete must hold the hearth jacket and lining from expanding and permitting cracks to develop.

It was customary, some years ago, to have a ditch around the hearth with water in it. The writer had the experience one time of looking down into such a ditch and seeing a red spot at the bottom. It took but a split second to see it growing, to realize it was molten iron coming up, and then to depart. Peculiarly the iron chilled and there was no explosion. I believe there should be no ditch nor water around the hearth jacket, and only the shallowest trench, which drains immediately, for taking away water incidental to a turned down tuyere, or that put on the outside of a burned tuyere, blow pipe, etc. It may seem that a good deal of time has been devoted to the bottom of the furnace, but when it is realized that weakness and accident here are very apt to cause heavy casualties as well as possibilities of putting a furnace entirely out of business, it behooves every management to spare no expense at this point.

Around the tuyere zone there are always numerous cooling plates which protect this region very well, if a suitable jacket encloses this section. The strongest and simplest construction is a heavy rolled plate jacket and this is also, I believe, the safest, for it lends itself readily to a cast steel tuyere cooler holder. This holder has two large lugs cast on it, which receive "L" shaped forgings which will prevent the cooler from blowing out, but which can easily be removed when necessary. Unfortunately, many safety measures have not resulted from a visualization of possible accidents, but are developments brought about by trying to

prevent a repetition of some fatal accident. Such was the circumstances which led to the design by the writer, of the safety lugs on this cooler holder. The lives of two men, one a very experienced general foreman, were lost by a violent tuyere explosion which blew the tuyere and a tuyere cooler, weighing 500 pounds, across the cast house floor. The hook end of the bridle was straightened out and the tuyere stock was pushed back to allow the passage of the cooler through the air.

A fatal accident occurred within the past two years, due to the failure of tuyere stock hangers, and at this plant they have provided a third hanger for further safety. This accident will be referred to later under operation.

The bands on the bosh, which is that section of the furnace between the tyeres, and the mantle, have been increased in size, exceptionally in the past 10 or 15 years. There was a very bad mass accident in the Pittsburgh district about 13 years ago, in which a heavy slip broke out a large section of bosh and killed a number of men. The extra expense of very heavy bands over light ones is negligible, and no scrimping at this point should be tolerated.

Likewise the shells of the furnaces today, in this country, have been strengthened to a point which was almost undreamed of 25 years ago. A very serious accident occurred within the past two years, when a furnace was being blown out and the shell gave way a short distance above the mantle and a number of men were killed and many injured. This would be improbable with shells of most modern construction.

An Efficient Distributing Top Is Important

A most important item, having a bearing upon the safe and smooth operation of a blast furnace, is an efficient distributing top which gives a uniform distribution of coarse and fine materials entering the top of the furnace. I believe that, while a distributing top is not a panacea for blast furnace troubles, a great many accidents to furnace employees have been caused, indirectly, by poor distribution of coke, stone, ore and other material charged.

Guarding against falling materials is an important part of accident prevention around a blast furnace. A type of bleeder valve, which permits only dust and quite small particles from the stock column to be thrown out when a slip occurs, is in quite extensive use. Covering the underside of a skip incline to prevent material falling upon men passing under the skip is very desirable.

Under the term accessibility will come a number of items, which in the past have been sadly neglected. Some years ago, a new furnace was put into operation with no means of getting to the top, except by a vertical ladder without back guard on the side of one of the stoves, or by going up on a skip. After a foreman was killed riding the skip, a stairway was erected. At some plants, elevators are now installed and I believe they can be classed, partly at least, as a safety measure. If a man gets hurt or gassed on top, it provides quick means for help to get on top and also a quick and safer way to get the injured man down. Some men become very wild under the effect of carbon monoxide gas and it is not the safest thing for others to take such a man down, even a well designed stairway. Where gas is apt to be present, I believe every effort should be made to provide stairways instead of ladders.

Under this heading would also come proper stairways to the top of the bustle pipe, and, if cooling plates are used above the mantle, to the platforms above the mantle. Also under this heading would come proper and safe means of descending into skip pits. All pits have to be cleaned, most of them daily. Yet the provisions for getting into some of them, would lead one to think the designer expected them to be used about once a year.

Proper handrailings, where the tops of large mains are used for walkways would

seem to require no mention, but a fatality occurred within the past three years on a supposedly modern plant, because of the lack of such protection. A large gas main which required fairly frequent cleaning by means of a water jet, introduced through small holes on top, was being so cleaned. One of the men got enough gas to cause him to fall to the ground. There was no handrailing along this main, but men were supposed to wear life belts. Proper handrailings have since been installed.

The use of water seals in gas mains have long been in vogue, for operation purposes and no doubt have been at times relied upon to protect men working in mains beyond. This is absolutely unsafe. Nothing less than a positive shut off should be relied upon, the safest of these being a steel plate, in some form of goggle valve. There are now on the market different forms of mechanically operated goggle valves which afford a quick shut off.

Self cleaning platforms around the bleeders on top of the furnace and the various walkways necessary on top, are much safer than the type which hold material thrown out of the top of the furnace. The latter become filled to overflowing and it frequently becomes necessary for men to use them before they can be cleaned. Parallel flat bars, laid with edge up and a proper distance apart are very satisfactory for this purpose.

Lubrication By Leading Pipes

In the stockhouse where drums are used in the bin system, lubrication of the bearings is most safely done by leading pipes down near enough to the floor or platform, with alemite or similar connections, so the oilers need not get near the moving machinery. This also is very applicable to moving parts on top of the furnace.

We will now lay aside safety in construction and devote a short time to accidents of operation and possibilities of preventing them. The writer of a paper, such as this, is confronted by the problem of having, as hearers and readers, not only men who have had a life time of experience in blast furnace work, but men who have had very little direct contact with this phase of metallurgical operations. A treatise on accident prevention may cover a great multitude of accidents and ways to prevent them, which would present very little new information to the skilled furnace operators, but which may be a guide to men of indirect contact with, or possibly about to be connected with, blast furnace work. The writer does not believe it is desirable in this paper to try to cover the usual safe practices, but rather to try to dwell upon a few items that may possibly be new to some operators and to some safety directors, in the hope that possibly someone of the items may be the cause of steps being taken, which will prevent accidents.

The Youngstown Sheet and Tube Company, at its Indiana Harbor Works, Blast Furnace Department, has completed in the past year a central oxygen station. In the past, as was customary in most blast furnace plants, we took all oxygen cylinders to the cast houses. The new central station is located half way between the furnaces and at the yard level. There is a brick house with substantial concrete roof, in which is located a manifold, to which ten oxygen tanks are connected at all times. This manifold is divided by suitable valves, so that five tanks are open on the lines going to the blast furnaces and five full tanks are in reserve. It takes only a moment to throw the five full tanks on the line when the other five tanks are exhausted. The exhausted tanks are removed and five full tanks connected and are then ready for use when needed. The lines from this central house to the cast houses are extra heavy pipe and were very carefully freed from oil before being used. The pipe lines are carried in well protected locations and there are three outlets in each cast house. Suitable signs are placed in the central station and at the various outlets, worded, "Compressed Oxygen, do not use any oil or grease." In the central house,

on each manifold, are suitable regulating valves which maintain a constant safe pressure.

We believe that this is a much safer way to use oxygen at blast furnaces, than having the oxygen cylinders in the cast houses, where there is always a chance for metal, slag or flames to come in contact with them. It is also a labor saver, eliminating the lifting of tanks to the cast house floors. With the central station, there is a minimum of handling, as the tanks can be delivered by truck from the storehouse to the station, all at yard level. Many plants have no pressure regulators on the individual tanks used at the cast houses and this practice is avoided by the central station. In some emergencies, a continuous flow of more than one tank capacity is very desirable and valuable time is often lost changing to a full tank, which gives another advantage to the central station.

The crossing of iron and cinder runners by cast house men is a hazard, when the runners are full of iron or cinder. Sometimes these runners are crossed by men who are not regular or skilled cast house men, and in this case the hazard is greater. We have provided safety crossings at our furnaces and believe that it is very advisable, especially when the crossing has to be made in front of the iron hole or cinder notch. I presume many blast furnace operators have seen, at different times, a sudden dislodgment of accumulation in the tapping hole, which resulted in a shower of hot coke and sparks down a considerable part of the cast house. A man crossing a runner in front of the iron hole at such a time would be in great danger. I once saw a man attempt to cross an iron runner and land one foot on the far side of the runner. His foot slipped and was immersed in the molten iron. Of course, many will say that there should be a rule against crossing a runner with iron or cinder in it, but I believe in establishing well protected, safe crossings, rather than depending upon enforcing a rule which is apt to be violated, especially in times of emergency.

Another safety feature which is not universally adopted is that of lifting the iron or cinder runner gates by means of cables from a remote and protected spot.

The snort lever for relieving the blast pressure on the furnace should not be in a line with, and close to the furnace tuyeres. This is a particularly unsafe location and should be at a distance and protected.

A Practice Which Cost the Life of a Man

Another unsafe practice which resulted about two years ago in the death of two men, one a furnace foreman, is that of driving up keys on a tuyere stock, with the blast on the furnace. Naturally it is the aim of blast furnace operators to gain all the time possible after delays, but there should be an imperative rule against the practice of driving tuyere stock keys with blast pressure on the furnace. A third tuyere stock hanger is an extra precautionary measure. I do not know of its adoption at any other plants than the one mentioned and very probably many furnace operators believe the usual two hangers are sufficient, if properly used.

In opening the iron hole there are three general methods. It formerly was the universal custom, and may be to a certain extent still, for the cast house crew to line up on each side of a drill, each man with one foot in the iron trough and the other leg resting on a knee outside. When the keeper judged they were fairly close to the iron, they drove a tapping bar. Sometimes they drilled into the iron and the men scrambled out of the trough. This practice, we believe, has very generally been superseded by other methods, as follows: One of the methods, is to drill through the clay in the outer hole with an electric or air drill, which drives a bit through the softer clay, as far as possible, and then to drive the tapping bar with sledges. This operation is varied at some plants by driving a tapping bar with a heavy air hammer. At other plants they regularly burn the hole out with oxygen, instead of driving a tapping bar. The operation of drilling the softer material out of the hole with a

suitable drill is quite safe. The men stand on each side of the iron trough and guide the drill and are in no particular danger.

The method of burning the hole with oxygen seems to be safer than driving a tapping bar, either by hand or machine, providing the oxygen is from a central station. There is only one man actually engaged in this operation and he is generally further from the hole when iron comes, than the men who drive tapping bars. There is still another method of opening an iron hole and that is by a specially built tapping machine which is swung into position and drills, not only through the clay, but the skull at the base of the hole. It is thus a combined drill and tapping machine. The whole operation is controlled by one man at a distance from the furnace, including the swinging of the machine out of the way when the iron is finally tapped.

The closing of the iron hole has long been accomplished with the well known clay gun. A recent innovation adds another clay barrel, and makes it unnecessary for a man, when closing the hole, to stand close to the gun and throw balls of clay into the clay barrel at each successive stroke of the piston.

Another Unusual Type of Accident

An unusual accident happened at one blast furnace plant, where men were changing tuyeres at the same time the iron hole was being stopped. The hole was not taking the clay very freely and some water was introduced into the clay barrel and as the plunger went forward, a violent kick threw flames and hot coke out over the men changing tuyeres. One man was killed and another seriously burned. It is our custom to close the hole completely and stop for tuyere changes afterward.

The handling of gas has presented little real danger since the advent of introducing steam into the gas mains, to prevent a mixture of gas and air in the mains, dust catchers, etc. This practice is so well established that I believe no further comment is needed.

The blowing in of a blast furnace is also made much safer by the use of steam to fill the mains, until the proper time comes for taking the gas down from the top of the furnace. After the blowing out of a furnace, I believe it is very common practice to rope off the cast house and keep employees away from the furnace for 24 hours. After the wind is off, the liberal use of steam on all mains, dust catchers, downcomers, etc., is part of this operation. The operation of a furnace with a weak shell, after the brick is pretty well gone, is hazardous, and the blowing out of such a furnace is certainly dangerous, as evidenced by a serious accident recently. I believe there are circumstances that justify digging out some of the stock in the furnace, rather than attempting to blow it clear down. Particular attention should be paid to positive means of preventing any accumulation of water on the large bell when blowing out.

When cinder ladles are used, a roof over the ladles to prevent water getting into them, is a proper safeguard. The danger when water and molten iron come together, is so well known, it would seem to require no comment. Yet only recently, there was an accident when a ladle of cinder exploded after it was almost full. Fortunately it did no damage beyond wrecking the ladle.

Every blast furnace plant should have apparatus to protect men when necessary for them to get into a gaseous atmosphere. This should include the hose mask, the mask with canister for removing light concentrations of carbon monoxide, oxygen inhalators, and self contained apparatus, which will permit the wearers to go into practically any atmosphere for a period of an hour or more.

Of course, when wearing no protective apparatus, great care should be exercised in going into mains or other apparatus which have held gas, to be sure the gas has been thoroughly expelled.

One source of danger is allowing gas to back up in the cold blast lines and to the

blowing engines. Even if an explosion does not result, a very disastrous fire may ensue from the oil in the cold blast mains. A regular gate valve, in addition to the butterfly valve in the cold air mixer line, and steam connections in the cold blast mains are wise precautions, even assuming the usual safe operating practices.

In conclusion I have only a few words to add. It is true that many accidents are results of "Careless Practice." Many of these accidents might just as easily have occurred at the steel department, for example. In other words, there is no special departmental risk in many of them. On the other hand there are always many sources of danger, peculiar to a certain line of work. It is the latter with which I have tried to deal.

CHAIRMAN BENNETT: I am sure there will be a bit of time for discussion and comments on this last paper as it is quite comprehensive. We will reserve the discussion until after the other papers have been read.

The next subject will be one that deals with foundries and I certainly hope the speaker will try to average somewhat what Dr. Chaney told us yesterday about the foundries. I am sure that we can take care of this subject in a nice manner. It gives me great pleasure to introduce C. L. Peake, director, industrial relations, American Radiator Company, Buffalo, N. Y.

Common Hazards in Foundries

C. L. Peake, Director, Industrial Relations, American Radiator Company,
Buffalo, N. Y.

Yesterday morning Dr. Chaney made a review of the findings which the Department of Labor annually makes with reference to the iron and steel industry and its accidents in the United States. You will remember how he pointed out that accidents in the iron and steel industry have been continually reduced over the period of the last 16 or 17 years. Each period of five years has shown almost a constant reduction. That, in itself, is a very encouraging indication.

On the other hand, it seems to me and to some of the rest of us that the most striking thing which Dr. Chaney had to say was that the single large classification within the iron and steel industry which has not shown such an improvement, was the foundry division. Here last year and again this year, instead of being an improvement, the curve remains mainly upon a level and indeed, from time to time, seems to be going up, and for that reason I am particularly glad to speak on the subject of foundry hazards.

In doing this I will divide the subject into two general divisions, as a large number of the foundries are still manually operated. Machinery is being introduced only gradually in some, but the hazards in this particular group are much the same as they are in the general group.

As soon as we think of foundry hazards, almost at once we think of iron burning; and yet, with reference to iron burns, this is perhaps the most encouraging with reference to the accidents. A large insurance company made a survey of about 14,000 cases of accidents in the foundry and it was found of these cases about a little more than 28 per cent of the lost-time was due to burns.

Knowing that this was the case, when the company I am connected with attacked safety work rather intensively, a number of years ago, one of the first steps it took was to introduce, as one of the company's own safeguards against burns in foundries, the use of leggings; and it was encouraging to note that last year the percentage of lost-time accidents in the American Radiator Company due to burns was only a little over nine per cent as compared with 28 and 29 per cent in the industry as a whole. If this was due to leggings, we believe we are justified in saying that we have made a step forward in accident prevention.

In checking up on the wearing of safety shoes, it was not very marked clear on down the scale until we compared that 27 per cent rate with larger foundries and in all these four foundries the loss of time due to burns ranged only from four to six per cent. This, we believe, is an encouraging indication that lost-time due to burns can and is being reduced in certain localities.

Now, you say it is one thing to talk about wearing leggings and another getting the men to wear them. That is perfectly true, but the wearing of foundry clothing is much the same problem as that with reference to goggles. The first thing is to find a legging which is reasonably comfortable and still efficient.

I notice that most of the leggings on exhibition here in the foundry exhibition are the spring type legging principle. Our condition is a little different from that of a man who is only working for twenty minutes with leggings and then takes them off. He puts them on at 8 or 9 o'clock and wears them continually, only taking them off during his lunch hour and again at 4 or 5 o'clock in the afternoon. We have found under these conditions that the spring type of legging becomes very uncomfortable, chafes a man right below the knee where the grip is and again at the ankle. Another objection is in case the spring flaps open it goes to the back of the leg and comes out and the hazard is just as great, and sometimes greater, than if he did not have leggings on at all.

For this reason, we have introduced a legging which has just one piece of steel on one side. It fits into a slot at the bottom and has a quick removable leather catch at the top. The leggings can be removed at once and we believe they are considerably more comfortable.

Selling Men on the Use of Leggings

It is one thing to suggest the wearing of leggings, but it is something else to get men to wear them. The method is much the same as we have used in the introduction of goggles. We sell them as far as possible as an individual proposition until we have 40 or 50 per cent of the men wearing them, and then some morning we have the foreman or superintendent (not the safety man), call his force together and say, "Here is a set of leggings which other men in foundries have found very effective to wear. We are going to wear these from now on." By this method alone is it possible to carry it out.

It is not enough merely for a man to wear leggings. They have to be checked up. A legging which is too large may prove to be a greater hazard than no legging at all. Every once in a while a report comes in of a man being burned who was wearing leggings, and we find, if he was wearing them, that the accident happened because he didn't have them on properly.

Let us touch for a moment the question of wearing goggles. It is enough to mention that in the last two years since the compulsory wearing of goggles by pourers, the record has been almost 100 per cent in our various foundries. We haven't had a single permanent eye injury due to splashing metal on the pourer. This has been due to the goggles, we believe. We have had scores of cases where the goggles have come in badly splashed with metal.

The real problem, after all, is the same as outlined in leggings, and that is to find a goggle which is comfortable and in this, I think, our experience has been a little different from that advocated, at least, by a good many goggle concerns. Our company has discontinued the use of cup goggles and has gone back to the rigid type of metal goggle, the type with side screens and full protection, because we find that they give better ventilation and the men will wear them much better than they will the cup goggle.

These last two mentioned hazards are fairly on the way to a 100 per cent reduc-

tion. I wish that was true with the rest of the hazards in the foundry industry and indeed with the rest of the hazards in most of our plants.

Perhaps this change has become more marked where the custom has been lately—and still is the custom—for a man to prepare his own sand, cut his own steel, temper it himself and when his day's work is up to pour it himself; because in the last few years this has all very largely been changed by the division of labor which has taken place in all industries. This is true particularly in the foundry industry of late, so that when a man comes in and prepares the sand, another man prepares the equipment; another man might be called a molder who puts up the work; another man pours it and someone else shakes it out. The problem of actual production in a foundry of that type is materially different from a foundry where an old time foundryman did all the work; and, of course, this brings the individual problem.

Whenever a change from one type of production into another is made, at once our difficulties begin. For one thing, we don't always know the hazards until the accident exists. We may say there is a good possibility of having an accident on a particular job, but human nature is such (and it is not peculiar to a foreman or to a superintendent), that until an accident of a certain type has happened in a particular shop, it is pretty hard to sell the idea that that accident has to be guarded against. So until we have accumulated certain experience, it will be hard to reduce our hazards. When one sort of a job has been carried on for 10 or 15 years, it becomes more or less routine and the problems are fewer, so that it is possible to crowd the safety angle pretty hard. But when new machinery has been introduced, and thousands, perhaps hundreds of thousands, of dollars have been expended to change over an operation, it is necessary as soon as possible to commence to realize returns on the expenditure for that operation. As a result, a constant drive against caution takes place and accident prevention has its place only along with the rest, although we can't crowd it out on the operation standpoint. The safety engineer, under those conditions, has a new job of selling safety and watching out for the hazards all over again.

Hazards About the Conveyors in the Foundry

Now, when we have introduced the new processes, what is the nature of some of them? Many of them take on the same sort of hazards we have in any other kind of shop. Perhaps the single largest change has to do with the introduction of conveyors in the foundry. Now, the power conveyor has shown itself to be dangerous and it is reasonably easy to make a man be careful around the power conveyor, but it is a different story around the gravity conveyor. It has a different current, and yet the temptation to step across a conveyor of that kind, and take the chance of twisting an ankle or breaking it, takes place more than once. A large casting may be coming down on a roll of conveyors and for some reason it isn't wanted, and it becomes necessary to stop that casting midway on the conveyor. The temptation to try to slow that casting is too hard for a man to resist. He slips, and a broken leg or an amputation follows; and so the answer is the same as it is with so many other things—you have to make sure that men understand that these conveyors are to be crossed only at the regular crossing and they are not to go over them unless there is a regular platform provided.

The shear hazard in the new foundry is particularly prevalent. A new molding machine will be set too close to a column. Someone will be climbing through and be caught between the two shears. Or, a roller machine will be set up too close to another machine, and before it is realized, a molder or workman will be caught between the two machines.

I noticed lately that instead of setting up a power conveyor with the table running over tracks, it had the table running over rolls and then the whole thing

was driven by a power chain; so it was necessary for the shears to be set up every time one of these tables crossed a roll. These are guarded against, if possible, back at the factory and the design is changed.

Then, there is that ever-present hazard that is present in any concern, the hazard of electricity. This is particularly a hazard in the foundry because, although we may introduce all the latest mechanisms and do our best to guard against this hazard, still the fact remains that there is always more grit and dust in the air in a foundry than in other shops and it is possible for this dust and grit to get into the finer mechanisms and a short or ground results.

The remote electrical automatic control is a very decided step into the future, so far as accident prevention is concerned. It has proved itself in some lines, and yet some of the most serious accidents we have had in the last year have been the result of the remote control becoming shorted in some manner and death coming as a consequence.

A Type of Switch Conducive to Accidents

The difficulty is, perhaps, that in most of these machines the switches are so designed that when the machine is set up in the morning and started it is not stopped again until noon, and maybe started again in the afternoon. So the switch has to be operated only once or twice a day. When a switch of that sort is put into a shop, an accident is quite likely sooner or later to be the result.

The hazard which we have always had more or less with us has been the tumbler hazard. I refer particularly, not to where the castings are fed into one end and taken out of the other as in the old type, but with the side open. I believe it should be an invariable rule that a tumbler of this sort should have an individual drive and interlocking guard so that the machine cannot be put in operation until the guard is closed and the door locked completely in place; because with the tumbler, if a man is hurt, it is not a scratched finger nor a broken finger. The penalty is quite likely to be an amputation, a crushed skull, or death.

But the hazard which probably is most prevalent, not only in the new foundries, but in the old foundries and throughout the entire metal industry, is the hazard to the fingers and toes of the employee. More than once a foreman has said: "Can't we get a pair of goggles for this man's fingers?" "Can't we put leggings on this man's toes to keep them from getting hurt?" But, as we know, the only protection to fingers, toes and feet, is the application of safe practice and constant education.

Now, I was in one of our shops just a week or two ago and noticed where two men were working on one particular form. It was a flask set up on a particular operation, set up on end and so balanced (the flask only weighed 500 pounds) that a man could push it in place with only a slight shove. The two halves were set up together and locked and the member on one side of the flask, when he pushed his side of the flask together, would keep his fingers completely out of the way. On the opposite side where another man was working, his practice was to take hold of the flask because he was able to get a better grip, reaching clear around with his fingers exposed on the closing point and just before it closed he would slip his fingers out. No accident has resulted yet, but unless this practice is changed, sooner or later, one or four fingers are going to be lost.

It is by watching such operations as those that we can eliminate our finger accidents, and the answer with regard to the feet is the same in a large degree. The introduction of the safety shoe, the shoe with a stiff toe, is a partial answer. We can show you cases, several of them, where a man has dropped onto his foot a casting weighing 500 or 600 pounds, and the man has simply gone to the first aid for dressing, where if he had had an ordinary pair of shoes he would probably have lost one or two toes, or possibly had a broken foot.

The biggest problem, though, is education and putting this into practice. Indeed,

that is the answer throughout with reference to the whole matter of foundry practice and is exactly the same as it is with all other metal industries and with reference to hazards wherever we may find them.

The answer is three-fold. First, practice and education, because the great bulk of our engineers' accidents are not the machine, but the result of poor practice.

The second is one that is almost as important, the question of layout within the shop. When a foundry is changed over from a manually operated foundry into a machine foundry, as a rule the old building is kept. Sometimes it is possible to erect a new building. As a rule, it is simply the old building, and when, as the process is changed over, there is a desire to increase the production per unit also. The result is that the layout is likely to be cramped. Congestion will result, and where there is congestion, there is an accident.

I don't believe we can eliminate a considerable number of accidents until we start checking up very closely on the matter of layout.

The third remedy is one we have heard ever since the safety movement began, the proper design and proper guarding of machinery and I believe that we are getting back to that direction somewhat without minimizing for a moment the importance of practical education.

Every New Machine Purchased Must Be Guarded

It is a rule in our plant that after they have written all their purchase orders and all their specifications, the requirement is that every new machine purchased must be guarded in conformance with the American engineering standards; and yet, very frequently, when you see a new machine come in, in spite of that, you will find that practically no attempt has been made toward safeguarding the machine at the shop where it has been made; and the answer is because many manufacturers have no idea of what standard guards are.

We have, just as an experiment lately, written to the manufacturer telling him what we think has to be done on the design and asking him whether he will be willing to change his design accordingly, and most answers have been very favorable. If every concern represented here would make it a practice to write the manufacturer of each machine which is not made according to standard safety designs, we believe it would be only a question of a short time until the manufacturer would construct machines which are safe. He is only constructing them unsafe because he thinks the average employer doesn't care very much whether they are safe or not. If we show him we are interested, he will change the machine, if he knows we want it that way and no other.

Of late, we have been hearing more and more about the dollars and cents side of accidents, and it is only fitting that we should. A week or two ago I had a man say to me: "I am not particularly interested any more in seeing a man hurt. It doesn't affect me a bit. I think the war has been largely responsible for the fact that broken bodies and deaths do not make very much difference any more." But he said: "The reason I am trying to safeguard my machinery is that I am trying to reduce accidents in my plant because I believe it is good business to reduce them."

Now, we may or may not agree with that sentiment, but we all know it is one of the reasons this safety congress is being held. There might not be so many thousands present if it weren't for the dollars and cents appeal behind it. Our employers expect that we will come back from the convention equipped to save our expenses a good many times in the course of the coming year because of our having taken an interest in accident prevention work. Yet, in spite of that, is that all? Isn't there another side to the thing?

Next to you sits a man whom you have never seen until within the last three-quarters of an hour, and yet, within the next hour, if that man's life were placed in danger, you would probably be willing to risk your life in order to keep him from

getting hurt. Whether we talk about it or not: "I am my brother's keeper"; and when it is simply some casual acquaintance that we are willing to watch out for, what about somebody closer? When I think about that little two-year-old boy that waved me goodbye, and of his eight-year-old sister sitting along side him, what wouldn't I do in order to make sure that they shall not even get a scratch or get into an accident that will hurt them in the least? To what length wouldn't I go? And this, I believe, is the reason that there is particular encouragement for the development of this great safety movement.

When we have a combination of economic worth with a sincere interest in humanity, then that, I believe, is the answer to any question of why the records of the iron and steel industry have been able to show a consistent reduction in accidents straight through from year to year over the last 16 or 17 years. It is the answer and I believe it has been a pleasure to all those who have worked shoulder to shoulder for accident prevention.

In the next few years, not only the iron and steel industry as a whole, but also the foundry industry, will witness further and corresponding reductions.

CHAIRMAN BENNETT: Our next subject is one of another specific operation in the iron and steel industry. "Coke Plant Accidents and Their Elimination," by Mr. George P. Wardley, superintendent of coke plant, Joliet Works, Illinois Steel Company, Joliet, Ill.

Coke Plant Accidents and Their Elimination

**George P. Wardley, Superintendent of Coke Plant, Joliet Works,
Illinois Steel Company, Joliet, Ill.**

The by-product coke industry had its inception in this country in 1892 with the construction of a modest little unit of 12 ovens in connection with the Solvay Process Company's plant in Syracuse, New York.

While it did not meet, at that time, with any ill will on the part of users of metal coke and the beehive operators, nevertheless, it did maintain a growing interest, although its growth was slight.

When the interest of the steel corporation in 1908 culminated with the Koppers' oven, the by-product ovens received added importance among the steel producing units, so that soon it was recognized as a necessary unit of any producing plant. Not alone in the field of domestic fuel, gas and coke, has it been acceptable, but the by-product coke oven industry has become one of major interest.

It is a singular fact that it was in the Joliet Plant of the Illinois Steel Company that the by-product oven industry, in 1908, recognized by importance of safety work, by the appointment of the late Captain H. B. Smith as a safety leader.

May I pause for a moment to pay a tribute to one who saw the silver lining of safety in the dark clouds of industrial accidents when it was not so clear to others? Behind the curtain of an abrupt manner this man had a heart of gold; stern and uncompromising in his efforts to reduce the unsafe practices of those days, he trod his path without the sympathy of many whom he sought to aid. Many of the cook-oven men who received their early training at Joliet have a vivid recollection of his persistence in making them pass a safety examination from a rule book. They looked upon him then as somewhat of a fanatic and a tyrant. But we look back upon this pioneer now as an evangelist of a new doctrine, "Thou shalt not maim or kill," and I pay my little psalm of praise to that man who helped to raise the dark cloud from industry.

If we are to discuss the elimination of coke plant accidents, it might be advisable briefly to consider the hazards in this industry. A coke plant handling 2,000 tons

of coal a day will find it necessary to load and unload 85 to 100 cars of material. The loading, unloading and moving of this many cars of different types of material necessarily brings many risks. In the oven operation in the curbing and conveying of 2,000 tons of coal a day, with its elaborate, mechanical, electrical equipment, we find many hazards. In the oven operation, we not only have the mechanical and electrical devices, but additional risk of handling hot material, such as coke and burning gases with the danger of explosion.

In the by-product department, including the benzol plant, again we have the mechanical and electrical devices, together with the chances of burns from steam, tar, acid, lime, caustic soda, noxious and poisonous fumes and explosive liquids: so that I realize the coke oven industry is in much need of safety precautions and devices.

The builders of the modern coke oven plants have cooperated with the operators and with the manufacturers of auxiliary equipment, to produce as safe an operating plant as they possibly can, and they have succeeded reasonably well with the limits of experience and foresight. But as no one has been able to protect a careless man against himself, it is this element which we must perfect, if we are to eliminate coke plant accidents and it is this phase which I propose to discuss.

The Safety Story of the Plant

This is a story of our plant. Beginning in 1912 we found that we had 55 lost-time accidents: in 1913, 52; in 1914, 22; in 1915, 15. In 1916 and 1915, I might say, operation had been decreased and the number of men had been decreased, and at that time we made a particular drive to see if we couldn't do something; we succeeded to that extent. But with war activity developing in 1916, and with the added operation at the plant, we found ourselves slipping and again went to the 30 mark. We pulled up a hole in our belt and started after it again and found we came down to 15; and by keeping after this thing, we were able to maintain 15 in 1918. In 1919 we dropped down to 13; and then in 1920, with the reaction of the strike and hiring a lot of new men, we went back to 15. In 1920 and 1921, we were not doing very much, the number of men we had was comparatively small, and so we had dropped down to four and three.

Then in 1923, with a lot of colored and Mexican labor, and in striving to get our production out, we slipped and went back up to seven. Again we went after this thing and in the following years we find ourselves with two and two, and in the last two years, we find ourselves with none. In other words, from Labor Day of 1925 until the present moment, we have had no serious accident that has caused the loss of a single day's time.

It is an interesting part of this, that in the first three years of this five-year period while we were able to limit the minor accidents of one to seven and eight to ten days, we suffered each year two of the more serious accidents.

In trying to find a reason for that, we found that all of those accidents had occurred in the operating department. Previous to that period, the repair and the maintenance labor and operating labor had been a fifty-fifty break, or in proportion to the number of men employed in the plant. When we got down to this period, the repair and maintenance department had succeeded altogether in stopping their accidents and the operating department had not. What was there in that that might give us some clue? In studying it over, we came to several conclusions.

One of them was that the repair man is not always called upon to hustle as much as the operating man. He has a chance of taking a little more time at the job he has to do and if it is a large break-down, invariably the foreman is there with him.

Another thing that entered into it was the question of whether the monotony of the operating man, having to do the same thing over and over again, had any

influence on his becoming careless. The repair man did not always have the same job, but had one hour at one end of the plant, another hour at the other end of the plant, each time on a different type of apparatus, and consequently this might have some bearing upon the problem.

Then another thing that entered into that was the question of the operating man having to stay on on his job up until the last moment of quitting time, where the repair man could possibly time his job to get through a few minutes before quitting time and be prepared to go home. The operating man who had to stay until the last minute, might have a tendency to hustle up and in that congestion produce an accident.

That is our story. That is what thus far we have accomplished.

Now, what are the tools with which we work? Being a department of a large plant, we are necessarily a part of the general safety organization. That has its value in that the safety department, being alive to safety, will concentrate and focus our attention sometimes on conditions which otherwise might not receive the consideration due them. We get, too, from this general safety organization, reports, service of their inspectors and committees from other departments, safety campaign slogans, etc. In our general safety organization, we have one man classed as an inspector whose duties are mainly those of an instructor. I don't believe this man is common to the general safety organization, but it is his duty to make contact with the newly hired man on the job as soon as possible. He takes to him a message of safety, the value of safety to himself and to his fellow workmen, his obligation to his foreman in reporting unsafe conditions and practices. Coming from the outside, he necessarily feels he has a big value in giving to that man a conception of safety.

The Instructor May Be Used as a Liaison

While the details of this operating job necessarily fall upon his foreman, nevertheless this instructor may be used as a liaison between the foreman and the man, if he happens to be a foreigner, since this instructor can speak several languages. I don't believe we can over-estimate the importance of that man.

Then again, he talks to the older men in the line of safety, men of the less skilled classifications, and holds a safety meeting with our big button men; and these big button men are selected in different groups to be the safety leaders in that particular group.

I might call attention for just a moment, to the fact that our general safety organization is a live organization. We feel that a good bit of our success has come from the cooperation and the assistance of that general organization.

In the whole plant, employing 2,400 men a day, 169 days have now passed without a single lost-time accident and that credit goes mostly to the general organization. We have our own department organization with committees having the function of investigation and inspection, but more and more we are coming to believe that if accidents are to be eliminated in our coke plants, the foreman is the man who is going to do it. A committee may investigate an accident and recommend something to prevent a like accident, but an observant foreman might have prevented the original accident. The foreman is in daily and hourly contact with his men and consequently is in a position to detect a false move in the human equipment, as he is in position to detect a false note in the mechanical equipment.

We are insisting upon our foremen developing the habit of observation. Not a casual inspection of his work, but a close observation of the man at his job; because we feel that if he will do that, there will come in that man's action, possibly some clue to an accident that might develop later on. Just the other day one of the foremen came to me and said, "I had a man come to work this morning and I noticed that part of his shoe was either torn or cut out and I said to him, 'I want you to be

careful today; and tomorrow I want you to wear a better pair of shoes. I don't want you to wear that kind because you are liable to have a burn." It wasn't two hours later until that man accidentally burned his foot with hot water, but fortunately it was a very minor burn.

We feel that near accidents are a clew to most of the accidents which happen, that in every serious accident which has occurred there has been a parallel in a near accident if we had been sufficiently observant to find it. How frequently when an accident has occurred have we heard such a man say, "I knew such-and-such a thing was going to happen because so-and-so was doing such-and-such." We don't hear that in our plant any more because we have tried to show our men that they owe it to themselves, just as much as they do to the fellow workmen, to report these little slips so that the foreman or the department superintendent can analyze the near accidents and see in them the possibilities of graver and more serious accidents. The foreman is in a better position to hear these things. It is difficult to have the men report these near accidents, quite difficult sometimes to have the foreman report them; but being in daily and hourly contact with his men, if he is an observant foreman, then we feel he is going to be in a much better position to find and catch these near accidents and from them enable us to learn a lesson.

The Foreman Should Be Rendered All Possible Assistance

Naturally, if we are going to put the burden of responsibility for eliminating accidents upon the foreman, we should assist him in every manner possible. That is our job and one of the ways that we have of assisting our foreman is in a safety letter. Each foreman is compelled every month to send a safety letter to the department superintendent. He is supposed to say that he talked about specific subjects to the men in his group. We have a way of checking that up, either by this instructor or by some other man going out to a man in a certain group and finding out whether that particular foreman has talked to him about a specific subject. This gives the foreman an opportunity to protect himself because if he has talked to his men on a specific subject and he has so reported, should an accident occur along that line, he has a written record that he can refer to. Sometimes this saves him criticism and possibly censure and maybe discipline.

Not long ago we had a case of a man at the change of turn, who had been warned that when the wind was in a certain direction and the steam hid the coke side of the walk, that it was dangerous for him to walk along that side and that he should use the steel work as a guide and go on the other side. The change came about eleven o'clock. He was in a hurry to go home. Conditions were bad. He didn't walk, he ran and fell off the walk. The result was a broken leg. The foreman was able to produce his written record that he had given specific instructions about that particular thing, so that there was no censure for the foreman at all. But since that time, as the winter comes along when these conditions prevail, we go to that foreman and recall to his mind the fact that that accident happened several years ago and that it is liable to happen again. We suggest that, besides telling the man of the condition and that he must not do that, if he is wise he will watch all his men at the change of turn, and see if they violate that rule or not. Thus he will be able to catch an unsafe practice which might result in a very serious accident.

When we receive a report of an accident from another plant, whether it comes from our general safety organization or from some visitor, we immediately transmit it to the foreman so that he knows about the type of accident, and if he has any conditions corresponding to that, he can be governed accordingly.

Then it is customary for us, ever so often, to review the accidents which we have had and to call the foreman's attention in the different departments accidents which have happened as much as five, six, seven or eight years ago. In this way we check

up on conditions surrounding such accidents and see whether there exists at the present time the possibility of a repetition.

In the six serious lost-time accidents which we have had in the last five years, only one of them indicated any failure of mechanical equipment, and I am not sure that was so much the failure of mechanical equipment as it was the failure of the man to treat the mechanical equipment in a fair manner. True enough, we will try to fix it so that even though it were treated in the same way again, that same accident could not happen.

Three of those serious accidents happened either at the beginning or at the end of the turn, indicating that the men were in a hurry to go home and were taking chances, or that the man coming on to the job was in a hurry to get his operation started and took a chance.

Safety Comes Through Close Supervision

Two of these serious accidents happened at an abnormal operating period. In other words, the operations at that particular time was not normal and smooth as it usually is, but they had piled up. It was necessary to hustle up, and these men, in hustling, in trying to do their work, made a false step, allowed themselves to get away from the safety instructions and a serious accident resulted.

So, as we review these things, we feel more and more than the accident elimination in the coke plant is going to come through a very close supervision of our men. That if we will closely observe them, not alone in the normal operating period, but will observe their actions under stress or under conditions of hurry, that we may find in that period some indication that later on will produce an accident.

Paraphrasing the comment of Will Rogers to a politician, "Accidents do not happen, they are brought about." So far as I feel now, the main man in helping to eliminate accidents in the coke plant is the foreman.

CHAIRMAN BENNETT: You will recall the first paper by Mr. Jaco of the Commonwealth Company, "Safety as the Foreman Sees It," in which he emphasized the inspiration the foremen receive from the management and also that the right and orderly way to conduct business is the safe way.

Mr. Underwood's paper on the "Safe Practices at the Blast Furnace" brought before us a good many of the late mechanical changes which bring about safety.

Mr. Peake on "Common Hazards in Foundries" brought out the use of leggings, goggles and the prevention of accidents and also the importance of some protection to the feet. He also put out other excellent points regarding the foundry accidents.

The last speaker's main point was the foreman's responsibility in accidents, besides the specific reduction in their own plant.

JOHN A. OARTEL (Carnegie Steel Co., Pittsburgh, Pa.): I have a question to ask one of the speakers, but before I do that I want to compliment the program committee on this program this morning. It is the best I ever heard, real practical stuff in all meetings. It hits us where we live, we fellows in the steel mills in this country.

A question I want to ask Mr. Underwood with reference to the oxygen installation and blast furnaces; has the piping a distinct color?

LAWRENCE H. UNDERWOOD (Youngstown Sheet & Tube Co., East Chicago, Ind.): We have an indistinct color, but it is conducted practically under cover most of the way through the gas houses and each outlet has the name on the enameled sign.

MR. OARTEL: Can any busybody or anyone else turn that on?

MR. UNDERWOOD: That is perfectly possible. It has a valve and a plug. They can turn it on but the only result is a waste of oxygen. I don't think it would be possible to injure any one.

E. H. GRAHAM (Carnegie Steel Co., Etna, Pa.): What is the line pressure utilized:

MR. UNDERWOOD: One hundred pounds.

GEO. MCCLAIN (Jones & Laughlin Steel Co., Pittsburgh, Pa.): I would like to ask Mr. Underwood a question with reference to provisions around his blast furnace for rescue work, we will say resuscitation. Do you have any crews that are trained in artificial respiration and things of that kind?

MR. UNDERWOOD: Yes; we have men in both the coke plant and blast furnace who are regularly trained in artificial respiration and use of apparatus. The emergency hospital is very close to the blast furnaces where we keep the H. & H. Inhalator, and it is also available for some of the other departments.

The coke plant is separated from the rest of the plant; it is located across the tracks, and we have the apparatus there for resuscitation and men are trained in that department separately.

MR. OARTEL: Do you have a mechanical means of respiration, a pulmotor or anything of that sort?

MR. UNDERWOOD: We have no pulmotor. The H. & H. Inhalator is the only one which approaches the pulmotor, but of course it is quite different.

MR. MCCLAIN: You use that for resuscitation, don't you? It is in no way related to making a man breathe when he quits breathing, or anything like that, is it?

MR. UNDERWOOD: No.

MR. SLOSS (Buffalo, New York): I would like to ask Mr. Peake what the American Radiator Company's attitude is in using force, as a matter of safety, in the wearing of goggles. Is it a rule absolutely laid down that men have to wear goggles and is it objected to if some do and some don't?

The Problem of Forcing Eye Protection

C. L. PEAKE (American Radiator Co., Buffalo, N. Y.): The men are required to wear them. As a matter of introduction we say, "Here is a pair of goggles. You have got to wear them." We sold them first to as high as 85 or 90 per cent of the men and they used them. Then the rest were told to use them and compelled to use them from then on.

With reference to shoes, we haven't got to the place where we are compelling the use of stiff-toed shoes. In some of the plants they are compelling the use of foundry shoes; that is, the regular standard congress type with the high bellows. I think the time will come probably when the same thing will be true with reference to some other departments where the total accidents are pretty high, but with reference to the stiff-toed shoe, we are simply urging its use at present. In time that will probably be a rule the same as with goggles.

MR. ROSEVILLE (Fairbanks Morse Co.): Do you use the all-metal goggle throughout the foundry?

MR. PEAKE: Not absolutely. We have made up a number of different units. We have 19 operating plants and in most of those plants they have standardized on one. The all-metal goggle is used by the pourers or what we call chainers, men who run the chain on chain hoists in connection with the ladle and clamp on the top plate before and after the pouring; but this is a patent goggle. There are one or two plants, however, which do prefer the cup type goggle for that operation. They have been using it for a long time and with their approval it certainly is just as safe as the other one. It is simply introduced, easier and better ventilated, but on shakeup we use the cup goggle almost universally and, of course, on grinding operations.

T. H. MCKENNEY (Illinois Steel Co., Chicago, Ill.): I would like to ask Mr. Peake with reference to a campaign on safety shoes. Does your company handle these shoes and do you sell them at cost or a little above? How do you do that?

MR. PEAKE: The company handles these shoes in all plants and sells them at cost plus ten per cent for handling. One of the methods used particularly so far

was checking up the pay line. When Friday or Saturday comes for paying off, safety men from the stock room will go out to the paymaster and inspect everybody's shoes and then start selling them and give the foreman the names of the men who need new shoes. Then if a man comes in with a pair of bum shoes, he is usually checked up by his foreman.

R. U. KELLEY (Copper Mining Co.): I would like to ask Mr. Peake on the foundry conditions regarding the throwing of electrical switches. I think he mentioned burns from this. Did you ever try the remote control, and if so, what success did you have?

MR. PEAKE: This fatal accident which I mentioned was caused from the remote control (and we are not sure yet just what was behind it) but it was the case of the push button having been improperly insulated. Whether it was due to the make or due to method of installation, we haven't been able to find out. The question we have in mind is whether the remote control, especially where it is used in a foundry, with automatic switch control, is not altogether a new hazard.

Protection of the Foot Still a Problem

CHAIRMAN BENNETT: Mr. Peake, do you think that there will be a time when we go further than covering the toes, that is, cover the instep with our shoes? There are devices out now.

MR. PEAKE: I wish we could, but you probably have noted the steel toe protector and instep protectors which are on sale here at the exhibit. We have experimented with this particular one, which was brought out a year or two ago. It is a little heavier, but we didn't feel free to compel the men to wear something of that weight. It is a very heavy thing, very awkward to carry around. I question just how much better protection it gives than the ordinary safety type shoe with the fibre toe. It does protect a little bit higher, but it is a very awkward thing for the men to wear.

E. H. GRAHAM (Carnegie Steel Co., Etna, Pa.): Was the tank machine practical, Mr. Underwood?

MR. UNDERWOOD: We have had ours in operation about two years, and it has proven very satisfactory. I was instrumental in getting that machine, so I can speak from an unbiased mind. The machine was bought before I went to this particular plant. We put it in operation and it is a big machine. It is rather expensive and yet it certainly has done very well.

W. S. STIEFER (Youngstown Sheet & Tube Co., Youngstown, Ohio): I would like to ask Mr. Oartel, in view of the excellent record he had in keeping down accidents, what his standard is by which lost-time accidents are based. Do you nurse your men or coddle them in such a way when they have an accident that it is not a lost-time accident? Just how far do you go in placing a lost-time accident?

JOHN A. OARTEL (Carnegie Steel Co., Pittsburgh, Pa.): The matter of a lost-time accident is based on whether a man loses a complete turn. If he were injured in the afternoon, or the latter part of his turn, and went home and did not lose a complete turn, it would not be a lost-time accident.

We do not coddle (that is the term the gentleman used) our men. We have had cases where a man was unable to do his own particular work but was able to do some other work in the plant and has done it, and that is what we do.

MR. STIEFER: I would like to ask both Mr. Wardley and Mr. Underwood what their opinions are in regard to the size of manhole tanks and also in regard to service in trenches. In a good many coke plants in the past it has been a practice to make these, and also to make the manholes, too small.

MR. UNDERWOOD: I think our general manhole is about 20 inches. I know that that it is true in our benzol stills. As far as trenches are concerned, we try very hard not to have them. We had some trenches in Benton Harbor which have

been filled up and done away with and we have practically no trenches left around there now.

The manhole proposition, of course, depends upon how careful we are. Any manhole would not be big enough to put men in the tank if it wasn't thoroughly inspected before you put them in. We have live mice at our coke plant. When men are going in, before they go in and also after, the mice are lowered into the tank for a certain length of time, then the men take mice with them. Of course, there is always a man right outside the manhole and a man in the tank.

T. H. MCKENNEY (Illinois Steel Co., Chicago, Ill.): Mr. Morey made an illustration of a man who was general manager who came down through the plant and saw a man who was not wearing his goggles and when the general manager referred to him the foreman said he had cautioned that man a great number of times and then he was disciplined. I am just wondering when is the right time to discipline a man. Should he be cautioned a great number of times, or how far should we go before we mete out that discipline.

We all agree, I believe, that a man is not injured the first time he pulls off some boner. Now just how far should we go before we discipline that man?

Discipline for the Man Who Needs It

E. G. QUESNEL (Commonwealth Steel Co., Granite City, Ill.): Probably I can answer that question for you, being with the Commonwealth Company and knowing this particular situation that was referred to. This man had been cautioned, as far as we could find out, three times; that is, the foreman and the man admitted that his attention had been called to his going without his goggles three times, at least.

We have an unwritten law at the plant whereby, if a man has been cautioned twice and he is caught violating a rule for the third time, he is then liable to be laid off. We give him the instructions the first time. If he doesn't heed them, it may be through lack of understanding, and he is again cautioned. If he still disregards it, the third time, he is apt to be penalized. That is one of the rules. Of course, in some cases we allow a man more time, but if he has been cautioned more than twice, why we lay him off.

R. B. KELLEY (Anaconda Mining Co., Anaconda, Mont.): I would like to ask you what to do in the case if a man contributes to an injury after general instructions on safety work have been issued. What do you do with the man if another man gets injured through his carelessness? Do you caution him again?

MR. QUESNEL: Do I understand you to mean, if an employee is injured through the carelessness of another employee, what do we do with the employee who caused the accident? If it was caused through carelessness, we lay him off for the duration of the time that the injured man is off. That is also an unwritten law, and circumstances govern that; but it is one of the ways in which we handle those cases.

MR. HODOR (Western Electric Co.): I would like to ask Mr. Peake which is customary, colored or clear lenses in the pouring of lead; also is it customary to use goggles?

MR. PEAKE: We are getting away from that because there are so many many cases in which we have had the goggles broken, the armored goggle.

CHAIRMAN BENNETT: Our time is practically up. Let me remind you of the importance of this round table discussion. We could carry it on all afternoon, but remember that you have a round table discussion at your hand the entire year. Write in the questions that you want to know, questions that puzzle you, questions you have asked here this morning; and if you don't want to ask them direct, suggest them to the National Safety Council. You may have a round table correspondence with the National headquarters staff at all times. A lot of that has been covered in the News Letter of the Metal Section, so if you happen

to have something new, help out the new officers and the new secretary, the editor of the News Letter, by sending in your new ideas, your new stunts; and then when problems are put up to you and the National headquarters staff asks you a question, give them a good reply. Answer it as completely as possible, because that is the only way in which we get any good out of the Section and that is by interchange of correspondence. As we stated yesterday, and Mr. Quesnell has told me since, it has increased materially during the past year. More of the plants get to exchanging their ideas and safety stunts every year and we are going to try to reach that end of definite accident reduction.

I think a great deal can be brought out of these round table discussions but remember, we mustn't let it all wait for a safety congress. Every day in the year we can have a round table discussion, although, of course, not as personal as when we are together.

I think that is one failure with any organization of this size, a lot of the smaller members and some of the larger members, don't use the safety advantages at hand. Any question you can put up to the National headquarters staff will be answered. If they can't answer at once they have about 700 or more members in this section and hundreds of members in other sections who ought to be able to answer, if the problem is solvable at all.

ADJOURNMENT.

Thursday, September 29, 1927

The third session was called to order at nine thirty-five o'clock by the chairman, F. G. Bennett.

CHAIRMAN BENNETT: The latter part of this program is going to be a round table discussion and we want all the time we can have for that. So we will start at once with the first paper on the program, by Mr. N. V. B. Ziegler, personnel director, U. S. Aluminum Co., New Kensington, Pa.

Conducting Safety Meetings

**N. V. B. Ziegler, Personnel Director, The United States Aluminum Company,
New Kensington, Penna.**

There are many kinds of safety meetings, some very good, some very poor, and some just medium. I have had the privilege of attending perhaps two or three hundred of them, in connection with my work. It so happens that I am a kind of singing safety evangelist, and in this capacity I have been actively present at nearly all of the big safety rallies and schools of instruction held in the Pittsburgh district for the past five years or more.

Many of the meetings made very little impression on me, while others filled me with enthusiasm and a desire to do my little part in the great work of accident prevention.

Why this difference? Why is one safety meeting interesting and effective and another uninteresting and ineffective? Well, I have observed this, that whenever the leaders and speakers are real safety men realizing the seriousness and importance of the problem, also the joy and satisfaction which come as a result of work of this nature, and are willing to put the thought, time and attention into it that meetings of so great importance deserve, a profitable meeting is usually the result. Men and women will go away inspired and fired with a determination to do more than ever before in the interest of safety. But when a meeting is hastily thrown together, without a definite plan or serious thought, the meeting is sure to be a failure. Certainly, it was built to fail. Have we reason to expect any other result?

I know of men, who claim to be safety men, who are continually making a joke of the safety movement, treating the whole proposition lightly and as if it were of secondary importance. Very little progress may be expected by attacking the problem in this manner. Some time ago one of my assistants attended a safety meeting at another plant. The superintendent of the plant was to make an address to his employees and when his time came to speak, the safety director, who was well acquainted with the superintendent, in introducing him said: "Boys, the big boss is with us tonight. Bill, get up and do your stuff." Do you think for a moment that the speech of that superintendent would have much serious effect?

I hardly think so. I believe such a procedure is all wrong. Life and limb are at stake, and this is no joking matter. Safety is a serious business and demands the best that is in us. It is all right to have a good, snappy, wide-awake meeting, lots of good entertainment, etc., but when the time comes for the safety message, it ought to be considered just as important and be treated with as much respect as we demand and expect of the minister and his assistants when they come before us on Sunday morning.

Why not? Religion and Safety are very closely related. Is there anything

more nearly like the story Jesus tells of the good Samaritan binding up the wounds of him who fell among thieves while on his way from Jerusalem to Jericho, than the work of the safety director who binds up the wounds of hundreds of thousands of human beings by removing the cause of injury? In fact, I think he is more of a good Samaritan than the original one because "an ounce of prevention is worth more than a pound of cure." It is certainly more important to lock the stable before the horse is stolen than after. It is a better piece of safety work to remove a board with a big rusty nail upturned than to allow someone to tramp on the nail and then hasten to dress his wound; yet how often we pursue this latter course. How many times, by our negligence, we allow conditions to exist throughout our plants which are unsafe until some day we have a bad accident; then we wake up and hasten to heal the wounded and remove the hazard.

Yes, safety is a serious business and it is encouraging to note that more and more, men and women are considering it so.

The Safety Address Must Ring With Sincerity

I have noticed time and time again that the safety address that rings with sincerity is the one that makes the best impression. Well do I remember the great, outstanding safety address given in Detroit last year by our good friend, C. H. Howard, President of the Commonwealth Steel Company. One cannot forget messages like that. They insure a successful safety meeting. Another safety address that I well remember was delivered by Isaiah Hale, of the Atchison, Topeka and Santa Fe Railroad Company. I was so impressed with it that I at once secured him for the large opening meeting of our Safety Lecture Course last fall. There were 1,200 or more at that meeting and he thrilled the audience with his sincerity and eloquence.

What did these men talk about? Just plain common every-day human interest stuff, showing us that we should be interested in safety, not only because we happen to be personnel men, safety directors and safety committeemen, whose duty it is to look after these matters, but also because of the service we can render humanity because it is right that we should strive to protect each other. You remember God taught us away back when Cain slew his brother, Abel, that we are our brother's keeper. This has never been changed. It is just as true today as it ever was. A selfish person is not a safe person, because he cares only for himself. The highways are full of such. They are the cause of most of the terrible accidents we are having daily. We also have them in industry—careless, indifferent, selfish. They are a constant hazard. Drastic measures should be taken to rid our plants of this type of employee. If they do not respond to training, let them go; your industry is better off without them. On the other hand, an unselfish person is a safe person as a rule because he is interested in his fellow man and will not knowingly do anything to injure him. We ought to be thankful that the great majority of human beings fall in this class.

We, of the United States Aluminum Company, pay a great deal of attention to safety meetings. We are organized as follows: A Safety Department as a section of the Personnel Division, with a safety director, reporting directly to the personnel director. There is a safety committee in every department of the plant. These committees work hand in hand with the safety director. These department committees are organized into one large safety committee. They elect their own chairman and the safety director acts as secretary. They have a regular order of procedure in conducting their meetings. Minutes are kept and read at the meeting and everything is conducted in a serious business-like way. These meetings are held once a month on company time, and last

one hour, from 4 to 5 p. m. The Company furnishes a box of good cigars at each meeting. Conditions of the whole plant are discussed and suggestions are made for improvement along safety lines. No part of the plant is overlooked as there are representatives from all departments.

The order of the business is as follows: call to order; reading of minutes; safety paper or talks, by one or two members of the committee, or perhaps by the safety director or myself; unfinished business; new business; review of accidents; roll call; adjournment. It is interesting to note how serious and business like these men enter into their committee work. We have found this the best type of safety committee organization we have ever had and we are seeing results.

Getting Closer to the Individual Worker

This is one type of safety meeting. Then we have another type which we have been carrying on for more than a year. Realizing that we were not getting close enough to the individual worker, we asked permission of our management to go into each department and conduct safety meetings throughout the plant. Our method is as follows: we notify the foreman of a certain department that we wish to hold a safety meeting; he gathers his employees together at some convenient point, and they are given two short safety talks, one by Mr. Hopkins, our safety director, and one by myself. The meetings are held at starting time, just after the noon lunch period. All is quiet; the machinery remains idle for 10 or 15 minutes while we talk safety to the employees, face to face, calling their attention to the great interest the company is manifesting by being willing to hold up production for this period of time in order to hold a safety meeting. We ask for their cooperation, telling them that we are helpless without their assistance, asking them to consider themselves assistant safety directors, showing them that they have all to gain and nothing to lose by getting whole-heartedly into the safety game.

We started out in this work with some timidity, wondering what effect the new move would have, but we soon found that it was the most popular move we ever made. We have been urged to return to departments both by the employees and managers, three or four times. They seem always to be eager to hear more about safety. Why? Because it is a subject which grips the heart and is of vital importance to all, and we are all anxious to learn more and more about how to keep from being injured.

Then we have another type of safety meeting, the large community safety meeting. We have been conducting them now for four years, during November, coupled with the general "Thanksgiving No-Accident Month." These are large meetings, 1,200 or more in attendance, with great enthusiasm, community singing, brass bands, orchestras, vocalists, and the very best of safety speakers available. These meetings create a great deal of community interest in the safety movement. The daily press gives space liberally. Industries 10 or 15 miles away send large delegations. The weather has no effect on the crowds, it appears. The series of meetings closes with a large banquet. The tickets are usually purchased by the various industries and presented to their employees as an appreciation of their attendance at 75 per cent of the meetings.

Also, we conduct safety meetings in the various public schools with good effect. We go into the rooms and talk to the children about safety and accident prevention. We always get a satisfactory response and we have the cooperation of the school authorities.

Thus, I have tried to tell you about the various safety meetings we are conducting in our community. What is the purpose of all this? Education, information, training, developing and keeping up interest in the general subject of safety.

Does it bring results? Yes, our records have been getting better and better year after year, this last year much better than ever before.

Some safety director might be saying "Yes, that's all right for you fellows, but I'm no public speaker. I can't get up on a soap box and talk, especially to my fellow workers." Well, neither are we public speakers, but we have found that if we are deeply enough interested in the subject we can talk about it, and that about the only reason we can talk at all is because of the interest we have in safety work and a sincere desire to rid our industry of accidents. All present today have this same interest and by a little effort and self confidence you can do it as well, and in most cases much better, than we can.

If the employees see that you are interested in them and their welfare, they will respond and compliment you on what you are trying to do, and follow your lead. Most of us are just waiting for some one to lead off.

It is necessary sometimes to put yourself out a little to show your sincerity. One of the most telling things we ever did was to come out at twelve o'clock at night to talk to the men on night turn. We have done this several times, and we have heard words of appreciation and statements from the men to the effect that "if these safety men are enough interested to come out at midnight, it is as little as we can do to be interested also."

We are guarding our machinery wherever it is needed, but we believe that the most effective work we are doing is the education of our employees through the medium of these personal touch channels.

In conclusion, I would urge all safety directors, general managers, superintendents, educators, mothers in the homes of our land, ministers, teachers automobile drivers, and men and women in public and private life, to get behind our safety movement, seriously and enthusiastically, for in no other way it seems to me, can we accomplish the purpose for which this great convention is assembled.

CHAIRMAN BENNETT: I am sure if that talk is to be prepared next year, whoever includes the speakers will include Mr. Ziegler's inspirational talk with those of Mr. Howard and Mr. Hale. We will proceed at once with our next subject, which will be handled by Dr. L. G. Harney, consulting surgeon, The American Steel Foundries, East St. Louis.

Health of the Steel Workers

L. G. Harney, M. D., Consulting Surgeon, American Steel Foundries,
East St. Louis, Mo.

Your secretary a few weeks ago, when he talked to me about speaking on the "Health of the Steel Worker," didn't realize what kind of a subject he had assigned to me. The health of the steel worker is no different from the health of the average individual in the same class and community in which he lives. Therefore, you can realize that he has probably assigned me a subject that means all the human ailments to which we are subject today.

I think it is time to really lay our cards on the table. Let me illustrate what I mean. I don't know how many of you have read Kipling, but he wrote a good many stories on "Tommy Atkins" or the "Soldier," and if you remember one of them, in a very graphic way that only Kipling probably can give, he described the feelings of a man who was frightened, scared. He described what the man said, how he felt, and then gave his impression of how that man must be feeling from what he said; and all of a sudden he woke up and ended the story by saying, "And this was I."

I think the time has come, gentlemen, when that point is going to come home to us, and instead of putting the burden on industry any longer, I think it is now time to wake up, as I am doing.

I am first going to take up a few of the things that I have inquiries about that may probably be of interest to you. The first point is the electric welder. You all know that nasty, little hurting burn that comes on in the eyes, when the eye begins to burn six or eight hours after, and if it is during the night you begin to lie awake with the pain. Let me say that I have investigated that very carefully and there are no X-rays in the welder. It is the same thing as sunburn—actinic rays. It affects the membrane of the eye, which is pretty hard to explain without going into a long scientific discussion; but I have had several cases over a period of time and have had it in my own eyes and there are no permanent results, either inside or externally.

On two occasions I have had men come to me who thought they had some trouble with the abdomen following exposure to the electric welder; and an investigation of these gentlemen showed, in one a case of gall bladder infection and in the other chronic appendicitis. There is, and can be, no internal effects from the rays of the electric welder.

I'll grant that you are going to have to take some things on faith today, but should any of you individually care to dispute the matter with me, I will be very glad to prove the statements I am going to make. I shall be careful not to make a statement which I can't prove, so I ask you to take it upon faith for the present.

✓ The Question of Exposure to Dust

The next point that I have in mind, and there has been considerable written about it, is the question of the sand blast, the exposure to dust. Thanks to your wonderful Safety Council and thanks to the present respirator, it is an absolute protection in the sand blast department. As you know, in most companies it is customary to inspect the sand blasters once in 90 days or oftener, to see if there is any indication of tuberculosis. I have had only one case in which tuberculosis developed, and careful investigation showed that this man's home life was the cause of the tuberculosis not, in my opinion, the plant itself. He had a child with a tubercular and enlarged gland that had broken open and a wife who was tubercular and had been for a long while.

I want to repeat that the up-to-date steel foundry is probably a more healthful place to work in than is the average home. With your ventilation, with your light, with your heating, with the convenient location of your laboratories, with your showers, with your locker rooms, I would say that you will find the up-to-date steel foundry a mighty healthy place to work.

The next thought that I might take up briefly is the question of core compound. You have probably all had experience of a core compound which has a phenol base and in the use of that, frequently there comes a dermatitis, a little burning and reddening of the skin. It gave us some trouble at first, but we soon found by unloading this material at night, putting on clothes simply for the unloading process and immediately removing them and then taking a bath, we got rid of this trouble. It is not permanent unless too often exposed or too severely over too long a time. At the present time we are having no trouble because we are carrying that point out.

Another inquiry which comes frequently is the effects of contact with the molten metal and the heat therein. You know most of us are swayed pretty much by emotions and we think something ought to be so because certain things that we haven't reasoned out may be true. We are really thinking of the fact that that metal has been heated to probably 2,800, 2,900 or 2,950 degrees Fahrenheit. Let's just reason a moment. What happens when you stick your finger in boiling water heated at 212 degrees? All right, that's common experience, we don't have to argue that at all.

Deduction No. 2 is that at no time is the heat which the individual is exposed to greater than 212 degrees. If so, it is nothing but a flash, because if you did you would get a burning of the skin just as you do in the hot water. No one has definitely measured the amount of heat that a man will be exposed to around the molten

metals, but what we all do know is that it is less than 212 degrees in which he gets a direct sustaining contact to the body.

What, then, is the trouble? We all know that on a hot, sticky, moist day in the summer time when we can't perspire, due to the fact that the air is filled with moisture, we do not get the cooling effects of evaporation or perspiration.

The next point that comes to your mind—and I know probably what you are thinking. You will say, "Well, but so many men are overcome by heat." Let's analyze this just a moment. Let's decide what heat exhaustion is.

Sunstroke, which may be experienced by being exposed to the sun, is one kind of a diseased condition. Sunstroke is demonstrated by high temperature, hot, dry skin and, if you have a severe enough degree, unconsciousness, and only comes from direct exposure to the sun. Heat exhaustion is characterized by cold, moist skin, plus unconsciousness only if it goes to that extreme. Death from sunstroke is not unusual. Death from heat exhaustion is rare.

Twenty Heat Exhaustion Cases in a Day

During a certain summer about five or six years ago at one of the plants with which I was associated, between seven and eight o'clock one evening we had 20 heat exhaustion cases. It was unusual and I immediately got upon the job, worked for days, and I will give you the answer that we arrived at.

The first thing, of course, that we thought of was our water supply. Carefully analyzed, we found it to be absolutely all right. We looked to any other unsanitary things that might be in this department. Nothing was found. What was the next problem? The individuals themselves. I was fortunate in treating all of these men and was able to follow them through (most of them were in the hospital) and here is what we found.

They were night men who had not slept well during the day. We had had a long period of six or eight weeks of very hot weather. The men's vitality was low, appetites were gone and almost invariably these are the facts as I found them. "I wasn't hungry this morning and I ate some cantaloupe and some plums instead of eating breakfast." They had been eating that way for several days. I came into the plant and in between the day shift and the night shift, the water supply had become very cold. The men came to work, filled their stomachs full of ice water and on top of plums and cantaloupe, there was one beautiful battle right there.

Since then, men in industrial work and those who are working on heat exhaustions, have definitely proven that heat exhaustions only come in those individuals who previously have a gastro-intestinal disorder. That may sound a little startling to you. You may want to question that. But, if you will check over, or your plant physician will check over, you will find this condition is there.

Those are the principal things that seem to occupy most of our minds today on the health as a probable or possible inherent hazard in the plant itself. This brings me to the point that I want to talk to you about. The question of "I."

Dr. Charles Mayo, two years ago last March, was quoted in the papers at a meeting of the Dental Society in Texas as saying that 87 per cent of all the deaths in America come from some type of infection, and of that 87 per cent, 87 per cent came from the teeth. I wish that Dr. Mayo had said, instead of the teeth, from a point above the lower jaw.

You gentlemen see daily in your plant a man who says to you some day "I stooped over to lift a core and I must have sprained my back." Gentlemen, without going through the process in arriving at this answer, maybe I can make you see that it is not possible for a normal back to be sprained by a simple lifting effort. Why? Just briefly, the sum total of muscles in the back are so superior to the sum total of the muscles of the arms that it isn't possible to put enough weight on the arms to sprain or overcome the muscle pull of the back. These men are frequently accused

of being malingerers. They are no such thing. The pain which they have in their back is many times greater than any injury that you can conceive of.

Some of the medical profession today are accepting what I am going to try to give you now. I am going to put in some of my own personal interpretations on this because I think it is worth consideration.

The average laborer's diet, gentlemen, is what? Meat, potatoes, bread, butter and coffee. That does not contain any of the vitamins which are necessary to good health. Have any of you been out camping and eaten the camp grub for a long while and began to get a sour stomach and wanted a pickle. A call of nature for vitamins, definitely and positively.

More Rough Food Is Essential

Our dentists tell us if we do not begin eating more rough foods that in the near future we will probably be a toothless race. Do you remember what your speaker said to you today, that you shouldn't quote a theory which is prejudiced? The dentists are prejudiced because it is in their line. Our breakfast foods are without roughage or coarseness and if we don't soon get a massage to the gums we are going to have a good deal more difficulty than we have had in the past.

What is a local infection? You gentlemen are hearing of this right along. Let's talk about it for a moment. When an abscess appears in some part of the body, it does not necessarily mean that all the symptoms from this abscess or this pus are localized at that point. When you get a headache, that isn't a sign that you have an abscess in the head; it is the sign of increased poisons in the blood, or toxinemia, as we speak of it. The infection that produces this most commonly comes from an area originally above the lower jaw, teeth, tonsils, adenoids, the different cavities that may get pus in them when you have a bad cold, and from that one or two things may happen. Either you will get painful areas lining the muscles of your back, or this infection or pus may travel to another part of the body.

It may be interesting to you to know, not just from the standpoint of the steel worker, but from the standpoint of the individual, doctors today are practically agreeing that before you can have appendicitis, gall stones, gall bladder infection, duodenal ulcers, gastric ulcers, that in the great majority of cases your infection starts at a point of entrance through the mouth. Our school inspections today are directed toward this and I think that is the place where the actual work is going to have to be done—habits of youth. I say this because at one of the plants with which I was associated, the plant manager at one time rather objected to the fact that men who had loose, pussy teeth that you could wiggle around anywhere, were not passed as first class risks. Some of the men were very expert workmen and naturally in good condition at that time, but were objected to by the plant manager because we were turning them down as not first class risks.

An Experiment With the Dentist

We then made this experiment. We took a certain number of these men, sent them to their dentist, had the teeth cleaned up and when they came back with their teeth in good shape (those that were capable of being cleaned), we put them to work; and again in 90 days we looked these men over and they were back to the same condition practically as before. Why? Because the habit of years cannot be easily overcome. We learn careless habits. In our youth we must learn the care of the mouth, the habit of those things that are best for us to do. Frequently, later in life, we cannot get people to learn to live that way.

Why do I bring this point up? There is practically no injury of a bone or joint that is not affected by a physical condition in this type of person. You take a joint, a sprained ankle, that ordinarily should last from two to three weeks, but in this type

of person it lasts four, six, eight and even twelve weeks. Gentlemen, you don't need to worry about what is the matter, your only trouble is to find out where the infection is and try to correct it. This brings up the point, what are we going to do about these physical examinations for the men who do not pass the examination for work? It is a question of simply informing these gentlemen what they have and try to let them get it corrected before troubles start.

Another thing that was interesting about those experiments was the question of checking these men with these conditions alone and finding out how soon these men would come in with back complaints or supposedly sprained ankles or some other condition similar to muscle mialgia, or rheumatism. You will be interested to know that 25 per cent of these men in the next three months (this was in the fall of the year when the cold weather produced certain things that we always find in the fall) came in with just what we anticipated.

How Toxemia Will Develop

You will say, "How does this particular thing interest us from the standpoint of the metal worker?" Maybe I can make you quickly see what I have in mind. How many of you have ever gotten out of bed in the morning when the wind happened to blow just a little too strongly on the side of the bed, and you couldn't get your neck around? What you are doing when you are carrying an infection, is somewhat like a man that is carrying a bank balance of only \$150. Suddenly something comes along when he has to spend \$300. He is \$150 in the hole, and it is a lot harder to get out and on the level again, and that is exactly what happens. Your resistance is low. This little exposure to the draft, sudden chilling of the body, quickly breaks the resistance farther and you start in to have trouble with toxemia.

We say, "Why worry about this particular thing, when it is the individual's viewpoint alone, rather than industry?" No, gentlemen; it is not. I think that industry today is beginning to look at these problems from the standpoint of an altruist; our life should be happy, definitely happy, and you can only be happy with good health. But there is something further than this; that is the duty we owe to mankind. I think lots of times we lose just the little contact that we need for knowing why these things are taught.

America is (I am sorry to say) at times pretty much mercenary. Maybe that is fine; maybe that's the motive force that drives us on. But we mustn't lose sight of the fact at all times that there is more to life, and I think industry is seeing that more and more as time goes on. What is my point? Did you and I have anything to do with the manufacture of electric lights or electricity, originally? Did we have anything to do with the planning and building of this building, of automobiles or of airplanes? Not at all. We are enjoying things that were given to us by our forefathers. Duty demands that we transmit to those who come after us the best also that is in us. Anything less than best is a slacking. Therefore, gentlemen, I do say, in maintaining my point, that the element of the individual in the steel industry must now be given attention because I think that industry, particularly in the metals section, has gone just about as far as it can go as regards any inherent hazards.

The Problem Is Up to the Individual

The problem now is up to the individual man, demanding that he himself do what he can to adjust the cause of absenteeism in sickness and industry.

CHAIRMAN BENNETT: We will proceed at once with Mr. Oartel's paper since he is called home on account of serious illness and we will defer the discussion of other subjects until after his slides are shown. I am sure we will have comments on Dr. Harney's excellent address.

Late Developments in Safeguards

John A. Oartel, Chief of Safety Bureau, Carnegie Steel Company, Pittsburgh, Pa.

While we are getting the lights, gentlemen, I want to say that this has proven a very interesting thing to me for the last three years. This is the third time we have put a feature of this kind on, and I had a little reaction just about a month ago. I gave these pictures to the NATIONAL SAFETY NEWS after the Congress and they published one in the September issue; and I had a letter from New York and two letters from near Pittsburgh, asking for information about that device, so I think this is something that is finding, or filling a want, in the iron and steel industry.

Now, as they are shown on the screen, I will read a description of them and maybe someone here is acquainted with the industry which has given me these photos, who will explain more than I can.

The first few pictures are from the Commonwealth Steel Company, furnished by our good friend Ed Quesnel.

Slide number one

Slide No. 1. Note the safety chains used on this electric magnet to catch the load should the power be suddenly cut off. This device was perfected and is now used by the Commonwealth Steel Company, Granite City, Ill.

Slide No. 2. This safety trolley pole for cranes and yard gantry was also developed by the Commonwealth Steel Company, Granite City, Ill. These poles are so constructed that should the wheel fly off the trolley wire, the spring will pull the pole clear of cross arms, which hold the trolley wire, thus preventing the pole from being broken. Note how short the pole has been made.

Slide No. 3. Note how the Jones and Laughlin Steel Corporation, Pittsburgh, Pa., has effectively guarded the moving parts on this hot mill. This guard is held in place by two eye bolts and is provided with a loop so that it can be very easily handled by the crane.

Slide No. 4. The Gorham Manufacturing Company, Providence, R. I., fortunately installs the safety device, shown in the lower left hand corner, on all drop hammers. This shows the value of this device, as the eye bolt on this machine broke a few days after the machine itself was installed. The operator's fingers were saved.

Slide No. 5. The end of the roll, illustrated here, is the point of operation. This half round iron guard is simple, but positively safe. This is another development by the Gorham Manufacturing Company, Providence, R. I.

Slide No. 6. This illustrates a very clever square shear guard developed by the Gorham Manufacturing Company, Providence, R. I. This guard is automatically controlled, drops ahead of the knife and follows the knife up.

Slide number two

Slide No. 7. This acid carboy inclinator, equipped with glass splash shield, is now used by the Gorham Manufacturing Company, Providence, R. I.

Slide No. 8. This plan is used by Midvale Company, Philadelphia, Pa., to refresh employee's memory on safety rules. Rules were printed in ballot form and submitted to every employee with the request that he mark with an X the particular rules which he considered as the most important to him. Seventeen hundred employees read over the eighteen rules and each one returned a fine ballot. The rule that received the most votes was No. 2 which read as follows: "If you are injured, no matter how slightly, while in the course of your employment with

the company, you must report at the works dispensary for treatment immediately."

Slide No. 9. This guard is now used by the Bethlehem Steel Company, Steelton, Pa., on all swing grinders of this type. Note that the operator is fully protected and that he is also wearing goggles.

Slide No. 10. This is another type of swing grinder used by the Bethlehem Steel Company, Steelton, Pa. Note that the wheel is provided with a very substantial retaining hood as well as an exhaust system vented to the outside.

Slide number three

Slide No. 11. This face mask is used by men at Bethlehem Steel Company, Johnstown, Pa., when cutting rivets with rivet buster in car shop. When men wore goggles these goggles were broken and the face cut from rivet heads striking some other object and flying back. A King face mask was equipped with standard goggle lenses and a one-half inch mesh screen on hinge.

Slide No. 12. This large collar is now used on all hot metal ladles of the Bethlehem Steel Company, Johnstown, Pa., to prevent the crane hook from catching on the ladle trunion and causing the ladle to tip.

Slide number four

Slide No. 13. Flickering red lights over passage ways from charging floor to gas producers are provided, as illustrated, in the South Works of the Illinois' Steel Company, Chicago, Ill. These lights are installed on each passageway in a position where they can be easily seen. This is a warning that engine and cars are entering the building on these tracks. About fifty feet outside the building is a switch arranged with a trigger (illustrated in *Slide No. 14*). in the rail so that when

cars pass over the trigger the light begins to flicker and continues to do so until the train passes out of the building and throws the trigger in the opposite direction.

Slide No. 15. This trough used by the Duquesne Works, Carnegie Steel Company, takes care of bars running back from the roughers. The bars run back and up this trough instead of coiling around on the floor which was formerly the practice and was considered a hazard in the mill.

Slide No. 16. This slide shows a section of cast house at blast furnaces of the Edgar Thomson Works, Carnegie Steel Company. The shutters in the runners are controlled from the cast house wall.

Slide number five

Slide No. 17. This illustrates a blow-off muffler installed on narrow gauge locomotives of the Edgar Thomson Works, Carnegie Steel Company. This muffler is similar in construction to the automobile muffler.

J. A. OARTEL: That's all, gentlemen. I want to say, if you want this feature to be successful, you will have to send in photos and they should be in to my office at least six weeks before the Congress starts because they have to be sent away to be put on this bill.

CHAIRMAN BENNETT: I am sure, Mr. Oartel, we appreciate very much your efforts and work along this line. I know it is certainly the hope of everyone assembled here that your wife's illness will not prove serious.

I am not going to take time to introduce all the incoming officers. I will present Mr. Northwood as chairman-elect to conduct the remaining portion of the meeting which is "Your Hour."

It gives me great pleasure to present Jack Northwood.

(Mr. J. A. Northwood, Bethlehem Steel Co., Johnstown, Pa., took the chair.)

CHAIRMAN NORTHWOOD: I attended the Public Speaking session this morning and

Slide number six

I have the method of doing it in my pocket, so I am all right. Public speaking is not my line, but I have one desire in our Metals Section and I think it is the desire of all of our executive committee, and the majority of our members, to make this Metals Section the biggest section of this tremendously big conference. We can do

Slide number seven

it, men, but we have all got to pull together. These are days of slogans and I would like to have our Metals Section called "The Friendly Section."

Now we speak a whole lot about what friendship means, friendliness, getting a little closer together; but what we want, fellows, is to get a little closer to each other. Our problems are all the same, no matter what kind of a plant we come from. It is the human element that we have to deal with. It is the human element that we have to reach. We have got to do our work with a spirit of enthusiasm and with all our hearts, if we are going to be successful in carrying on our no-accident pro-

The Midvale Company **SAFETY CENSUS**

1-28-27

In an effort to determine their relative importance, and to improve them, we submit to every employee in the Works a copy of our Accident Prevention Rules, with the request for criticisms and suggestions. Use reverse side for remarks.

Check the particular rules which apply to YOU PERSONALLY.

- ☐ 2 If you are injured, no matter how slightly, while in the course of your employment with the Company, you must report at the Works Dispensary for treatment immediately.
- ☐ 17 A neat and orderly plant means fewer accidents. Cultivate the cleanliness habit. After you eat your lunch, all paper and rubbish must be placed in trash cans.
- ☐ 18 As so many injuries in the plant occur to the feet, you are advised to wear the heavy box toe safety shoe. For further information, ask your foreman.

No. _____ NAME _____

Write your number, sign your name carefully, and drop in ballot boxes. We must receive a return from every employee in the Works. Reply promptly; do not make it necessary for us to go after you the second time.

THE SAFETY COMMITTEE.

Slide number eight

grams. It is getting harder each year in all our plants. The harder it gets, the more necessary it is for us to put our heart and soul into it and give it all we have.

There are men here in our Metals Section from all over the country. We have one man from our company who is from San Francisco, who came here to attend this conference. I just wonder what his impression is, whether he feels that we are friendly and earnest, or what it is.

Can we not get together a little closer, introduce ourselves to the other fellow? Men have been coming to this conference for years and never met John Oartel, who is an outstanding safety man from our Pittsburgh district. Well, now, John isn't a hard man to meet. Step up to him. A man came to me yesterday and wanted to know if I wouldn't introduce him to Mr. Oartel. Great guns, go up and tell him who you are and he will introduce himself to you.

Now, fellows, that's the spirit we want to get. Let's pull a little closer together and I am sure we will accomplish bigger things and better things for this coming year. It is a great game we are in. It is a game of life and it is worth while. It takes us all.

Mr. John Eib of the Illinois Steel Company is one whom I want to introduce at this time as our new secretary. He is going to be the editor of our News Letter. Fellows, what that News Letter is depends on you as individuals. What you send in to John Eib for the News Letters is what is going to make that letter a success and a help to us all. I don't know how many of you fellows enjoy that, but I look

Slide number nine

forward to receiving it and peruse it very carefully. It is worth while. I know what it means to edit it. I acted as secretary for one year and it is a hard job to pull out from the atmosphere something that we want to get across that will be of interest to the other men throughout our section.

We have 700 members in this section and we want those 700 men to feel free and easy in bringing their problems to us. Perhaps, we can't help you solve them, but we will do the best we can. Just give us the chance. Write in to John Eib, of the Illinois Steel Company, at Joliet, and he will get the question in the News Letter and someone in the organization will be able to give you the help that you need. So much for that.

Now, then, I don't want to jump your outgoing chairman and I don't want to jump to "Your Hour" until we have that discussion on the talk of Dr. Harney. That, to me, fellows, was the most practical talk on health in the plant that I ever heard, and

*Slide number ten*

I know that there are some men here with questions to ask Dr. Harney about that talk. Let's be snappy about it. Let's be quick about it. Let's put some pep to it and we will have something that's worth while.

O. D. MOORE (Pennsylvania Railroad Co., Philadelphia, Pa.): We have three electric welders in our shop and use them in welding coppers and wet places on angles and things of that sort and quite frequently it becomes necessary for us to have fitting gangs in this welding department. There are about two helpers and a foreman. We had an awful lot of this difficulty of which you spoke, of men going home at night and getting up the next morning and not being able to come back to work and they lost two or three days' time (their own time, of course, because

Slide number eleven

they get no compensation) and then they come back and refuse to go back into the welding department again because they figure they are the losers and are not getting anything out of it and you can't blame them.

Of course, we send them to our eye specialists and he fixes them up temporarily, but they refuse to go back to work. We hit upon the idea of going to an optical company and getting amber colored glasses. They are so constructed that they have a shield on the side so the light from the welder can't get in.

Are injuries in these cases permanent? I would like to ask Dr. Harney if he thinks our efforts in that direction are right, and if not, what he would suggest?

DR. L. G. HARNEY (American Steel Foundries, East St. Louis, Ill.): Gentlemen, in talking to you, I only laid the ground work of what I hoped that you would ask me and this first question I am just delighted with.

Yes, your goggle is the thing. It is an amber glass you say?

MR. MOORE: Very light amber glass.

DR. HARNEY: The Julius King Optical Company is using a glass for the electric welder and that is your protection for electric welders. Now, I went out, personally, when these things came out, and stood around the electric welder purposely to get a burn. I did it just as deliberately as anything could be done. It was about 3 o'clock in the afternoon when I left. About 1 o'clock the next morning, I was in a confused state, my eyes just simply burning terrifically, and my

Slide number twelve

first thought was that I had happened to get something in my eyes. As soon as I got awake enough, I knew what was the cause.

With all my experiments, I find that packs of ice put on those eyes immediately give you the quickest results. Just take some ice, put it in a cloth and lay it right on your closed eyes. It is nothing but an increased congestion and I find, by my own eyes, they were feeling first-class, without the application of adrenalines, borac acid, etc. It isn't really an infection unless it has gone too far. Your cold application will probably give you the quickest and most satisfactory relief and ice is the thing I would use.

Your goggle is your protection, and that is what you must use, because anyone who gets exposed to that ray (and you don't have to be right on it) will find it

*Slide number thirteen*

painful. In electric welding on the street-car tracks, you will sometimes see a sign up, "Do not look at this light." It is purely an actinic ray and has that quality of burning even at quite a little distance. We have looked over these eyes during electric storms with static electricity when they get this sort of burn from arc when switch blows out and I know one man who has worked for 20 years with such frequent exposures and I had the privilege of examining his eyes to see if it would make a permanent burn. It did not. It is purely a congestion.

Now, then, your men don't want to go back to work. Why? Because they don't know these facts and I don't blame them, after having the amount of inflammation and that awful feeling. I would be afraid to go back to the same thing if I didn't know it couldn't do me any permanent harm. Your treatment is in your ice packs, and your goggle should be supplied as a protection to all electircal welders.

MR. MOORE: Will these light amber goggles do the stuff?

*Slide number fourteen*

Slide number fifteen

DR. HARNEY: The welding goggles are to be preferred.

MR. MOORE: In this case, you will understand, the fellow who is doing the fitting cannot see the marks on the blue print and that is where the trouble comes in.

DR. HARNEY: He can't see until he turns on the light in the welder, and makes contact. You won't be able to see it until the electric welder or the arc is in operation, but you will with that.

MR. MOORE: You will understand, the fellow who is fitting material together will have to take them off when he is doing it. That means the other fellow will have to stop.

DR. HARNEY: You will not be able to do close work without the electric welders and you can signal the other fellow before you turn it on.

WM. A. HAUKAP: We do a lot of welding, and we have found that the American Optical Company goggles never wear. The Novi-weld Lens Goggle will, and

Slide number sixteen

we get sufficient protection from this goggle and you can absolutely read a blue print. I have read many of them myself, as I happen to be an inspector as well as safety supervisor. Of course, you can't do that in the first fifteen minutes, you have to get used to it.

W. S. ELLIS, JR. (American Steel Foundries, East St. Louis, Ill.): I think he is going to get into trouble if he does have Novi-weld goggles; that is for acetylene and it takes a darker shade where you are around the light very long.

MR. HAUKEP: We have been using them for about eight months and haven't had any trouble. They will give you the protection.

CHAIRMAN NORTHWOOD: There isn't any one special goggle of any kind. They all have the different shades. Some call for the darker shade for welding.

MR. HAUKEP: I believe there are 14 different shades and almost any one of them will protect you. Of course, if you have very heavy work, it should be a little bit darker lens.

Slide number seventeen

E. G. QUESNEL (Commonwealth Steel Co., Granite City, Ill.): For the information of members who have employees only occasionally subject to the welder light, such as cranemen traveling above the floors and getting flashes from a distance, and men working in the blue print rooms where they have to look at their incandescent arc occasionally—frequently we were having quite a little trouble with that and we couldn't put a colored glass on them because it interfered with their vision.

We ran across a lens known as "Ark weld," which is almost transparent. One shade of it, as far as I can tell, is absolutely transparent. It is made in three shades, the darkest shade has just a tinge of color. Now, this lens enables a man to take the electric welding flash or the incandescent arc flash without any apparent harm or discomfort to the eyes, and our cranemen are now wearing these lenses as well as the men in the blue print rooms and we are having no trouble whatsoever from flashes when they are from a distance.

It is a new glass and, so far as I understand, it hasn't been on the market very long; the glass is ground about one-half inch thick. It can be ground to prescription and also can be ground to the regular goggle lens, but it gives you lots of comfort and does not interfere with the vision.

CHAIRMAN NORTHWOOD: All right now, so much for our electric welding side of the question. Is there anything else in Dr. Harney's paper that we want to bring out?

S. G. SLADER (East St. Louis, Ill.): Referring to the question of sprains to the back, Dr. Harney, I gather from your talk that it was impossible for a man to strain his back because the back muscles are stronger than the muscles of the arm. The question in my mind is whether or not a man can strain his back by the position he places himself in.

DR. HARNEY: That same point was brought up when I talked to a group of doctors. You will notice that I said "a normal back cannot be strained by a simple lifting effort." Now, then, if you don't come in that "normal" class you are going to take me into the abnormal class, which, of course, this is not the place to discuss. That is a matter ingrained and not of disease.

The Pain Really a Form of Rheumatism

I think maybe in my talk I just didn't quite make plain what this pain in the back is due to when you make your lift. This is really a form of rheumatism. Someone said he had found a cure for this, which was, "Don't let it happen." I think preventive medicine will be found so that in the future you will not try to cure a thing which has happened; you will try to prevent it from happening, and the medical profession is beginning to recognize that today.

What happens in these backs? They get a little inflammation around the joints from any source. The muscles become painful, just like any muscle around an inflamed joint. A lift is made, the muscles come into contraction and the muscle being painful, the more the contraction the more painful it is, and so you have got a vicious circle. Now, then, this pain which comes on immediately and is awfully disabling in this type of back—not the back that has a dislocation, nor the back which has a displaced something—but the normal back, cannot be injured by a simple lifting effort. Now, then, here's what I am getting at. If this back which is of the rheumatic, or lumbago type, it doesn't carry over what I want, as not being injured, but diseased.

If this type of back is treated as an injury, he will be going from six to eight months or a year with a painful back. If the cause of this pain (and it is the doctor's job to definitely demonstrate that there cannot be and is not any injury), is treated as an injured back by putting on an adhesive plaster and you don't stop to remove the cause, then the man seldom gets well soon. In a series of over 500 cases, it took from ten days to three weeks as a maximum.

It is the very point I am bringing home to you now, that too many of these diseased backs are being treated as injuries. Given a diseased back of this type and they are one of the easiest backs that I know of to have injured by a simple lifting effort. Am I going to say nothing happened there? Not at all. I tell you that a diseased back must always receive a proper test. Why? Because it is a potentially weak back.

Keep the Body in a Healthy Condition

Now, then, don't try to treat that back as an injured back. What I am after, gentlemen, is to try to get these men back to work as soon as possible by finding the cause and removing it. Take, for instance, a little yeast advertisement which you will see in every big magazine, "I have been feeling badly when I get up in the morning. I have pimples on my face." Eat yeast and get well. That isn't as silly as it sounds. What is he doing? He is putting in the vitamin content that puts your food over in the right way. But why get to the place of taking yeast the rest of your life? Why not do the things to prevent it? Then watch your symptoms disappear.

No, the normal back may not be injured in the way I told you; the other type, yes; but it is up to the doctor to find what you have got.

CHAIRMAN NORTHWOOD: I don't think there is one thing that gives us as much trouble as that old bugaboo of a sprained back, and sometimes it puzzles the doctors to determine what it is. It is a hard problem and I am very glad it has been brought out in this discussion.

J. F. COLLINS (Youngstown Sheet & Tube Co., Youngstown, Ohio): I would like to ask the doctor if he connects heat exhaustion and muscular cramps with men working in a hot temperature?

DR. HARNEY: Yes, sir; that is a very peculiar thing. This gentleman is the greatest ally. Now he has asked the question, and has brought up a point that I would like to have raised before. What is my answer on the question of muscle cramps in heat exhaustion? Do I think it has any connection with heat exhaustions or any connection with toxemia?

After a Little Party Is Over

How many of you have been out at a friend's party some night when you had a little poker game, and the next morning you drank lots of ice water and had a little headache? What do you suppose was behind that, gentlemen? Here is what happens. It is really very interesting, too. This man who collapses from potential heat exhaustion, is already a man who is filled with toxic products that ought to have been eliminated before that time. Why is it on this particular day the man gets heat exhaustion? Because he is physically unfit. Why doesn't every man who is exposed to the same heat conditions suffer from heat exhaustion? Because he happens to be in better physical condition.

There is too much toxemia, for your intestinal tract is a long tube and the big colon is nothing on earth but a cesspool. Now, I am not trying to criticise God's construction of us. But it is a cesspool. This man may have been drinking alcohol, which takes up water and holds it so that the water is not available for washing out the poisons of the body. Have you ever watched your wife put sugar in water so that finally the sugar will settle to the bottom? There is a point of saturation for these poisons beyond which you may not go. If you have a four-inch sewer and want to flush that sewer out, you can't put in one inch and hope to flush that out thoroughly. We create in urine, each day, 1,500 to 2,000 c. cm., or approximately a quart and a half, of water. A quart and a half of water is probably six to eight glasses. Therefore, if you don't put in enough water to clean these poisons out of the system they can't be carried out. Consequently, each man should drink in twenty-four hours at least one glass of liquid for each ten pounds of his weight.

Heat Exhaustion Denotes Intestinal Trouble

This man of the heat exhaustion is a previous intestinal tract individual. We have proved that beyond a doubt. What is happening? He has such a low degree of clearance for his toxemia that when his heat exhaustion comes on his muscle contraction starts in. Due to what? Due to an over-abundance of toxemia in these muscles when he works and the arm gets stiff, just like the day you have gone out and pitched a game of ball when you are not used to it. The blood supply was not able to take away the toxemia. It is another proof (thanking you for bringing it up) of the thing that I am telling you, that heat exhaustions primarily are first intestinal toxemias, and toxic muscles always cramp.

CHARLES W. HANKO (Pittsburgh Steel Co., Monessen, Pa.): We had, the first part of this month, about ten of these cases. You know last month was pretty cold and the first week of this month was very hot; we wondered if the weather conditions didn't have something to do with it. We had some of the most foolish back ailments you ever heard of. One fellow got a sprained back, and another fellow who

was wheeling a 25-pound piece of ice through our plant, as he was setting the wheelbarrow down, got a sprained back. We had a hard time trying to convince him that he didn't have a sprained back. Of course, the doctor said it was due to his job and he agreed that it was weather conditions and I just wondered if the doctor would agree with us on that statement.

DR. HARNEY: I absolutely will. Here is the thing. In cold weather there are two elements. In cold weather people drink less water than they do in hot weather. The elimination by perspiration is relatively very much less then. Now, these attacks may come on. You get a little chill and that is how it happens.

Here is the same thing again. What happens when you walk out first from a warm room. The vessels of your face contract and you turn pale. After you are in a little while your face begins to glow and this is adjusted. There is a sudden contraction of the muscles and that is what happens in these cases; and still a further degree, you have to eliminate the size of the vessel. Your weather has a lot to do with it.

Information of Value to the Medical Man

I tell these men when I am treating them (when I find out the causes), "You are getting along all right now in the summer time, but when cold weather comes on again you probably will experience another of these attacks if you don't take care of it." We have more trouble with this in the winter than we do in the summer.

CHAIRMAN NORTHWOOD: Is there anything else in Dr. Harney's paper that you want to bring up?

J. B. ORBISON (American Radiator Co., Kansas City, Mo.): I would like to ask Dr. Harney if we can carry the message back to our plant doctors in quoting his name in connection with the points that he brought out in reference to back injuries or sprained backs, because that is something in our plants which we have in an aggravated condition.

DR. HARNEY: Yes, I will be very glad to have you do it. I will even go farther than that. I was not able, of course, to go into the scientific reasons why this is so. I will even do more than have you quoted this meeting; I will be very glad to mail him a paper I wrote in which there was a beautiful bunch of discussion; I will be glad to mail him that for his own investigation. I mean, he don't have to accept my stated opinion, he can go back and check those things through. It is a very interesting study.

MR. ORBISON: I think we are overlooking a very vital thing in connection with this Congress, in that we don't have our medical doctors from our plants in attendance, as well as our so-called safety directors. I think that is something to give attention for the coming year.

CHAIRMAN NORTHWOOD: I think you are right.

Problem of Compensation for a Lame Back

R. B. KELLEY (Anaconda Mining Co., Anaconda, Mont.): The doctor has brought out a point which is very annoying to us in the mountains and that is this back ailment. I would like to ask the doctor, as physician for his company, if an employee came in with a lame back, would he consider it a valid reason for that man to collect compensation under the law of the state?

DR. HARNEY: I have probably been more open in my statements to you gentlemen today than I have ever been before in my life, either in a medical group or elsewhere.

You have had me in a little bit embarrassing position, but I am going through. The manager of my Casualty Department is sitting within three feet of me and I am going to tell you what they do. For seven or eight years he has been my good help in sticking with me and being convinced of the things which I am showing are true.

Here is what we have been doing with our cases, gentlemen. The legal right for a man to collect under this sort of a condition is being aired in the courts every day. I am brought into court practically two or three times a week to answer the question that you are giving. In Missouri, with the new Compensation Act, they have said that where no evidence of bone injury or injury to the soft tissues can be demonstrated, either by X-ray or clinically, that the man will be entitled to approximately three weeks' disability and that is the end of it. In Illinois, that isn't being held so. But today the courts and the arbitrators are beginning to recognize that what I have told you gentlemen today is an accepted fact.

This plant with which I work has done this and it is highly complementary. When a group of medical men once said to me, "Well, what do you do with each case?" I said, "In five years, if you can find one single case in a back injury, sprain or otherwise, outside of a broken back, that has been brought before the arbiters, I will make a donation of one thousand dollars to any charitable organization you can name."

Treatment Prescribed for the Cause

What do we do? We put them to bed at once. We put them on a diet and try to find a treatment for the cause, wherever it may be—intestinal tract, teeth, tonsils, bladder or elsewhere, and this company has been nice enough, because our period of time is from ten days to three weeks, to carry it on the basis, in the majority of cases, of a casualty. We do not explain to the men when they first come what it is. Why? Because they aren't in a position to accept it. But when you tell a man at the end of three weeks what is wrong, with a back that hasn't let him sleep day or night, you will find he is interested, ready to receive what I am trying to tell you gentlemen today. At the end of the time, we tell him where his trouble is, what he can do to get rid of it, and then he accepts it. Why? Because we have proved the statements that we made, and there has been no case brought up where they have been treated by this particular company, simply because we give the best results and best interests for the men.

If they are treated that way, there ought to be only a short time of disability.

The question of legality isn't for me to answer. I can only tell you that in the cases in Missouri, and some in Illinois, some of them were beaten and some of them were not, where there has been a case of injury; but that is a question of policy and I can't tell you what to do. That is what your plant will have to decide for itself.

R. B. KELLEY (Anaconda Mining Co., Anaconda, Mont.): We have in our employ a great number of men. The back condition is one we have the most difficulty with. I will now be able to go back to our medical practitioner that is employed with the company with an argument that seems to be accepted here this morning by the Metals Section, that a man must suffer an injury before he can collect from his employer compensation that he has never earned.

Additional Points in the Problem

CHAS. W. HANKO (Pittsburgh Steel Co., Monessen, Pa.): I would like to ask this question again, whether they treat this as a welfare case or otherwise. I believe if it is treated without making some decision, we are throwing ourselves open to the fact that we are assuming the responsibility for that accident. That is the thing which we talked of and we have tried to come to some conclusion, but we can't do it and I would like to know just how they treat that. Because if you do that the Compensation Board is liable to tell you that you have accepted this man as injured by treating him. I would just like to know whether you make that distinction or not.

F. H. ELAIN (American Steel Foundries, Chicago, Ill.): These questions we have accepted as a casualty case. What else can we do? If we refuse to treat the man,

if we refuse to pay him compensation, he takes it into the compensation period and then there is the expense of the lawyer and all those things that go with it. We make that in our reports. We try to protect ourselves there. We would rather give this man medical attention, possibly a few days or maybe a week's compensation, and get him back to work, than to fight the thing when there is no fight coming, and perhaps accept a larger cost to the department of the company.

CHAIRMAN NORTHWOOD: In other words, that comes right down to a company policy.

MR. KELLEY: I don't want to be misunderstood in denying the employee, because that is not the intention at all. We furnish the medical attention and hospital accommodation for all of our employees no matter what happens, but what we really don't understand out there is this. (and the doctor has quite clearly stated what we should do), that where we have so many back injuries, isn't it possible for it to occur from some other reason besides actual results from the employment?

MR. HANKO: I don't want to convey the idea that our company is trying to get away from paying any just claims, because we are trying to do anything we can and will continue to do so. What I asked is just how you would handle that? We are trying to do the just and right thing.

CHAIRMAN NORTHWOOD: I think we have gone pretty far on this discussion and I think the time has come when we can reach the question of "Your Hour." Now that doesn't mean "Your Hour" as an individual man. We would be here until next week. The question cards have been passed and some of the things you fellows want to bring up, now is the time to do it. Do it in as short and concise a way as possible and we will try to answer you in the same way.

Real Safety Men Are Sincerely in Earnest

T. H. MCKENNEY (Illinois Steel Co., Chicago, Ill.): Just before you pass on to "Your Hour," you have discussed the doctor's paper but you have called for no discussion on Mr. Ziegler's paper.

There is just one thing that Mr. Ziegler said in his paper that I don't like. His paper was very fine. I am willing to accept all of it but that part in which he said he knew of some safety men who were making a joke of the safety movement. I do not agree with him. I don't think he meant that. I think he should have said, and I don't like to see it go in the records, some so-called safety men. I don't know of any safety men who make a joke out of the safety plan. Every man engaged in safety work is a 100 per cent safety man and he does not like to make it a joke.

N. V. B. ZIEGLER (U. S. Aluminum Co., New Kensington, Pa.): Thank you, Mr. McKenney. I am willing to accept that. He would be a so-called safety man.

C. L. LOCKHART (Milwaukee, Wis.): I was interested in how the Midvale Company operated 95 days without an accident. I have a plant of 700 men but I haven't been able to equal that record. I came very close to it and we would be happy if we could run just one month without an accident.

We have not been lax in putting in safety devices. We have our committee and so on, but we haven't come anywhere near the record shown on the screen today.

The thought comes to me that probably I am too quick in terming an injury an accident and I would like to know what the Midvale Company terms an injury before it is termed an accident?

CHAIRMAN NORTHWOOD: Is there anyone else here who can answer that definitely? If not, I will say this, that the accepted understanding of an accident causing lost time is the man who fails to return to work on the turn following the turn in which he was injured.

R. G. FENLON (Carnegie Steel Co., Duquesne, Pa.): Before we go into the dis-

cussion of "Your Hour" I would like to suggest that we give Dr. Harney a vote of thanks in coming here and talking to us this morning on things that are interesting and of very great importance to every man who has to do with safety in the steel organization.

C. L. BAKER (Bethlehem Steel Co., Johnstown, Pa.): I want to second that motion. It certainly has been a pleasure for me to sit here and hear a doctor talk out loud in a meeting and say exactly what he thought.

(The motion was duly made and seconded, to extend a rising vote of thanks to Dr. L. G. Harney).

CHAIRMAN NORTHWOOD: Now we can get into "Your Hour" and answer the question "Should a foreman be held responsible for the accidents in his department?" Who is going to answer the question?

The Foreman Acknowledges Responsibility

W. S. STIEFER (Youngstown Sheet & Tube Co., Youngstown, Ohio): For the last six years, I have been a foreman and I feel he should be held responsible for the safety of those men, that he should be held responsible for accidents in his department. I feel that because of this, he should be held responsible for the education of those men in the ways of safety.

I think that is the fundamental reason in the test that should be applied in making that man responsible for the safety of the men under his care.

E. E. ARMSTRONG: I do not agree with this. In fact, I don't think it is fair to burden the foreman entirely with the question of educating his men in safety. We started out the first of 1927 with a new idea. In 1926 we were carrying on safety lectures in our departments as outlined by the speaker who presented "Safety Talks" which were being given by myself and my assistant.

We thought, well now, let's give the foreman a chance to do this talking. The men will probably listen to him more than they will to us. He can probably get the message across a little better than we can. We tried that. We wound up in 1926 with a very fine record. The first four months of our program of having our foremen carry on our safety lecture talks was a flat tire. The foremen are men who can talk production and they can talk machines but when they get up in front of a bunch of men and try to give them the message of a safety education and what it means, they can't do it as well as a man who spends his entire time on safety work and working out safety problems and things that mean safety to the average man in the shop.

Personal Talks on Safety Helped Reduce Accidents

So we discarded that idea. The first four months of the year we ran up 32 accidents. Eighteen of them were in our iron foundry. The foreman asked us to come over and take over the talk. We did so and we can't say this is the reason it stopped, but we know in 1926 what happened.

We went out there and started our talks from the safety department ourselves and we have had two since then.

I don't think we ought to give the foreman the entire burden.

CHAIRMAN NORTHWOOD: I don't think that was the idea of this foreman at all to give the foreman the entire burden; but the foreman being directly over his men in production, he can show and direct them the safe way in getting that production. That is my feeling on the foreman's responsibility. He is the key man.

J. F. CHAPMAN (Colorado Fuel & Iron Co.): I may be asking a very old question, but it is one of those that is of interest to us; and that is the production of a

rule book where you have to use it around the plant. I want to ask the men here their personal opinion as to the value of a general rule book to give to all employees; or the making of a rule book for individual departments in the steel plant which shall be given to the men who are working in that department; or whether there is some other scheme which they think is still better of getting over to the men the safety rules which the company wants the men to know and follow.

O. D. MOORE (Pennsylvania Railroad Co., Philadelphia, Pa.): We have a definite set of safety rules. At the time the foreman is given a copy to study, personally, he is also supplied with sets to mail to every employee who is on our pay roll. We figured that by mailing these rules, they would more likely enable the men to receive them and hang on to them than if we handed them out in the shop. They kept them in better condition; there is also the possibility of their being read and talked over.

Since that time it has been our counsel to send a set of these rules, along with a letter explaining the purpose of our safety effort, to every new man who comes in our employ. That is general throughout our entire shop. Our steel plant is just one big shop and the other shops are closely related to the main plant.

CHAIRMAN NORTHWOOD: Our plant of 3,000 men went 169 days without an accident.

New Men Ought to Be Thoroughly Instructed

JOHN P. EIB (Illinois Steel Co., Joliet, Ill.): This question of a rule book kind of gets my nanny in a little way. I think possibly I get more letters and more talks about giving rule books. I am still one of the old-fashioned fellows who believe a man who comes into a steel mill to work ought to have a thorough instruction on how to do it safely. What you do with a rule book all depends upon the justification in issuing it.

We give a rule book to every man. We have them printed in ten languages. But if you simply hand that rule book to a man who comes in to get a job with you, you are just wasting the time, effort, paper and money. If you follow that up step by step so that you know, and the man knows, and the foreman knows, that the fellow does know the hazard and risk of his job, you have accomplished something with rules.

We have spent a lot of money on rule books at our plant, but we do not start right in with the office where the man gets his first contact with the company. No matter where you go they have an employment office. There is the first contact a man gets. Needless to say, he is entitled to courtesy because it is there he forms his first impressions. If he doesn't get that courtesy there, he certainly doesn't care much about your company before he ever starts to do a tap of work. There is the place where we try to get that first contact along with the safety standpoint, along with the rule book.

Then we follow that up with the men. We have a man who goes to the employment office every morning where he gets the names and numbers of the men who have come in to work since the previous morning and he goes to each department and there, in conjunction with the foreman, they talk over the risks and hazards of this man's particular job and what is expected of him from a safety standpoint. You know then that the fellow has had his first step in education.

We started a long time ago to make sure that that was carried out, by having a printed form sent out from the employment office, divided into three spaces, whereby the place was provided for the man to sign, the foreman to sign, and if necessary the interpreter.

Then, after a man has been there a little while, it is followed up with an oral examination of that man's knowledge of the rules in the book. We don't expect him

to give them out word for word. I couldn't do that and I wrote a lot of them myself, but he can give an understanding, or his understanding, of the rule.

The safety button is still awarded at our plant. It is old-fashioned. But it is the idea of starting in at the employment office, following it down step by step, whereby you have the positive assurance that the man really does have the safety instruction on his job and that is what you want. You can't expect a man to cooperate with you from a safety standpoint if he doesn't know what you are driving at; and it is the job of your organization to see that that man is instructed. That is why I rose to the question of a rule book, because I feel it is what you do with it, whether you get any value out of it or not.

J. H. CHAPMAN (Colorado Iron & Fuel Co.): That is just along the lines I want to get hold of from one of the steel companies. Anyone who would sit down and read that rule book through, and read it intelligently—I don't believe he could do it in an hour and a half. A new employee is interested in his job. He is interested in going to work. He wants to get his money. He wants to get his job so that he can get his money. He is interested in that part of it. The rule book is something that he thinks is all right, maybe, to stick it in his pocket and that is about all he does with it.

I am glad that point was brought out. We need to have these rules and regulations gotten over to the man personally and the hazard of his job particularly called to his attention. It has been my idea that a rule book which has the general rules of the company and then in addition has some specific rules for the individual department where the man is employed, is the thing to give to an employee, rather than a general book having rules for all the departments, together with the general rules of the plant.

Foundation of Safety Laid in Employment Department

C. L. BAKER (Bethlehem Steel Co., Johnstown, Pa.): I don't think John Eib is so old-fashioned. I have an idea, after listening to him talk for a minute, in regard to his contact with the employment department, that there is where the foundation is laid for the wonderful record that the Joliet Works has made.

You have got to bring in one factor that I want to mention to John, and that is the doctor's physical examination. Dr. Harney is the right kind of a medical examiner in connection with the man coming into the employment of any company. When I say the right kind of examiner, I mean a doctor who does know something about medicine, who does know the plant in which the man is going.

You know, there is just a little peculiar trait about those old doctors, in my experience. A lot of times they cure and don't give you bad medicine. They impress you. Why? Because of their sincerity. The medical examiner is in a more wonderful position. Naturally, we have due respect for him because if we don't do what he tells us to, he makes us think he will compel us.

Now, I want to testify to the rule book. I want to see the man from Colorado. I have a word from a man of his, a message that I want to pass on to him. Give the employee a rule book that is a simple thing which doesn't take him a week or month to find out applies to the department he goes into. Then follow it up. The follow-up proposition in our safety work seems to be today the thing that is getting results.

Now, gentlemen, I am going to digress a minute and say a personal word about your chairman for next year. I think you all ought to know something about him, more than you do.

I am happy this morning to tell you how proud we are in the Bethlehem Steel Company to see one of our men having this wonderful place at the head of the Metals Section. I suppose a lot of you fellows are wondering whether this man is a real safety man or not, and wondering what is happening in the plant that he is taking

an interest in. I am going to tell you a few things about him. I don't say that the records made in this plant are entirely up to Ned, but I do say that he does have the cooperation and backing of a plant management in safety work from the general manager down. Cooperation is what gets results today, in my opinion.

Now, there have been some records made in that plant in the last three or four years that the management is proud of and I am going to tell you just a few that have happened in this last year. They are going on just now so that you will get the idea of the kind of leader you have for this Metals Section next year.

A number of you are acquainted with the wire gang. We have a wire mill gang with one inch and three-quarter wire rod, wire products, nails, etc., a separate unit of the Cambridge plant. It starts off by itself, starting in the steam plant, machine shop, electric power station, etc. Now that department this year has operated the entire year with one lost-time accident. They had that one in January and since January they haven't had a man with a lost-time accident.

We have coal mines running out right into the plant where the coal goes directly into the coke oven. They have two coke plants, two blast furnaces and all down the line, to the steel car shop (they used to call it the bracher shop).

The Latest Is the Best Accident Record

We just made a record last month of ten lost-time accidents in the entire plant. That was the best we ever did. We had 13 in May, 13 in June. Our general manager the other day said: "Say, I think it is about time you fellows went without any lost-time accidents"; so we are going to try in October. We are not going to make any noise about it and ask each department not to have an accident, because every department has gone over a month this year without a lost-time accident. We also made up our minds and the electrical department has gone 140 days straight ahead now without a lost-time accident.

We have a wheel plant which is a forging process, rolling and forgings. It has gone 146 days without a lost-time accident.

I merely point out these things to show what interest the chairman of your Metals Section takes in accident prevention work, and I will speak for him, for the cooperation of every member of the National Safety Council, to make it broad, but particularly the membership of the Metals Section. I particularly want to see the Metals Section continue to be the outstanding section of the National Safety Council. It is entitled to it. It has fathered safety; its leadership is pronounced all over the country in accident prevention work. I want to see you maintain him; I want to see you grow; I want to see this section the outstanding section of the National Safety Council and I want you to give your committee your closest cooperation for this next year.

Don't forget the fellow who publishes your monthly Letter. He has a hard job; I know it. Send him a note that will be encouraging; and I wish you, this next year, the greatest success that the Metals Section has ever had.

CHAIRMAN NORTHWOOD: This is not a testimonial meeting. It puts me in kind of an embarrassing position, but I want to say this, that your executive committee who arranged our program this year wants your criticism on it. We want you to let us know what you want for next year and we will try to give it to you. Do you have any constructive criticism as to what we should bring up and what we should have for our meeting next year? Let us have it, fellows; it's your meeting. Let's make it the biggest meeting we have ever had.

Mr. Blank is the chairman of our program committee for next year and I want you to come down here, Mr. Blank, so these fellows can see you and know who we can kick to if the program isn't the best we ever had.

E. F. BLANK (Jones & Laughlin Steel Corp., Pittsburgh, Pa.): I will appreciate very much a letter from any of you and all of you in regard to what your ideas are

of the subject or suggestions for the program next year. We want to make this program bigger and better every year. Some of these fellows are making it pretty hard to beat, but if we have your help this next year, with your suggestions, I am sure that we can even go further.

D. B. FITCH (Youngstown Sheet & Tube Co., Youngstown, Ohio): As a suggestion for next year, I move by all means that you invite Dr. Harney to this section.

JOHN P. EIB (Illinois Steel Co., Joliet, Ill.): There is just one thing more that I want to say. This meeting is about to close and as a fitting close, it seems to me that it should be the sense of the meeting (I say this not only as a member of the Metals Section, but from having been on the executive committee during this past year), that we express our appreciation to our retiring chairman. It has been, to repeat again, a privilege to work under Fred Bennett.

There is one thing else that I want to express. To my mind, in all of the years that I have been coming to the congresses, his graciousness this morning in turning over this meeting to the incoming chairman, to me is a most admirable thing; and I think that there should be an expression to Mr. Bennett for his wonderful year of service and I am sure this meeting will not only second, but give a rising vote to him.

(A rising vote of thanks was extended to Fred Bennett, retiring Chairman.)

F. G. BENNETT (The Buckeye Steel Casting Co., Columbus, Ohio): I only have one thing to say and that is to thank you for your cooperation for the past year.

ADJOURNMENT

SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Mining Section

New Section Officers

Chairman, C. A. McDOWELL, Pittsburgh Coal Company, Pittsburgh, Pa.
Vice-Chairman, GEORGE MARTINSON, Pickands, Mather & Company, Hibbing, Minn.
Vice-Chairman, A. W. DICKINSON, The Union Pacific Coal Company, Rock
Rock Springs, Wyo.
Vice-Chairman, J. P. HODGSON, Phelps Dodge Corporation, Bisbee, Ariz.
Vice-Chairman, F. C. MILLER, The Colorado Fuel & Iron Company, Trinidad, Colo.
Secretary, DANIEL HARRINGTON, United States Bureau of Mines, Washington, D. C.
Poster Committee Chairman, H. C. HENRIE, Phelps Dodge Corporation, Bisbee, Ariz.
Membership Committee Chairman, H. I. YOUNG, American Zinc, Lead and Smelting
Company, Mascot, Tenn.
Publicity Committee Chairman, THEODORE MARVIN, The Explosives Engineer, Wil-
mington, Delaware.
Slide Committee Chairman, H. G. HENSEL, The Youngstown Sheet and Tube Com-
pany, Chicago, Ill.
Engineering Committee Chairman, J. M. CARMODY, Coal Age, New York City.
Statistics Committee Chairman, RUSH N. HOSLER, Pennsylvania Compensation Rat-
ing and Inspection Bureau, Harrisburg, Pa.
News-Letter Editor DANIEL HARRINGTON, United States Bureau of Mines, Wash-
ington, D. C.
Executive Committee—THE OFFICERS AND
B. C. YATES, Homestake Mining Company, Lead, S. D.
B. F. TILLSON, The New Jersey Zinc Company, Franklin, N. J.

Retiring Officers

Chairman, HOWARD I. YOUNG, American Zinc, Lead & Smelting Co., Mascot, Tenn.;
First Vice-Chairman, C. A. McDOWELL, Davis Coal & Coke Co., Thomas, W. Va.;
Second Vice-Chairman, GEORGE MARTINSON, Pickands, Mather & Co., Hibbing, Minn.;
Third Vice-Chairman, A. W. DICKINSON, The Union Pacific Coal Co., Rock Springs,
Wyo.; *Fourth Vice-Chairman*, J. P. HODGSON, Phelps Dodge Corp., Morenci, Ariz.;
Secretary and News-Letter Editor, DANIEL HARRINGTON, U. S. Bureau of Mines,
Washington, D. C. *Committee Chairmen*: *Poster*, JOHN L. BOARDMAN, Anaconda
Copper Mining Co., Butte, Mont.; *Publicity*, THEODORE MARVIN, The Explosives En-
gineer, Wilmington, Del.; *Program*, R. V. AGETON, Tri-State Zinc & Lead Ore Pro-
ducers' Assn., Miami, Okla.; *Membership*, H. W. GIESSING, Commerce Mining &

Royalty Co., Baxter Springs, Kans.; *Statistical*, H. G. HENSEL, The Youngstown Sheet & Tube Co., Chicago, Ill.; *Engineering Representative*, R. DAWSON HALL, The Coal Age, New York City; *Executive Committee*, The OFFICERS and B. F. TILLSON, The New Jersey Zinc Co., Franklin, N. J.; T. T. READ, American Institute of Mining & Metallurgical Engineers, New York City.

Tuesday, September 27, 1927

HOWARD I. YOUNG, Chairman

Manager, American Zinc, Lead & Smelting Company, Mascot, Tenn.

The first session of the Mining Section of the National Safety Council was called to order at nine-thirty o'clock by the chairman, Howard I. Young, manager, American Zinc, Lead & Smelting Company, Mascot, Tennessee.

CHAIRMAN YOUNG: The first order of business is the reports of the various committees. Mr. John L. Boardman, chairman of our Poster Committee and safety engineer of the Anaconda Copper Mining Company, Butte, Montana, will present his report covering the activities of his committee during the past year.

Report of Poster Committee

Official notification of our appointment on this committee was received on December 7, 1926. We immediately planned to place as much emphasis as possible on the hazards of falling coal and rocks; handling material; and cars and motors, these being the three most prominent hazards in both coal and metal mining.

In order to get a diversity of ideas and give a large number of members an opportunity to express their views, we requested the Chairman, Mr. Young, to appoint a large committee, and the following members were appointed: Anaconda Copper Mining Co., John L. Boardman, Chairman, Bureau of Safety, Butte, Montana; Berwin-White Coal Mining Co., E. B. Creighton, Supt. Ins. Dept., Philadelphia, Pa.; Calumet & Hecla Consolidated Copper Co., Calumet, Michigan; The Cleveland Cliffs Iron Co., W. Conibear, Safety Engr., Ishpeming, Michigan; Colorado Fuel & Iron Co., 801 Boston Bldg., Denver, Colo.; East Butte Copper Mining Co., O. A. Dingman, Butte, Montana; Homestake Mining Co., C. A. Brooks, Lead, South Dakota; Old Ben Coal Co., J. E. Jones, Safety Engr., West Frankfort, Ill.; Mine Rescue & First Aid Assn., W. G. McBride, Gen. Mgr., Globe, Ariz.; Phelps Dodge Corporation, C. W. Moore, Safety Engr., Bisbe, Ariz.; and Pickands Mather & Co., M. D. McIntyre, Cleveland, Ohio.

Request was mailed to each of the members appointed to submit a minimum of five poster ideas each, covering the three accident hazards mentioned.

Response to this request has been rather generous, as we have submitted material for 33 posters, in addition to copies of the daily bulletin service furnished by the A. C. M. Co. up to June 1, and many other posters submitted direct by members without going through the hands of the chairman of this committee.

On December 24, 1926, the plan of enclosing one copy of each mining section poster with the monthly News Letter was approved, but not followed successfully.

To date the committee has received 47 letters and three telegrams, and has sent out 40 letters and two telegrams.

We exhibit all posters printed for the Mining Section in the NATIONAL SAFETY NEWS from January, 1927, to September, 1927, inclusive. There are 15 in number, of which nine were chosen from the 33 submitted through the chairman, and six were selected from those submitted direct by members of the committee or by other members.

We find that during the same period, the Metals Section was allowed space for 19 poster units, as compared with our 15 units, but we call attention to the fact that these two sections are so very closely allied that frequently mining men may find the metals section posters very useful. We also wish to call attention to the very valuable posters of others, such as the Public Safety Division, and the Health and Chemical Sections, many of which may be used with profit by members of the Mining Section.

We recommend that when possible, exceptionally good posters which may be applicable to several of the allied sections, be printed in two unit size or larger.

We wish to take this opportunity to thank the members of the committee who have responded so generously to our request, for this work, and to express our special thanks to Mr. Gardiner, Director of the Poster Service, for his excellent cooperation and assistance throughout the year.

John L. Boardman, Chairman.

CHAIRMAN YOUNG: Gentlemen, you have heard the reading of Mr. Boardman's report. What is your pleasure?

FRANK A. POLLOCK (District Safety Engineer, Oliver Iron Mining Company, Eveleth, Minn.): I move the report be adopted.

P. M. ARTHUR (Director of Safety, American Zinc Company of Tennessee, Mascot, Tenn.): I second that motion.

CHAIRMAN YOUNG: It is moved and seconded the report of Mr. Boardman's committee be accepted. Is there any comment? If not, all in favor of that motion make known by saying "aye"; contrary, "no." It is so ordered.

Mr. Boardman, I want to express to you and your committee my appreciation of the work you have done. You certainly have put into your work a great deal of thought and effort and it is very much appreciated.

The chairman of our Membership Committee, Mr. Henry W. Giessing, safety engineer for the Commerce Mining & Royalty Company, of Miami, Oklahoma, will report the activities of his committee.

Report of the Membership Committee

In reporting the activities of the Membership Committee, Mining Section, National Safety Council, we wish to advise that, partly from choice and partly from suggestion, the following members were solicited to serve on our committee:

Mr. L. D. Anderson, Chief Engineer, U. S. Smelting, Refining & Mining Co., Salt Lake City, Utah.

Mr. D. A. Thomas, Montevallo Coal Mining Co., Aldrich, Alabama.

Mr. Everett H. Parker, U. S. Bureau of Mines, Berkeley, California.

Mr. Everett H. Parker, Elm Orlu Mining Co., Butte, Montana.

Mr. K. T. Sparks, Hecla Mining Co., Wallace, Idaho.

Mr. J. E. Jones, Safety Engineer, Old Ben Coal Corp., West Frankfort, Illinois.

Mr. C. J. Ennis, General Manager, McIntyre Porcupine Mines, Ltd., Schumaker, Ontario, Canada.

Mr. W. G. McBride, General Manager, Old Dominion Copper Co., Globe, Arizona.

Mr. Henry S. Richards, Safety Engineer, Blue Diamond Safety Dept., Winchester, Kentucky.

Mr. Baltzer Leonard, Safety Inspector, Harwood Coal Co., Harwood Mines, Pennsylvania.

Mr. G. E. Fatherolf, Safety Director, The Jeffrey Mfg. Co., Columbus, Ohio.

Mr. D. M. Stranaha, Safety Engineer, New York Zinc Co., Edwards, N. Y.

Mr. F. A. Dunyon, Safety Engineer, Utah Apex Mining Co., Bingham Canyon, Utah.

Mr. W. T. Kemp, Chief Safety Officer, Woodward Iron Co., Woodward, Alabama.

Mr. Dan Harrington, U. S. Bureau of Mines, Washington, D. C.

Mr. J. J. Forbes, Chief Safety Service Section, U. S. Bureau of Mines, Pittsburgh, Pa.

I am sure these men are all interested in accident prevention and strong for continued increase in the membership of the National Safety Council.

I received several letters of acknowledgment, saying they would be glad to do their bit in the community in securing new members.

Realizing that my facilities would not permit me to keep in constant touch with this committee, the names were forwarded to Council headquarters. In a letter to each member I stated that any information and all literature necessary in securing members would be furnished by the Council for the asking.

Cancellation and acceptance slips mailed me by the Council show approximately 29 cancellations and 38 acceptances. A great many of the cancellations were later reinstated. In the Tri-State district alone, I believe, two or three were again reinstated.

I sincerely wish I might have been in position to give this work more time and attention. I appreciate Mr. Cameron's letters of acknowledgment on different occasions, of a little bit of help I might have been.

As chairman of the Membership Committee I want to thank Mr. Howard Young for his interest. I know he has given time and gone out of the way to talk membership. I wish also to thank every member of the committee for the support given, and will be glad personally to render any service I can in the future.

Henry W. Giessing, Chairman.

Reports of Other Committees

CHAIRMAN YOUNG: You have heard Mr. Giessing's report. What is your pleasure?

R. V. AGETON (Safety Engineer, Tri-State Zinc & Lead Ore Producers' Association, Miami, Oklahoma): I move the report of the Membership Committee be adopted.

H. T. HARPER (Superintendent Service Department, Tennessee Copper Company, Copper Hill, Tennessee): I second the motion.

CHAIRMAN YOUNG: It has been moved and seconded the report of the Membership Committee be accepted and filed. Any comments at this time? I might say that the Council reports a net gain in membership of nine during the year. I think when you consider the conditions that exist both in coal mining and metal mining, you will all agree that the Membership Committee has, under the conditions, done a wonderful job. If there are no comments those in favor of accepting the report of the Membership Committee will make it known by saying "aye," contrary "no." (It is so ordered.)

Our Publicity Committee has as its chairman, Mr. Ted Marvin, managing editor

of *The Explosives Engineer*, Wilmington, Delaware. I will ask Mr. Marvin to make a report of the activities of his committee.

MR. MARVIN: The work of the Publicity Committee is rather limited and its results are intangible, I believe, except for one thing. As I say, the main purpose is to supply material for articles on mining to the NATIONAL SAFETY NEWS. Throughout the past year various men were designated to send in articles. On this committee were Mr. Pollock of the Oliver Iron Mining Company, Mr. Mills of the Alabama Safety Council, of Birmingham, Alabama, and myself. There has been mention of National Safety Council activities—that is, the Mining Section activities, made in various publications, and editors of various publications have at times received information as to activities of the Section. That is about the limit of what the Publicity Committee has done. Its real purpose has been to furnish articles on mining to the editors of the NATIONAL SAFETY NEWS, and I believe that has been done.

CHAIRMAN YOUNG: Gentlemen, you have heard the report of the Publicity Committee; what is your pleasure?

Report Accidents to the Bureau of Mines

R. DAWSON HALL (Engineering Editor, McGraw-Hill Publishing Company, New York, New York): I move the report be adopted.

MR. HARPER: I second the motion.

CHAIRMAN YOUNG: All in favor of accepting the report of the Publicity Committee will make it known by saying "aye"; contrary "no." (It is so ordered.)

CHAIRMAN YOUNG: Mr. H. G. Hensel, Safety Director, Youngstown Sheet & Tube Company, Chicago, Illinois, has been chairman of the Statistical Committee that was created this year. We will now have his report.

MR. HENSEL: There is not much to report in connection with the Statistical Committee for the reason that it was decided at the first meeting of your Executive Committee, that there would be no committee appointed, for the reason that no attempt would be made by the Mining Section to gather statistics independently of those gathered by the United States Bureau of Mines, and as your Section is cooperating with the United States Bureau of Mines, they thought there was no need of duplicating the work.

I would like to urge, however, that every member of the Mining Section report their accidents directly to the United States Bureau of Mines, who will gladly furnish the blanks necessary for such reports. You can secure those blanks by getting in touch with Mr. W. W. Adams of the United States Bureau of Mines at Washington, D. C.

All members of the Section are also urged to enter the National Safety Competition which is sponsored each year by the United States Bureau of Mines. This will enable them to make a comparison and to study the trend of accidents in the entire mining industry.

This year we find from their report that 257 mines competed for the Sentinel trophy, as compared with 210 in the previous year. I am speaking of 1926 and 1925. As many of you do not have comparisons for the past year I would suggest that you get in touch with the National Safety Council and get a copy of their pamphlet which is entitled: "Annual Industrial Accident Experience of Members of the National Safety Council for the year 1926." On page 11 of this pamphlet you will find the report of the Mining Section. This report is published through the courtesy of the United States Bureau of Mines. I wish to call your attention also to the fact that in that report for the year 1926, there was a decrease shown over the frequency rate for the year 1925, and in 1926 this frequency rate for the entire industry reported was 76.98. In 1925 it was 99.99. The severity rate for 1926 also is decreased over the previous year from 8.51 for 1925 to 8.47 for 1926.

I understand that it is the intention of the National Safety Council to continue to gather statistics in this manner through the United States Bureau of Mines for their report.

CHAIRMAN YOUNG: Gentlemen, you have heard the report of the Statistical Committee. What is your pleasure?

MR. HARPER: I move it be accepted.

MR. ARTHUR: I second the motion.

CHAIRMAN YOUNG: It has been moved and seconded that the report of the Statistical Committee be accepted. Any comment on the work of the Statistical Committee? This is a new committee and if anyone has anything to offer at this time we will be glad to hear it. If there is no comment, all those in favor of accepting the report make it known by saying "aye"; contrary "no." (It is so ordered.)

Mr. R. V. Ageton, Safety Engineer Tri-State Zinc & Lead Ore Producer's Association, Miami, Oklahoma, is chairman of our Program Committee, and they are responsible and deserve the credit for the program prepared for this meeting, which I believe is going to be very instructive to all of us. Mr. Ageton will now make his report.

A Program Planned to Answer Questions

MR. AGETON: I think the Program Committee, consisting of Mr. Hall, Mr. Harrington and myself, started out this year to try, in our program, to answer the questions that were brought up last year. We have our three morning sessions and our two luncheon periods. The Tuesday luncheon is under Mr. Jack Ryan, of the Mine Safety Appliances Company, Pittsburgh, Pennsylvania, and I am sure that Jack has something up his sleeve.

As you also noticed, we have a joint luncheon tomorrow at noon with the Mining, Quarry and Cement Sections, and Mr. Curtis has some very good things there.

In addition to our regular program there are two things that I would like to call to your attention. The first one is the observations of industrial silicosis by Dr. R. R. Sayers, of the United States Bureau of Mines, which will be held at two o'clock this afternoon. On Thursday morning, Dr. Meriwether will discuss mine dust on health, and Dr. Sayers this afternoon is going to discuss other phases that we will not get from Dr. Meriwether's paper.

I would like also to call your attention to the fact that Mr. Pollock is giving an article on Friday morning at nine-thirty o'clock on "Safety Engineers in Small Communities."

CHAIRMAN YOUNG: Gentlemen, you have heard the report of Mr. Ageton on the program of this Section. What is your pleasure?

MR. MARVIN: Mr. Chairman, I move the report be accepted.

C. A. MACDOWEL (Safety and Personnel Manager, Pittsburgh Coal Company, Pittsburgh, Pa.): I second the motion.

CHAIRMAN YOUNG: It is moved by Mr. Marvin and seconded by Mr. MacDowel that the report of Mr. Ageton's committee be accepted. All those in favor make it known by saying "aye"; contrary "no." (It is so ordered.)

Mr. Ageton, I want to thank you and your committee on behalf of the Mining Section for the good work you have done.

Gentlemen, we now have the pleasure of hearing the report of our secretary, Mr. Daniel Harrington. You are all familiar with the good work he has done as secretary and editor of the monthly News Letter.

DANIEL HARRINGTON (Chief Engineer, Safety Director, United States Bureau of Mines, Washington, D. C.): The secretary has very little to report. As a matter of fact, practically all the secretary has done as secretary, is to get out the monthly News Letter. I would like to ask that if you have any criticisms of it, if you have

any suggestions to make in connection with it, that you let me know, either now or by letter, I don't care which. I would just as soon it be shot at me one way as the other.

The one thing that I would like to say in connection with the monthly News Letter, however, other than to ask for suggestions, is that if you have any data which you think would be acceptable for the letter, please send it in. You have been invited to do that but only three or four have done so during the year.

About the only thing, other than the handling of the News Letter, that has come up during the year is that there was one meeting of the Executive Committee held here in Chicago, and at that meeting the principal business transacted was the discussion in connection with the program. There was other business but it was of comparatively minor importance as far as the report is concerned. Now, as to the status of the Section, I have the following information: Total number of members in the Mining Section on September 16, 1926, was 227. New members added during the year, 35; memberships cancelled during the year, 29. Memberships transferred from other sections, 3. Total number of members in the Mining Section at the present time, 236. That corroborates, of course, the statement given you by Mr. Giessing.

CHAIRMAN YOUNG: Gentlemen, you have heard the report of our secretary; what is your pleasure?

MR. HARPER: I move it be accepted.

MR. ARTHUR: I second the motion.

CHAIRMAN YOUNG: It has been moved and seconded that the report of our secretary be accepted. Is there any comment? If not, all those in favor will make it known by saying "aye"; contrary "no." (It is so ordered.)

At the request of the Council Headquarters, the Nominating Committee for this Section was appointed on July 12. Mr. Yates of Lead, South Dakota, was chairman; Mr. John L. Boardman and Mr. Hodgson were members. Mr. Yates and Mr. Hodgson are neither present at the convention and I am going to appoint Mr. C. A. Brooks, who is associated with Mr. Yates and Mr. W. A. Siebenthal, of Morenci, Arizona, who is associated with Mr. Hodgson as members of that committee. You will meet with Mr. Boardman, who will act as chairman of the committee, during the afternoon and be prepared to make your report at the meeting tomorrow morning.

I wish at this time to appoint a committee on resolutions who will report at the end of our Thursday morning session. I will name as chairman of that committee, Mr. Frank Pollock. Other members, Mr. Bannister and Mr. Henrie.

The first paper we have on our program today is "Statistics and Their Bearing on Accident Prevention," to be presented by Mr. H. G. Hensel, Safety Director, the Youngstown Sheet & Tube Company, Chicago, Illinois.

Statistics and Their Bearing on Accident Prevention

H. G. Hensel, Safety Director, Youngstown Sheet & Tube Company,
Chicago, Ill.

A necessary part of any educational campaign is statistics, as a record of the progress made. Statistics are true indicators of your progress in accident prevention. They will point out the cause of the most serious accidents or the causes of the most frequent accidents and that is of vital importance. Statistics alone will not prevent accidents, but the study and analysis of statistics are essential in determining what to do.

If we have our attention called to the fact that numerous or serious accidents are occurring due to a certain cause or on a certain occupation, it is then an

easy matter to direct a strong campaign to prevent accidents from that source.

It will indeed prove very true that statistics are a waste of the time and the effort used to compile them, if we do not use them to advantage.

I believe statistics can be made interesting for all the employees of a works or mine, but I also believe that it is best to devise a plan of presenting the statistics to each group so that the most benefit will be derived from them.

It seems to me that in presenting the statistics it is best to consider the groups as follows:

- 1st. Plant or Mine Management (general superintendents, district managers, vice-presidents, etc.)
- 2nd. Department heads and foremen.
- 3rd. All other employees.

To the miners and other labor, I believe an effective means of presenting statistics to them is to put on the bulletin boards short, snappy statements of the week's or month's accident record, the number of lost time accidents and the comparison with other mines in the same company, or a comparison with last month's record. This should be accompanied with a record of one of the accidents that occurred in the department during the past month, and this record can be briefly written on the board with chalk, or, still better, show a photograph of how it occurred. Great stress should be laid on the fact that an unsafe practice caused this accident, if that was the cause, and the best known method of preventing the accident should be depicted.

A Weekly Report of Accidents by Department

For the superintendents and foremen a weekly report of accidents by department should be issued and some classification given of the accidents that have occurred during the past week, and a comparison with the previous week should be shown. The bulletin can also give brief histories of some of the most serious accidents and how they might have been prevented. This is of unquestionable value to the foremen in their drive for a clean accident record and he can use such a bulletin to advantage in safety meetings of his men.

The report for the mine or works management can be made on several different bases, but I believe it should be made on whatever basis the management thinks gives them the best picture of the situation each month. The following schemes for presenting statistics are typical, I believe:

First. Some managers desire the accident record to be shown on a dollars and cents basis, showing them a total estimated cost of the accidents during the past month and by departments. This is particularly true of an operation carrying their own compensation risk. Others want the cost per \$100 payroll, cost per ton and cost per man.

Second. Another plan is to show the accident frequency and severity rates by departments and for the operation as a whole.

Third. Still another plan is to show the number of accidents according to occupation and the percentage that each occupation has as compared with the total number of lost time accidents. This system gives the safety engineer and mine management information as to just what occupations are having the most accidents, and such information should be of great value to the department head if he is given to understand that he must use it.

Fourth. Some organizations classify the accidents in their mines and works as to the day of the week on which the injury occurred, hour of the day when accident occurred, married men and single men, and age groups.

Fifth. One classification which I noticed recently was according to length of time

men had been in the employ at the time of injury, and in that particular group I noted that 43 per cent had been employed less than two months. This means that the new employee should be reached on accident prevention and the hazards of his job should be explained to him at once. He should be shown the safe way to do his work, not merely told to work safely. The necessity of prompt first aid treatment should be made clear to him.

Sixth. Some people have graphic charts made which show the trend of the accident record as compared with previous months and years. These charts I have found are of interest to many executives and they can see at a glance whether there is a decrease in the number of accidents or an increase, and use such charts at their meetings of department heads.

Seventh. At one mine I visited recently there had been drawn large circles on sheets of paper and the circle was divided into sectors according to the causes of accidents during the past month. Each sector was a different color to attract attention to the most general cause of the accidents. Another circle depicted by sector the location of the accident by occupation in the mine. I was told that the men and foremen were much interested in these charts.

At one of our works we are issuing, in addition to our other monthly reports, a monthly report of safety meetings of workmen held by foremen, showing the attendance record and percentage of attendance as compared with the number employed. Department heads have been asked by the management to see that each man attends a meeting twice a month.

The Accident Record of the Mining Section

I desire to call your attention to the report recently issued by the National Safety Council which is entitled "Annual Industrial Accident Experience of Members of the Council for the Year 1926." This report is issued in pamphlet form and contains all of the statistics gathered by the Council. I would suggest that you refer to the particular section in which you are interested and compare your records with the records of the other companies shown therein.

I want to call your attention briefly to the record of the Mining Section as depicted in that report wherein it shows that during 1926, 257 companies reported accidents having a total of 95,177,047 hours working with 94 fatalities and a total of 7,327 lost time accidents and a frequency rate of 76.98 and severity rate of 8.47. In 1925 there were 210 companies reporting with 68,518,787 hours working and 68 fatalities, with a total of 6,821 lost time accidents, and a frequency rate of 99.99 and a severity rate of 8.51. From this you will note that there was a decrease in both the frequency and severity rates for the year 1926 as compared with the year 1925 and I am also glad to say that there was an increase in the number of mines reporting accidents to this section; in 1926 there were 257 as compared with 210 in 1925.

I am advised that these figures are originally reported to the U. S. Bureau of Mines at Washington, D. C., and that they are then sent to the National Safety Council to be used in this report.

I would like to urge that every company that is not now reporting to the U. S. Bureau of Mines at Washington, D. C., to do so, so that this report will be a correct picture of the accident record of this section and by doing so you are also cooperating with the National Safety Council who are cooperating with the U. S. Bureau of Mines in this statistical work.

If you desire blanks to be used for making your reports same can be secured by writing to Mr. W. W. Adams, Chief Statistician, U. S. Bureau of Mines, Washington, D. C.

It is also a fact that the companies which report to the U. S. Bureau of Mines are entered in the National Safety competition and are competing for the Sentinel of Safety Trophy each year.

I would like to impress upon you the necessity of having statistics issued and in the hands of those concerned promptly each month and also of the importance of talking over the accident records made with department heads and the management.

CHAIRMAN YOUNG: Thank you very much, Mr. Hensel.

Mr. W. W. Adams of the United States Bureau of Mines, Washington, D. C., will discuss Mr. Hensel's paper at this time.

MR. ADAMS: Mr. Hensel has covered this subject in such a thorough and admirable manner that I will not take your time to discuss his paper in detail. I presume copies of it will be made available to the members of the Section, isn't that so?

CHAIRMAN YOUNG: Yes, it will be published.

MR. ADAMS: I wish, however, to emphasize one or two points. I have an idea that what we need most in accident prevention is more statistics on accidents. That is a natural view for one specializing in statistics, I suppose, but it is my opinion that if we had more statistics of the right sort we would have fewer accidents.

Mr. Hensel spoke of the importance of accident frequency and accident severity rates. That is one point which I would like to impress upon all of the gentlemen here because I think that is the most valuable feature of statistics.

Give General Circulation to Good Statistics

The year ended in 1926 with 257 mines and quarries that succeeded in remaining in this safety race throughout the period and in 1925 there were 210 mines and quarries that succeeded in completing the race. There are a number of companies that do not report their accidents in this detail, to the Federal Bureau, and it is not necessary, of course, that they all should; but may I suggest whether you do or not, that you supplement any statistics that you keep for your own local needs, by calculating your accident severity and accident frequency rates for your plant as a whole and make those two rates available to other companies that would be greatly benefited by knowing of your experience. In most of our statistics we deal with the average rates for labor groups. Now, those average rates are instructive, but they do not, by any means, represent the best that can be accomplished by individual companies. I think it is far more important for us to be able to send around the country the best accident rates that any company has been able to establish over a year's time. We circulate these average rates, but let us supplement them by making available to the whole mining and quarrying industry the best severity and frequency rates that any company establishes.

CHAIRMAN YOUNG: Thank you very much, Mr. Adams. Mr. Ageton, you have a discussion to offer on this paper.

MR. AGETON: I have asked Mr. Oliver M. Wampler, Safety Director of the Eagle-Picher Lead Company, of Joplin, Mo., to discuss this paper for me. I am not in shape to go into the thing very thoroughly at this time. I received Mr. Hensel's paper, and there are just two things that I would like to say. First, regarding the importance and the value of the "Sentinals of Safety Trophy Contest." Of course, we feel the value and necessity of it down in our district more than some of the rest of you do, because (I am going to brag a little) we have won the Metal Mining Trophy two years in succession; but I think that the good effect of having your companies in there and getting your standing is wonderful. They can get their standing with the other companies and with the average.

There is another feature which is very dear to my heart Mr. Hensel brought out, and that is the presentation of proper statistics to the men at the face—the men in the ground. We have made during the past year a series of posters, each one of which we have tried to make humorous. We have succeeded, I think, because

some of the men whom we mentioned threatened to sue us for using their names. On each poster we presented one vital thing.

CHAIRMAN YOUNG: Mr. Wampler, you have a discussion to make.

OLIVER N. WAMPLER (Safety Director, Eagle-Picher Lead Company, Joplin, Mo.): Mr. Ageton asked me to discuss for a few moments our annual safety reference book which we compile each year. I don't want you to feel that that is the only statistics we get out, but we feel that we get a great deal of good out of this yearly reference book.

We do most of the things that are outlined in Mr. Hensel's report, in that we get out the weekly statistics of accidents which have occurred and present those to the management and to the individual foreman. And in monthly meetings of the foremen we give a report of not only the accidents that happened to the individual foreman's mine, but to the company as a whole. We also get out a chart each month which we post at each mine to reach not only the foremen, but the workmen. This chart takes in both the mines and oxide plants of our smelters. One interesting phase of this chart is the fact that our general manager rather objected to the comparison of the oxide plants with the mines, stating that everybody knew that mines were more dangerous than oxide plants and, therefore, it was not a fair comparison. Last month our mines had half the lost time accidents per number of men working that the oxide plants did, so that shows you can compare most any line.

Comparison of the Various Records

In regard to this yearly report, we get this out as to cause of the accident and it is practically a copy of the questionnaire which the Bureau of Mines gets out each year. We use this form for two reasons: One is that it is much easier to fill out the United States Bureau of Mines questionnaire at the end of the year; and also the fact that the Tri-State Lead and Zinc Ore Producer's Association uses the same form. Therefore, we are able to compare not only the record of the individual mine as to the company as a whole, but as to the Tri-State district as a whole. One important thing in this report, is the last sheet showing everything that enters into the cost of our accident prevention work including insurance. Being a self insurer, our management is very much interested in the comparison with the regular basic rate, and we try to use a great deal of care in including everything that an insurance company might include in their report. We believe that our board of directors pay more attention to this last sheet than to the rest of the report.

CHAIRMAN YOUNG: Gentlemen, the meeting is open for discussion. I know there are a lot of you here who are handling statistics in other ways, and we will be very much interested in hearing your method and your experience and your opinion. Mr. MacDonald, would you tell us something about the Phelps Dodge Corporation work on statistics?

WILLIAM T. MACDONALD (Mill Superintendent, The Montezuma Copper Company, Phelps Dodge Corporation, Nacozari, Sonora, Mexico): Gentlemen, I am quite unprepared to make this discussion. Mr. Henrie was to be here this morning for that purpose.

I think, gentlemen, that the point to work toward is a reduction in the number of accidents. We must work, of course, toward a minimum, and the irreducible minimum as we all know, will be zero in accidents.

In 1924 among the employees of the Montezuma Copper Company, numbering approximately 2,300, we had a total of 104 lost-time eye accidents. In the year 1925 we commenced the present active safety campaign. During that year we introduced the use of various goggles—screen goggles underground principally, glass

goggles in the shops and so forth, this campaign going into full effective approximately the middle of the year 1925. During that year, we had 21 lost-time accidents due to eye injuries. During the year 1926, the entire year, we had two lost-time accidents. I am very happy to say that unless we have had an accident since left the property, this year to date we have had no lost-time accidents due to eye injuries.

To get off of the main track for a moment, I will state that practically all our labor there is Mexican native labor. It has been said that it is very much more difficult perhaps, to inculcate the ideas of safety among Mexicans than it is among the American labor. I realize, of course, there is a great deal of foreign labor included under what I have just termed American labor. Whether that be so or not, the fact remains that the record is as I have stated, or substantially so, since I am not entirely sure of my figures.

Men Saved From Serious Injury by Hard Boiled Hats

In the matter of hard-boiled hats as a protection against head injuries, I am very happy to say that we have on record now some 28 cases of men who have been saved from serious injury—several of them certainly from death, by the use of the hard-boiled hat.

The chairman, Mr. Young, asked me to make a few comments on statistics. I don't know that I have touched very much on statistics, but I would like to say that the Montezuma Copper Company, as a branch of the Phelps Dodge Corporation, believes very thoroughly in a campaign of education in selling the idea to the different division bosses, to the foremen and of course, to the men themselves. We take the attitude that the safety idea must be sold to perhaps 50 per cent or more of the men. By that I mean that if you are engaged in a goggle campaign, we get 50 per cent of the men voluntarily to wear the goggles or the safety hats. From that point on perhaps it may be necessary to assume what might be considered something of a hard-boiled attitude on the part of the management, in that we then arbitrarily post rules saying that all men must wear goggles or must wear the safety hats before they are allowed to pass onto their respective jobs.

MR. AGTON: What kind of goggles do you wear?

MR. MACDONALD: That is a point rather near to my heart. In my opinion it doesn't make any difference essentially what kind of goggles you wear, the attitude is to do something. Without being personal in any way, we know of certain companies that have spent perhaps a year in endeavoring to get the best goggles or the best hard-boiled hat. That is a most desirable thing to do, but the point of it is, in our opinion, to get the one that perhaps you think at the time is best or, is at least a good one, and make the men wear them. We use mostly the glass goggle, the Wilson goggle, and in the other we use a so-called all-vision or, wide vision metal goggle; metal screen goggles. We had some little trouble with the goggles rusting underground and had aluminum frames made and so forth. The point of the thing is, however, to do something and make them wear a goggle of some kind, or a hat of some kind without experimenting a year to possibly determine which may be the best kind and later on find out a new one has been developed.

Make Statistics to Suit the Men Concerned

CHAIRMAN YOUNG: Mr. Boardman, how do you handle your statistics?

JOHN L. BOARDMAN: We have a wonderful set of statistics. We call it a wonderful method of keeping statistics, but I have gotten a brand new thought out of the paper and I have been wondering how many of you fellows got the same idea; and that is, are we making our statistics to suit the men concerned? For instance,

now, the vice-president up there in the office wants to know how much those accidents are costing, and when he sees the compensation bill come in and it is rather high, he begins to ask questions. He has one important point from which he views statistics. He has also another important point, of course, which we all have, and that is the sentimental side of it. So when he sees his compensation going up he asks the mine manager what is the matter here. The mine manager wants to know not only about the cost but he wants to know the reason for it, so he is concerned with how these accidents are happening. He wants to know whether these men are falling in chutes or whether the ore cars and trains are injuring them, or whether handling material is injuring them, or what is doing it. Then the foreman not only wants to know all that as well as the cost, but he wants to know in which particular part of the mine the accidents are happening. But all this knowledge is not going to prevent accidents. The man in the mine wants to know something else. He wants to know who is getting hurt and how, so you see there are your four ideas or four subjects of knowledge for statistics.

Getting the Accident Story Over to the Individual

Now, we classify our accidents, of course, as to cause and all those other things mentioned in the paper, and then after we have gotten that all done we have to show this man down in the mine how he is getting hurt. For instance, as a case in point, we were having a number of semi-serious accidents extending over 14 days' disability, which we seemed unable to prevent. We began an investigation from the miner's viewpoint. We found that 25 per cent of all compensable accidents were injured toes; 30 per cent were injured fingers, injured below the metacarpal bones in the hand; 25 per cent were injuries below the metacarpal bones of the feet. Now, from the viewpoint of the workman who is suffering these injuries, what is the answer? One thing is safety shoes; another thing is greater care in watching after the fingers. Fifty-five per cent of all of our compensable injuries for a long period of time were injured toes and fingers. And the way to prevent that is to get the man who is injured to see it and thus bring your statistics down to the man who is hurt, and that is what statistics are for. They do the manager good—they do the vice-president good and they do the foreman and shift bosses good, but the real service is to the man who gets hurt, and that is the thought I got out of the paper today.

H. T. HARPER (Superintendent Service Department, Tennessee Copper Company, Copper Hill, Tennessee): Taking for granted your statistics have been compiled for different departments, the idea is to get it across to the employee. The ordinary employee does not understand what you mean when you show a reduction of 97 per cent. You have a frequency rate of 97.05 or 13.3. The ordinary man does not get it.

Here is our method of presenting facts to the employee. This is for the sulphuric acid department of the Tennessee Copper Company for the year 1923. We had a frequency rate at that time of 90 per cent. For the year 1927 it is zero. In other words, we have now rounded out eight months of this year in the sulphuric acid department, a group of some 140 employees, without a single lost-time accident. Reports are made for the different departments and are put on a large board at the entrance of the plant for everybody to see. Each department is listed separately. You don't need to give them any figures at all. Here is the power and electric department, its record for the past four years. The last two years you will notice no accidents at all represented by this star. I find that is the most desirable method of getting the employee's attention. He reads and runs. He doesn't stop to get any figures at all.

I might say that the frequency rate for the entire plant of the Tennessee Copper Company in 1923 was 188.25. For the first eight months of the year 1927 it has been 15.5, a reduction of 91.8 per cent. In the mining department the frequency rate in 1923 was 288.72. For the first eight months of this year it is 28, a reduction of 90 per cent.

CHAIRMAN YOUNG: We would like to hear from some of the coal operators.

C. A. McDOWELL (Safety and Personnel Manager, Pittsburgh Coal Company, Pittsburgh, Pennsylvania): It is rather interesting to listen to the statistics as given by the metal mines, but I notice that no one in the room representing the coal mining division has made any remarks. I have just gone into a new field of endeavor in this kind of work, coupling it, in fact, with the operating end.

Showing the Costs in Compensation

Where I came from I presented a paper last year. We carried on very extensive statistics and it covers all the phases as presented in the paper here this morning. One thing I noticed that brought to our attention very forcibly the accident statistics, was this: Each month we put out what was termed an accident report in relation to compensation. On that report we showed the injured man's name, how he was injured, the number of days lost—that is, the actual number of days lost, also the scheduled days lost.

Then we showed, following that, the amount of compensation paid to that man on a maximum basis; the amount of compensation paid to the hospital and then the total compensation paid. Down in the right-hand corner we made a summary by mines. Of course, the top part of this sheet was in detail. Now, we have been talking about accident statistics and how to get these statistics to the face—to the men who are working at the face, but we haven't stated so far just how that should be done. We put that across in what we term "Personal contact." We had our superintendents, foremen and assistant foremen meetings monthly and in some cases, where our accident rate was high, we had them semi-monthly. These reports were put down on the table before these men and they were told exactly what happened. Then they in turn took this information to the boys at the face. That is really the only way that you can get accident statistics across to the men. At least, that is my opinion, and experience seems to show from other statistics that it is really true. It falls to the foreman in general, or the assistants or whatever you might term them, to talk to these men as they go about their daily work, and tell them just exactly how these accidents occur.

CHAIRMAN YOUNG: We have with us today a representative from Canada, Mr. A. W. MacDonald, superintendent of industrial relations of the British Empire Steel Corporation. I wonder, Mr. MacDonald, if you will take a few minutes to tell us how you handle your accident statistics in Canada.

Bulletin Board with Names of Mine Foremen

A. W. MACDONALD (Superintendent, Department Industrial Relations, British Empire Steel Corporation, Sydney, Nova Scotia, Canada): Our accident statistics are somewhat differently compiled from those of the gentlemen who have spoken before. I listened with a good deal of interest to Mr. Hensel's report. We carry out the same system in connection with the making of our accident statistics. In our mining department we have, in addition to what Mr. Hensel has outlined, at each mine mouth a bulletin board with the names of all the mine foremen. The dates—the days of the month run across the top of the board and as every accident case happens in that mine it is chalked up against this mine foreman or over-

man, as we call them. It is the duty of these overmen, at all times, to keep preaching the doctrine of safety and the right way to work to their employees.

We figure our accident statistics for the management on the basis of man days worked and tonnage produced as well as on the percentage basis of employees injured. Our compensation law in the province of Nova Scotia is different from the compensation laws in some of the states. A lost-time accident with us is an accident that entails the loss of six or seven days, according to whether an employee is a six-day worker or a seven-day worker—that is, as far as compensation is concerned; and in addition to figuring accidents on the severity basis and on a frequency basis, we also figure them on a cost per ton basis—on a dollars and cents basis—but we don't stress that point in talking accident prevention to our men, we don't mention dollars and cents at all. We go at it from a more humanitarian side, pointing out to the men, talking to them and by the aid of posters from the National Safety Council and others that we make ourselves and through competitions, the tremendous importance of carefulness. We have competitive contests and award prizes to the mines showing the best accident record. We have reduced our accidents a great deal and we hope that the future will bring even greater results. Although we have been working at accident prevention for a matter of six or seven years, since 1920, it is still in its infancy. We now feel that it is a matter of educational process and that eventually we will get all our men to take the same viewpoint of it as our mine foremen and executives.

We have a safety committee and these committees are shifted every two months. That is, new men are put on these committees and eventually we hope that every man working for us will have served as a member. Our employees are very largely English speaking men. We only have seven or eight per cent foreign labor in our mining operations, out of 16,000 or 17,000 employees. Out of that number we only have about eight per cent who are not English speaking, and although it may seem an anomalous thing, a contradictory thing to say, I think it is harder to do safety work and get it across right among men who are English speaking than it is among some of Brother MacDonald's Mexicans, or some of the laborers you people in the United States employ.

Statistics That Run Forward and Backward

CHAIRMAN YOUNG: Your chairman is handicapped in not knowing personally everyone in this room, consequently he cannot call upon you.

F. C. MILLER (Chief Chemist and Safety Director, Colorado Fuel & Iron Company, Denver, Colorado): When it comes to statistics, I think the Colorado Fuel & Iron Company has records both forward and backward. In fact, I sometimes think we have too many statistics. However, they run on a horizontal plane of departments and take, for instance, the total number of accidents, that would be one line; and then for the different departments as to the number of injured, that is compared in length with the total length. Of course, that is graphic. But what we endeavor to do is to find out the number of accidents in one department and then find ways and means to prevent the accidents. We are placing more time at present upon prevention than upon the real statistical record, to the miner himself. That, we feel, is the part for the management. We work in conjunction with the United States Bureau of Mines. They send a car to our mines each year, for demonstration purposes, and we have a car of our own—a safety car—and we go around to each and every mine and teach first aid to the miners. In fact, it is absolutely necessary now that each man receive instructions in first aid before he is employed. That is one of the rules we have just established, and it has this advantage: it gets a man to thinking safety. It is like these posters. You may smile as you look at them and ask, "What good are they?" But with persistence

it isn't long until the miners are looking at them regularly. In fact, it is becoming a part of their daily work to look at the new posters. In other words, it is making the men think safety.

Our district is divided. We have in all about 30 coal mines. They are divided into three districts, separate by themselves. We don't total all of the accidents but we total the accidents for the mines in that district as they are all in that district somewhat analogous. Men working in a shaft are naturally working under different conditions from men in the stope. Men working with mule haulage have different conditions from those working with electric haulage. Therefore, it is hardly fair to compare electric haulage with mule haulage, but it is fair to compare one or more mines having mule haulage with others in that same district. There is where our statistical work comes in.

Handling the Problem of Goggles

As to goggles—it is all right to say, "You must wear a goggle"; but we endeavored to put that on rather hastily and we discovered it was really more dangerous to work with the goggles on than off, because the men simply could not see, and in the humid condition of the mines the glass goggles, at the end of about ten minutes, were useless. Then we tried the wire gauze, but unfortunately they started to rust within a few days and became useless. After experimenting with various forms of goggles, we adopted for the present one that is slightly conical and made of gauze. It gives you a very wide vision and permits of a larger mesh. It has a tendency to deflect the particle without going through the mesh and yet it doesn't retard the vision. We would be very grateful indeed to anyone who could lay a goggle upon the table and say, "That is it." Because we have been in the game now two years and we are a long way from the right solution; although our compensation for one year was \$84,000 for eye injuries, and after persistent cussing and discussing and with the use of goggles, we have reduced that to about \$5,000. So that is a very laudible undertaking; but on the other hand it is to the men that we look. When a man loses an eye, why, he has lost his means of making a living, because to put a man under ground with only one eye means that you are heading him toward the cemetery; so we leave him outside. We feel that if we can prevent eye injuries, even though it costs us \$90,000 a year to prevent them, it is money well expended.

We had a strike at one of our mines because we endeavored to put in the electric lamp. They were using carbide lamps and, of course, they would burn themselves once in awhile; but that was all right as long as they had plenty of light. They did not care how often they singed their noses or eyebrows while working. Finally we simply told them that if they wanted to strike they could strike and if they wanted to go back to work they could go back to work with the electric lamp. After a period of using electric lamps in this mine, something happened to our charging station, and the men were obliged to go back to their carbide lamps, with the result that they worked one day and on the second day went on a strike, saying they would not work with the damn things.

General Use of the Electric Lamp

In all of our mines at present, I am pleased to state, we are using permissible powder. There is no one in the mine excepting the shot firers when we shoot, and each and every person uses an electric lamp, with the exception of the fire bosses, and they use electric lamps in conjunction with the very latest improved safety lamp; so when it comes to safety, I think the Colorado Fuel & Iron Company has made wonderful strides. But, of course, it is up to all of us at this meeting to further the progress that is being made in safety. We feel that we have contributed

our part, and if each and every one will do in a like manner, I feel that within a short period of time we will cut our accidents down like that little star, to nothing, and I hope to God we do.

CHAIRMAN YOUNG: Thank you very much, Mr. Miller. We have time for one more speaker. Who is it going to be?

E. A. STOCK (Safety Engineer, St. Louis Smelting and Refining Works of the National Lead Company, St. Francois, Missouri): I don't know whether I am a little out of order here or not, but I think they were speaking about statistics, Mr. Chairman.

Two Good Months Without Lost Time Accident

We have been in the safety game, I think, about eight or ten years and this year is the first we have gone 62 days without a lost time accident. We employ approximately 800 men in lead mining. We are not in the Tri State district. We are located in St. Francois, Mo. St. Francois is known as the largest lead belt district of the world. We mine lead exclusively. Now, about the statistics. We have regular monthly meetings, and we have our foremen's reports. We give a copy to every foreman at these meetings and then post them on the bulletin boards. We use the National Safety Council service and keep our bulletin boards up in tip-top shape. We paint them about four times a year and have the janitor go over them and clean the glass every so often. We do not use mining section posters exclusively, but if there are suitable posters listed in the catalog from the metals, tanners or any other section, we use them. We have about 450 men that work underground and the rest of them on the surface. Of course, we have them mining underground and machine shops and locomotives and everything else; and just this one word about statistics: We put these posters on the board and also a calendar. For every lost time accident we put up a red sticker the day it happened and the object of it. Someone said, to try to get this to the men at the face, and I believe that is the way our men get it, because they have to pass these bulletin boards. We have them conveniently located at each mine. We have three mines and we have this bulletin board at each mine where the men pass and must see it.

We don't believe in purchasing safety. It is for the man's own good that he works safely. That is the way we look at it. Of course, at our foremen's meetings every month we pass out cigars and chewing gum and cigarets. But that is as far as we go. We use the wire screen goggles.

Goggles Are Used When Sledging

Of course, in mining, underground, as you all know, a miner's time is occupied in picking up a rock and shoveling and loading the cars; but when he is sledging, that is when we ask him to wear these goggles. That is the time he is going to have his eye injured. We know that a man cannot put the wire screen goggles on his eyes and wear them for eight hours underground. He can't do it but he can use the goggles when sledging.

Now, one question. I came here mainly for this question and I would like to have somebody tell me how we can eliminate injuries to the feet from falling material. One of our problems arises from rocks rolling down a bluff and causing fractured toes, bruised feet and contused toes. If somebody has any good thoughts I would like to hear from them on that.

CHAIRMAN YOUNG: I think that would be a good subject to bring up at the round table discussion tomorrow.

The next paper is a review of the work of the Mining Section since its inception, by Mr. R. Dawson Hall, engineering editor, the Coal Age, New York City.

Review of the Work of the Mining Section Since Its Inception

R. Dawson Hall, Engineering Editor, "Coal Age," New York City

In a sense the Mining Section of the National Safety Council dates back to the year 1912, when the First Safety Congress was held and Dr. Joseph A. Holmes, the founder of the U. S. Bureau of Mines and then its director, made an address on "Safety in Coal Mining."

At the Third Annual Congress, in 1914, mining was not forgotten. H. M. Wilson, then engineer-in-chief of the U. S. Bureau of Mines, addressed the Governmental Session on "Cooperation for Safety by Government and Industries."

Here, we should go back to the year 1912 and the foundation of the American Mine Safety Association, of which H. M. Wilson became secretary. This institution had only a brief career. It met twice in Pittsburgh and once in New York City. The latter meeting was a failure, though a first aid and mine rescue meeting at Terre Haute was a complete success. The Association gave all its attention to first aid and mine rescue and but little to safety. Its membership ultimately transferred its allegiance to the National Safety Council, and the Mining Section was formed. The vote of the members making the transfer was cast at Sewickley, Pa., July 15, 1915. The new section held its first meeting at the Council's Fourth Annual Congress, Oct. 20, 1915, in Philadelphia, with H. M. Wilson as chairman.

Thereafter safety and industrial relations formed important subjects of discussion. At the Philadelphia meeting a committee composed of B. F. Tillson, New Jersey Zinc Co., John Lloyd, Lehigh Valley Coal Co., and W. G. Wildin, Lehigh Coal and Navigation Co., presented by-laws for the conduct of the section which were adopted. Mr. Wilson was re-elected chairman.

At the meeting held at Detroit in 1916, J. W. Paul, who had been appointed chairman of the committee on standardization, brought in a report advocating the formation of standards on (1) first-aid contest rules, (2) mine-rescue contest rules, (3) mine signs (4) danger signals (5) signalling codes (6) miners' lamps, (7) general safety rules. It seemed to be the opinion that papers should first be read and discussed on these subjects and that, following these, codes should be prepared.

Various Committees Were Formed

As a result of Mr. Paul's suggestion, working committees were formed, one on "Mine Rescue, First Aid and Contests" another on "Accident Statistics," a third on "Ropes and Safety Devices in Hoisting and Haulage," a fourth on "Mine Hygiene and Sanitation," fifth on "Mine Fire Prevention and Fighting," a sixth on "First-Aid Methods and Rules for Conducting and Judging First Aid Contests" and a seventh on "Mine Rescue Training." Out of the appointments came some excellent papers and discussion but no definite effort at drawing up conclusions. The members were not circularized and asked to give the subject their comment. Had this been done, more effective work might have been accomplished.

Until 1921 no attempt was made to draw up comprehensive Safe Practice Pamphlets, for that was the form of document which the National Safety Council found best in accord with its purposes. The attitude of the Council is, I believe, favorable not so much to rules of prescribed action or practice as to

an outline which will indicate practices which operating companies have found helpful in promoting safety, or appear likely to have that effect.

Says the report of the proceedings for 1921, "As a part of the program for the year, the chairman asked Mr. Gillette to take the responsibility for preparing a Safe Practice Pamphlet on 'Maintaining Safety Interest at Mines.' He stated Prof. Stock had agreed to be responsible for preparing a Safe Practice Pamphlet on 'Mine Haulage.' Mr. Kudlich agreed to prepare one on 'Hoisting,' Dr. Sayers one on 'Hygiene and Sanitation,' and J. W. Reed one on 'Mine Fire Prevention and Fighting.' Dr. R. M. Raymond agreed to prepare one on 'Ropes.'"

Of these, only three were actually presented. One was that of R. R. Sayers on "Mine Hygiene and Sanitation" and another by R. Kudlich on "Mine Hoisting Equipment," which were read at the meeting in 1922 held at Detroit. That by Mr. Gillette was presented and held so that further suggestions made at local meetings might be incorporated. All these papers are to be found in the proceedings for 1921. The other pamphlets were never prepared. At the same meeting the members accepted a form of accident report which has, I believe, been in use ever since in collecting information regarding casualties from members of the National Safety Council.

Standards Needed for First Aid Contests

It is unfortunate that Standards have not been prepared for the judging of contests in first aid and mine rescue work. To such standards there would be no real objection. Safe Practice Pamphlets on the methods of operation should also be prepared and published. This activity should be vigorously prosecuted to completion, for the papers presented at the various meetings have plowed the ground from which a plentiful crop of safe practices might be garnered, more complete than any heretofore collected.

The safe practice papers to which reference has been made might with advantage be mimeographed and sent to members of the Mining Section for their comment and then be rewritten by a committee in accord with the suggestions made. Then they should be submitted to the Executive Committee of the Council for publication. Later this committee will make the usual more general submission of the pamphlet to members and finally after revision reprint it as a Safe Practice Pamphlet to form part of the regular series.

Such pamphlets are more valuable than papers or discussion. They are more complete and methodical, and they have more authority because they represent the opinion, not of one man in one locality confronted with peculiar conditions, but the broad and well-considered conclusions of many men having a wide range of experience. Lacking a secretary for the section, little has been done, but with the wealth of material available in the proceedings and in other directions, it is time that some effort be made to formulate a compilation of statements of preferable operating methods.

Under the administration of B. F. Tillson, that began after the meeting in 1917 and concluded in 1923, meetings of the Mining Section of the National Safety Council with the Industrial Relations Committee of the American Institute of Mining and Metallurgical Engineers were held yearly at the annual February meeting of the latter society. Few of these papers, if any, were reprinted by the Institute and so are not available. The joint meetings continued till at least 1924.

Mr. Tillson also interested the U. S. Bureau of Standards in the testing of ropes magnetically so as to ascertain defects in ropes that outwardly were in good condition. A tentative report was made to the Industrial Relations Committee of the American Institute of Mining and Metallurgical Engineers. It might be well to ascertain the final disposition of this inquiry.

In 1919 Mr. Tillson urged the need for a technical service in the Mining Section and sought that dues be doubled to bring the necessary \$10,000 a year for the services and traveling expenses of an engineer. It was found difficult to get a response to such a plan, but Mr. Tillson believed that if it were started it would result in a disposition to pay larger dues or in such an increased membership as would make the Executive Committee favorable to financing a paid secretaryship.

Good Publicity Was Secured

In 1921 he induced the U. S. Bureau of Mines to cooperate with the Executive Committee of the National Safety Council in providing a paid secretary, C. L. Colburn. This lasted for two years. Mr. Colburn was paid by the bureau, but some of his traveling expenses were paid by the National Safety Council. He visited mines for the purpose of gaining and imparting information; he wrote articles for the NATIONAL SAFETY NEWS; he took photographs of safe and unsafe practices and prepared safety posters, he made talks on safety when opportunity presented. During the first year, 78 mines and 14 "mills" were visited, 42 being coal mines, 35 metal and 5 non-metal. Of the 14 "mills," 6 were breakers or coal-washing plants, 5 were concentration plants at metal mines, and 3 were mills connected with non-metal mines. He wrote 17 articles for the NATIONAL SAFETY NEWS.

During the second year he visited 49 mines, one smelter and 3 mills, and wrote 28 articles dealing with safety for the same publication. During that year he addressed 16 different meetings and traveled 26,747 miles. In all he took 261 photographs, from which 32 safety posters were prepared.

After July 1, 1923, the National Safety Council discontinued its financial support of the paid secretaryship, but nevertheless three articles were written for the NATIONAL SAFETY NEWS and material was furnished for 8 posters.

Mr. Colburn assisted in a Mine Safety Conference held in Duluth, Minn., in 1922 where more than 80 delegates were present from the Lake Superior Iron Mines. He promoted the Northwest Mine Safety Conference held in Butte, Mont., 1922, at which 125 picked men were present. He promoted and acted as chairman of the Southwest Mine Safety Conference in Globe, Ariz., in 1923, in which 110 picked delegates took part.

It was hoped that after a trial the Mining Section would be so firmly established that the secretary could be paid out of the dues of the Mining Section, but that did not prove to be the case.

A Section News Letter Inaugurated

Bad times in both metal and coal industries made two of the three local sections fail after their first meetings. It should be added that owing to Mr. Tillson's activity, Mr. Guerrant, safety engineer of the National Safety Council in 1919, made a tour to some of the mining properties to compare for approval a Safe Practice Pamphlet on "Mine Cars and Haulage" which was published as a second pamphlet on "Mine Rescue and Training."

In the year ending with the meeting of Sept. 29-Oct. 1, 1925, the "Monthly News Letter" was inaugurated. This is sent monthly to members of the Mining Section. T. T. Read, the secretary of the section, and safety service director, U. S. Bureau of Mines, was the first editor. Since that time, Daniel Harrington, also secretary of the section and chief of the Safety Division of the U. S. Bureau of Mines, has edited the monthly letter.

In all, 114 papers, excluding one on the activities of the Mining Section and

the proposed increase of dues, have been presented. The printed proceedings, excluding papers equally germane to the mining industry read in the general sessions and in those of other sections, totals 1,440¼ closely printed pages. An index has been prepared dividing these into their appropriate subjects.

**Subject Index of
Papers Presented to National Safety Council
1910-1926**

General:

1910 (1); 1912 (1); 1924 (1); 1926 Alabama (1); 1926 (2); (Safety Kinks) (1). Total 7.

Industrial Relations:

General 1919 (2); 1920 (2); 1922 (Safety Practice Pamphlet) (1); 1926 (1). Total 6.

Vocational Training for Safety and Efficiency 1925 (1).

Safety Propaganda:

Interesting Executives 1921 (2). Total 2.

Interesting Shift Bosses 1921 (2); 1923 (1). Total 3.

Interesting Miners 1920 (1); 1923 (1); 1925 (1). Total 3.

General Interest 1926 (1).

Fire Aid:

Contests. 1918 (1); 1920 (1); 1921 (1); 1925 (1). Total 4.

Stations 1921 (1).

Rescue (see Mine Fires):

Training 1919 (1); 1922 (1); 1925 (1). Total 3.

Apparatus and Fire fighting 1919 (2). Total 3.

Stations 1917 (2). Total 2.

Accident Statistics:

1917 (1); 1918 (2); 1919 (2); 1922 (1); 1924 (1). Total 7.

Sanitation:

General 1917 (1); 1922 Safety Practice Pamphlet (1). Total 2.

Water 1921 (1).

Toilets 1921 (1).

Industrial Nurses 1925 (1).

Drilling:

Health of Drillers 1918 (3). Total 3.

Hoisting:

Ropes 1917 (3); 1918 (1). Total 4.

Ropes in General 1922 (1).

Practices 1922 (1).

Devices 1920 (2); 1925 (1). Total 3.

Signals 1925 (1).

Mine Fires:

General 1917 (1).

Fire fighting 1920 (2); 1923 (1). Total 3.

Fire Prevention and Fire Fighting 1921 (3); 1922 (1). Total 4.

Explosives:

General 1918 (1); 1926 (1). Total 2.

Stray Current 1924 (1).

Explosions:

General 1920 (2); 1924 (1).

Gas 1925 (2). Total 2.

Rock Dust 1926 (1).

Transportation:

General Underground 1922 (3); 1923 (1). Total 4.
 Tracks 1923 (1).
 Mine Cars 1918 (1); 1923 (1). Total 2.
 Locomotives 1921 (3); 1923 (1). Total 4.
 Animals 1921 (2). Total 2.
 Derailments 1923 (1).

Ventilation:

General 1917 (2); 1918 (1). Total 3.
 Auxiliary 1922 (1).

Loading Chutes:

1919 (1).

Roof and Ore-Falls:

1920 (2); 1925 (2). Total 4.

Lighting:

1917 (1); 1918 (2). Total 3.

Electrical Apparatus:

1917 (1); 1924 (2); 1926 (1). Total 4.

Signs:

1921 (1).

Coal Breakers, Washery and Ore-

Dressing Plants: 1918 (2). Total 2.

Open Pits:

1920 (2); 1925 (2). Total 4.

Grand Total, 114.

CHAIRMAN YOUNG: Thank you very much for your paper, Mr. Hall. I am going to ask Mr. Harrington of the United States Bureau of Mines to lead the discussion of this paper.

MR. HARRINGTON: Mr. Hall has given you, to my mind, a very comprehensive resume of the National Safety Council's activities as far as the Mining Section is concerned. He has brought back to me memories which had slipped my mind for a number of years. It seems to me that even though the Mining Section is not able to employ a paid secretary, that the Mining Section has not failed in performing a very useful function in the mining industry.

I attended my first meeting of the National Safety Council six or seven years ago, when the meeting was held in Milwaukee, and I have been attending meetings of various descriptions—technical meetings on mining chiefly—for the past twenty years or more, and I can very freely say that I got more real benefit out of attending the meetings of the Mining Section of the National Safety Council than from any other meeting that I ever attended, and I don't make any exception of any of them—the American Institute of Mining Engineers or any other.

Safety Ranks Before Dollars and Cents

One reason for that is this: That, of course, it affects me from a safety point of view. I am essentially and intrinsically a safety man. I know nothing but safety, and in attending other meetings (I don't care where you go) there are very few of them that are not devoted largely to the dollars and cents point of view, and they forget the safety side of it. The meetings of the National Safety Council Mining Section don't forget the safety side of it and they do side-step, or side-swipe (if you want to put it that way), the dollars and cents point of view.

That is the real advantage I see in the National Safety Council Mining Section,

and I can't understand and I have never been able to understand, why mining companies throughout the United States, coal and metal, have not paid more attention to the Mining Section of the National Safety Council than they have done. There is a certain amount of money involved in it, yes, but there are also in these meetings discussions which they cannot get any place else. I defy you to go any place where you have more accurate discussion than you get in the meetings of this Mining Section. They are thrown open to everybody, and as far as I have been able to find out, they are participated in by nearly everybody. At least, there is a freer participation in the discussion in these meetings than you will find in almost any other.

Discussion Brings Out Many Valuable Points

One of the difficulties in most meetings, as I take it, is that there are too many papers and not enough time for discussion. You are asked to read a paper before some—we will say the larger societies—and you will be one of a dozen. There will be so many papers prepared where the only thing that the men who prepare them can do is give a short abstract. Well, by the time you have given your abstract the time is up and somebody else's paper is on. Here it isn't that way. There are comparatively few papers. There is plenty of time generally for discussions and you get real discussions.

Now, one of the things that came up before the meeting of the Executive Board of the Mining Section here in Chicago during the winter, was the matter of trying to employ a paid secretary, and we canvassed the situation and found a number of points of view as to the possibility of securing money for that purpose. I think it would be a very fine thing if it could be done. If there were a paid secretary, he could devote a considerable portion of his time to getting out to you and to me and the rest of us the wealth of information that is contained in the discussions of the National Safety Council Mining Section. They are published in the transactions, and if they were taken out of the discussions and published in connection with the Monthly News Letter, they would be timely and they would hit home and the people who would really be interested in them would get them to read.

If you people have in mind some philanthropic mining man who would like to let loose about \$10,000 or \$15,000 a year, it seems to me there isn't a better place for it than the employing of a real, live, up-to-date secretary for the Mining Section, who will devote all of his time to it and the mining industry of the United States can get all kinds of benefit from that sort of a thing.

CHAIRMAN YOUNG: Has anyone else any discussion on this paper? If not, we will go on. There was distributed on the chairs a question card. If you have any questions that you wish to ask at any time or that you wish to present at the round-table discussion, just write on this card and hand it to the secretary at any of the sessions.

Now, I certainly am gratified to see as large an attendance as we have here this morning. I am going to ask the secretary if he will please announce the number that registered.

MR. HARRINGTON: I have looked over the registration cards, and there are 64 registered, essentially as follows: 20 gypsum plants; 20 from coal properties; 32 from metal; three from steel mills, and several from various outside agencies; and by the way, I would like to know if there is anybody here who has not signed a registration card. I might say that those "outside agencies" include such animals as editors and representatives from the Bureau of Mines.

ADJOURNMENT.

Tuesday Luncheon, September 27, 1927

J. T. RYAN, Chairman
Mine Safety Appliances Company, Pittsburgh, Pa.

Keeping Everlastingly At It

**Harry L. Gandy, Executive Secretary, National Coal Association,
Washington, D. C.**

I hope I can get across a real message today, for I am called upon to speak of the untiring efforts of the bituminous coal mining industry in the interest of safety. Memories of safety demonstrations that I have witnessed enhance my appreciation of the opportunity to meet with you on this occasion. Ten days ago I attended the State Safety Day meeting of West Virginia, where not only were the contests on a high plane but where a considerable section of the industry publicly pledged itself to continued warfare against accidents. Knowledge gained through intimate contact with operators in every bituminous field of the country, knowledge that these operators, ideally and practically, have made the cause of their employee's safety their cause, enables me to discuss this subject with the utmost frankness. The bituminous industry brings its brief to the bar of public opinion; a brief that is a straightforward statement of performance.

The safety movement is now well under way throughout the industry, both in the small and the large operations. It is organized not only to hold down but to further decrease the accident rate, notwithstanding the fact that the continuing introduction of machinery means a constantly increasing hazard. Employers generally realize that safety work is an investment which pays dividends in lower costs and in the health and happiness of employees. It may be true that some few operators have not grasped the fact that the over-all cost of accidents is perhaps four times as great as the compensation and medical payments. However that may be, the safety movement is driving home the facts, and distinct progress is being made.

My observations respecting safety should be prefaced by the statement that relatively there is little new in the safety movement. This work consists largely of efforts to bring home to every operator and miner the stern, every-day facts and to keep everlastingly at it. The only claim which I can make to any degree of originality lies in the words of Carlyle, "that man is most original who can borrow from the greatest number of sources of information." Safety statistics, practices and principles have been cussed and discussed from many forums. It is our responsibility to make the discussion bigger, better and more productive of good results. I emphasize only the obvious when I add that in the brief time I have here today I cannot deal with technicalities, with description of mechanical safeguards or with analyses of mining methods and systems. I can, in the main, only review the salient facts relating to the safety record of this industry.

A year or so ago the National Coal Association prepared a symposium of answers received by its safety committee to a questionnaire addressed to the industry as to particular efforts to promote mine safety. The information obtained furnished a most encouraging picture of the efforts of bituminous opera-

tors to advance the safety movement. This digest disclosed that the work of federal and state agencies and the practical experience of bituminous coal operators have pretty thoroughly established what is safe and what is unsafe in mine operation. There remains the vital measure of seeing that that knowledge is utilized and that the spirit of safety is instilled in every member of the industry, from the executive down to the "mule skinner."

First aid and mine rescue work are being promoted in all fields, and much energy also is being directed toward accident prevention. With respect to first aid work, I am informed that the U. S. Bureau of Mines has, to date, trained over 210,000 bituminous miners. There is a steady increase both in the membership of the Holmes Safety Association and in the number of local chapters thereof, the latter now being 175. A most favorable safety factor is the marked improvement in state mining inspection. Daniel Harrington, who directs the safety work of the U. S. Bureau of Mines, states that there is a decided tendency on the part of state mine departments to employ "better men with more scientific training." Mr. Harrington also bears witness to the progress that the bituminous industry is making in its safety work.

The National Coal Association, the nation-wide organization of bituminous operators, is continually disseminating safety literature and information and is engaged in constant study and effort looking to the establishment of improved practices and the firm inculcation of the safety idea in the heart and soul of every miner and mine-owner. It is promoting cooperative studies of falls of roof and coal by the U. S. Bureau of Mines, state mining departments and the industry. Only a few days ago the Association received a letter from the Bureau expressing appreciation of the support given to the International First Aid and Mine Rescue Meet held within the past month at Pittsburgh.

Cordial Relations with the Bureau of Mines

I could discourse at length concerning our amicable relationship with the U. S. Bureau of Mines. As a typical example, I cite briefly the record of Mr. J. G. Bradley, of West Virginia, a former president of the National Coal Association and its representative on a committee named by Secretary Hoover of the Department of Commerce to outline a program for the Mines Bureau. As a member of this committee, Mr. Bradley urged that the Bureau, "continue unfalteringly its missionary endeavor toward the prevention of accidents, its encouragement of an increasingly higher standard of safety and the actual rescue work in emergency cases." What is more, Mr. Bradley declared against any plant that would reduce the Bureau appropriations for this work and stated that if officers of the Commerce Department, "are to discharge the duties toward industry laid on them by the law, they must have the funds necessary to the collection of data, performance of experiments, study of results and dissemination of information." The safety committee, the directors and membership of the National endorsed this position of Mr. Bradley and are not only on record but also "in harness" with respect to the fulfillment of his recommendations.

It should be remembered that the U. S. Bureau of Mines is not clothed with regulative power. The Federal Constitution would not permit that. The Bureau is purely an educational force. The committee named by Mr. Hoover reported that the laws and regulations governing the actual production of coal are those of the states in which the mines are situated, and it is well that this is so.

Dr. T. T. Read, upon his resignation as safety service director of the U. S. Bureau of Mines, said, in part: "I have no faith at all in making mines safe

by law. If regulations are made that the operators regard as not being necessary, you will merely have a situation such as that created by certain sumptuary legislation which people joyously and openly disregard." Dr. Read stressed the need of first securing the whole-hearted cooperation of the operators. This is necessary to bring about the adoption by the industry of the safety practices recommended by the Bureau. I think his point is well taken.

In speaking of the efforts of operators, aided by their National Association, to reduce mine accidents, I am reminded of another statement made by Dr. Read, when he said: "I regard it unfortunate that many people in the past, in trying to awaken greater interest in observing safety precautions, thought it necessary to emphasize the loss of life in the coal mining industry, rather than what is being done to reduce the loss of life. The coal industry deserves great credit for what is has done," continued Dr. Read. * * * "It can fairly lay claim to having made substantial progress in making coal mining safer. The question is sometimes asked whether all the effort put into accident prevention has shown results. As far as the coal industry is concerned, we can say quite definitely that it has. * * * The coal industry may well congratulate itself that its safety movement has not only been well handled but has shown definite progress." This statement should carry great weight, coming as it does from the former safety service director of the U. S. Bureau of Mines, who is now assistant secretary of the American Institute of Mining and Metallurgical Engineers.

Statistics Sometimes Inclined to Be Misleading

There must be something back of such statements. Let us consider for a moment the actual figures of fatality records. Remember that, in all cases, unless I specifically cite the anthracite industry, I am speaking only of bituminous mining. Combining the figures of the two industries is misleading. Fatality statistics are frequently based on man-hours, but in order to appreciate the meaning of such figures one must realize that it requires about two and one-half times as many man-hours to get out a ton of anthracite as a ton of bituminous. The life cost of producing a ton of bituminous coal is considerably less than that of anthracite. When we consider the mining of coal in terms of fatalities, statistics based on production ratios are significant.

Let's see what the fatality record kept by the Bureau of Mines shows. In 1911, the first year of the record, the fatalities per million tons of bituminous coal mined were 4.82, while in 1926, the figures was only 3.56. The Bureau has monthly statistics from 1916 only and the lowest monthly fatality rate as shown by that record was scored in March of the present year, when 60,151,000 tons were produced at a fatality rate of only 2.31 per million tons. Comparing the record of the coal industry here with that of foreign countries for the five-year period from 1921 to 1925, inclusive, we find that the American record was 3.96 per million tons of coal mined, including anthracite, as against the record of Great Britain of 3.98, Belgium 6.54 and Prussia 10.30. The record for France for 1925 is not yet available but the four-year average from 1921 to 1924, inclusive, was 5.68. The American record for bituminous alone for the same five-year period was 3.67. Those are government figures and constitute eloquent testimonial to our safety work and point to continued progress.

As a matter of information, I quote the record of causes of fatal accidents in bituminous operations in 1926, wherein we find that 48.18 percent of the fatalities were caused by falls of roof and coal; 18.38 by underground haulage; 18.09 by

explosions; 4.51 by electricity; 4.12 by accidents above ground; 2.23 by explosives; 1.31 by shaft accidents; 1.26 by mining machines; while 1.92 per cent were from other miscellaneous causes.

Divers and numerous are the plans advanced to reduce the accident rate. A somewhat common notion, especially among theorists, is that the best way to bring about the millenium is by laws to make mines safe. Such a procedure is doomed to failure, as I have pointed out through a statement quoted from a former government official who was rich in experience in the safety movement. Owing to the variable conditions in different mines, it is simply not feasible to provide identical regulations for all mining districts. Mines cannot be placed in one of two classes, safe or unsafe, any more than colors can be classified as either pink or green.

I am sure you will appreciate the significance of the statement which appeared in the September 1 issue of *Coal Mining Review*, published by T. L. Lewis, formerly a high official of the United Mine Workers of America. In commenting on the high percentage of accidents from falls of roof and coal, he said that a rigid investigation would disclose that the lesser proportion of fatalities occurs in mines which have the most dangerous draw slate or roof. Mr. Lewis adds that, "Safety First, in its effect, depends upon the individual and not the management of the mine." Experience of insurance carriers supports the conclusion of Mr. Lewis.

Not a few accidents from falls of roof and coal and other causes can be traced to dependence of miners on their supposedly accurate knowledge. Some miners continue to blunder through their failure to make the prescribed examination and take sensible precautions, thinking they know almost to the minute how long a roof will hold. A narrative from *London Tid Bits* illustrates one way in which this so-called accurate knowledge operates. An old woman was going down a coal mine for the first time in her life. As the cage descended, she noticed how they were dependent upon a single rope to which the cage was attached.

That Rope Was No Doubt Quite Safe

"Do you think it is quite safe?" she asked a miner, as she glanced up at the rope. "Don't you fear, mum," was the reply. "You're quite safe. These ropes are guaranteed to last exactly twelve months and this one isn't due to be removed until tomorrow."

And to show the pride of the miner in his possession of this "accurate knowledge," I am reminded of the reply which Mr. Chuggins made to a policeman, who had said to him reproachfully, "You were going 40 miles an hour." The motorist countered with, "I'm no deliberate law-breaker. I'll admit I'm ashamed of myself, but I'm kind of proud of the old flivver." That reply reflects the mental attitude of some miners. They know they *should* live up to the rules; the idea is drilled into them at every safety meeting; but they apparently delight in relying exclusively on "accurate knowledge."

Because accidents at the face of the seam are the most common form of mine accidents, that phase of the subject is today engaging the most serious attention of the industry. The personal equation is of outstanding importance. It must be made doubly sure that the worker has heard and heeded the safety message, which is a message of admonition for his own protection and that of his fellow workers.

Along this line of thought, I was impressed with the statement issued this month by the motor vehicle commissioner of Connecticut, who, in speaking of an outstanding safety improvement in the way of a new four-track highway,

Wednesday, September 28, 1927

The second session was called to order at nine-thirty o'clock by the chairman, Howard I. Young.

CHAIRMAN YOUNG: We are going to change the order on the program a little this morning because the Nominating Committee has asked for a little more time in getting together before they make their report.

The first paper this morning is, "Foremanship Training Conferences and Their Bearing on Accident Prevention," prepared by Mr. McHenry Mosier, superintendent of mines, Phelps Dodge Corporation, Morenci, Arizona. Mr. Mosier is unable to be present and the paper will be read by Mr. H. C. Henrie, manager of Industrial Relations of the Phelps Dodge Corporation.

Foremanship Training Conferences and their Bearing on Accident Prevention

**McHenry Mosier, Mine Superintendent, Morenci Branch, Phelps Dodge
Corporation, Morenci, Arizona.**

The Arizona State Department of Vocational Education conducted the first Foremanship Training Conference in Arizona in January, 1923, for the Miami Copper Company. The next Conference was a joint meeting held in January, 1924, when the Miami, Inspiration and Old Dominion Copper Companies participated under the auspices of the State and Federal Governments. Since that time conferences have been conducted in various mining camps in Arizona, including every Phelps Dodge Branch, by leaders furnished by the Arizona State Department of Vocational Education.

The first conferences were demonstrations of methods covering a limited field. At the follow up conferences, more specific problems in production, safety, supervision and leadership were discussed. The underlying object of this work was to increase the efficiency of Industry in Arizona, first by showing the responsibility of supervision to those who direct labor and later by reaching the individual worker through some form of vocational education. As stated by the leader at one series of conferences, the purpose was:

- (1) To get group opinions of foremanship problems.
- (2) To encourage the habit of analysis of these problems.
- (3) To promote a better understanding through discussion of the problems of fellow foremen.

It was emphasized that nothing was to be given in the form of lectures, but that all that would come from these conferences would be the result of the conclusions reached by the group itself. In this leader's opinion, after a full systematic discussion of a problem, in almost every case, the conclusion of a group is right. Regardless of the purpose of any of these conferences, safety work, accident prevention and other closely allied subjects, have always been introduced and have proven important and valuable topics.

The first development of the idea of cooperation at Morenci was expressed through foremen's dinners held at frequent intervals where all the company officials met in the evening to discuss an operating problem or some topic relating to the welfare of the company and of the men. As an extension of this idea a series of Foremen's Conferences was started early in the year 1924. Further expression of this idea of cooperation is found at Morenci in

the weekly meeting of superintendents with the manager, for a round-table discussion of operating problems; and in the weekly meeting of the mine foremen with the mine superintendent, where every problem arising at the mines is frankly discussed. Another form this cooperation takes is the committee system of safety work, inaugurated in March, 1925. This was patterned somewhat after the method used by the United States Steel Corporation and was outlined by H. C. Henrië at the Fifteenth Safety Congress, at Detroit. By this system, the sense of individual responsibility for safety is carried directly to the workmen themselves.

The First Foremanship Training Conference

The first intensive Foremanship Training Conference at Morenci Branch was held for three weeks during March, 1924. The conferences were begun with a group of 13 superintendents and other department heads participating. This was followed by a group of 15 foremen and finally by a group of 15 shift bosses. The subjects discussed included:

- (1) Duties and responsibilities of each group.
- (2) Safety.
- (3) Analysis of specific accidents.
- (4) Leadership.
- (5) Cooperation.
- (6) Labor turnover.
- (7) Giving orders.
- (8) Instructing.
- (9) Loyalty.
- (10) Job analysis.

The second conference was held by the mine foremen for one week in February, 1926. The topic was Standardization of Mining Methods, the entire week having been devoted to a job analysis of stoping operations. So far as known, this is the first complete job analysis of such large scale operations which has ever been made by a group of men so intimately connected with them. This year a conference was conducted for two weeks in April for the benefit of the shift bosses. The first subject treated was safety work, with analysis of accident hazards and means of their elimination, followed by a discussion of operating problems.

These intensive conferences have been supplemented with other conferences of foremen to establish operating and construction standards, with the idea that the most efficient way is the safe way. There was an excellent illustration of this in the Mining Department last year when the stoping foreman presented a report on "Drawing through Grizzlies" which was accepted and put into effect as standard practice. In underground transportation this idea has been carried still further, by including in the conferences all the workmen in the haulage crews, from which has resulted the present standardized operation of trains.

At Morenci the purpose of the original Foremen's Conference was indirectly to reduce production costs, by encouraging men to think analytically and by effecting better cooperation among the men who discuss their problems together. This year the prime object of the conference was to promote safety work. It is interesting to note in the minutes of all these conferences, the frequent references to standardization, to efficiency and to safety of the men. Even in the first series of conferences, in 1924, all groups agreed that looking after safety was one of the most important responsibilities of each group; while the shift bosses were unanimous in saying that it was the most important. This is not surprising because safety work and other forms of cooperation are inspired from

the top of an organization and it is the attitude of the management that safety work is a major operating problem. Some of the other contingent factors allied with safety work, which these conferences have assisted in promoting are:

- (1) Standardization and efficiency.
- (2) Improved morale.
- (3) Staff leadership.
- (4) Better instruction of working force.
- (5) Effective discipline of working force.
- (6) Reduction in labor turn-over.
- (7) Increased plant pride.
- (8) Better knowledge of plant policies.

The effectiveness of safety work at any plant can be gauged by its accident record. The frequency and severity rates for the Morenci Branch of the Phelps Dodge Corporation follow:

Accident Frequency Statistics Lost Time Accidents

Department	1923		1924		1925		1926		5 Months 1927	
	Per		Per		Per		Per		Per	
	No.	Shifts 1000	No.	Shifts 1000	No.	Shifts 1000	No.	Shifts 1000	No.	Shifts 1000

Totals	454,427	431,776	34,472	5,875	7.58	1.36	82.06

Calculated on method used by the United States Bureau of Mines.

The following data on the plant will assist in interpreting this record. It shows that efficiency and safety go hand in hand. The smelter output is 5,000,000 pounds of copper per month. The concentrator treats 4,200 tons per day. The mine operates six days per week and produces sufficient ore to run

the concentrator seven days. In the mine the stoping efficiency has increased approximately 50 per cent each year over the preceding year. Full production was attained in 1925, since which time the overall mine efficiency has increased 50 per cent. During this same period the milling costs have been reduced 20 per cent, while smelting costs have been lowered 15 per cent. Most of the manual labor is performed by Mexicans, who constitute about one half the employees of the District.

The improvement in the Morenci safety record is due to many causes, chief of which are the following:

1. Attitude of Management: An increasing desire to eliminate all accidents has been manifested.

2. Closer Supervision: Supervisors are paid a safety bonus, based on the number of shifts supervised without an accident. Foremen and shift bosses have fewer men. Work is planned farther ahead. More attention is given to smaller details.

3. Better Cooperation: This is not only manifested in each department but between departments as well.

4. Analytical Investigation of all Accidents: The investigating committee of three or more includes at least one workman. The cause of the accident is established and the responsibility for it is fixed regardless of whether the accident resulted in loss of time or not. Recommendations are made for avoiding a similar accident in the future.

5. Standardization: An increasing number of operations are becoming standardized, while most construction work is on a standard design.

6. Better Instruction of Workmen: Duties of each job are becoming more specific. Men showing especial aptitude for certain work are kept on that especial work so that they develop into specialists. As a rule each department promotes its own men to the better jobs. If many new men are acquired at one time, a school of instruction is established.

7. Better Discipline: For infraction of safety rules, a warning is given for the first offense, a lay-off for the next, and a discharge for the third offense.

8. First Aid: Training employees in first aid helps create the proper attitude for safety work. In addition to saving life, it also prevents minor injuries from becoming serious. Last fall over 600 employees took the Bureau of Mines course in First Aid Training.

9. Better Spirit, or Increased Plant Pride: Morenci is known as a desirable place to work. There has been a recent improvement in streets, walks, parks and appearance of public buildings. The winning of the Holmes Trophy last year, at the Bureau of Mines International Safety contest, together with the development of a State Champion First Aid Team, has helped.

10. Smaller Labor Turnover: The percentages are shown here since 1923:

Per Cent Annual Labor Turnover

	Mining Dept.	All Others	Total
1923	102.71	88.40	91.98
1924	112.35	95.75	104.93
1925	84.38	77.27	81.13
1926	61.05	60.00	60.49
1927 (5 Mo.)	51.72	45.00	47.88

These factors collectively represent safety education. Many of them are inspired from the highest officials of the corporation and are filtered downward through the organization. Great credit is due the operating staff.

(1) For developing the proper attitude towards safety work.

- (2) For making the safety of the workmen the first consideration in all their plans.
- (3) For getting the safety idea across to the individual workman.

The holding of a Foremanship Training Conference reflects the policy of management. Every successful organization has a definite morale or spirit. Where cooperation exists Foremanship Conferences naturally find a place and function smoothly.

Where cooperation does not exist, the Foremanship Training Conference, with the approval and assistance of management can be made of material value in establishing this vital factor of a safe and successful plant. Although there is not a direct relationship between Foremanship Training Conferences and a plant's accident rate, yet there are many indirect benefits such as clearer analytical thinking which eventually promote better plant safety. Foremanship Training Conferences are not a golden cure-all for a sick organization but we, at Morenci, endorse them as tending to promote some of the very things responsible for a good safety record.

The Foremanship Training Conference of Great Value

MR. HENRIE: I think the principal point Mr. Mosier has in mind in his paper, is that these foremanship training conferences which were originally introduced and promoted by the federal and state vocational training departments, have been of great value, not only to the Morenci branch but to all the mining companies of the state. Perhaps this was the first agency which was successful in getting mine foremen and shift bosses together and getting those men to really talk freely—express their opinions and arrive at certain definite conclusions concerning their work and duties.

Now, it might be of assistance to the group here if I would outline just how this conference work is functioning at present. The particular conference I am speaking of now is not handled by the vocational training department, but rather by the individual organization itself. It became necessary to reorganize the safety and accident prevention work of the corporation in 1925, because it was apparent we were not getting results, and the present form of safety organization was instituted.

After the system had been introduced it was soon evident that while we were talking about instructing workmen to do things safely, there was considerable doubt in the minds of the individual foreman and boss as to what really constituted safe practices. By that I mean one foreman would have an opinion as to how to do a given piece of work; the foreman, say in the adjoining division, might have some thought of a different idea. Naturally, if men were to be instructed in the safe way to perform a given operation, there first must be some clear idea in the minds of the supervisors or officers, as to how this work should be done; and, of course, where a large number of men are employed, procedure should be uniform.

So we instituted a method which had for its object really the education of the foremen and the bosses in safe practice. It was realized that if a safety engineer should go down into the mine and tackle a certain operation, the first foreman that would see it would be ready to punch the plan full of holes. So taking advantage of the excellent results which had been obtained in the conferences held by the state vocational training department, we adopted this idea, and I will use the mine department as an example. These conferences are held in every department. The mine superintendent was instructed that at least twice a month, he should have a conference with all of his foremen—night foremen and shift bosses, at which time the matter of standardizing work, or, rather, finding the safe and efficient way of doing a given operation be taken up. It sounded all rather complicated.

The start was made this way: After analyzing our accident record we found that

about 52 per cent of our accidents were occurring in haulage operations; and of these 30 per cent of the accidents happened directly at the chute or, in other words, in the operation of loading an ordinary mine car of ore from the chute. Maybe from a chute door; maybe running a car over the foot; maybe pinching their fingers, but all were tied up with that one operation. Since that appeared to be quite a hazard, that was the starting point for the mine departments.

The mine superintendent at his first meeting simply put the matter up this way: Well, boys, here are the figures—there is where the accidents are happening. Now, we have got to figure some way out. Let us take this matter of loading a car. How do we do that work?" Well, it was surprising, practically no two men agreed. We got the men talking. One man would venture an opinion and another one, so finally we started at it in a systematic manner.

We found that the mere operation of running a small egg car under a chute and loading it could be divided into 22 separate and distinct operations. This bunch of foremen and bosses finally agreed that if a man would perform those 22 operations in a certain way, why, men would be pretty safe. Naturally when you are working on that, a thousand and one other questions were woven into the discussion—construction of your chute, height of the chute door, height of chute mouth above the drift, your trolley wire and method of guarding the trolley wire. In other words, in starting on the mere problem of loading a car you really take in all operations and all construction, so to speak, surrounding the operation. Well, anyway, that group perfected this standard procedure.

The Collective Opinion Looked Good

Now, I am not saying that perhaps some one man couldn't go out there and find a better method. The whole point is this: It represented the collective opinion of the foremen and shift bosses of the mine. It looked good. And, of course, experience in the conferences conducted by the state vocational training department seemed to indicate that where the group opinion was practically unanimous, you can consider the decision of the group as right. In any event, you had a practice which was agreed upon by the foremen and bosses. Naturally, they would carry out that practice—put it into effect because it was their own idea rather than an idea given to them by some efficiency engineer.

Naturally, after this standardization of loading a mine car was made, the next question that came up was, "Well, now, what are you going to do with it?" These men were told, "Now, we will mimeograph this—each foreman and boss will get a copy. We want you to study it because this is the way we will do that particular operation from now on. We will also post a copy of this method on each loading chute. It is up to you to instruct every man you have in this method of doing the work and see that he does it. If he doesn't follow this method, we want you to warn him. Go over it with him and then if he doesn't line up, put somebody else on the job who will. On the other hand, if we come through your division and find men loading haphazardly, find that this practice is not being followed, you are responsible—not the man." After that operation had been disposed of, naturally, other operations were considered.

Those so-called safety standardization conferences have now been in effect two years. You appreciate that perhaps there are a lot of operations connected with mining which it would be very difficult to standardize, but there are a lot which can be standardized and have been. However, as an educational measure we have found that this method of getting the foremen and bosses together and allowing them to work out the solution of a particular problem and then insisting that they put their own conclusion into effect, has been of wonderful assistance in reducing the accident record, not only to Copper Queen, or the Morenci branch, but all of the Phelps

Dodge Corporation property. In fact, the method has been so successful that it has been adopted by the management of the corporation and is being used at every branch.

CHAIRMAN YOUNG: The discussion of this paper will be led by Mr. C. A. MacDowell, safety and personnel manager, Pittsburgh Coal Company, Pittsburgh, Pennsylvania.

Conferences Really the Beginning of Safety Work

MR. MACDOWELL: I don't think there is any doubt in the minds of those present who have followed this safety movement daily, that conferences of all kinds have a material bearing on accident prevention. Foremanship conferences have been reaching the desired goal, and the fact that they have been successful, I think, has been proven indeed by the paper that has been presented. It is a little different, however, probably, as it might relate to the coal mining section, although I don't think so personally. Personally we cannot have too many conferences, and I do not know of a better way to promote or put across accident prevention work than by conferences.

In foremanship training conferences an opportunity is presented to set down specifically the right way to do things. They are the seat of what I term "personal contact." I have always contended that accident prevention could be put across as an ideal, by personal contact. Naturally, then, the first group of employees that we would desire to reach would be the foremen, who must be taught the correct way, and they in turn reach the men under their jurisdiction at their daily occupations by personal contact.

These conferences are really the beginning of accident prevention work. In a sense officials, as you know, are responsible for the safety of the men under their supervision. We must then assume that all officials, or the entire official family, are the key men to the situation and circumstances at all times, as they are constantly meeting with the men at their working places several times daily. They have an excellent opportunity to tell these men the correct ways and means of preventing these accidents. We are told that 90 per cent of all accidents causing injuries are due to carelessness, and the immediate thought is, "Carelessness on the part of the employee or the person injured." Now, that may be true in a sense, but it seems to me we should not overlook the responsibility and probable careless attitude of the officials—officials who visit this man daily. Now, by such conferences all officials are instructed in the personal contact program to cover all emergencies that may arise. Foremen and others cannot be trained to responsibilities, safety leadership, cooperation, efficient labor turnover, instruct loyalty, giving orders, standardization, general efficiency, improved morale, effective and proper discipline and industrial policies, without having such conferences. I know such conferences have been successful. Some have been conducted differently from the outline given in the paper this morning, but the material goal was the same. The success was noted not only as it related to accident prevention but in all phases of the industry.

I am heartily in accord with conferences of superintendents, foremen and assistants, fire bosses and, in fact, what may be termed occupational conferences, all of which help in the ultimate success of the undertaking.

It is also apparent to me that a safety program has not been successfully put across in some instances, because of the indifferent attitude of leaders to have foremen and other conferences; and you will find that the accident rates of such companies are exceptionally high.

Now, a new type of conference has been developed in recent years, where the superintendent, the foremen, the assistant foremen and all others, including miners, gather together in monthly meetings, and they may be termed safety conferences of a mine, but at the same time it is a conference just the same. No lectures are given. Con-

clusions are reached, however, after considerable discussion and instructions issued by the chairmen who in these cases happen to be the superintendents. It was surprising to find the amount of frankness shown by the individuals and the results were excellent.

To substantiate what I have just given you, I know of one company who has this record from actual statistics, compiled for eight years: A 52 per cent increase of production for each fatality; a 35 per cent decrease in frequency rate; an 80 per cent decrease in severity rate; a 75 per cent decrease of explosive accidents; a 66 per cent decrease of natural deaths to employees; 15 lives saved by artificial respiration and general first aid treatment. That is given by the medical men themselves. One hundred per cent first aid employees; 22 per cent decrease in turnover of employees; a 21 per cent increase of the staple force of employees. As to compensation—and that is generally brought up at all these meetings as to just what it is costing—in one state this company had a decrease of 22 per cent of their compensation rating. In another state 60 per cent decrease. In another state 54 per cent. In that state with the 54 per cent decrease, they had an increase of weekly benefits during that period of 33 1/3 per cent; an increase of pensions of 50 per cent, and this all figured on a basis of an increase of the earnings to the employees of 66 2/3 per cent.

CHAIRMAN YOUNG: Thank you very much, Mr. MacDowell. Mr. J. C. Wright, director of the Federal Board of Vocational Education at Washington, D. C., will now discuss Mr. Mosier's paper.

Convincing Testimony of Conference Value

MR. WRIGHT: This is a very important subject. I don't know how many of you know that I happen to be the man who put on this first conference to which the gentleman referred to in his paper, at the Miami Copper Company, in Miami, Arizona. Previous to that I had put on several conferences with the Stonega Coke & Coal Company down in Virginia. Some four years later I was asked to come back to a banquet that was held of foremen, and I asked the general manager and vice-president why he was continuing the foremen conferences. He told me that he had continued to invest money in those conferences because he saw the value of them. I said, "What is it that you can point to that indicates that the conferences are of value?" He said, "Well, Mr. Wright, I do not believe that there is any tangible results coming out of a foreman's conference that you can point to and say that that is a direct result and an only result or is due only to that particular conference. But," he said, "I am absolutely convinced that it was our foreman training conferences which enabled us to continue at full production during a rather adverse period," that they had gone through in that time.

Now, I am of the opinion, gentlemen, that his statement is very largely true, that the tangible results which come out of a foreman training program are rather difficult to measure. The intangible results are those which you cannot set up and point to as being specifically due to that program. Oftentimes it can be measured in opinion and, therefore, I am very glad this morning to hear these figures set up by the two preceding gentlemen, as indicating in your mind a very tangible result coming out of a foreman training program.

I am going to run over some of the principal factors which affect, in my opinion, the question of accidents in any industry.

The first of these is pride in the individual's job. I am talking about a foreman—his attitude of mind, his sense of responsibility for his job, realizing that he has a real job and that he isn't just drawing wages. Realizing that he is a part of the organization; that he has a responsibility for others—for men and for materials, and for enabling the concern with which he is employed to make a profit, for otherwise

they cannot continue to do business, and an appreciation for the needs of cooperation in order that the organization may accomplish its purpose; an interest in his work, not only on his part, but on the part of the men themselves. Those five factors in my opinion, are factors which can be improved by the foreman conference training program. Such facts as experience, as technical information about the business, such as mining, are not properly part of the program of foreman training.

When I appeared in 1921 or 1922 down at Norton, Virginia, before a group of 20 hard-boiled miners from the four different coal companies in that region which were cooperating in that program, I was just a little bit nervous because it was my first contact with that group and I wondered how they were going to receive me. In order to break the ice I said to them, "Now, I suppose that you gentlemen are here for this program and it is my duty to see that the program becomes successful. I do not often pose as a mind reader, but I am going to undertake to read your minds this morning. You gentlemen are all sitting here and thinking and wondering what it is that this man is coming down from Washington to tell us about digging coal here in Virginia." And, of course, I got a response, because they were wondering about what I was going to tell them. And I followed it up by saying, "I am not down here to tell you how to dig coal—I never dug a ton of coal in my life—I don't know anything about coal mining." I said, "In fact, you gentlemen know how to dig coal; if you did not you would not have been made foremen and, therefore, the program that we have before us today is not one on how to dig coal. It is not dealing with the technical work of a miner, but we are dealing with that job which you now have in addition to your ability as a miner and your position as a foreman—a new job which has been placed upon your shoulders since you entered the coal industry."

The Job Did Not Concern Technical Matters

It broke the ice and we got along very well after that because they did not hold me responsible for knowing anything about digging coal. My job there was to conduct a foreman training conference at which we discussed the responsibilities of a boss; and the responsibilities of bosses are very much in common, dealing with specific industries and with specific ways and methods of doing things, and the specific types of individuals.

Then I would like to present as a factor affecting accidents in industry which can be improved by a program of foreman training, as an appreciation on the part of the foreman of the cost of accidents; the ability on his part to analyze the causes of accidents. In this connection at a later conference in that same region with the Stonega Coke & Coal Company, we had in the group one general mine foreman. He was rather a popular fellow; a leader among that group. In fact, he had quite a history. He did not say very much in the conferences, but when he did speak it was to the point. We were discussing the question of carelessness on the job. We had analyzed it as to cause of carelessness and what we could do about it; the placement of responsibility; and after we had practically finished with the program, he said: "Mr. Wright, I have a case that I would like to put up for discussion and for the placement of responsibility." I said, "All right, go ahead."

"Well," he said, "a year or two ago during the war, I was coming through an old entry that we had reopened and the safety engineer was with me—the inspector as he called him, and he called my attention to an overhead trolley wire where it had been fastened to a support. That support was giving way. 'Now,' he said, 'you ought to have that fixed.' I made a note of it and went out and got an electrician and told him to go in there and fix it. When he went in he cut the wire on one side, and when he cut it he let the tension on the other side pull the support to one side and down fell a lot of loose rock which killed him. Now," he said, "who is responsible?"

Well, we began analyzing the problem. The group began to discuss it and out of it came these facts: That the electrician was an experienced man; he was a young fellow, but had been on the job three or four or five years—most of his work was outside; that this general foreman and the inspector had come by this place and observed the condition and that the man had gone in there and been killed, and the question was: Who was responsible? Well, there was a diversity of opinion. Some felt that the company was responsible because that was an old entry way, and that it should have been completely re-timbered and gone over before they attempted to use it again. Others felt that perhaps the inspector had some responsibility; and most of them felt that the man himself had been responsible—that he should have known better, and the question was about to be left there when the general foreman spoke up. He had kept still during all this time.

The Foreman Who Convicted Himself

He said: "Well, Mr. Wright, if you have no objection I would like to express my opinion. I think the foreman was responsible." That meant that he himself was responsible for that man's death. "Well," I said, "Why?" Well," he said, "I came through there at the time and my attention was called to this and I had an opportunity to inspect that working place and to note the working conditions. I knew this electrician and I should never have sent him back there to repair that without going back with him, or without having examined that place carefully in advance and told him about the dangers he was going into. Now, a further detail was gone into, but the important point is this: That because of that discussion on which we had been spending three or four hours, this foreman had come to a full appreciation of his responsibilities for the men and for the prevention of accidents, and he had in analyzing this situation in his own mind; he established his own responsibility because he saw how he could have prevented this accident.

Now, I believe that is a very valuable result that you get from a foreman training program. But when we consider the question of setting up foreman training conferences that have a specific objective in prevention of accidents, we run into some difficulties. It is all right for me as a teacher, or as a parent, to undertake to make boys be good. We all desire our children to be honest. A teacher desires his children to be honest and truthful and have high ideals and so forth, but it is my experience you don't get very far when you set out and say: "Well, now, son, I am going to teach you how to be honest—I am going to make you be honest—I am going to make you be truthful." When we approach that problem directly, I don't think we get very far. My experience is that such objectives as honesty, as truthfulness and a great many others of a similar character, can best be approached in an indirect way; and I believe that accident prevention work, so far as it is affected by a foreman training program, is the result of a lot of things that you do with foremen without telling them directly that you are going to bring about a reduction in accidents. That naturally comes out of it and cannot be avoided.

In addition to these other items that I have given you, there comes a question of leadership. A foreman needs to be a leader and one of the objectives of foreman training programs is to assist him in being a better leader. When men don't know how to do a thing, simply ordering them to do it does not get results, but if the foreman has an appreciation of his responsibility as a teacher or instructor, he is going to get a great deal farther with it and will be able to organize and plan his work. He will have an appreciation of the losses that come with excessive labor turnover, and lastly, an appreciation of results that may be accomplished through the use of safety devices.

Now, I want to discuss very briefly the question of developing a foreman training

program. Reference has been made several times this morning to the fact that the federal government through the federal board for vocational education, and state governments through state boards for vocational education, have interested themselves in this program. The experience that has been gained has covered some nine years, and these two agencies are not out for the purpose of filling the need throughout this country for improvement of foremanship, through the conducting of conferences organized and conducted by their representatives. These two agencies, the federal government and the state governments, through the board for vocational education, believe that the improvement of foremanship is very important from the standpoint of vocational education, and they believe that their responsibility is to help the other fellow to help himself.

Organization Conferences Often Possible

In many instances the program can best be conducted by the organization itself. There are other concerns where the numbers employed are too few to warrant the industry putting on a program of its own, and some other agencies need to do the job, if we are going to make the service available. There are other industries that are large enough to carry on this work themselves, but they do not care to do so and they are willing to take the advantage of a service that is available. Now, from the standpoint of these two governmental organizations, their objective is to help industry to help itself, in so far as it relates to foreman training. Some of this work is, therefore, carried on directly by the federal government and to the extent we carry it on, it is only for the purpose of demonstrating the value of a conference program. That is one objective, or, for the purpose of developing people who can conduct a foreman training conference. In other words, it becomes a training school. Some of these conferences in this country are now carried on by local public schools within their community, through what we may call cooperative programs.

We have assumed that all that was necessary is for the industry to say, "Yes, we will put on a program of foreman training and we will get our foremen in and have them join these meetings,—come together in these groups and that is all that remains to be done." That is far from the facts of the case. The most difficult factor that needs to be overcome in making a program of foreman training successful, is the presence of a skilled conference leader. We have long since passed the time in our educational work where we believe that the mere possession of knowledge on the part of a teacher enables the teacher to teach efficiently. We have institutions, normal schools and universities and various other institutions today, that are training teachers because they are realizing that the job of teaching is itself a trade or a profession, requiring special preparation beyond the mere possession of the thing that you are going to teach. Well, a conference is only a method of teaching, as has been pointed out here by the first speaker. Instead of getting up and lecturing to people, as I am lecturing to you, we change the method to one where the entire group participates. In fact, in the conference as it has been developed, it is not necessary for the conference leader to be an expert in that particular industry. As a matter of fact, it is often a handicap because the danger is that he will revert from a conference leader to a lecturer and begin to tell them how to do it.

Down at the Miami Copper Company in Miami, Arizona, when the first conference was put on there, I asked the manager to have a group of general foremen, an assistant mine foreman and general superintendent of the mine. I always want somebody of the management to sit in on an initial conference. It accomplishes a good many things; first, the removal of suspicion that something is going on and going to happen that will be undesirable and that is the easiest way to remove it. Second, you have at hand someone to whom difficult questions can be referred, and this gentleman was an exceptionally good man. I asked him in the beginning to keep still, to

be an observer, until he was called upon or it was evident that he was to speak, in order that the men would not be embarrassed by having their opinions measured up along with the general superintendent. But we came along one day to a problem similar to the one that Mr. Henrie put up to you, from one of his mines, in which the question of prevention of accidents was the paramount one; and as in the other case, this accident happened to deal with one of those ore cars, not at the loading end but at the dumping end of it. It seemed on that particular type of car it was a frequent occurrence that men would get their fingers cut off or mashed in the dumping of the car. When they would dump it up the thing would kick back on them and pinch a finger off. Well, that was a case for discussion, and we used the usual procedure of trying to determine the cause and how it could be removed.

One of the foremen finally got to the point where he began to get so restless that he couldn't sit still any longer, and he said: "You know, I have a notion about that car—how it could be improved and reconstructed, so as to prevent that situation from happening again." Well we immediately began to dig in on him, and he went to the blackboard and attempted to illustrate his idea. He didn't have any luck because he was not a draftsman. He didn't know anything about drawing, but here is where our superintendent came in. I saw that he was likewise getting so full of a desire to speak that he couldn't sit still any longer. So I asked him to help and he went to the blackboard and began to draw out the parts, and by questioning this fellow he got from him his idea. It wasn't long until they sketched out a change in the construction of the car which would presumably prevent this accident from happening. The men agreed and disagreed until finally it was the general consensus of opinion what it was the desirable thing to do. Well, that ended the session. The next morning I came on the job as usual, and there was nobody in the room. I was alone. The hour for the group to be there was at hand, and I began to wonder just what had happened to all my pupils; had they played hookey this morning? By that time, however, one of them came running around the corner, and he said: "They told me to tell you that they were all down here at number five shaft, and we have one of those mine cars up there, and we are having it taken over to the shop and are going to have that change made on it."

Where Opportunity to See Need for Improvement Lies

Now, I am giving you that simply as an illustration of a procedure by which improvements can be made. You must not forget that the man who is intelligent enough to be a foreman and who is working right next to the job, is the man that has the greatest opportunity to note the need for improvement. The conference is a means of self-expression. It gives him an opportunity to express his opinion and to have his opinion either appreciated or depreciated by his fellow foremen.

Now, I want to sum up by saying: "Do not attempt," as the gentleman reading the first paper said, "to make foreman training conferences cure-alls for all evils." If you do, you will expect so much of it that it will begin to fail and the result will be that it will be discredited. It is a method for improving foremanship, and to the extent it does improve foremanship and your accident rates decrease, it certainly is desirable. But there are many other desirable results from a good foremanship training program: and I want to leave with you the other point, and that is to make certain that you have successful conference leaders before you undertake it. That doesn't mean that conference leaders are so difficult to get that we could not have an adequate supply. It simply means that the men who are going into those programs should have the benefit of the experience that has been accumulated during the past nine years, in order to enable them to make certain of success. What we need in this country today is an adequate program for training

conference leaders, and then industry will take care of the question of foreman training.

There seems to be a consensus of opinion that something should be done about a program for training conference leaders. Certain states are going about it as a phase of teacher training in the same way that they train teachers for the shops and for vocational schools. The character of the training program is entirely different. The best conference leader is one who has had considerable experience in industry, and within these various organizations you have men who are qualified by what I may choose to call basic qualifications, through experience, through temperament, and a desire to serve their organization. In that way they can be given this additional training.

In all of my conference groups, I have always asked that somebody be present who would be expected to continue the program in the future as a conference leader. Sometimes you make a mistake. In one instance the man was very successful; in another instance he came to me before the conference was over and said: "Mr. Wright, it is no use for the management and you to expect me to go ahead and do this work after you leave. I am too nervous. I have got to get up and tell these fellows. I can't sit here like a Chinese idol, like you do, and let this discussion roll around here until the fellows have it all out of their system. I have been around the mines and have seen this and that, and want to get up and tell them; but at the same time I know I shouldn't do it." And I agreed with him.

The conference leader must regard himself not as one who knows how all these things should be done, and what a foreman needs to know; but he must realize that, as was expressed in the beginning, the group probably does know. Out of the 20 men there will be somebody who has had experience; and the group opinion, if it is properly directed and properly drawn out, will be better than that of any single individual.

The Rank and File of Men Are Dependable

CHAIRMAN YOUNG: Doctor Wright, we wish to express our appreciation for the time you have given to come down here and for this talk on this most important subject. The meeting is now open for discussion.

MR. MCAULIFFE (President, Union Pacific Coal Company): I think that the paper read by Mr. Henrie is very close to the bottom of your safety problem. The trouble, in my opinion, lies very largely in the directing force. I confess that I have more confidence in the rank and file of our men who, as a matter of fact, take the punishment, making progress, than I have in developing leadership that belongs to the directing force.

Now, my thought is, that one of the first things we must do is to try to give citizenship to our foremen. The majority of them are suffering today from what might be called an inferiority complex. They came out of the ranks. They live in the camps. Their blood relatives are working at the face, and working alongside of them. Now, I have thought that no man should ever be promoted to a directing position in a mine (and I am speaking now of coal mines because I have no knowledge whatever of any other form of mining) unless he has the material that bids fair to make him a successful leader. Failing in which, I think it would be very much better for the company to relieve him entirely, rather than to put him back a disaffected being—put him back where he came from.

Now, we want to start that theory of citizenship. Get these men to develop the measure of self-respect that must go with leadership. No man ever led troops successfully unless he felt, at least, a certain measure of superiority over the average of the rank and file that he led. That is a sentiment that we will have to

create to get the results out of our leadership. Now that matter of citizenship in leadership, permanence of position, I think is quite vital to the success of that program.

Then I want to mention two or three other things. I am very fond of reading the results of the work started by Frederick Taylor, a man who came out of the ranks, educated himself under rather adverse conditions and started the movement that put the manufacturing industry of this country, or, a major portion of it, including our railroad shops, on what might be called a real efficiency basis. Perhaps that word has been overused and overstressed, but Taylor laid down the principles, that there are better methods for doing every task and the first way to get results is to educate the man who is responsible in that method, and thereafter use him in turn to get the method carried out by the men.

Getting the Matter Over to the Foremen

How can we get that over to our foremen? I think there is a dearth of text books directed to the particular industry that these men are engaged in, written in such simple language that can be readily read and understood. Perhaps we want something more in that direction. Again, how many of us make an effort to get our foremen to read one or more technical papers? They are all text books. They come along weekly and monthly, and it is quite astonishing how few copies of the Mining and Engineering journals are read by our foremen. We could help them in that direction if we would make the effort. Of course, a simple way would be to take a list of these men and mail their names with the voucher to the publishers, and instruct them to forward these publications; but that is not the way to get them to read books or magazines. Unless they have a feeling of personal interest in owning this thing, they are not going to read it, and in many instances they will not take the wrapper off of it. Inspiring lectures, of course, are tremendously helpful. As Doctor Wright said, it is quite important that the man who undertakes to direct this organization of foremen must, using the modern expression, "know his onions."

I have a profound respect for academic knowledge, but these men are rather critical, and it is quite important that the man, who, in the last analysis issues the instructions, is relatively well informed on his subject. After 25 years hanging around coal mines, I would be somewhat hesitant about attempting that task myself, and I know it can be done better by men who have a better knowledge of the situation.

R. V. ACETON: When your program committee put this subject: "Foremanship Training Conferences and Their bearing on Accident Prevention," in the program, we did not think that foremanship training conferences were a cure-all. We meant to bring out exactly the point that is stated in the paper, that is, the bearing of these conferences on accident prevention.

Down in the Tri-State district, in the past two years we have had approximately 180 men—foremen, who have attended these conferences. The conferences were brought about through the cooperation of the federal board and the state boards of Oklahoma, Missouri and Kansas, with the assistance of the Oklahoma School of Mines.

We give a district prize for every two months of work without a lost-time accident—what we call our "peak flag." In the past two years there have been approximately 70 of those flags given out to the foremen in the district. We have about 187 mines in the district. Of those 70 prizes 65 were won by foremen who had attended these conferences. That seems to me to be significant.

I wish to emphasize what Mr. Wright has said. You cannot bring your foremen in and say, "We are going to teach you fellows how to prevent accidents; we are going to teach you how to be better foremen; we are going to teach you loyalty."

In this regard let me just state that some time ago I got up in one of these meetings and stated that I was a firm believer in positive suggestive methods, using positive suggestive psychology, and the main thing that interested me first in these foremanship training conferences was the fact that I thought that they used positive suggestive methods. I found out later that they do use positive suggestive psychology in putting the thing over to foremen. The conference leader will set up a topic of conversation. He doesn't tell them the whys and wherefores; they bring them out themselves. I don't think we have had anything in our work down there that has had a better result than our foremanship training conferences, and I hope that all of you will find some way of putting them across in your own district and in your own mines.

CHAIRMAN YOUNG: Mr. Miller, would you please tell us something about the Colorado Fuel & Iron Company's experience in handling foremen?

Wonderful Interest Shown by Men Underground

F. C. MILLER (Chief Chemist and Safety Director, Colorado Fuel & Iron Company, Denver, Colorado): The Colorado Fuel & Iron Company works with the federal government, the United States Bureau of Mines and with our vocational training. At the present time I have 66 classes and about three thousand students in the vocational training.

It is truly wonderful to see the boys underground, who are taking the electrical courses, call attention to the condition of wiring and various electrical appliances, which is frequently beyond the knowledge of the men who are working close to these appliances; and they are corrected. I feel that we have saved a number of injuries through these boys being able to call the attention of the electricians to conditions that exist. That is something you would hardly look forward to, but it has been done. Therefore, I say, there is nothing better than vocational training for the prevention of accidents.

Now, as I stated yesterday, each and every man must take a course in first aid before he can receive a ticket to the doctor. First of all, he must know the elements of first aid. Each man carries on his person a little first aid packet. They purchase them from the company, costing fifty cents; and should he meet with a slight injury, why, he immediately takes care of himself, and that evening he goes to the office and whatever material he has used is replenished free of charge. Then when he leaves the employ of the company they give him back his fifty cents. So a man is really out nothing, and each and every man has that little packet.

Now that may seem foolish, but in one instance we had a miner traveling out of an entryway and a rock weighing less than half a pound dropped from the roof and struck him on the foot. He limped a little bit and cussed, as he is very apt to do, and continued to work; and at the end of about ten days the foot began to give him trouble and he consulted the doctor. Well, it seems as if it had just bruised the skin a little, but the socks that he was using set up blood poisoning and in a month the man was dead. That shows that, no matter how slight the injury, it should be taken care of immediately. Therefore, we care for all injuries, no matter how trivial—if you only smash your finger it must be reported to the doctor. According to the laws of Colorado, we have a right to resist compensation if a man does not report an injury within two days, no matter how slight.

In mine foreman training we find that the men that are best for putting over the conferences are men who know little or nothing about the trade. It is for this reason when you bring in a gathering of foremen, they are very apt to chew the fat—want to talk about setting props and this, that and the other thing; whereas, a man leading the conference who knows nothing about props and other trade terms will quickly get down to foreman training. We have accomplished a great deal, par-

ticularly at the steel plant. You would be surprised to know how the men are beginning to attend these conferences. To start with, we didn't beg them. We said, "Bill, you have got to go." That was the start, and now we have come to the point where we have too many; we can't teach them; and that shows how the thing is building up.

CHAIRMAN YOUNG: Is Mr. Comins here today? I would like to have the manager's viewpoint of these foremen conferences and their importance.

W. H. COMINS (Manager, National Lead Company's Plant, St. Francois, Missouri): I am very glad to speak a few words for two reasons: I have noticed this Tri-State District has ganged together and have been putting their stuff before the meeting, and there are only two of us from the lead belt, which you know, is just south of St. Louis.

In our company, so far as this foreman training is concerned, we haven't gone very far, but we are doing a lot of accident work. When I say that in 1925 we received honorable mention on this safety trophy you will realize that we are working hard. I think in 1926 we did better, but, of course, there is this old "if"—if we hadn't killed a man. But I mean our severity and frequency rate were still better after you eliminate one unpleasant accident.

Some Positive Suggestive Psychology

I was impressed by this talk on foremanship training, which we have been a little slow in adopting. Speaking about positive suggestive psychology, brings this to my mind: Coming up on the train from St. Louis the other night, we were sitting in the club car. We left at twelve-five in the morning and things were a little quiet. A gentleman came in who was not just normal. He immediately started a conversation about Tex Rickard, Hornsby, and so forth, but we stopped that pretty soon. Then I made the remark about this slow count at the stadium. That started him and it seems that he was an ex-lieutenant of Marines, and in our conversation he said, "The morale in the Marine Corps is something wonderful," and that is where I got my inspiration about this positive psychology. He said, "A first lieutenant in the United States Marines is equal to any Major in the armed forces of the United States." He said, "Any United States Marine is equal to any three men in the armed forces of the United States." He said they taught that from the first day they joined the Marines. He said if they don't like the corps they are busted right away. He said, "We make 'em or we break 'em."

Now that is the point I am coming to on this safety business—accident prevention. We are working on this in a modified way, and when I go back I am going at it stronger. I am going to make every foreman feel sure that his company has the best accident record of any in the United States, and that he has to advertise it to the men all the time. I believe that that part of psychology is a wonderful thing, and that is why I want to take my hat off to the Marines for giving me this inspiration—that when I go back every foreman at St. Francois must believe that he has the best company and the best safety organization in the world.

CHAIRMAN YOUNG: Thank you very much, Mr. Comins.

Nobody has the exclusive use of the floor. We want every section to be heard from. Is Mr. Fred E. Middleton, Uniontown, Pennsylvania, here?

FRED E. MIDDLETON (Superintendent, W. J. Rainey, Inc., Uniontown, Pennsylvania): I have been very much impressed this morning in the matter of vocational training, and I feel I have been honored as a superintendent from the W. J. Rainey Company, by being selected to come to this National Conference.

Having been a superintendent the past 15 years, and mining over fourteen million tons of coal during that period, we have never had a fatal accident in our mine.

We have with us today Mr. Adam W. Forbes, our mine foreman, and Mr. Ben

Bradley, our assistant mine foreman, who so ably conducted that safety campaign during a period of 10 years.

I would like to say that our foremen have at all times been on their toes, from the starting time in the morning until the closing time in the afternoon, conducting that great campaign of safety first.

I feel it a great privilege to be here with these gentlemen from various parts of the United States and to listen to the ways and means they have in preventing accidents. I feel it is one of the greatest inspirations of my life, to realize that when I came to Chicago I would be able to learn, from this group, the wonderful things I now have to carry back to the bituminous mines of Pennsylvania. I want to express my sincere thanks to you, Mr. Chairman and to the gentlemen, for the hearty cooperation with which they have approached this subject, and for the manner in which the campaign was put over.

CHAIRMAN YOUNG: Mr. Middleton, I wonder if you will ask one of your foremen, who are present, to take about two minutes time in talking. He has no doubt, something interesting to tell us from the foreman's point of view.

ADAM W. FORBES (Mine Foreman, W. J. Rainey, Inc., Uniontown, Pennsylvania): I am mighty glad to be with you this morning. I am mine foreman under Mr. Middleton, at the Stewart works in southwest Pennsylvania.

We have established a great record in our mine, as Mr. Middleton told you, and we believe it to be one of the greatest mine records anywhere. We feel that the record of the W. J. Rainey Company in producing fourteen million tons of coal over a period of years without a fatality is remarkable and really entitles us to the prizes we have won.

DANIEL HARRINGTON: What is that record? Give us the details of it.

A Record of No Fatal Accidents During Ten Years

MR. FORBES: Our record is no fatal accidents over a period of ten years, mining during those years fourteen million tons of coal.

I didn't come to make a speech this morning. I came to hear you gentlemen talk. But I do want to say that we are going to push along just the same in the future as we have in the past, and we hope to keep our perfect record for years to come.

CHAIRMAN YOUNG: Is Mr. T. W. Romans here? Are any of the foremen or assistant foremen here who were in the first class down in Virginia that was conducted by Dr. Wright? (No answer.) I am going to ask one more man—one more speaker. Mr. Boardman, I would like you to tell us about the Anaconda Copper on this foreman training.

JOHN L. BOARDMAN: We conducted foreman training classes under Mr. Noel (I believe that was the name of the instructor), and we found them very successful. As pointed out by several speakers here, we got a great deal out of them other than safety, but, of course, I was most interested in this conference on account of the safety factor in the course.

One of the greatest things we got out of the foreman training conferences was that we put over to our boys, particularly our shift bosses, the fact that they were working for a mighty good corporation; they were working for the biggest mining company—the biggest copper mining company in the world, and that is good positive suggestive psychology; because as soon as these men had been through the preliminary course in foreman training they began to realize they were a part of a big organization and it certainly did wonders towards getting these men to pay attention to the things in safety that we were trying to put across.

I am very glad that we had the foremen's conferences and we expect to continue them as soon as we are able to clear up some of the things that the conferences have brought out, that we were lax in doing.

CHAIRMAN YOUNG: We have time for one more. I am going to ask Mr. A. W. MacDonald to tell us in two minutes something about their foremanship training.

A. W. MACDONALD (Superintendent, Department of Industrial Relations, British Empire Steel Corporation, Sydney, Nova Scotia, Canada): We have not yet arrived at the period where we have any actual foremanship training such as has been outlined here this morning under government auspices or under government aid; but the foremen in our mines have all to pass through the government mining schools and must have certificates from the government mining schools before they can take jobs in a mine as foremen, and in that way we find a great deal of satisfaction. These government schools are conducted by the provincial governments in the winter season. For instance, from the first of the year until the examination time in May or June, these classes are held and these foremen take advantage of them. We find that although the company has not taken any real steps towards foreman training, outside of what comes up in the conferences held daily and weekly between the mine manager, the district superintendents and the foremen, that they get practically the same instruction (I presume they do) as outlined in the paper read by Mr. Henrie this morning. I think the probabilities are that, after listening to the interesting things that I have gathered from that paper, we may and probably will give some consideration to foreman training.

CHAIRMAN YOUNG: Gentlemen, Dr. Wright will close the discussion.

DR. WRIGHT: Gentlemen, I will sum up in thirty seconds the essence of a conference.

If I have a dollar and you have a dollar and we swap, you will have my dollar and I will have your dollar. Neither of us is any better off. But, if I have an idea and you have an idea and we get together and swap, then you have two ideas and I have two ideas. That which you had you still retain; that which I had you also now have. It pays to swap ideas, but it doesn't pay to swap dollars.

CHAIRMAN YOUNG: The next paper is one that should bring forth a large amount of discussion. "Accident Prevention in Its Broader Phases." will be presented by Mr. Eugene McAuliffe, President of the Union Pacific Coal Company.

Accident Prevention in Its Broader Phases

Eugene McAuliffe, President, Union Pacific Coal Company

It is with pleasure that I make this attempt to respond to the request of the National Safety Council for an address on "Accident Prevention in Its Broader Phases." The aims, purposes and achievements of the Council occupy a position so exalted, and so detached, as to justify every person participating in its deliberations.

As a people we have always been wonderfully responsive to the call of distress, whether such came from at home or abroad, but only within the past few years have we attempted to apply systematic preventive measures toward the reduction of those industrial accidents which, taken in the aggregate, reach appalling proportions. There has, perhaps, been shown in the past too definite a tendency to measure personal injury accidents as a collective matter and in terms of dollars and cents, with insufficient thought given to the human suffering resulting therefrom. By human suffering, I mean not only the agony that flows from crushed, bruised and bleeding bodies, but likewise the torture of soul experienced by those who are related to and who, alas, too frequently are dependent upon, the victim.

The industry that I will specifically refer to is the one with which I am identified, the mining of bituminous coal, an industry which I firmly believe offers an outstanding field for improvement in the work of accident prevention.

I will not attempt an undue use of statistics; I may even resort to what is very often disparagingly referred to as generalization. My generalizations will, however, be directed in every instance toward that which is remedial. Regardless of what may be heard from individuals speaking from the street, the political forum or from the pulpit, our theory of life, including accident prevention, should be postulated on the fact that the world and the people are growing steadily better. This condition assumes progress, and any fraction of society, however occupied, that does not move forward is failing in the task assigned to it. Much as I regret the necessity for making the statement, I am in candor compelled to say that the bituminous coal industry is lagging, not only behind our European neighbors in mine accident prevention, but likewise it has failed at home, in that other great industries classed as hazardous have made startling and commendable progress in the work of accident prevention, while little, if any, progress is being made by the coal industry. What is our coal mine accident record? Let us look at it calmly, dispassionately; it offers little that is flattering.

Death Rate per Thousand 300-Day Workers in All Coal Mines, Anthracite and Bituminous, for Four Five-Year Periods

Period	Men Employed		Average Days Active	Killed per Thousand 300 Day Workers	
	Average Actual	Equivalent in 300 Day Workers		Men Killed	Thousand 300 Day Workers
1906-10	675,067	484,454	215	13,288	5.49
1911-15	739,169	541,489	220	12,583	4.65
1916-20	760,381	599,781	237	12,097	4.03
1921-25	811,803	484,071	179	11,077	4.58

This comparison suggests commendable progress through the first three five-year periods, with a sharp recession during the five years ending with 1925. The figures for the principal European coal producing countries for the five-year period 1921 to 1925, inclusive, together with those shown for the United States, however, offer a further and more startling comparison. Read them carefully.

Country	Average Number Men Employed	Total Men Killed	Killed per Thousand 300 Day Workers
United States, bituminous.....	652,921	8,825	4.87
United States, anthracite	158,882	2,252	3.71
United States total	811,803	11,077	4.58
Great Britain	1,175,114	5,495	1.13
France	250,026*	903*	.97*
Belgium	161,930	812	1.00
Prussia	600,964	6,227	1.86*

*For four years, 1921-1924, only.

When the number of men killed per thousand 300-day workers is reduced to a percentage basis we can more readily grasp the shocking destruction of human life suffered in our American mines as compared with the loss of life sustained abroad.

Country	Period	Killed per Thousand 300 Day Workers Per Cent Ratio	
		Thousand 300 Day Workers	Per Cent Ratio
United States, bituminous	1921-5	4.87	100
United States, anthracite	1921-5	3.71	76
United States total	1921-5	4.58	94

Great Britain	1921-5	1.13	23
France	1921-4	.97	20
Belgium	1921-5	1.00	21
Prussia	1921-4	1.86	38

The figures quoted have been compiled and made public by the United States Bureau of Mines; they are the most authoritative available. To talk in terms of tons produced per fatal accident means little, if anything, and with the present trend toward mechanization and increased production per man-day such will in the future mean even less. The best comparison possible is that based on million man-hours of exposure; such, however, are not as yet generally available; the 300-day year comparison is the next best.

I have striven for years to find a valid explanation for the abnormally high death rate shown for our American mines, but with little success. It is a fact that the unit production of coal per man-day shown for our mine workers is far ahead of that reported for European workers, but that situation is largely accounted for by the difference in depth of cover, pitch and thickness of seams, and most of all in the fact that back filling, with a resultant greater extraction per acre-foot, is carried on abroad. Doubtless the greater percentage of men employed in European mines in "filling" work, which tends to remove them from the more active and dangerous zone of production, represents a saving factor, but surely no such secondary situation can be responsible for Great Britain, France and Belgium, when taken together, showing a loss of but 20.5 men to each 100 lost in our bituminous mines, or 21.8 men to each 100 lost in all American mines. We must go farther afield for an answer.

It is the mental attitude maintained by employers, employees and labor union officials generally that is responsible not only for the unfortunate accident record shown in the coal mining industry when compared with European conditions, but also for the further fact that we are not even making negligible progress toward betterment.

Discussion of the Subject of Rock Dusting

Let us touch for a brief period on the much discussed subject of rock dusting. For the information of the few who do not know what is meant by rock dusting coal mines, I will make the following brief explanation. Rock dust, consisting of shale, lime rock or other inert material, low in combustible and silica content, and pulverized sufficiently fine to admit of not less than 50 per cent passing through a 200 mesh screen, will, it is claimed, when distributed along the haulage and airways, and providing the per cent of coal dust when mixed with same is kept sufficiently low, check an explosive wave passing through a coal mine. Explosions have their beginning in the ignition of gas, fine coal dust, or both; they have birth in a relatively limited space and in the beginning cover but a limited area. The rapid expansion of the air, gas and dust mixture occupying this limited area, however, creates violent air blasts, which, traveling through the mine, stir up the coal dust that has found lodgment in the rooms and galleries, this dust when in suspension creating a most explosive mixture, making it possible for the originally small flame wave to travel through the mine, with resultant disaster to the men employed therein. If, however, the mine is thoroughly rock dusted, the pioneer air wave preceding the flame wave will stir up the rock dust as well as the existing coal dust, and if the combination of inert rock dust and explosive coal dust, when combined and in suspension, is made up of not less than 60 to 75 per cent of incombustible matter, the flame wave will die for want of material upon which to feed.

Do we seriously suffer from explosions in our American mines? Where did the theory of rock dusting originate? Has it preventive value? These are

all questions deserving of answer. The U. S. Bureau of Mines publishes annually a list of coal mine disasters. This list extends back to 1869. Until 1916 those only in which 100 or more were killed were listed, thereafter the death of 5 or more men was classed as a disaster. In this list we find a total of 118 disasters, with the maximum number of deaths for a single disaster 361. Referring to a more recent accident, it will be recalled that an explosion occurred in a new and modern mine located in Southern Illinois on January 29, 1926. *Coal Age*, page 206, issue of February 4, 1926, said of this accident:

"That there were only five fatalities with 1,235 men at work is attributed to the use of rock dust, which limited the effects of the blast to a small area. At strategic points throughout the workings, rock dust is stored in platforms easily tilted by the slightest rush of air from an explosion. It was that which filled the air with stone particles and confined the effects to the immediate vicinity of the explosion. Rock dust also is scattered on the floors of the entries, keeping coal dust from getting into the air."

If the statements of the coal company and state mining inspection officials can be accepted, it was rock dust, and rock dust alone, which prevented this mine taking first place as the scene of the greatest world coal mine catastrophe, that doubtful honor held by France since March 10, 1906, the date of the Courrieres catastrophe, when a coal dust explosion in a non-gaseous mine occurred, killing 1,100 men, the explosion traced to a blown-out shot. Courrieres was not rock dusted.

Experience in Many Mine Explosions

Has rock dusting a preventive value? We can well give thought to this most important question. In the sixteen months period, January 1, 1926, to April 30, 1927, inclusive, we have experienced 15 major explosion disasters in the bituminous mines of the United States. By a major disaster is meant a disaster killing five or more men in one accident. In addition to the 15 major disasters, two incipient explosions occurred during the same period, killing in one case one man, in another four men. In the 17 explosions, 432 men were killed. A summing up of the results presented by the 17 mine explosions indicates that the major explosions occurred in mines partly rock dusted and in non-rock dusted mines, 555 out of 934 men who were exposed escaping with their lives, a salvage record of 59.4 per cent; in the rock dusted mines a total of 2,135 men were exposed, of which 2,078, or 97.3 per cent, escaped. Rock dusting will not prevent local gas or dust explosions originating in dry and gaseous mines, but the evidence does show that rock dust, if properly applied and thereafter maintained in quantity, will prevent great, wide, sweeping, cataclysmal explosions that wreck mines, destroying all life within their path.

Where and when did the suggestion for rock dusting as a preventive of mine explosions originate? Is the theory one of recent origin and what is the background upon which it rests? These are pertinent questions deserving of answer, more so because of the fact that in many quarters the statement is made that rock dusting is an academic theory fathered by technicians without practical experience, some of whom are employed by the U. S. Bureau of Mines. Sir Humphrey Davy, English scientist, invented his safety lamp in 1815. Twelve years before, in 1803, the first suggestion of record to the effect that coal dust may have been a factor in the Walls End (Newcastle-On-Tyne) mine explosion was made. Then came the great scientific and electrical engineer, Michael Faraday, and the world renowned geologist, Sir Charles Lyell, who in 1845 connected coal dust with the propagation of mine explosions in Great Britain. du Souich of France talked coal dust as a source of disaster in 1833 and as the number of men employed in British and Continental mines grew in number, more and more explosions occurred, until Verpillieux, a

Frenchman, undertook a series of experiments that were continued for a period of three years, 1864 to 1867. Then came Vital, another Frenchman, in 1875, and Galloway, who reported his laboratory experiments to the Royal Society of London in the following year. The years passed, explosion followed explosion, but it was not until the often referred to Altofts mine explosion occurred in Great Britain in 1887 that "stone dusting" was proposed as a preventive of mine explosions.

Discovery of the Value of Shale Dust

It was there that William Garford (later knighted by his sovereign), acting in his capacity of general manager, noted the fact that the explosion waves had not penetrated naturally shale dusted galleries within the mine, and it was out of Mr. Garford's observation that the statement was first made of record that inert dust, when mixed with coal dust, would neutralize the explosive properties of the coal dust. For the sake of brevity I will pass other and equally important steps made toward the acceptance of the theory that rock dusting would serve to mitigate the loss of life sustained in mine explosions, closing the record with the statement that the Mines Department of Great Britain under general regulations, effective January 1, 1921, ordered that all mines not naturally wet should be stone dusted, unless and when treated with water, the dust in the roadways to show, in intimate mixture, not less than 30 per cent of water. With the occurrence of explosions in naturally wet mines, an amended order was issued on November 20, 1924, which, in substance, removed the exception to naturally wet mines, and the British regulations now make it substantially necessary to rock dust all mines, in as much as a 30 per cent water mixture artificially applied would, by damaging the roof, floor and ribs, make operation extremely difficult if at all possible. French and German mining commissions have made exhaustive studies of the value of rock dust, and I am informed that rock dusting is now an almost universal practice in French mines and is being rapidly extended to the German coal mines.

Study of the Causes Leading to Mine Explosions

In the foregoing I have touched briefly on foreign experience and practice. What have been the findings of our own people? In 1908 the United States Government, through the Technologic Branch of the U. S. Geological Survey, undertook a study of the causes leading up to mine explosions, conducting extensive tests in 1908 and 1909. In 1910 the U. S. Bureau of Mines was created by Act of Congress, and Dr. Joseph A. Holmes, who had been foremost in the work of Federal mine safety investigation, was made Director. Dr. Holmes was a man in whom was combined the skill of a great scientist, coupled with a splendid knowledge of mining and mining hazards, and with the newly created Bureau of Mines behind him, he at once set out to find the cause of, and the remedy for, the great loss of life sustained in our coal mines. The achievements of Dr. Holmes and his staff quickly moved the Bureau into first place, British and Continental engineers coming to America to obtain the advice and assistance of our men.

I will not attempt to list the activities started and the tasks accomplished by Dr. Holmes. He worked ceaselessly and untiringly, receiving as compensation a pittance, dying from exposure received while in the performance of his work. Men who admired and appreciated Dr. Holmes undertook the creation of the Joseph A. Holmes Mine Safety Association, an organization of men committed to mining safety methods, this body, undernourished and half forgotten, is little heard from today. Other men of high engineering and scientific ability succeeded in turn to the position first occupied by Dr. Holmes, and again

candor compels the statement that whatever the Bureau's achievements may be along other lines, it has not only failed of growth in recent years along coal mine safety lines, but as a result of the spirit-breaking repressive statements emanating from the industry it has tried to help, it no longer occupies the inspiring position attained between 1910 and 1912.

Wherein lies the trouble; has the Bureau a hold on the domain of coal mine safety work? The loss of life suffered in our coal mines, when compared with the losses sustained in British and Continental mines, suggests "Yes" as the proper answer to the question. Has the Bureau, through its representatives, sought unusual powers, or has it involved any handicaps on the coal industry?

Locked Within the Bureau Are Many Startling Facts

The Bureau is totally without mandatory powers, it has no authority to enforce its findings—it may only investigate and thereafter, when such investigation includes references to a particular condition within a given mine or mines, makes public the conditions therein found only after it has received the express consent of the owner of the property. I will hazard the statement that the Bureau's public utterances, expressed through its bulletins, represent but the tamest portions of its findings; locked within the Bureau and in the memories of its engineers, with all the secrecy of the confessional, lie facts that would make Bureau bulletins tame reading. It is no longer safe for a Bureau of Mines engineer to express an opinion (even within the confines of an engineering conference) as to the causes leading up to a catastrophe costing the lives of say 100 men, and it is only recently that a brief statement outlining the total loss of life suffered in coal mine accidents brought down on the head of the department a barrage of criticism which, emanating with an association that essays to speak for the industry, was taken up and passed on through many channels. Is it to be wondered that the Bureau, starved financially, reduced in numbers, finds in petroleum and metallurgical research and the newly discovered application of geo-physics to mineral discoveries a more pleasant atmosphere? There is merit in the theory of self-determination, but such supposes sane methods, constructive methods, the willingness to do what is fair and just. There are many notable and meritorious exceptions to the general rule, but the coal industry, taken as a whole, in its attitude toward safeguarding life, voluntarily insists on remaining in safety matters in a nebulous zone.

Records in the Bureau of Labor Statistics

To base criticism of mine safety work on a comparison of results obtained abroad might, if taken alone, fail of conclusiveness; let us therefore briefly review the progress made in certain other not too remote industries. The Bureau of Labor Statistics has been collecting a record of accidents occurring in the iron and steel industry since 1910, and it has constantly endeavored to present these statistics in such a way as to make them significant and useful in accident prevention. These statistics show that there has been a steady decline in both accident frequency and severity in the industry. From 1910 to 1925 the decline in frequency was 62.1 per cent. and in severity 51.9 per cent. This steady and quite considerable decline is also shown in all departments, with the exception of foundries. Considered from the standpoint of accident severity, machinery causes the greatest amount of damage, while handling of tools and material is the major factor in the frequency of accidents.

The coke industry is a closely related industry. The U. S. Bureau of Mines has maintained a record of accidents occurring at coke ovens since 1918, the results for the period 1918 to 1925, inclusive, shown below:

Number of Employees, Days of Labor Performed, Fatalities, and Injuries at Coke Ovens in the United States, 1913 to 1925

Year	Average Days Active	Men Employed		Days of Labor Performed		Total	Number Injured Per 1000 240-Day Workers
		Actual Number	Estimated Number	Actual	Estimated		
1913	329	22,289	22,289	7,333,000	7,333,000	2,200	29.64
1919	289	22,742	22,742	6,570,000	6,570,000	4,021	145.66
1920	319	22,124	22,124	7,059,000	7,059,000	2,412	114.12
1921	257	16,284	16,284	4,179,000	4,179,000	2,720	131.62
1922	284	15,124	15,124	4,290,000	4,290,000	2,119	92.77
1923	324	22,113	22,113	7,191,000	7,191,000	2,202	101.18
1924	303	20,424	20,424	6,147,000	6,147,000	2,204	75.54
1925	310	22,124	22,124	6,847,000	6,847,000	2,404	70.51

A weighted comparison of the figures for 1913 to 1925 inclusive, the last half of the period covered by the table, indicates that the death ratio in this period was but 79 per cent of that shown for the preceding four-year period.

The Norfolk and Western Railway is a large enterprise, covering 44.5 per cent of the tonnage it originates in this country, and is one of the greatest coal-producing regions in the world, and a territory of considerable importance. To some extent at least it is a national industry. What is its record in the matter of accident reduction? In March, 1923, the company put an accident prevention campaign into effect; the results, based on the record for the preceding year, 1912, are set forth here.

Number of Accidents and Accident Frequency Rates (per 1,000,000 ton miles) on Norfolk & Western Railway in Specified Years, 1912 to 1926.

Year	Volume of Business Represented by Ton-Mile	Number	Total Accidents Per Cent of Decrease from 1912	Accident Frequency Rates (per 1,000,000 ton-miles)	
				Rate	Per Cent of Decrease from 1912
1912	9,021,204,776	2,675	—	.297	—
1915	11,022,466,620	1,331	31.6	.166	44.1
1920	11,659,836,023	1,632	39.0	.140	52.9
1925	14,493,093,806	1,678	37.3	.116	60.9
1926	17,608,196,616	1,436	46.3	.082	72.4

Is the per cent of decrease in accident frequency of 72.4 per cent in 14 years worthwhile? Could the Norfolk & Western Railway afford to stand still? The answer is too self-evident. As the results shown by comparisons made from one railroad or one mine, even for a period of 14 years, may be questioned as not being fully determinative, let us take the record of all Class I railroads. Here are the figures with the roads divided into seven classes, as shown by Interstate Commerce Commission records, accident bulletins 92, 93, 94 and 95 public documents, impartially compiled on a uniform basis for a three-year period:

Casualties to Employees on Duty per Million Man-Hours, in Train, Train-Service and Non-Train Accidents, All Class I Railroads, 1923, 1924, 1925 and 1926, Compared

Year	Total Casualties	Man-Hours Thousands	Casualty Rate	Per Cent Reduction in Casualty Rate
1923	150,012	4,356,964	30.89	—
1924	122,315	4,473,186	27.34	11.49
1925	116,099	4,448,377	26.10	15.51
1926	108,746	4,557,527	23.86	22.76

By casualties is meant all accidents which are reportable under the rules laid down by the Interstate Commerce Commission, whether minor, major or fatal.

Wherein lies our difficulty? Are the men in charge of coal properties poorer citizens, are they poorer business men than those who operate the railroads, the steel plants, the coke ovens, the cement quarries and mills; are they less considerate in their attitude toward human suffering and loss of life? Such is not the case. As a class the men in charge of our coal mines represent an average cross-section of our citizenry. The industry is, however, lacking in the conduct of its business and managerial affairs. It insists on thinking, when it thinks at all, in terms of speculative sales opportunity, refusing to give thought to the creation of what might be termed a sound manufacturing and merchandising program, such as rebuilt the railroads, made the steel industry, and as an extreme example, made our American automobile industry the most highly refined industry the world ever saw. Starting at the very bottom when the automobile was "without form and void," that industry has, through the co-ordination of inventive genius, highly involved mechanization and masterful salesmanship, made strides unparalleled in the history of world invention and production.

An Unwillingness to Foster Progressive Methods

The coal industry, widely scattered and divided along labor, market and transportation lines, will always offer extraordinary difficulties toward the adoption of constructive policies, but that situation is accentuated and intensified by the fact that the men who speak for the industry decline to ally themselves with the progressive methods now generally employed by other similar industries, and the gradual strangulation of the mine safety activities of the U. S. Bureau of Mines is but one expression of this strange psychology. Where direct criticism of the Bureau's activities, as in the case of the press release before referred to, is not forthcoming from an association or an individual, attempts are made to neutralize the Bureau's public findings by giving prominence to the fact that approximately 50 per cent of the men killed in coal mines die from falls of roof or coal, generally one at a time, and the statement is made and reaffirmed that the individual worker's carelessness is the greatest factor involved. This means that we are flouting the real issue, that of bringing our mine casualties down to the record maintained by European operators or the relative showing made in other American industries.

The evil flowing from this almost generally expressed doctrine of negation lies in the fact that the certain companies (the number no longer small, and growing yearly) who are desirous of reducing accidents find it very difficult to sell even the hope of accident reduction not only to their employees, but to the operating officials in charge of their properties, the majority of whom came from the ranks of mine workers. A spirit of fatalistic indifference is in the blood, and with self-constituted spokesmen shouting, "Stand back, everybody, let us alone and we will fix things," with nothing being fixed, it is only natural that the industry is slipping backward while every other line is going ahead in the work of accident reduction.

One of our most eminent coal mining engineers, in an address delivered before the American Institute of Mining and Metallurgical Engineers in October, 1926, set forth the fact that there are 22 state legislative acts relating to the safety of coal mines and the men employed therein, all differing on one or many salient points. The U. S. Bureau of Mines, as has been said, has only recommendatory authority over coal mine safety matters, such coming under the jurisdiction of the laws of the state in which the mine is located. The laws of many states are archaic, insufficient, contradictory, conflicting—in a few instances the men, who are appointed to

insure their enforcement are fairly paid, some of these men are very competent, others are mere pawns of the mine workers union, of certain operators or of politicians. There is nothing permanent to the position; kicked out, as they all are sooner or later, the majority of these men must go back to a coal operator, a politician or the union for a job. Scientific or engineering training is a seldom required qualification. Too frequently these men come in out of a fog, passing out the same way. Such is not the character of inspection provided for the enforcement of safety regulations in British and Continental mines.

The last abortive effort toward betterment of mine safety work was brought forth for confirmation at the last session of the meeting of the American Mining Congress held in Cincinnati, Saturday, May 21, 1927. The sponsor was a man of known scientific achievement, an educator who was, it is true, but half-way within the industry, but one of the thousand who have pointed the way toward the betterment of the industry. May I quote the calm, dispassionate statement of another authority, who, like the infant's sponsor, was half alien to the industry:

An Opinion on the Cincinnati Conference

"With a mind singularly free from bias we attended the safety conference which had been called for the day following the close of the regular program of the Cincinnati Convention—a conference that merits more than passing reference. Of course, when a real safety matter is at stake we will freely admit that we are on but one side of the question—first, last and all the time.

"But this time there seemed to be no cause for choosing sides, for no one seemed to know in advance just what was the purpose of the meeting, except that it had been announced that the paper 'Shall There Be Developed a National Safety Code,' had been held over from Friday in order to serve as the key address of Saturday's conference. This did not seem to presage a battle royal, for it seemed to be right in line with what had been under way for the last few years. Nearly everyone has known of the work of the American Engineering Standards Committee and the Mining Standardization Correlating Committee which passes on proposed mining codes before they are submitted to the former body for final action.

"And so the author presented his paper. It was a good paper for it was a sensible one—he was not calling for legislative action, for laws stated the *minimum* requirements; he was not asking for Federal inspection, for inspection is a state function; he said that many laws were without good reason, citing for illustration the great variation in ventilation requirements as disclosed in J. A. Garcia's study of the matter presented last October at the Pittsburgh meeting of the American Institute of Mining Engineers; he mentioned the rock-dusting code formulated as a standard by a committee of the A. I. M. E., and a code for underground electrical equipment prepared by the Bureau of Mines; he said that many mining companies had standard codes of their own which showed not only that codes were needed, but that it was possible to construct satisfactory ones.

"The general tenor of the author's remarks seemed to be: Let us not delay any longer; let us get action and prepare definite safety codes covering ventilation, illumination, safety inspection, testing and taking down roof, and kindred subjects; these will not be laws but guides that will show clearly what the industry itself considers safe, standard practices.

"From then on there was considerable discussion, but little action—much to our surprise, for this seemed to be a program on which most men could agree, a program that has been under way for some time and simply needed a little impetus to make it move faster. As we left the meeting we were at a complete loss, and still are, for the motive that resulted in inaction. The specter of legislation seemed to bother some, but no legislation was involved. It could not have been misunderstandings, for the purpose of the author's talk seemed clear. It surely was not jealousy, for out of the men present a quorum could have been gotten for a meeting of almost any mining organization you could name."

The well-loved secretary of the American Mining Congress said a few encouraging words relative to the infant's antecedents: a representative of the Bureau of Mines made the statement that the Bureau had received requests from seven states asking for suggestions upon which to base an adequate mine safety code; certain other sympathizers urged action, but those who favored such were in a hopeless minority, and so the tenderling died in an atmosphere too chilling for anything as rare and exotic as a suggestion leading to the consideration of a mine safety code.

One of the Privileges and Duties of Government

The writer is definitely and firmly opposed to every theory leading to the government's owning, operating or even oppressively regulating coal mines; this opinion applies with equal force to railroads, canals, telegraph and telephone lines and to all public or quasi-public utilities or industries. It is, however, the privilege and duty of every well ordered government to educate and inform its citizens, including those who are in charge of a great and extra-hazardous business, upon which the nation depends for service. The government of the United States is engaged in educating and informing practically every branch of industry within its broad area, including the railroads, our great agricultural industry, our banking system and other activities of like import. The coal industry, which functions with less regularity than many other important industries, through its spokesmen demands that it be allowed to go its own way regardless of where the way leads. As has been shown, Great Britain employed in 1925 in her coal mines 1,117,828 men, killing a total of 1,126 or 1.21 deaths per thousand 300-day workers. In the same year our American mines employed 311,303 men, and of this number we killed 2,215 or 4.79 per thousand 300-day workers. Great Britain has a comprehensive mine safety law, one which is enforced. I am told, without quibbling. In any case, the results speak for themselves.

During the ten years ending with 1925 the deaths from coal mine accidents in our American mines totalled 23,147, a good sized city. Allowing but six feet as the overall length of the coffins this army of men would require for burial, such would, if placed end to end, make a thin black line 26.3 miles long. Is the picture a pleasant one? Is it not high time to attempt a betterment? The coal industry needs—

1. The formulation and adoption of a modern, scientifically prepared code of mine safety standards, writtten in such manner that they can be adopted by the several states.
2. The establishment of the principle that men chosen for the inspection of coal mines and the enforcement of safety laws should be selected for their fitness expressed through engineering education, coupled with practical experience. Such men should be well paid and retained in

office during competency and good behavior. They should be set apart from and kept aloof from the influence alike of coal operators, labor unions and predatory politicians.

3. The United States Bureau of Mines should be reinforced, numerically and financially, and the broadest opportunity should be afforded the Bureau to expand and make prompt publication of its mine safety research work. It is the only body in existence with a sufficient background to work effectively along scientific lines with the mining bureaus of Great Britain and Continent, the exchange of knowledge thus made possible multiplying three-fold the value of the Bureau.

4. The coal industry should be made to understand that the continued excessive loss of life so long experienced will no longer be tolerated, and if independent action is not taken then and then only, repressive laws should be enacted.

Cost does not enter into improved mine safety; workmen's compensation costs have been going up at a tremendous pace; in certain instances compensation insurance is now being denied the industry, the growing rate of accidents invalidating every existing rate computation.

Royal Commission of the Coal Industry

I would like, in passing, to abstract a few words from the report of the Royal Commission of the Coal Industry for 1925, as relates to Great Britain. Page 139:

"Comparisons are sometimes based on accident rates computed per million tons of mineral gotten, but output is affected by too many factors to be a satisfactory standard. For example, one hundred tons of mineral was the product of 97.7 man shifts worked in 1914, and 137 man shifts worked in 1920, an increase in the latter year of forty per cent in the number of man shifts."

This means that for the same tonnage or production there was a substantial increase, even after allowing for the reduction in the length of the shift—in the length of time which workers were exposed to accident risk. A falling off in output per man employed has the effect, therefore, other things being equal, of inflating accident rates if they are computed on the tonnage of mineral.

The very cheerful figures read by Mr. Gandy yesterday were based on tonnage produced per fatal accident. I do not think the United States Bureau of Mines engineers fully subscribe to that yard stick.

I want to read just a further short paragraph in the report of the British Royal Commission, page 192, after reciting the accident situation in British mines, the report says, under the heading: "Comparisons with Previous Periods":

"The most striking fact brought out by comparison within the past is that within the last fifty years the death rate from accidents has been more than halved among the men employed underground, and nearly halved among the men employed on the surface."

The rates were per 1,000 men employed underground, from 1873 to 1882, 2.57; from 1922 to 1924, 1.13. On the surface from 1873 to 1882, inclusive, .92; from 1922 to 1924, inclusive, .47.

I think, gentlemen, that I have submitted a sufficient number of authoritative statistical comparisons to convince any fair minded man that: First, there is room for improvement; second, that other American related industries are making the improvement and that we as coal operators, are not only standing still but the evidence would seem to point to the fact that we are going backward.

CHAIRMAN YOUNG: Mr. McAuliffe, we certainly appreciate the time you have

given in preparing this very interesting and instructive paper. The meeting is now open for discussion.

DANIEL HARRINGTON: Mr. McAuliffe has certainly given the National Safety Council's Mining Section, as well as the entire coal industry, something to think about. In addition he has taken a few pot shots at the Bureau of Mines, and has given us something to think about.

I happen to be in the peculiar position of being on the spanked end of both of these propositions, both as a portion of the coal industry, in which most of my experience has been, and as the head of the safety division of the Bureau of Mines. Unfortunately, while I think I have just as much reputation as the next fellow for scrapping, in this particular instance I don't feel at all like scrapping. I feel as though he has done what somebody else ought to have done a long time ago, as far as the Bureau of Mines is concerned. I can't say that I represent the entire Bureau of Mines, but as far as I am concerned, personally, I am perfectly willing at any time to take constructive criticism from Mr. McAuliffe or anybody else. In this instance, Mr. McAuliffe has given us what I consider absolutely constructive criticism, and I include the Bureau of Mines and coal industry in that, though, as I say, I only represent a small portion of either one.

I feel, too, that in so far as Mr. McAuliffe's criticism is concerned with the Bureau of Mines, that we in the Bureau are in pretty fair position, though we have been criticized. Mr. McAuliffe is one of the best advocates of Bureau of Mines propaganda, and he is an advocate of your Bureau of Mines propaganda in the way that it counts. He puts it into effect in the mines over which he rules, and I think he rules them pretty thoroughly, and does it by actual contact. He is a high official of mines, who knows his mines; doesn't run his mines from a chair or a desk in an office. He goes underground, and he knows what is in the mines. He knows the men in the mines; and as a result of that, Tom Jones, or Jim Smith or somebody else does not put anything over on him. The Union Pacific Coal Company, of which he is the head, uses a large portion of the Bureau of Mines teachings. Their mines use all enclosed lights. They use rock dusting. They use permissible explosives. They use a lot of other things which we have advocated for years. I feel that if other operators throughout the United States would go as far towards carrying out the things that the Bureau of Mines has advocated as the Union Pacific Coal Company does, that the mine accident record of the bituminous industry would be negligible; or if not negligible, would not be nearly as bad as it is.

Additional Experience With Rock Dusting

Now, Mr. McAuliffe has referred to a number of things in connection with his paper, other than criticism of the Bureau of Mines, and of the coal industry. One of the things I wish to bring out is some of his references to rock dusting. He shows very definitely that he is in favor of it. His mine shows he is in favor of it. But I want to call your attention to the fact that rock dusting does not mean bringing in a half a ton of rock dust today and leaving it on the road, and forgetting it for a year or two years. If you are going to go into rock dusting, do it; do it right. If you don't do it right, don't do it at all. And if you go to rock dusting, make up your mind, you are going to rock dust every day in the week, and every week in the year, and every year that you are operating a mine. If you don't do it, keep the rock dust out of your mine. You make up your mind you are going to rock dust as you ventilate and timber and haul. No mining company would feel that it could ventilate its mine today and forget it for a month. You know what would be the answer to that; the same answer applies absolutely, gentlemen, to rock dusting. If you rock dust today, and forget it for a week or a month or a year, you might as well have left that rock dust out of the mine in the first place.

And as far as the Bureau of Mines' part is concerned, so far as I am concerned, representing the safety end of the Bureau of Mines, I would rather a lot that you do not touch rock dusting at all unless you do it right.

Now, I would like to call attention to another thing in connection with the accident record of the coal mines of the United States. Mr. McAuliffe has pointed out the dark side. We have had this morning the other side of it pointed out by a representative of the Rainey Company. Here comes a man representing a large tonnage of coal, operating mines for years without a fatal accident. If an individual coal company can have a record extending over a period of ten years, why can't the industry? The "why" of it is the industry doesn't do the thing that the individual company does, and the industry can, if it will.

There is only one other point which I care to cover. I want to cover it in connection with what has been said yesterday and today. There has been a decided tendency, particularly in the general sessions of this Congress, to throw the responsibility for accidents on the individual miner. It doesn't belong there. The responsibility for accidents in the industry rests squarely and absolutely upon the mining companies, and until they shoulder that responsibility you are going to have the present day accident record that we have in the United States.

Accidents Should Be Laid at the Door of Management

CHAIRMAN YOUNG: If you will pardon the chairman for making just a few remarks on Dan Harrington's last statement.

I think that accidents should be laid on the shoulders of the management. Accident prevention work, if effective, starts at the head of the mining company. If the manager is not sold on safety and does not give safety a very important place in his operating program, the chances are very favorable that this same atmosphere will be found among your superintendents; among your foremen and among your men. Whereas, if the management is sold on safety, such as has been shown by Mr. Henrie in his wonderful paper this morning—the safety atmosphere has permeated throughout the whole Phelps Dodge Corporation, and their record is certainly something of which they can be very proud. It is something to make us all go home with the thought that we haven't yet reached the ultimate goal in our accident prevention work.

JOHN RYAN: Mr. Chairman, I certainly want to congratulate Mr. McAuliffe in having the courage to withdraw the veil and probably destroy some of our illusions.

With reference to the question of rock dusting which he has touched upon at quite some length, I can readily see how a man who has studied the whole history of the question has lost patience with an industry that has seemed to be lax in taking up a safety measure that has been so thoroughly worked out and proven. Yet, I must say one word in defense of the industry. It is that there are some excuses for it when we have men who are paid for enforcing safety, who will even go so far as to publish books and papers in condemnation of the subject and distribute them widely and freely.

They have gone so far in some quarters as to leave the impression that this whole subject has been developed and fostered by the Bureau of Mines. Yet, we have heard the history of it very completely—the history of the movement of rock dusting in Mr. McAuliffe's paper; and God knows it was started and proven long before the Bureau of Mines was ever in existence.

Now, let us briefly look into some of the records that have been made in some of the foreign countries where rock dusting has not only been practiced but has been made compulsory. It really started, I think, with the Courier explosion. That was the incentive for some very definite constructive work on the problem. Where this Courier mine is located, in the northern part of France, employing about 200,000

men underground, a very gaseous field is indicated by the fact that all of the mines are on a closed light basis. They have not killed a man by explosion of gas or coal dust since 1917. Great Britain, as Mr. McAuliffe has told you, employs better than 1,100,000 men in their coal industry. Approximately 900,000 of those are employed underground. Of the 800,000 men employed in our industry 650,000, roughly, are employed underground. Of course, in comparing the hazard of explosions, we have to confine it, or, should confine it to the underground employees. Although only a few months ago I was at an explosion in which six men were killed on the outside from an explosion that occurred underground. So even the outside employees are not entirely free from them. In a three-year period in Great Britain and employing 20 per cent more men underground, their record of fatalities from explosions of gas and dust was 35, 29 and 19. Unfortunately in this year they had an explosion which killed 52 men in South Wales, but it was purely a gas explosion. It was confined to a gas explosion by the fact that the mine was rock dusted right up to the working space. The evidence brought out that if it had not been rock dusted the probabilities were that the fatalities would have reached about 600.

To give you an idea of how thoroughly they investigate in Great Britain, the inquiry into the cause of that explosion took 12 days.

Objection to Making Rock Dusting Compulsory

Now, in rock dusting, of course, there is great objection to making it compulsory. I am against making it compulsory in this country, providing the industry will see the light and do it voluntarily. They should, and perhaps eventually will, but they will have to proceed more rapidly than they are at the present time, because not two per cent of the coal mines of the United States are now rock dusted; and of that I don't believe one per cent is adequately rock dusted.

Now, what is the cost? The average cost on the ton basis (and that is where it ought to go, because it is a fit cost for the consumer to stand), is about one-half to one cent a ton. Now, some of it will be higher, but lots of it is lower. A recent explosion which took approximately 100 lives will cost, or, did cost, approximately one million dollars in compensation and in the rehabilitation of the men. That would have paid for the rock dusting of about four-fifths of the mines of the United States for this year.

CHAIRMAN YOUNG: We have time for one more man.

MR. HARRINGTON: Why doesn't somebody in the coal industry talk—some of you coal men.

CHAIRMAN YOUNG: Some of you coal operators that are very interested in this subject, talk.

Mr. Bannister, have you anything to say on this subject?

H. T. BANNISTER (General Safety Inspector, Madison Coal Corporation, Chicago, Illinois): I was out of the room, Mr. Chairman, and did not get the full benefit of the paper. I am very sorry that I did not as I would like to have heard it.

R. DAWSON HALL: I don't know as I care to say anything in mitigation of what Mr. McAuliffe has said, because, as I think, sometimes we need very greatly to have our minds stirred up by these things. Mr. McAuliffe said that we were going backward instead of forward.

Well, that is true of Great Britain, too. It is an unfortunate situation. It is one that we need to keep in mind. There is a risk that with the number of dangers coming in, I think, especially mechanical haulage, although Great Britain hasn't gone so far as we have in that direction, there is a risk of increasing the rate of accidents. In 1873 to 1882 it was 2.24; in the next ten years it was 1.81 in Great Britain—1.39, 1.33 and 1.15. That takes us up to 1922, but now let us take it year by year. In 1913 it was 1.55; next year, 1.08; next year, 1.36; next, 1.32; 1.34;

1.39, and then it improved in 1919 and became 0.94. In 1920 it stood .088, and in 1921 it stood better than it had stood at any time, it stood .066; and then again the fatal slump which we have found in our country. In 1922 it was .095, as against .066. In 1923 it was 1.06; in 1924, 1.098, and 1925, 1.02, and 1926, 1.08. So Great Britain has been dropping backward, too. Unfortunately it is true, not only in mining but also in a number of other things. This country has a large death rate in suicides, in murders, in drownings, in a number of other features which tend to show that we have some kind of a complex which is against safety in the United States.

As regards some of the other industries which have shown such wonderful improvements, I think that has been due largely to the fact that they were neglected so long and did so little work in the safety field, that when they started to do good work they were able to reach a higher degree of success than we have been able to reach in the coal fields.

You remember our efforts in that work. They came long after those of Great Britain started, about the time of the Avondale disaster, in about 1861, if my memory is correct; and ever since that time we have had safety laws. We did not start as late as some of these other industries and consequently have not gotten so far. Yet, one field doesn't like to talk about those things and attempt to take one iota from Mr. McAuliffe's paper. It is necessary that we go ahead in safety and realize what a large field we yet have before us and what possibilities we are able to achieve. I think when you get Mr. Mosier's figures and see what wonderful results he has obtained in the way of reducing the frequency and severity of accidents, you will feel that there is a great deal that we can all do and there is a great possibility that we have not yet taken up. Even though we may not agree altogether with some of the things Mr. McAuliffe has said—cannot see them quite from his point of view—yet, at the same time, we realize that he has called attention to a very great need in the coal industry.

Steam in the Air Currents

I was talking to a man the other day down in Cincinnati. He used to be an inspector for Mr. Carl Scholz and he began to tell me about the great advantages of heating and moistening the air entering the mines. He was evidently strongly against rock dusting. He told me that this dampening went up to the very face of the works and proceeded through just as fast as the work proceeded. It also increased the temperature of the in-take so that there was not that change in temperature such as results when cold air is allowed to come into the mines during the wintertime, and the result is that many falls were stopped. He had been for years in the Fairmont region, where they had been putting steam into the air current and he believed that was the system. I told him that I thought it was very true, but putting rock dust in the mines was impossible unless you had a metallurgical mine—a mine for the purpose of producing coal for metallurgical purposes; to dust it would be to ruin it for some purposes. But I said that where a concern owned their own mines they might be able to put up with a very bad appearing product and manage to sell it to their own people; but while there was this difficulty there was no reason why the greater part of the mine should not be thoroughly rock dusted. If he thought it so important that the mine should receive this steam there was no reason why he should not adopt both principles. I asked him why that could not be done, and he admitted that he thought that was the best thing to do under the circumstances.

There is no question about it, you may not be able to put your rock dust in certain places—in certain entryways—in a satisfactory way; you may not be able to put it right at the face of the working, but if you have found steam is a splendid

thing and you have been using it, there isn't any reason why steam should not continue to be used; and I am sure that that, combined with a sprinkling of rock dust, would do a great deal toward making these mines immensely safer than they are at present.

CHAIRMAN YOUNG: I am sorry we have not more time for discussion. We will now have the report of the nominating committee.

JOHN L. BOARDMAN: The job of the nominating committee is rather difficult because we are faced with this situation: There isn't a man in the section that isn't capable of filling the various positions and there isn't a man in the section who isn't entitled to the honor. When a man has gone through the chairmanship and done so well as our present chairman, he should certainly be offered the position for another year. However, there are two reasons why we are considering something different—why we are not doing that. The chief reason is that we asked the chairman if he would serve again, and he said, "I do not choose to become a candidate." You can take that for what it means.

MR. HARRINGTON: Give it to him—make him take it.

Report of the Nominating Committee

MR. BOARDMAN: Another reason is that it has been the policy of the section for some time to change the chairmanship each year. We believe that ought to be done in order to pass the honors around and give each branch of the industry representation.

Now, we have a man who has been pulling his load for a number of years and we would like to give him the honor of being chairman for the coming year. I refer to Mr. C. A. McDowell, assistant general manager of the Pittsburgh Coal Company. We recommend that he be given the chairmanship for next year.

We want also to follow the policy of the section by providing various vice-chairmen who will advance from year to year until they are in line for the chairmanship. With that in view, we recommend George Martinson, safety engineer of Pickands, Mather & Company, as first vice-chairman; A. W. Dickenson of the Union Pacific Coal Company to second vice-chairman; J. P. Hodgson of the Phelps Dodge Corporation, third vice-chairman; and we want to fill the fourth vice-chairmanship by recommending Mr. F. C. Miller of the Colorado Fuel and Iron Company. Of course, for secretary we are confronted with a difficult situation. We have to have a man for secretary who has the time and ability and the proper connections and we can't do any better than to ask Mr. Daniel Harrington to continue.

Now, we believe that the only job in the whole business equal to that of chairman in importance, is the membership committee; and we want to recognize the excellent work of our present chairman by recommending him for the chairmanship of the membership committee for the next year. For Poster Committee, H. C. Henrie of the Phelps Dodge Corporation. Owing to Mr. Marvin's excellent service and his connection with the publishing business, we wish to recommend that he be continued as chairman of the Publicity Committee. For the Engineering Committee we wish to recommend J. M. Carmody, of the *Coal Age*; and we feel that the other committees should be filled by the incoming chairman. Gentlemen, I move the adoption of the report.

W. T. McDONALD: I second the motion.

CHAIRMAN YOUNG: It is moved and seconded that the report of the nominating committee be accepted. Are there any nominations other than those made by the committee? If not, all in favor of adopting the motion as submitted by the nominating committee, make known by saying "aye"; contrary, "no." The motion is carried. Now, I want to ask for a little information from some of you old timers.

Is it customary to vote on the nominations after the section has adopted the report?

R. V. AGETON: No.

CHAIRMAN YOUNG: I want to say that we have here a typewritten list of all those who were present yesterday and I would suggest that you get a copy of it because there may be some representatives of the mining companies here that you haven't had an opportunity to meet yet and this will give you a full list of those attending the mining section. I want to ask those who did not register yesterday to please come forward here immediately following the adjournment, and fill out one of these cards.

ADJOURNMENT.

Thursday, September 29, 1927

The third session was called to order at nine-forty o'clock by the chairman, Howard I. Young.

CHAIRMAN YOUNG: The first paper for today is to be delivered by Dr. F. W. Meriwether of the U. S. Bureau of Mines. Dr. Meriwether has been spending his time in various mining sections. I believe for the last two months he has been spending all of his time in the Tri-State Section, with headquarters at Picher, Okla.

The Effects of Mine Dust on Health

F. W. Meriwether, M. D., U. S. Bureau of Mines, Birmingham, Ala.

I won't burden you with reading a lengthy paper that I had prepared for this meeting, but will only give you a short resume of some work we did in the coal mines several years ago.

As many of you probably know, even ancient medical history records the harmful effects of dust. Some of the older writers make mention of the number of husbands the miners' wives had. We know in this day it was due to the inhalation of dust.

Within the last few years the medical profession has been making a rather close study of the effect of dust. It was early found that the higher the percentage of silica in the dust, the higher the percentage of pneumoconiosis, or lung disease. This coupled with the fact that the incidence of tuberculosis in coal miners was very low, led many investigators to believe that coal dust was harmless.

In order to prove whether this was true or not, the U. S. Bureau of Mines conducted a series of experiments or studies in a number of the coal mines in several different states. During this investigation we made atmospheric dust samples in all the mine studies. We studied the mining methods and mining conditions and the seams of coal. In addition we made 514 physical examinations where the pictures turned out good. We made, in addition, a large number of examinations in which the pictures were poor.

The data given to you is based on the 514 physical examinations. The other examinations are taken into consideration but not correlated with the good pictures.

From the result of this work, we believe that coal dust when inhaled in large quantities over a long period of time will produce pneumoconiosis. I wish to say to you that it is just as erroneous to say that coal miners are liable to contract pneumoconiosis as to say that coal dust is harmless. In other words, the harmful effect of coal dust is confined to a comparatively small number of men working in the coal mines.

This work showed that several other factors entered into the incidence of pneumoconiosis. Among the first is age. We found that a man entering the mines late in life, let us say after 40 years of age, contracted pneumoconiosis much more quickly than a man entering early in life, say 20 years of age. This is not only true of pneumoconiosis caused by coal dust, but it is also true of that caused by silica dust or silicosis.

Another factor that has entered into it is the race. As many of you probably know, the incidence of tuberculosis is greater in the colored race. We were astonished to find that the incidence of pneumoconiosis was greater in the white race. A study of the working history of the men showed that in mines employing colored labor, the white man occupied official positions or operated machinery, that

the negroes did the lower classes of labor, that in addition, the negroes would not remain at the same job for long periods of time. We made an effort to correlate the negro and the white labor, using the same position or occupation as a basis over a long period of time. We could find only a few instances of such in our work, but the data gained indicates that even where the negro and white are occupying the same position in the mines, the incidence is slightly greater in the white race.

However, as I say, the figures are very small and if we could collect statistics all over the country, this might be changed.

We tabulated the histories, the habits and especially the diseases of the men to see if the habits or diseases in prior life had any effect on the incidence of pneumoconiosis. We particularly studied the family history of tuberculosis. Apparently the family history of tuberculosis has no relation to the incidence of pneumoconiosis. We also carefully studied the effect of smoking tobacco on the incidence of pneumoconiosis. Apparently the two have no connection.

The only diseases that we could correlate with the incidence of pneumoconiosis was whooping cough and measles. Why the curve of these two diseases followed that of pneumoconiosis is rather difficult to say.

These factors probably have some bearing on pneumoconiosis, but the important factor and the one that I wish to emphasize is the occupation. These two things in connection with occupation have a very definite bearing on pneumoconiosis: First, is the length of time the man has been mining; and second, the occupation underground.

Many Years of Exposure Necessary

We found that men do not contract pneumoconiosis from coal dust until they have been subjected to clouds of dust for many years. The earliest case is about fourteen years. The average is much longer.

The second thing is that we found that only certain occupations underground were producing dense clouds of dust. We found in these particular mines where we were taking atmospheric dust samples that 97 per cent of dust on an average was produced at the face. This varied from 94 to 99 per cent in these particular mines. We found in the mines studied, that on the average, 63 per cent of the dust was produced by machinery, 34 per cent by shoveling and 3 per cent on the roadways.

Now you can readily see that only the small group of men working around mining machines, and by mining machines I mean undercutting machines, shearers and loaders, or coming in contact with dense clouds of dust, are particularly subject. The shovelers to a lesser extent than the machine man, and the men occupying such positions as timberman or bratticeman and so forth, have very little dust hazard, if any. In fact, the investigation of farmers throughout the states in which this investigation was conducted showed that the farmers had as much fibrosis as the average coal miner occupying the positions I named.

Occupation is your most important factor in its influence on pneumoconiosis. The symptoms of pneumoconiosis can be detected by an ordinary layman. The most important one is shortness of breath. You men who have slope mines will notice the older men will walk out of the slope and rest at frequent intervals. You will also notice that these old fellows have a rather large or rather a barrel shaped chest and that while resting, their neck muscles are more or less brought into play which increases their respiratory efforts. If you will question the old man, you will find that he claims he has asthma, or as he says, miner's asthma. It is pneumoconiosis.

Another important symptom, is cough expectoration. Unfortunately there is an

idea in the mines that it is necessary for a man to cough and expectorate the dust breathed during the day consequently you cannot rely too much on the cough expectoration because many of them have a chronic cough brought on by habit rather than disease.

Pain in the chest is another symptom. However, it is not so constant. In the last stages of the disease you will get loss of weight. In the early stages there is apparently no effect on the weight. The respiratory and pulse rate is decidedly increased in pneumoconiosis by exercise. The blood pressure of those having pneumoconiosis has no change. This is of some diagnostic importance to doctors. The blood pressure in tuberculosis tends to fall. With pneumoconiosis it tends to remain normal; if anything, slightly increased. We use it in our present work in the Picher District. Whenever we find a man with a low blood pressure, changes in the lungs, we always feel certain we are dealing with a case of tuberculosis or tuberculosis complicated with silicosis or pneumoconiosis.

A Marked Decrease in Lung Expansion

I could go into the physical science or methods of diagnosing pneumoconiosis, but I am certain to the laymen it would be a burden. I might mention that the most important, in other words the cardinal, physical sign in diagnosing pneumoconiosis is a decreased lung expansion, but I wish to caution this body in using this physical sign in the colored race. We early found that we could not get the negroes to expand their lungs. At first we thought it was due to ignorance, not knowing how to expand the lungs; we took the time to try to teach each individual to properly expand the lungs, and we signally failed. Whether the colored race are unable to expand their lungs with ease and readiness like the white race, or whether it is due to perverseness, I cannot say, but at least in a large number of these examinations we could not get what we call a normal lung expansion in the colored race. So in using the physical sign in pneumoconiosis, it should be used with a good deal of caution when you are dealing with negroes.

No diagnosis of silicosis or pneumoconiosis should be made on physical science and symptoms only. It should be confirmed with an x-ray picture. The x-ray picture of pneumoconiosis due to coal dust and that to the silica are very similar. The early changes and those of the later stage are practically the same, with this slight difference: that the density of the pictures is less great in coal than it is with silica, so much so that a man seeing a large number of cases of each of the diseases can readily distinguish typical cases.

In our picture clinic where we are dealing entirely with silicosis and pneumoconiosis due to silica dust, we occasionally find a coal miner from Indiana and Illinois particularly in the last few months, coming into this district to obtain employment. A number of these men have had silicosis and we can readily detect that the silicosis in those men was due to coal dust and not the dust that they encountered in the Picher field.

The conclusion drawn from this work was that coal dust when breathed in large quantities over a long period of time, and I mean years, will produce pneumoconiosis; but that the number of men in coal mines subjected to such clouds of dust was and is comparatively small, that it is largely confined to the men working on and around machinery.

That being true, the methods to control the dust hazards from a health point of view in the coal mines is much simpler than in the metal mines. In other words, by introducing water on the cutter bar of the undercutting machines, the shearers and on the loaders, you can largely kill the majority of dust produced in the coal mines. The water not only will kill the bug dust produced by the undercutting machine, but will wet the bottom and will decrease the amount of dust

produced by the shoveler in bucking out his bug dust. It leaves the bottom wet, and when the coal is blasted down, less dust will be produced in shoveling. In other words, the control of the coal dust hazard from a health point of view in coal mines is comparatively simple.

Another thing that I wish to call to your attention in stopping pneumoconiosis in coal miners is your sanitary and welfare measures. I realize that coal mines are making wonderful strides in the improvement of their living conditions. Some of the coal camps I visited in this country are not only on a par, but probably better than the average industrial plant. While this is true, there are other camps that have not made such progress. The men are living in more or less unsanitary living conditions. All business men in this day and time recognize the importance of sanitation and welfare. This also includes the constant attendance of a company physician.

We would like to recommend that this company physician's duty should be not to tend to the sick and accident cases, but to make a study of the occupation of the men underground. You often see miners trying to induce their company physician to go underground to play jokes on him, to scare him. That should not be the attitude. They should attempt to take him underground to teach him what they have to contend with each day. Every industrial physician should be as familiar with the underground workings as he is with the surface occupation of the men that he has to deal with. More than that, he should make a physical examination of every employee in that mine at least once every 12 months. This is important for more than one reason. First, it will aid in defending the company against unjust compensation claims; but more important, it will detect in the early stages physical defects as they develop. That will enable the man to obtain medical treatment and correct such defects. It will enable you to find silicosis or pneumoconiosis in its earlier stages and advise the man to leave the mine for a period of time.

In Later Years Recovery Is Doubtful

In the early stages, that is, the first stages, pneumoconiosis will remedy itself. Nature will throw off the dust within 18 to 24 months. In the later stages, especially when it becomes complicated with tuberculosis, the chance for complete recovery is comparatively small.

In other words, I wish to urge on all the mining men of the country to take the physician into his daily life as well as into his sick home. Treat him as you do the industrial lawyer. Have his daily advice and guidance on how the men should work, the jobs that they should fill and their physical and mental condition to fill the position that you wish to have filled. If you will undertake such work in your mines, I assure you that after it is once put into operation, you will never again do away with it.

CHAIRMAN YOUNG: Dr. Meriwether, on behalf of the National Safety Council, I wish to thank you for this excellent talk you have given us on this most important subject. It is very vital not only to the coal industry, but to the metal industry.

Dr. Meriwether's paper will be discussed by Mr. Daniel Harrington, Chief Engineer of the U. S. Bureau of Mines.

MR. HARRINGTON: I am rather glad to welcome Dr. Meriwether to the ranks of the bolshevists on coal dust and I am going to be rather curious to follow up what our friend, Mr. Hall, is going to say in connection with what Dr. Meriwether has just told you.

About three or four years ago I sent a paper to the American Institute of Mining Engineers on essentially this same subject and Mr. Hall printed part of it.

He came out with a very caustic editorial in connection with what was said. I am going to be rather curious until I learn what he is going to say in connection with that paper.

I wish to place myself squarely with Dr. Meriwether in practically everything he has said and I feel as though I am competent to do it in view of the fact that from 1916 to 1924 the greater portion of my time was taken up in the study of the effects of dusts on the health of underground workers. That study included not only coal dust but any kind of dust found in mines. In that study I had an opportunity to go underground and do various kinds of work underground relating to dust occurrence and its effect on health in more than 25 states of the Union, including mines which had silica dust, coal dust, limestone dust, in fact dust of almost any description that is mined underground. After about eight years of that kind of study in which I was thrown in pretty close contact with the people who are eating the dust, as the men themselves say it, I want to say that any kind of dust, I don't care what it is—limestone dust, marble dust, coal dust, hematite dust, silica dust, granite dust, any dust if breathed in large quantities is going to kill; and sadly it doesn't kill soon. It takes time. It is not a merciful form of execution, and that's about what it is, an execution.

Coal Less Harmful Than Silica Dust

There is no question that certain dusts are more harmful than others taken in relatively equal quantities. It is a certainty that coal is not nearly so harmful as silica dust. It is equally certain that not all forms of silica dust are equally harmful; but again the same rule applies, that if you get plenty of that dust, you are going to get harmful results ultimately.

Dr. Meriwether brings out the fact that comparatively few workers are harmfully affected by dust in coal mines. That is true up to a certain point, but it is also true that all face workers, which includes those who load coal under contract, those who dig coal with a pick, those who undercut the coal, those who overcut the coal, those who shear the coal—all those men are the ones who are very likely to be harmfully affected by coal dust.

I have had a number of rather odd experiences in connection with studying the effect of dust and particularly coal dust on miners. Very often you find the coal mining man, the coal superintendent or general manager, will practically tell you that you are an anarchist if you say that coal dust will harm persons who breathe it. I have had that sort of argument with general superintendents, and with superintendents. I have gone underground with those same men and have tried to get them to stay with me while I was observing the effects of dust while men were overcutting or undercutting the coal. But they would not stay in a working place during the period when the place was being cut. It was harmless, all right enough, but they wouldn't stay in there and allow their precious lungs to breathe it. That's the attitude of a large number of our coal mining men toward the dust.

In one coal mine in the West where we made a study of dust, the coal mine superintendent happened to be sympathetic with us. He happened to believe, from his own personal experience, that coal dust in itself might be harmful, and I asked him why he had that particular attitude when nearly all the others had a different view.

He said in 1913 he was superintendent of a coal mine in the West and that about two years previously they had introduced an electric undercutting machine, cutting wholly into coal. In the spring after they had had a very heavy tonnage run, the doctor of the camp came to him and said: "See here, we have something that has to be corrected. We are getting at the hospital every day four or five

of your machine men who are affected by slight hemorrhages. I am afraid it is going to be serious. They claim that the dust that they are eating (as they say it), is harming them. I wish you would look into it and see what you can find out."

So this mine superintendent was on the job. He went underground, talked to the men, stayed with them, found out that they were being affected by the dust. He talked it over with his underground officials and they finally decided that they couldn't eliminate the mining machines. The mining machines were absolutely necessary for the kind of work they were doing; so they were compelled to do something with the method of using the mining machines rather than eliminate the machines. They hit on the idea of placing water on the cutter bar and this was done in the spring of 1913. So far as I have been able to find out, they have had since that time no particular difficulty in that district as to their machine men.

R. D. HALL (McGraw-Hill Publishing Co., New York City): Undercutters?

A Talk With an Old Anthracite Miner

MR. HARRINGTON: Yes. I will give you the district—Hanna, Wyoming.

Recently I had an opportunity to talk to an anthracite miner, an old timer, a man who was 68 years of age. I was interested in his condition because I have had a bee in my bonnet for a number of years that there were some dust troubles in that region, although I had never had an opportunity to investigate them myself.

I asked him what was the situation over there. He at first didn't understand what I was driving at, but I gave him an outline along the line I am giving you now and he immediately woke up. He said that he had worked in the anthracite mines wholly on coal. He didn't drive any rock tunnels he wasn't accustomed to that type of work, that he had left the mines when he was 36 years of age. He said from the day he left the mines and before he left, whenever he climbed any sort of an incline, he had to stop to rest in order to get his breath. In other words, he had what Dr. Meriwether gave to you as one of the cardinal symptoms in pneumoconiosis, shortness of breath.

He then went on and gave me the names of brothers, uncles, cousins who had been compelled to leave the mines before they were 50 years of age, all of whom had died before they were 60 and all of whom had the cardinal symptom, shortness of breath.

As Dr. Meriwether said, it is far easier to remedy the matter of dust hazard in coal mines, as far as health is concerned, than it is to remedy it in metal mines, although it is remediable in metal mines also. If the mining companies will give their working forces the ventilation that the working forces should have, they will sweep out of the working forces a large portion of the harmful dust. If they will also put water at the working faces so the men can use it on the cutting bar or the cutting chain of the mining machines while they are cutting, particularly the top cutting or shearing machines, but also the undercutting machines, they will have eliminated probably 75 per cent to 80 per cent of the possibility of trouble from dust in the air of coal mines. In addition to that, in addition to aiding the health of their miners, they will also have eliminated a very large portion, not 75 per cent of it, however, of the hazard as to coal dust explosions.

There is a tendency at the present time to introduce into coal mines a machine which is being barred (and rightfully), from metal mines, and that is the dry jack hammer. The dry jack hammer is a machine which in my opinion should not be allowed to go into any mine. The dry jack hammer is being introduced too much, in my opinion, into coal mines at the present time. I wish to call your attention, gentlemen, particularly coal mining people, to the fact that in metal mining where they have the dust hazard and the dust trouble, the greater portion of it comes from dry drilling and particularly dry drilling of upper holes.

The coal mining people ought to keep that in mind and they should not introduce into coal mines a hazard which is being rapidly eliminated from metal mines.

One of Dr. Meriwether's statements, while true as to the district in which he was working, is not necessarily true as to all coal mining districts; and that is that it takes 14 years or thereabouts to have a man's health affected by coal dust.

I was talking about this subject with a prominent coal mining man in the West about two years ago and he gave me this sort of history. He hadn't thought about it as being particular pertinent until after we had had about an hour's discussion on this very subject. He was mine superintendent of a mine in 1912 and his mining company introduced mining machines for the first time. Previous to that the coal had been cut by the miner's pick.

About the the time of the introduction of the mining machines there were six Italian miners who went to work for him. They were apparently a higher type of the Italian race and were accustomed to or inclined to mechanical ideas, mechanical work. They chose to take up machine mining and did nothing but machine mining. The machine on the bottom cuts wholly in coal, does not cut in rock because the rock is too hard to cut, there is no possibility of cutting the rock. He said within six years of the time that these six men went to work on those machines, all six were in their graves from what he called "lung diseases," and he said there was absolutely no question in his mind but that they had died from eating coal dust, as he termed it.

Gentlemen, I know that's radical to tell coal mining people, that coal dust is harmful; and the coal mining people can substantiate their stand as to the harmlessness of coal dust by volumes of expert opinion written in the United States, England, South Africa, Australia, all over the world. Notwithstanding all of that information, all of that expert opinion, there isn't a shadow of doubt in my mind that coal dust in large quantities, as it is being breathed every day in our coal mines, is harmful.

And another thing, not only is coal dust harmful to the health, but all of us or practically all of us agree that coal dust in its influence on mine explosions, carries into their graves several hundred coal miners per year, probably 250 to 300. There isn't a doubt in my mind that coal dust breathed into the lungs of coal miners carries into their graves far more than 250 to 300 miners per year.

CHAIRMAN YOUNG: Thank you, very much, Mr. Harrington.

Mr. Hall, would you discuss the paper?

The Itinerant Miner a Statistical Problem

R. D. HALL (McGraw-Hill Publishing Co., New York City): I don't feel much disposed to say anything about the subject. All the statistics in the past have been rather favorable to the idea that coal dust was not harmful to miners. The trouble with statistics is that when a miner would get pneumoconiosis, he doubtless would leave the mines and they would say he didn't die as a miner from the disease, and consequently the statistics are quite apt to be false and misleading. That is frequently the case with statistics which are based on occupational diseases.

It seems to me that Dr. Meriwether has proved a very good case against coal mines in his statements today and there is perhaps something that we may be rather pleased to note in this direction, because if we begin to believe that coal dust is a hazard to the miner in the way of giving him an occupational disease, we will do something to correct it, doubtless; and if we correct it, we will stop a great many of the explosions which are now doing so much to jeopardize the life of the miner and the life of the men who work away from the face.

Personally, I rejoice to see anything that is true, even if it should happen to prove that I have been misled by statistics. I don't think that any of us ought to object for one moment to being shown that in the past he was wrong. As far as I have been concerned, I have never endeavored to suppress the truth. I published Mr. Harrington's paper some time ago and I understand it ought not have been published. I learned afterwards that Mr. Harrington had delivered this address without getting due permission; but we published this article and I am sure we have never desired at any time to suppress the facts when the facts were proved. The statistics were all against Mr. Harrington at that time, and I presume it is getting about time for us to make apologies to him.

MR. HARRINGTON: No apology is needed at all.

CHAIRMAN YOUNG: Gentlemen, we have twelve minutes for the discussion of this paper. Mr. McDowell, have you anything to offer?

All Top Cutters Were Discarded

C. A. McDOWELL (Pittsburgh Coal Co., Pittsburgh): I have always been very much interested in the coal dust idea and the probability of its being injurious to our men.

I might say that I have one mine in mind where we use top cutters and we have spent considerable time in this study, with the result that before I left the Davis Coal and Coke Company last year, we discarded all top cutters, took them out of the mine entirely and scrapped them. We use the bottom cutter.

What brought it particularly to our attention was the fact that we could never get men to work on the top cutters. We even went so far as to use the sprinkling system, and even that did not eliminate entirely the dust hazard from an injurious standpoint to the man himself, and from the standpoint of making it a hazard insofar as coal mining is concerned.

We found afterwards, however, that it was an inefficient program, and in that particular seam of coal we got more efficiency by the use of what might be termed the bottom cutter.

I have been very much interested in the dust hazard in another way. I have in mind a dry cleaning plant which might be a subject for discussion just a little later, as to whether or not the dust that originates or comes from this dry cleaning plant is harmful to the men working around the plant and whether it is a dust hazard. It has gone so far that at the present time I have issued orders that no smoking will be permitted on this plant. I didn't mean to bring that up at this time, but as it came to my mind, I wanted to mention the fact. If you want to start a discussion, Mr. Pollock, under your paper, you can start it.

CHAIRMAN YOUNG: Mr. Miller, you have coal mines in the West. Would you discuss Dr. Meriwether's paper for a couple of minutes?

F. C. MILLER (Colorado Fuel & Iron Co., Denver): Our medical department has not as yet been able to decide definitely that the coal dust is particularly injurious, especially in our bituminous mines. In our anthracite mines they have found several cases where the dust has proved injurious to the men. But from a chemical point of view, it seems that a percentage of dust in air is just the same as depleting the percentage of oxygen; that is, instead of working with 20 per cent of oxygen, it would be about the same as working with 16 per cent of oxygen. That is a new phase that we have only started to investigate. It was brought about in one of our mines where the conditions are the same on both the east and the west sides, but on the west side we started to humidify with the sprinkling system, and strange as it may seem, the men are able to mine more coal on the west side where the air is clear than they do on the east side where

it is dusty. The men come out at night tired on the east side whereas on the west side they come out comparatively fresh at the end of the day's work. That is a new phase of the game for you men to study.

CHAIRMAN YOUNG: Are there any other coal representatives ~~present who have~~ anything to say on this subject?

W. A. SIEBENTHAL (Phelps Dodge Corp., Morenci, Ariz.): ~~I should like to ask~~ Dr. Meriwether a question.

I have read some of Sayer's papers on silicosis and I gathered from ~~these that~~ the harmful dust is so small as to be invisible. Is that true?

DR. MERIWETHER: Yes. The smaller it is, the more harmful.

Dust Was Fatal to Many of the Miners

CHAIRMAN YOUNG: Are there any other questions? I would like to have ~~this~~ paper discussed by the metal miners for five minutes.

I just want to say one word on that. I happen to be a metal miner myself and was located in the Joplin District at the time tuberculosis was at its peak. Nineteen years ago I started mining in Cartersville, Mo., in the sheet ground section and I am safe in saying that today 75 per cent of the miners that were employed in our mines at that time have died from the effects of dust that they were working in at that time.

The operators of the sheet ground mine did not fully appreciate what could be done, and it was only through the good work of the United States Department of Health and the United States Bureau of Mines that we were shown the way out, so to speak. We did not eliminate the disease entirely. They still have trouble down there, as Dr. Meriwether has advised.

I think during the war period all of the operators down there got a little negligent in looking after the sanitation end of it, and they are paying the price today.

The abatement of rock dust is just as important to the mining industry as the prevention of accidents, because we are all working to keep our men physically fit, and rock dust certainly gradually reduces the efficiency of the workmen who are in daily contact with it.

I am going to ask Dick Ageton who is located in Miami, Okla., to say a few words on the rock dust question.

R. V. AGETON (Tri-State Zinc and Lead Ore Products Assn., Miami, Okla.): Four years ago, the Bureau of Mines sent Dr. Friend, Mr. Myers and myself down into the Tri-State District to make a study of the dust situation. The first study had been made in 1914 by Dr. Lanza and Dr. Higgins, of the Bureau of Mines, in the old field, and they found silicosis and all lung diseases like tuberculosis very prevalent among the miners of that district. That was in the old field, up in the Joplin District, that Mr. Young was speaking about.

We made most of our investigations in the Tri-State District of Oklahoma, Kansas and Missouri. We found conditions very bad. There was a great deal of dust being formed, so many dry drilling machines instead of the water type, and quite a large majority of the men examined both physically and with the X-rays showed some form of silicosis, tuberculosis, or both.

We started a campaign for the prevention of silicosis and at the present time we have the dust fairly well under control.

We found in our study that in a six-foot hole drilled dry about 60 per cent of the dust was formed in the first two inches collaring the hole, and one of the hardest jobs we had in the Tri-State District was to get the men to start the hole wet. We found that if the hole was started wet this prevented about 60 per cent of the dust.

Dr. Meriwether is in charge of a cooperative clinic in our district now sponsored by the U. S. Bureau of Mines, the Metropolitan Life Insurance Company, and the operators of the field, and from April of this year until the present time, the clinic has examined about 3,000 men, giving them complete physical and X-ray examinations. This has been done for two reasons; first, to find out the exact status of the disease; and, second, as an educational measure—as far as the men are concerned—to give them a better idea not only of dust prevention but of health and sanitation, and how to take care of themselves so that they will not get the tuberculosis complication.

I might say in conclusion that we have found there is not a great deal to do in dust prevention. It is merely a matter, as some gentleman said yesterday, Mr. McDonald I believe, of educating 50 per cent and getting hard-boiled with the other 50 per cent.

We are doing wet drilling. All drilling is wet. We have wet jack hammers and everything else. There is practically no dry drilling in our mines. The second thing is to wet down the stopes and the laybys or partings (where the cars switch) at least twice a day. The third thing is absolutely no blasting on shift, that is, while the men are on the ground. The fourth thing is adequate ventilation, getting fresh, pure air up to the face and getting the impure air containing the dust out, so that the men do not breathe it.

Dr. Meriwether can probably tell you the exact figures, but I am firmly convinced that it would take four or five times as long to contract silicosis in our mines at present as it would have four years ago.

Mr. Young spoke a moment ago about rock dust not only from a health standpoint but from an accident standpoint. A man who has contracted silicosis, or silicosis complicated with tuberculosis, is not the individual he once was and consequently he is more subject to accident. He hasn't the pep, he hasn't the vitality, and a rock that he could have dodged three or four years ago will come down and bump him off with greater ease once he has contracted the disease.

I think it is of vital importance to prevent the formation of dust, and not only that, but to make frequent and thorough examination of your men for two reasons; first, to find out how they are physically, and second, as an educational matter.

CHAIRMAN YOUNG: I notice Mr. A. W. MacDonald is here. I wonder if he could tell us something about the work on dust prevention in Nova Scotia.

Most Mines Damp in Nova Scotia

A. W. MACDONALD (British Empire Steel Corp., Sydney, Nova Scotia, Canada): In Nova Scotia the large percentage of our mines are so damp, so wet, that we are not bothered with dust. Where we have dusty mines, we don't use mining machines, or use them very little. Where there is dust we load out of the mine as a separate operation.

Shooting is not allowed where there is any accumulation of coal dust and we haven't resorted to the watering because we are able to get rid of the little dust that we have to contend with, without going to the expense of laying pipes and carrying water into the coal face.

I have listened with a great deal of interest to Dr. Meriwether's report. We may eventually get to the point where coal dust will be a larger factor than it is today and when it comes to that point, we will, of course, take care of it.

Our mining laws are such that all of these various hazards are covered and the operator is obliged to take care of them, but fortunately so far we haven't had anything in the way of a disaster or explosion to amount to anything since 1917. And the dust problem is not, as I said before, a very great factor with us.

CHAIRMAN YOUNG: The next feature of the meeting will be a round table dis-

cussion conducted by Mr. Frank Pollock, safety engineer of the Oliver Iron Mining Company of Eveleth, Minnesota. Mr. Pollock will now take charge of the meeting. (Mr. Pollock took the chair.)

CHAIRMAN POLLOCK: I don't see why Mr. Young is leaving this place.

When Mr. Ageton gave me the job, he said I had 45 minutes to put over this round table discussion and he gave me the names of ten people, each of whom he wanted to speak for five minutes. I wrote those ten people and they are all here.

We will hear first from Mr. W. A. Rowe of the American Blower Company.

Advantages and Disadvantages of Blower Fans for Auxiliary Ventilation

W. A. Rowe, American Blower Company, Detroit, Mich.

I urged Mr. Pollock to assign this paper to someone who is more active in the mining game than the mining apparatus manufacturer, but he asked me to go ahead with it. So I did, and in order to get some data together, I wrote to Mr. Harrington, and Mr. Richardson, of Butte, particularly on the lines of the disadvantages, because you couldn't expect a blower man to tell you anything wrong with that system.

The auxiliary fans might be classified in two parts, and I think probably the first part could be covered if I just read Mr. Richardson's personal letter to me in which he states:

"Equipment for auxiliary ventilation of mines falls into two divisions:

"(1) Booster fans, used to increase circulation in remote sections, which are not dead ends;

"(2) Blowers for ventilation of dead ends, used in conjunction with canvas or metal tubing.

"The main advantages of a booster fan are, as has been stated, the circulation of an increased quantity of air in a remote section of the mine, where this cannot be obtained with the main surface equipment"; or, parenthetically, I might say, with the main surface equipment at its present speed, or water gauge where it would be necessary to increase the water gauge on which the whole mine is operating in order to accomplish the same thing.

So far as the booster fan is concerned, he says:

"The other noteworthy features of this auxiliary system are mostly disadvantages. Most important, I believe, from the operating point of view, is the fact that booster fans generally necessitate the use of an increased number of doors to control the circulation, and this is particularly undesirable on main haulage ways. The electric cable, and other equipment required to transmit power, always creates a fire hazard, particularly in heavy-timbered ground. Crushing of the timber may break the cable, causing a blowout. Where these fans are placed on the inlet air course, they frequently create undesirable high air velocities in main workings, and cause a certain amount of trouble from the dust. Doors and other stoppings are seldom air-tight, so a great amount of re-circulation of air occurs in a closed circuit. It has been my experience that the total circulation of air through a mine is seldom materially increased by the use of booster equipment."

I can hardly reconcile that with a later statement in his letter in which he says:

"While the foregoing is mainly a recital of the disadvantages pertaining to this auxiliary system of ventilation, still I do not think that in a mine of any great depth or extent, it is practicable to do effective ventilation work without the use of booster equipment."

I want to bring in the booster fan, although I don't know that it was contemplated in the subject; but the booster fan is merely a means of saving in the cost of your ventilation—that is, if you are ventilating alongside of remote workings carrying a higher pressure on that particular branch of your mining.

I think possibly the disadvantages Mr. Richardson had in mind in his outline, plus the disadvantages that might accrue with any electrical equipment at the remote corner of a workroom, were in the use of auxiliary ventilation not concerned with the primary ventilation system—that is, the blowers used in connection with canvas or metal tubing.

Metal mining is so different from coal mining it is difficult to see how we would get away without boosters, because most of the work in metal mines is done in dead ends and blind ends where there is no air circulation. Because of that you get higher percentages of CO², you get traces of carbon monoxide from the explosives. You have dust. You have high temperature and high relative humidities, all of which are lowering the capacity of the workman, decreasing his resistance against disease or hazard and all of which can be overcome by the use of blowers through tubing.

In the discussion, therefore, of the advantages of the blower system, it occurred to me like some other academic question, like you might say to a man overboard at sea, "What are the advantages of swimming or not swimming?" I think probably the disadvantages, if any, are concerned possibly with the electrical end, buying suitable electrical equipment, possibly the purchase of standard ventilation sets from sources of supply which have to do with building an industrial ventilation, which were not intended for mine use. Secondly, carelessness in the installation, in the electrical wiring, and these are troubles which I think we could turn over to the electrical man with a great deal more possibility of practical solution than to the manufacturers of the fan. That probably covers all the subject which the time permits.

CHAIRMAN POLLOCK: We will now hear from Mr. Dixon, engineer for the Jeffrey Manufacturing Company, on the same subject.

Auxiliary Ventilation

T. C. Dixon, Jeffrey Manufacturing Company, Columbus, O.

I shall not attempt to cover fully this issue of ventilation in the short period of time allotted to this subject, but I believe I have summarized the most important points in relation to auxiliary ventilation.

The use of auxiliary fans is the first change in the system of ventilation that has caused any appreciable comment in the last 75 years. As dissensions and premonitions were voiced by the people when our country changed from the horse and buggy to the automobile, so has the same objections come up when the ventilation system in the mines is changing from brattice cloth and line curtains to small fans and tubing. The old methods are known to be defective, however; no one is making such a declaration when voicing opposition to the auxiliary fans.

Under old conditions many explosions and burnings have occurred which lowered the efficiency of ventilation. The use of auxiliary fans may not entirely eliminate these troubles, but they surely are a step in the right direction if properly used.

Methods mean nothing unless carried out under proper supervision to insure the safety which is the innate right of every man working in the mine. It also means the education of the employees regarding the dangers resulting

from abuse or misuse of the equipment or plans of operation. In the gaseous mines of Pennsylvania every man in the mine knows that it is serious offense to pull down a line brattice or curtain, or leave doors open; otherwise he has not been properly instructed by the officials under whom he works. The same may be applied to auxiliary ventilating equipment.

Many of the ventilation problems today would be solved if 50 per cent or more of the total air handled by the mine fan on the surface could be carried to the working faces. The greater percentage of the air is lost through leaky stoppings and doors. By the use of auxiliary fans and permission of the United States Bureau of Mines, these stoppings could be reduced in number by changing the law requiring breakthrough's or crosscuts at short intervals. The small auxiliary fan will furnish sufficient air to ventilate efficiently headings 600 feet in length.

An Objection to Re-Circulated Air

One of the main objections voiced by a great many is that the air is re-circulated. This will happen if the fan is not placed correctly, but it is a matter that can easily be remedied and readily observed by the management or inspectors, for the relative location of the fan to the room or development roadway can be noted on the most cursory inspection. If the fan is properly placed, however, the risk of re-circulation does not exist.

There is another objection to these small fans, and that is, the sparking of the motor although I believe it can hardly be compared with a trolley locomotive as a source of danger; and if the fresh air current where they sit is really fresh and pure, I fail to see how they can prove a menace to the safety of the mine. To combat this objection, however, there has been designed a flame proof blower for use in gaseous mines.

Another objection is that the auxiliary fan will become a permanent fixture of the ventilating apparatus. The small auxiliary fan is used only until the main air current can be economically brought to the face. The use of any auxiliary fan as a permanent fixture should be discouraged in any new mine, although in some of the old mines which were developed without any thought toward ventilation, the booster fan is the only remedy by being used constantly and as a permanent fixture in a long split.

In many properties, particularly in metal mines, temperature frequently reaches 100 degrees F. and even higher. Tests have shown that the efficiency of mine workers decreases as the temperature of the air rises above 70 degrees F. This is especially true if the air is highly humid, a condition that is frequently found in deep mines. More serious than the decreased efficiency of the mine is the actual danger to health. If, through inadequate ventilation, a man must continually breath air that is hot, humid and saturated with gases or finely divided dust, he may become subject to some respiratory disease.

In all metal mines there is the problem of expelling powder gases so that the men can return to the working faces after blasting without too much waste of time. The use of small blowers and tubing is more efficient for this purpose than a compressed air line, in that it enables the men to return to work sooner.

In conclusion, I will say that by the use of auxiliary ventilation we shall rid ourselves of many uncertain and dangerous curtains and doors; by the elimination of unnecessary stoppings we shall preserve our air currents from short circuits and leakages; we shall attain closer supervision and favorable for operating by the use of concentrated methods of mining; we shall limit the number

of places by reducing the number of development entries; we shall strengthen the roof by eliminating the many breakthrough's and also, we eliminate the dangers to trip riders and motormen which are caused by curtains and door.

CHAIRMAN POLLOCK: I believe here is a point on which we could have a little discussion. I will take five minutes' time and will give it to three different men who are interested in discussing these papers on ventilation. I believe the coal miners are more interested than the metal miners.

D. HARRINGTON (U. S. Bureau of Mines, Washington, D. C.): I want to be one of them. I am absolutely with the gentleman who advocates the use of the blower fans or the auxiliary fans for metal mining and absolutely against the use of them in coal mines. In my opinion the only place they ought to be in or around the coal mine is on the surface and whenever they are put under the surface or under the ground, they become a menace immediately.

The gentleman said something about the Bureau of Mines having something to do with determining the distance apart of the breakthroughs or crosscuts. The Bureau has absolutely nothing to do with that one way or another. As to comparing the sparking of motors on auxiliary fans with the sparking of motors on trolley locomotives, they are totally different subjects, because the motor fan is put up to the face, sometimes at the face, while a trolley locomotive or a trolley wire shouldn't be, and very seldom is, within 200 or 300 feet of the face. Anybody who puts it anywhere around 500 feet of the face ought to be put in jail.

As to explosions, there have been a number of explosions caused by defective doors, by defective stoppings, by lack of stoppings. There have also been a number of explosions caused by auxiliary fans and not very long ago, and I had the opportunity to go underground and investigate the placing of auxiliary fans with the direct idea of finding out how safely they were placed, and I could write a book on the unsatisfactory placement of them as they are actually used in mines.

JOHN L. BOARDMAN (Anaconda Copper Mining Co., Butte, Mont.): Mr. Harrington didn't mention one possible danger of fans which cannot be eliminated in the manufacture. We have had one or two fires from auxiliary fans for the reason that the bushings became somewhat worn and the impeller tipped a little bit and struck the fan housing, causing sparking, which set fire to the fan tubing. Of course, that is a danger in coal mines which cannot be eliminated by electrical manufacturers.

The Matter of Motor Bearings Is Important

MR. HARRINGTON: You might also give them the instance of the moving of the fan.

MR. ROWE: I meant to cover the question of bearings before I sat down. I think the matter of motor bearings is one of the most important things aside from the sparking, and I urge all our men to advocate a ballbearing motor for that work because they are reaching the point where they are reliable. Recently a new type of bearing has been brought out by one of the large manufacturers, which, I believe, will run for a year without oiling; and I think a bearing of that type, which will run for a maximum of time without attention, is the first essential in that type of apparatus, particularly as we are getting to more and more high speed apparatus.

J. P. VICTOR (Brule Mining Co., Stambaugh, Mich.): I heard the discussion of sparking in coal mines. I have heard that at several different conferences, and the question in my mind is why they are using direct current for that type of fan in a place where they have gas.

A polyphase motor hasn't any contact of any type that will give you any trouble from sparking; and by the use of ballbearings and the proper type of roller bearings, I think, you will get away from all the troubles which were created by the

roller striking the housing; and furthermore, the proper inspection and maintenance of equipment will reduce your hazards considerably.

CHAIRMAN POLLOCK: We have a big program here so I think we had better go on.

The next paper will be given by Mr. W. J. German of the DuPont Company.

Advantages and Disadvantages of the Miner's Electric Cap Lamp

W. J. German, Technical Representative, E. I. du Pont de Nemours & Company

The subject assigned for this paper includes two topics—the advantages of electric cap lamps and their disadvantages. It will not be difficult to deal with the advantages, but the second topic will be hard to discuss, because the disadvantages of electric cap lamps are few.

I have worked underground since 1898 and have used four kinds of individual lights: first, the old oil torch; second, the enclosed flame safety lamp; third, the carbide lamp; and fourth, the electric cap lamp.

When working in mines these days with my path and my work uniformly lighted by the miner's electric cap lamp, I cannot help looking back over the past and recalling many accidents that could have been avoided had the men been equipped with electric cap lamps.

The distinctive features of the electric cap lamp are: first, that the source of light is inclosed in a glass bulb; second, that the light is automatically extinguished the instant the glass is broken; and third, that such a lamp of approved type gives uniform, constant illumination for 12 consecutive hours without being recharged. I shall not enumerate the merits of the electric cap lamp from the mechanical standpoint because it has been proved over many years that this type of lamp is efficient and practical and I wish to devote all the time allotted to me to showing how the electric cap lamp increases safety and economy in mining.

Accidents Occur When the Light Is Blown Out

In my study of transportation accidents in coal mines I have found that when brakemen or trappers are injured or killed on mine locomotives or mine cars, the accident is generally due to having their light blown out by the air currents. This is an occurrence which is only possible with open flame lamps. Air currents cannot blow out the electric cap lamp, and furthermore, the light is uniform. With an open flame light, the brakeman's attention is continually distracted from surrounding dangers by the necessity of adjusting his lamp. Obviously the work of brakemen and trappers is made much safer if they are equipped with electric cap lamps.

In the past many accidents have been due to the fact that men who were not trained and equipped to locate unexpected accumulations of explosive gas have walked into such accumulations with their open lights and have ignited the gas. This kind of accident is not only frequent in coal mines, but also occurs from time to time in other underground work. I recall my experience in the Cleveland waterworks tunnel in 1916, where 19 men lost their lives in a gas explosion. This tunnel was being excavated in soft clay just 60 feet from the bottom of Lake Erie. No one in charge of this project expected gas to be encountered, but it was, and the explosion occurred, causing tragic loss of life.

The following analyses of two samples of gas found at one time in this tunnel will give an idea of the percentage of explosive gas that may appear in a place where not any is expected.

Cleveland Tunnel Sample X		Cleveland Tunnel Sample Y	
CO ₂	0.5	CO ₂	0.6
O ₂	11.6	O ₂	11.7
CH ₄	42.9	CH ₄	45.6
N	45.0	N	42.1

The electric cap lamp does not take the place of the flame safety lamp for detecting gas but it does remove the ever-present danger that men wearing open lights will walk into that of igniting an accumulation of gas. It also greatly increases the opportunity for miners to escape after a mine explosion. Such an explosion may generate gases which will support life but which are explosive. Open lights would ignite these gases and produce a second explosion, whereas, with closed lights the miners could find their way out through the gaseous area into safety.

The Electric Cap Lamp Lessens Danger of Explosion

The electric cap lamp also lessens the chances of coal dust explosions for there is no exposed flame to ignite coal dust suspended in the air. Likewise it helps protect the miner when he is handling his explosive by removing the danger that flame from the lamp will come in contact with the explosive and set it off accidentally.

The most treacherous thing about coal mines is fires. We grow much excited when we see a building on fire and are filled with concern regarding the safety of the people inside, but there are fire escapes and many other means of getting out of a burning building. Just stop and picture a mine with several hundred men working underground miles from the entrance. A fire starts and gets well under way before the men are warned of the approaching danger. There they are, trapped. They are not burned usually, but are eventually smothered by the poisonous gases coming from the burning coal in the mine. I will mention two cases as illustration.

At the Amsterdam, Ohio, mine fire in 1919, it took several days to get behind the fire and locate the 20 men who were trapped there. We found 19 of them sitting dead in a circle behind a barricade which they had not completed in time to keep off the poisonous fumes. This fire was started by a flame coming in contact with greasy waste in a fan room underground.

In 1923 an open light in a coal mine of the Carnegie Coal Company at Oakdale, Pa., set fire to some oil which had seeped into the mine. While many lives were endangered, none were lost, but the property loss ran around \$100,000.

I dread mine fires because I visit hundreds of coal mines during the year and many times I picture the results if a fire should get under way at certain points in the mines and block off the entries, which would be the only means of escape. Mine explosions are bad, but mine fires are worse.

In coal mines it is a common practice for the men and boys in each section to have a place to rest and eat their lunches. These places are usually arranged with benches and boards covered with strips of canvas and old clothing to make the seats comfortable, and in some cases canvas is hung to protect them from the cold intake air. I can recall many mine fires that have been started at these places by open lights, which resulted in danger to the whole mine and sometimes loss of life. A miner's electric cap lamp furnishes the necessary light

for the men without any of the danger of the open flame lamp. It removes one of the main causes of mine fires. Obviously, also, the electric cap lamp greatly increases the possibility of rescue work after a mine explosion or mine fire.

The fact that the electric cap lamp gives a greater light over a much larger area than an open flame light, and, at the same time, a light that is uniform throughout the day and requires no attention, adds greatly to the safety of the miner who is so equipped at the working face, where danger is ever present and where the majority of accidents to miners occur. Especially does it aid him in detecting dangerous roof conditions and thus protect him against falls of rock or coal.

Indeed, the better illumination afforded by electric cap lamps assists the men in every operation of blasting and loading. In this day and time when most coal is purchased on the basis of the analysis of the ash content in the coal samples, and when many mines have been closed because of their failure to ship clean coal, it is a very great advantage for the coal loader to be equipped with a light that is uniform the whole day through so that the impurities can be easily located and picked out of the coal. Some of our largest coal producers who sell their coal on a low ash guarantee take care of most of the preparation at the working face.

Better Work Done With the Uniform Light

Moreover, mining has speeded up in recent years and we have in our mines high speed mining machines such as arc wall cutting machines and mechanical loaders. With this kind of equipment, it is an advantage for the men to have their work lighted with a lamp that requires no attention and causes no delay for recharging or adjusting. With mechanical loaders costing around \$15,000, a few minutes delay due to the crews' lamps requiring attention runs into much money.

The Warrior Coal Company, near War, West Virginia, equipped all their underground workers with electric cap lamps because the superintendent figured that the men could do better work with a uniform light. He also figured that they could do more work if they were not obliged to stop to charge their lamps and adjust the burners. After three years of experience with electric lamps the officials of this company state that they have profited by the change and that they would not care to go back to the old method of open lights for their men even though the laws do not require them to use closed lights in this mine.

Last, but not least, the electric cap lamp increases the miner's bodily comfort. The old oil lamp kept the miner's head hot all during the working day. This same thing is true of the present type of open light. Many good looking miners have become bald-headed because of this excess heat on their heads. If you will look closely, you will see that I am speaking from experience. With the electric cap lamp, this excess heat is eliminated and the miner feels better to do his daily work.

In summing up briefly the advantages of electric cap lamps we find:

1—The use of electric cap lamps lessens the hazard of gas explosions. This is illustrated by the record made by Great Britain in the year 1924. Approximately a million men were employed underground but only six per cent of all these underground employees used open lights. In that year 35 men were killed by explosions. Out of these men more than one-half were killed in open light mines.

2—The electric cap lamps increase the opportunity for miners to escape in case of mine explosions.

3—Closed lights greatly reduce the hazard of coal dust explosions.

- 4—Closed lights reduce accidents from handling explosives underground.
- 5—Electric cap lamps lessen the chances for mine fires.
- 6—The electric cap lamp has proved to be one of the most important pieces of equipment for entering mines after explosions and at times of mine fires.
- 7—The brighter and more uniform illumination provided by the electric closed light safeguards the miner at the working face and especially reduces accidents from falls of rock and coal.
- 8—Electric cap lamps reduce haulage accidents.
- 9—Electric cap lamps facilitate cleaning the coal at the face and eliminate costly delays of mining machinery due to charging and adjusting lamps.
- 10—The electric cap lamp increases the miner's comfort through decreasing the heat on his head.

The disadvantages of electric cap lamps being mentioned in the title of this paper. I suppose I must find some. The weight of the battery strapped on the man is the greatest disadvantage of the electric cap lamp, but men soon get accustomed to this weight and do not mind it. In the past leaky batteries have caused lights to burn but this difficulty has been practically eliminated by new types of battery cases. In fact, the slight disadvantages that I can find in the miner's electric cap lamp are so far out-weighted by the many advantages, I will not take up time and space to discuss them.

From 1908 to 1914 gas lights were extensively used on automobiles, and some of you can recall the troubles of those days. Just stretch your imagination a little and picture the traffic trouble we would have today if we depended on flame lights for our cars. You must agree that the electric lighting of our automobiles has been an advantage. Just so much of an advantage is to be gained by equipping underground workers with electric lamps instead of the open flame lights.

CHAIRMAN POLLOCK: The time is short. We will have the next paper.

Mr. Theodore Marvin, editor of the *Explosives Engineer*, will give us a short talk on the ten best accident measures he has seen during the past year.

Ten Good Safety Measures

Theodore Marvin, Editor, *Explosives Engineer*, Wilmington, Del.

I was assigned the duty of describing ten of the best safety measures that I have seen during the past year. I thought maybe the best way to do it would be to let Wilyum Jan tell it to you in cartoon form. I don't believe there is any use in even going over them, although it could be done quickly.

The first one is the matter of apparatus for holding a cartridge of dynamite so that a delay electric blasting cap can be pushed into it or can be placed inside of the cartridge without breaking the blasting cap itself. Some have such a long fuse on the end of the cap it is very difficult to push them in by force. By having a cartridge punching box which will hold the cartridge and the use of a rod to make a hole in your cartridge, the cap can be inserted easily.

Number two merely states that your explosives will be in a safer condition and be kept better by painting your magazines with aluminum paint.

Number three is the matter of a clothes fuse pin on which, if you are driving a drift, you have a number of fuse ends hanging around—you may have as many as 20 or 25. In some instances it is pretty hard for one man to light all the fuse ends quickly and get away. By use of a fuse pin, a piece of wood about 24 inches long with a split in the middle, you will thread the fuse ends, then take your cap lamp or whatever means you are going to light it and run it along the whole bunch.

It is also used to hold up the bottom fuses. If the bottom of your drift or your room or whatever blasting area there is, is wet on the bottom, you can use one of these pins to hold up the bottom fuse and connect it with the top one to keep it out of the water.

The fourth is merely a suggestion about safety pictures which are shown underground at the Oliver Mining Company. That was described last year, I believe.

The fifth illustrates the use of single leading wire instead of duplex wire to eliminate shorts. I will say it helps to eliminate shorts. It will aid considerably in eliminating fires.

The sixth shows everything which carries explosives should have a sign on it. That may perhaps eliminate some accident. People should know what is in an explosive carrier and they should know if a certain carrier is an explosive carrier and if it carries explosives.

Number seven refers more to quarries and open pit mines. If black powder is being used and the area is wet and you still want to use black powder, black powder can be placed in paraffin bags. That will keep the water and moisture away from it for a longer period than if the bags were of plain paper.

The flares shown in number eight are lighted just before your blast or your fuse is lighted, if it is by fuse and cap, and the flare burns. It is of such a length of burning which will extend over and pass the blasts. Therefore it warns people who have not been forewarned about the blast, to keep away from there.

Number nine refers to what was said this morning by Dr. Meriwether. I will read that: "Physical examination of all employees, patterned after the new clinic in the Tri-State Zinc and Lead District, Picher, Oklahoma, increases safety because men should be 'Fit to work and should fit their work.'"

Number ten is just a hint that because of the reduction in accidents and the saving of lives during the last year because of the National Safety competition, I think it would be a good hint to suggest that those who are not in it join in and help with the campaign of safety in reducing accidents.

CHAIRMAN POLLOCK: I suggested to Mr. Marvin that next year he bring with him this Wilyum Jan. We would like to see him in person. He said he would.

Next we will have Mr. MacDonald tell of a special picnic they had for a good record in one of their safety mines.

WM. T. McDONALD (Montezuma Copper Co., Phelps Dodge Corporation, Nacozari-Sonora, Mex.): I wish to assure you at the start that this part of the program was not included in the original plan, because only a few moments ago I was handed a little note stating that they would like to hear me tell something of a little picnic which occurred among the mining employees of the Montezuma Copper Company in Nacozari.

(Mr. MacDonald then related the amusing story of the picnic.)

CHAIRMAN POLLOCK: I am going to ask Mr. Bannister to give his paper on "Haulage Accidents and Their Prevention." Mr. Bannister is from the Illinois Coal Mines.

Haulage Accidents and Their Prevention

H. T. Bannister, Madison Coal Corporation, Chicago, Ill.

When they asked me to talk on underground haulage and prevention of accidents, Mr. Pollock, my good friend, said I would only need to talk five minutes. I think if you will bear with me that long I will appreciate it.

When I came on this job about nine years ago with the Madison Coal Corporation, we were having a good many haulage accidents.

After making a careful study of it, we found that there were five outstanding hazards—electrocution from trolley wire, men being thrown off the front end of motors and being run over, men being rolled between ribs in cars, men being caught by trips

breaking in two, stepping out after the front part of the trip had passed and let the back end run over him.

We started on the trolley wire first. We experimented with several different types of guards, one of them being the wood trough. We found that was very unsatisfactory for the reason that the mules going from one end to the other would pass the trough and the men would have to pass under the bare wire coming out in the evening.

We then tried rubber belting. It was unsatisfactory for the reason we couldn't get it to fit closely enough around the wire. We then tried a rubber lined linen hose. We also found that this was unsatisfactory for the reason that it collected the humidity of the mine and became a conductor itself. We standardized on a rubber hose rubber lined and rubber on the outside with a cord filling. We have to flare it at the end so the trolley wire will enter it easily. We standardized on that hose in 1922 and we haven't had a single electrocution since that time.

Our next problem was the brakeman or trip riders; cars on the back end of the trip would jump the track, causing a sudden jerk to the motor and throwing the trip rider off in front. We got up some drawings, and designed a cab for each end of the motor so that the brakeman or trip rider would have the same cab space as the operator of the machine.

No Accidents After the Cab Installation

We took them to some of the manufacturers. They laughed, but we told them we wanted the equipment regardless of the cost. I will say the cost was considerable but we have the satisfaction of knowing that since we installed the cab for the trip rider, we haven't had a single fatality, due to that cause. That was in 1923.

The law of Illinois requires manholes to be placed at intervals of sixty feet on the opposite side of the track from the trolley wire. They also require these manholes to be painted white or whitewashed, and we had some trouble with men being caught between the manholes and rolled between the ribs of the car. We decided that the whitewashing and painting of the manholes was not sufficient, so we placed an electric light on each and every manhole. The Illinois mining law requires a clearance of 18 inches between the rail and the rib. We decided if 18 inches was good, 30 inches was better, and we laid the track and widened the entrance so we got 30 inches of clearance between the rail and the rib on the manhole side. It is a rule with our company and it is rigidly enforced that if any man puts anything in the manhole, a coupling, tie or any material he may find lying along the road, if he is a company man he is discharged at once. We also have the rule that there must not be any material of any kind piled on the travel side of the track.

We then came to roof falls and sharp edges. We tried painting those white. We didn't get the results we thought we should. We went along and placed electric lights in any break in the roof where the fall has caused a sharp edge. A motor runner or a trip rider will for some unknown reason rise up in the cab and try to look over. If there is nothing there to attract their attention, they bump their heads.

We then tried several different types of markers, and we had very poor success with home-made markers. We had a fellow killed one day and I was worried; we said we would have to get ground line tail lights. I am pleased to say that the men have learned to expect that electric tail light on the back end of the trip and you couldn't push one out of the manhole until they see the tail light pass. That has been our experience in southern Illinois and in the past four years and three months of working time we have had only one man killed on our haulage.

JOHN L. BOARDMAN (Anaconda Copper Mining Co., Butte, Mont.): May I ask Mr. Bannister to give us the details of the guard for the trolley wire, please?

MR. BANNISTER: Mr. Boardman, we use a three-inch rubber hose. We have it split by the manufacturer. They can do it cheaper than we can. We cut holes at each hanger or each support of the trolley wire and the support is placed through the holes and the weight of the hose bears on the bell of the hanger.

MR. BOARDMAN: Then the split parts just lap over?

MR. BANNISTER: Just lap around the wire. You cut the end off so as to make an easy entrance.

MR. BOARDMAN: How do you put it in the frogs?

MR. BANNISTER: You have to use a double hose when you come to a frog.

MR. BOARDMAN: Would it be possible to use a second-hand hose?

The home made split hose safety device on trolley wire

MR. BANNISTER: It is possible, but not advisable. If you have a good rubber hose that is rubber on the inside and outside both, that second-hand hose would be just as good as a new hose, but a linen rubber lined hose will take moisture and will become a conductor.

MR. BOARDMAN: What is the price?

MR. BANNISTER: The last price I had on this hose, if I remember correctly, was thirty-six cents a foot. You can get some for twenty cents. We get ours from a rubber company in Chicago. I would have to ask the purchasing agent who it is because all our supplies are bought through requisition. I can get you that information before we leave Chicago.

FRED E. MIDDLETON (W. J. Rainey, Inc., Uniontown, Pa.): How far does your rubber hose extend below your trolley wire?

MR. BANNISTER: It covers the trolley wire completely.

D. HARRINGTON (U. S. Bureau of Mines, Washington, D. C.): Have you written that in the form of a paper? You should write that up.

MR. BOARDMAN: There seems to be a great deal of interest in this subject, which indicates it is a safety kink of value, and therefore I would request that Mr. Bannister write it up as a special and send it in to be included in the minutes of this meeting.

MR. BANNISTER: Mr. Boardman, this kink was shown at Detroit last fall with

Mr. Forbes' picture and was discussed, but I could write a short article and have it included in the minutes.

CHAIRMAN POLLOCK: Are there any other questions?

C. A. McDOWELL (Pittsburgh Coal Co., Pittsburgh, Pa.): I would like to make a suggestion that Mr. Bannister write this in such a form that Mr. Harrington can include it in a news letter.

I would like to say, gentlemen, that Mr. Bannister wrote this up probably three or four years ago in the NATIONAL SAFETY NEWS. It was illustrated at that time.

MR. BOARDMAN: Can you give us the month?

MR. BANNISTER: It was January, 1925.

MR. McDOWELL: I used this after I saw what he had done. I used this in a Pennsylvania mine and we found it very satisfactory. It was with the company I was with formerly and we used it for eighteen months in about eight or ten places and we had no trouble whatever with it. We put it up and that was the last of it, and I am sure it was eighteen months until I left that company and it wasn't necessary to put up any additional wiring or anything of that kind. I don't know what the labor cost was. I know it wasn't necessary to go back and put up a board.

MR. BANNISTER: I will give you the reason for setting up the rubber hose guard. We had what we thought was a proficient trough guard. We just barely had room for the trolley wheel to get through safely. We were working a four-foot seam. The trip wrecked one evening just inside the door. Along came a hardheaded miner. He couldn't wait for anything. He had to get out of the mine right then. He was wet with perspiration. His own son said to him, "Father, don't go through; you haven't room." He said, "The hell with the room." He went through anyway. He shoved his shoulder up to the trough guard and got 500 volts and it killed him, and I thought right then and there that I had to get something that would cover the wire below as well as on the side, and that is where I got the rubber hose idea.

J. P. VICTOR (Brule Mining Co., Stambaugh, Mich.): Why do you use 500 volts for trolley haulage?

MR. BANNISTER: I will say we resurrected a lot of old properties that we took over and the installation was already made. This was a Kentucky property. The installation had already been made and the whole business didn't justify our changing the installation.

Electric Currents in Mines

H. T. Bannister, General Safety Inspector, Madison Coal Corporation,
Glen Carbon, Ill.

Trolley wires, feeder cables and entry circuits in general should be installed as permanently as possible with sufficient clearance to minimize danger of contact with locomotive crew, or men using the traveling way. Unavoidable conditions will frequently limit the clearance that can be obtained, but the importance of this as a safety measure should not be overlooked. Hangers should be of best type and at short distances apart, depending on conditions.

Definite rules should be prepared by the Safety and Electrical Departments which will govern the installation of all circuits, due consideration of course, being given in the preparation of such rules to the local conditions in each mine.

Although the mining law specifies guarding of electric wires only at traveling ways, yet it is equally important to guard wires where the locomotive crews pass under same. After experimenting with wooden troughs canvas covers rubber belts, etc., we have finally standardized on a 3-inch rubber hose that is split, placed between the clamps and hangers so as to hang over and around

the wire and flared open at each end to allow the trolley wheel to enter. The hose opens easily for the trolley to pass, closes again at once, and thereby affords complete protection. Since using this method of protection, we have had no cases of shock to men or animals, but previously had experienced some serious accidents, one of them fatal, where other types of protection were in use.

Section line switches are frequently installed in such manner that the locomotive crew is required to throw them as they pass. This is generally done while moving at a fair rate of speed and is a prolific cause of minor, and occasionally, of more serious accidents. Where this can not be avoided by the use of switches automatically controlled by trolley clips, the motorman should be compelled to stop his trip to throw the switch, which itself should be guarded with fibre shields to prevent injury through getting burned by an electrical arc, which has frequently happened. Protective shields of this character can be readily made and installed at the trifling cost of 40 or 50 cents each.

The Large Trolley Wheel Reduced Arcing and Flashing

We have found that under our conditions the use of as large a trolley wheel as possible reduced arcing and flashing to a marked degree, resulting in less hazard to the eyes of the locomotive crew. We get appreciably better results from the five-inch wheel than from the ordinary four-inch size generally used. At points where flashing is troublesome we have found that greasing the wire with medium cup grease greatly reduces it, and one application remains effective a surprisingly long time.

When all possible measures have been taken for the safety of the locomotive crews, attention should be as carefully given to elimination of injury to others who must unavoidably use the haulage ways traversed by the locomotives.

The most effective safety measure in this respect is provision for a separate traveling way entirely for the men, but this unfortunately is seldom possible. Where this cannot be done the provision of safe clearance between the locomotive and the ribs and timbering, together with free and unobstructed refuge places, at the legal distances, is of first importance. The refuge places should be kept well white washed, and illuminated as much as practicable, with an electric light at each one where restricted clearance or other conditions create a special hazard.

Signs should be placed at switches and curves, warning of the danger of derailments at such places.

Special provision should be made for the safety of trappers, switch-throwers, and others whose duties keep them in close proximity to the tracks. This can very effectively be provided in the way of a recess out in the rib which will afford ample protection from a derailed locomotive or car.

Fatal injuries have frequently been caused by men stepping out of a refuge place without noticing that the trip had broken in two, and then getting run down by the following cars. We have had two such occurrences in our own experience which could have easily been avoided if the men had watched for the rear end markers. The ordinary markers do not readily attract attention, but we have begun the use of storage battery rear end lamps, showing a red light, and believe the men acquiring the habit of watching for them as the trips pass. We have had no accidents from this source since putting them in use.

CHAIRMAN POLLOCK: I would like to ask whether or not your electricians work underground with the current on.

MR. BANNISTER: They do not. We have an automatic breaker on every section of the mine and regardless of whether it is trolley wire, machine wire or what it is,

the automatic recircuit breaker is thrown out and locked out and the man who is going to do the work puts the key in his pocket before he starts working on the line, if it is even putting a jumper across from one room to the other. That is a standard rule and our boss is pretty strict; if we violate some of his rules and he finds it out, we generally get off the payroll.

CHAIRMAN POLLOCK: We will continue by asking Mr. Boardman to tell us about the first aid carried on by the Anaconda Copper Company.

JOHN L. BOARDMAN (Anaconda Copper Mining Co., Butte, Mont.): I wanted to tell you all about first aid, but I haven't time and so I am going to get along with the first half of it by making a couple of simple statements.

First aid of the injured is a necessary part of the work of every mine safety engineer. First aid is very valuable not as an adjunct to accident prevention particularly but as a means for preventing the seriousness of accidents after they happen.

Now I hope that you will all grant me that and get away from the necessity of proving the case because I have other things to say. The only question then that comes up is whether you can get a great value out of first aid training by giving it to your men and paying them for taking it as individuals, or whether you can get a greater, broader interest in first aid through the conducting of first aid contests.

First aid contests have been subjected to a very great deal of criticism. Many of you men know that if I feel I have a holler coming, I holler, and I have hollered against first aid contests for several years; but here is what I have found out about them.

First Aid Contests Were Difficult to Judge

When first aid contests first started, we didn't know how to judge them. You can't judge a first aid contest like you judge a baseball game or a prize fight because there is nothing definite to judge. To judge a first aid contest, you have to have all the teams doing the same problems and have them ruled by the same man. Then you have an ideal judging.

For many years we didn't do that, and consequently there was a great deal of friction and criticism, and it was due us. Recently, however, first aid contests have been developed into a method of judging that is just about as fair as we can possibly make it.

By the way, before I go further, I want to say that having conducted and been interested in more than 100 first aid contests, I have yet to see one contest which has been deliberately unfairly judged; but up until recently I hadn't seen any that was fairly judged. I mean by that that there was no deliberate attempt to misjudge a first aid contest at any time, and yet due to the inadequacy of the system of judging the contests, none had been absolutely fair. But within recent years we have a system of judging first aid contests that works out adequately, in that the problems are made first, then a committee of judges meet, discuss that problem and work out a standard for performing the work according to the manual of instructions that is given them.

Gentlemen, that is as close in approach as you can possibly get to an individual judging of a number of teams. The judges have all agreed that that is the way to work that problem and that method of working the problem is written out fully, it is before each judge as he judges the team, the judge has no right or room for giving his personal feelings in the matter at all, it is a standard method of judging.

They have in my own home town, since this new method of judging has been made popular, made the men real sportsmen. We have no kicking, no fighting; when the contest is over, the men feel good, even the losers, and it is very successful. Therefore we have re-entered first aid contests and for the past few years we have always supported the International Meet by sending at least one team.

Gentlemen, the main part of my subject is this. We have invited the Bureau of Mines to hold the next International Congress, that is the 1928 First Aid and Miners Contest, in Butte, Montana. Perhaps I am a little previous in making this announcement because the Bureau has not decided where they are going to hold this contest, but I am doing it for the reason that I want to get before you men personally our invitation to come and see us. If I had to wait until their decision is officially made, I would have lost this opportunity.

Therefore, if you find later that the Bureau has turned us down, please excuse me, but here is the reason why we want that contest.

We are on four transcontinental railroads. We have adequate hotel facilities for handling even a larger convention than the International Contest will be. We have absolutely ideal weather in the summer time for holding such a gathering out of doors. We have hundreds of well trained first aid men who have asked me to extend you a cordial invitation. They want me to tell you that we want you to come and we will be glad to see you. We have offered the Bureau of Mines the money to defray the expenses of this contest, so there will be no soliciting from guests.

We feel we can handle the contest. We want you to come and we want you to send a winning team. Of course I want you to understand that we are going to try to win if we can. We are going to do our best to win, but if you win, it will be perfectly all right with us.

Organize for the Coming Western Contest

Now gentlemen, another advantage and the chief advantage to you in sending a first aid or mine rescue team to Butte, Montana, for the next contest will be this: The trip is so attractive that you can offer this trip as a prize for winning contests locally and you can stir up more interest in first aid than by any other method that I can think of. By comparison you may take the system which we use. We offer the trip to the International Contest as a prize for winning our inter-departmental contest. We started out about the first of January and we tell all of our employees that the first eight teams are open for volunteers. We then organize a number of volunteer teams from each of the mines and each of the departments in the smelters. These men train for a month and then go through a series of local first aid contests. The two winners from the mines, the two winners from the Anaconda Smelters and the two winners from the Great Falls Smelter then contest to see which of the six shall represent the Montana operations of the company at the International Contest.

If you will do that at home, if you will ask each of the levels in your mine or each of the mines, if you have more than one, to get up a local competition, you are going to get an interest in first aid, a voluntary interest in first aid, if you please, that you couldn't get in any other way, because you are giving these men something of real value.

Now the expense of the thing is not so great although it looks great perhaps if you look at it as a whole without looking at the benefits. This year our contests and first aid training probably cost us over \$5,000 for the month end operations; sending the team to Pittsburgh, Pennsylvania, cost us \$2,900. Just the expenses and material for the team from Butte to Pittsburgh and return, which covers also cash prizes for the local elimination contest. We paid the expenses of the team from Great Falls and Anaconda to Butte and bought the material and things like that to wear. It was well over \$5,000, but, gentlemen, when you compare this possible \$5,000 of expense with the fact that we have interested every man on the job in first aid and have trained hundreds in first aid, then the cost per unit of interest is not very great.

CHAIRMAN POLLOCK: I am going to ask Mr. Webb of the West Pennsylvania

Electric Company to give us a five minutes talk on "Mining Safety in the Coal Mine."

MR. WEBB: The West Pennsylvania Electric Company owns and operates two large bituminous coal mines, one known as the Allegheny Pittsburgh Coal, at Logansberry, and the other known as the Windsor Power House Company, at Windsor, West Virginia. They have a ready capacity of 4,500 tons of coal per day and the entire output is used exclusively in the generation of electricity by steam.

We think or we believe that we have done some fair work in safety in those properties. As an illustration of that, the Allegheny Pittsburgh Coal Company, employing about 500 men, has not had a single fatality since the year 1922. In addition, that mine has been able to operate for six consecutive months, which means approximately 180 days, without a single lost-time accident. When you say that a mine can operate six consecutive months without a single lost-time accident, I think you will agree with me that we are doing some real constructive safety work on that particular property.

Training the Workmen to Work Safely

You will wonder perhaps how we do it. Of course, it is old stuff to say we make the physical conditions safe, but we do. We even do more than that. We educate our workmen to work safely, and that's the biggest thing of all. Of course, this bituminous coal mine, which is on a sixty-seven foot seam of coal, has good roof conditions (Jack Ryan knows the conditions are rather exceptional there), but in order to make it safe we do a multitude of things to safeguard the men.

For example, we have flood lights at all cross-over points. We have plenty of manholes and we have the switch throws parallel to the track and set back three feet so no coal can fall over the cars and injure the man. We have safety bulletin boards down in the mine. But even after we do all of that and more, the big thing in reducing accidents in my mind in the coal mining industry is to get right down to brass tacks and educate your workmen. I have always found that you can strive to educate the adult but it is a pretty hard problem. The right way, in my opinion, to get at the man and educate him is through his children; and we of course have at these mines large villages to accommodate the workmen and their families. Very, very frequently I go into the schools there and talk safety to these kids. We have found that very effective because if you sell a child safety and sell it to him in the right way, then he will go home and in turn sell it to the parent. I don't mean that you can go up and stand in front of a bunch of six-year-old children and talk to them as I am talking to you. The man who does that talking has to be able to change his age and his character and his disposition and everything else and put himself directly on the level with the children he is talking to. When he does that, he will get it across, and the child in turn, if impressed, will go home and sell the idea to the parent. That has been very helpful to us in promoting safety on this particular property and the results show that it must have been worthwhile.

In addition to that, we have our safety measures and when Charley Reynolds (perhaps some of you men may know him) calls a meeting of these miners he doesn't mean maybe. Every Monday night they have a meeting and there are at least 300 miners who attend that meeting. It is a combined safety and first aid meeting and about 80 per cent educational. That is the thing that assisted this mine in operating since 1923 without a single fatality, and they were able to operate these six consecutive months without a single lost-time accident.

Down at the Windsor plant conditions are entirely different. They have a three-foot seam of coal and they have a treacherous, a notorious roof condition. Back in 1923 they suffered seven fatal accidents at that mine, which was a pretty unfortunate condition. We applied the educational principles to that mine very strenuously and the consequence has been a real reduction there also.

Last year there was only one fatal accident. This year there was but one, and that mine was able this year to go 90 consecutive days without having a lost-time accident, which shows again where the educational work can be made effective by reaching the men not only through their children in the schools but by reaching them by ways and means that are best known and properly applied by all the men present in this conference.

Of course, lots of physical conditions, unsafe physical conditions, have been corrected at this mine. For example, since 1923 approximately 15 miles of roof timbering have been put in to make that mine safer. Of course that is one big thing that has been done to promote greater safety in operation. But still, men, I maintain you cannot get away from the educational proposition. From 80 to 90 per cent of the whole thing is absolutely educational. When we educate our men to do their work safely, no matter how you do it, if you have to work through the men's children, or if you have to put it to him direct, the main thing is to get it to him, saturate him with it; and when you have him saturated with the safety idea, then you are going to be able to reduce the accidents just as we have at these mines.

A Seventeen Months Record Without Accident

BENJAMIN BROCKBANK (Castile Mining Co., Ramsay, Mich.): I listened with quite a little interest to the wonderful record that has been made by the coal mines and metal mines. I can't sit down without mentioning one of our properties and we have with us Mr. Smith or Mr. Jack who can tell about the wonderful record of the mines at Crystal Falls, Michigan. I think it is probably 17 or 18 months without a lost-time accident in the metal mines.

ROBERT JACK (Bristol Mining Co., Crystal Falls, Mich.): I can give you the figures on our records. It is 17 months without a lost-time accident and we have 70,000 shifts with 577,000 man hours and a production of 500,000 of iron ore. Our tram cars, loaded the way we load our two-ton cars, would reach from Crystal Falls, Michigan, to Chicago.

CHAIRMAN POLLOCK: Any other remarks?

F. C. MILLER (Colorado Fuel & Iron Co., Denver, Colo.): I might say the Colorado Fuel and Iron Company has introduced first aid in the schools and the boys and girls are now competing as well as the men.

MR. WEBB: That gave me a thought. We do the same thing. We teach the boys and girls in the school first aid, and last year at the Springdale mine a team of girls was brought down by the Bureau of Mines and given the test that men take. They were successful in passing the test with a very high average and were given regular certificates the same as men get; and at the time we understand that was perhaps the first girls' team in the United States to receive the Bureau of Mines Certificate.

MR. BOARDMAN: Mr. Chairman, this is a little experience Mr. Marvin might want to take down.

In Butte, Montana, we had last year eight accidents from children playing with dynamite caps. The caps were found on the streets and in the homes. So the safety men of the community put on a lecture in each room up to and including the eighth grade during the last week of the school year this spring.

To date we have not had a case of children injured by playing with dynamite caps since the lectures.

H. W. GIESSENG (Commerce Mining & Royalty Co., Miami, Okla.): I have a statistical sheet that says about six words. We have a mine in the Tri-State District belonging to the Federal Mining and Smelting Company, a Munsey mine. It isn't a large mine but it has 58,528 shifts and 23 months without a lost-time accident.

D. HARRINGTON (U. S. Bureau of Mines, Washington, D. C.): Mr. Chairman, I want to say something right now. In connection with these good records that you

people are giving us, I would appreciate it very much indeed, both as Secretary of the Mining Section of the National Safety Council and as head of the Safety Division of the U. S. Bureau of Mines, if you would send to me these records, give them to us and we will give full publicity to them and we will probably be able to get a lot of good for you and the industry by giving this information out. The trouble with us, both in the National Safety Council and in the Bureau of Mines, is that we can't get to these records. We get these records only in the safety competition which is handled by Mr. Adams and which does not include all the mining companies of the United States.

We would very much like to get all these records and we will guarantee to give you publicity on them.

GEO. MARTINSON (Pickands, Mather & Co., Hibbing, Minn.): I am very much interested in these records. I just recall, if the Albany mine, which is located at Hibbing, goes to the sixteenth of February, 1926, we will have gone six years without a lost-time accident. During that time we have shipped over 2,000,000 tons of iron ore and 3,250,000 yards of rock stripping.

CHAIRMAN POLLOCK: Can anybody beat that? I want to say that I believe the Missabe range has gone into it stronger than any other mining section on safety education in the schools. I know there isn't a week that goes by that I don't speak somewhere in the schools in Eveleth, and one thing that has impressed me a lot is that in our schools we teach swimming to all the youngsters from the fifth grade up. We haven't had a child drown in the last three years from the schools of Eveleth. Any child that graduates from the junior high school has to be able to swim the length of the tank.

Another thing we have started in our schools is to teach every pupil to run an automobile after he is sixteen years of age. You may say a youngster of sixteen years should not drive a car, but how many do? Isn't it better that these youngsters learn the road laws and how to handle a car under guidance of somebody who knows how than to go out in dad's car and try it on the highway?

If there are no more questions on this last paper, I would like to go to something that is near to my heart; that is regional conferences. This year in Duluth we held six or seven Lake Superior Councils and we had 350 men registered. I believe we had one of the best conferences that was ever held in Duluth and I am going to ask Mr. Bawden, who was chairman at that conference, to tell us something about it.

Married Women Received the Bureau Certificates

A. A. BAWDEN (Pickands Mather & Co., Ironwood, Mich.): I will say first in regard to the Bureau of Mines Certificates, while in our district we haven't issued any to school children as far as we know back in 1922 or 1923 the Bureau of Mines in our district trained two teams of our married women and they received the Bureau of Mines Certificate.

Our company issues a first aid badge about the size of my watch that our men very proudly wear at their work, and as a token of reward we issued badges to the women getting these Bureau of Mines Certificates. Until this day one of them very proudly wears her badge on her chest whenever she goes to any social function. She is taking real good care of it.

I am particularly glad to be able to give this record of our program up there at this time because Mr. Agaton is here. He was one of the moving spirits in the organization of this chapter which was started under the Bureau of Mines and eventually it has become the local section of the National Safety Council.

As Mr. Pollock stated, at our last meeting we had in the neighborhood of 325 to 350 attendants at our conference which lasted two days that were jammed full. We

had a very good safety exhibit which was our first experience along that line. I will just go through this program in order to give you an idea of what we have been doing.

We have for a number of years had a mayor of the city in which the convention was held welcome us to the city. We had an address by Mr. Earl E. Hunter, Manager of the M. A. Hanna Company. We had a paper on "The Necessity for Mechanical Ventilation of Mines," by Mr. W. H. Carrick, safety engineer of the Corrigan-McKinney Steel Company, who was formerly an engineer with the Bureau of Mines. The discussion led by Mr. Krogdahl, mining engineer of the Oliver Iron Mining Company and formerly a Bureau of Mines engineer, was very interesting.

There was a paper on "Physical Examinations and Accident Prevention" by Mr. P. A. Carmichael, superintendent of Lorretto Mine, M. A. Hanna Company; a discussion led by Mr. George Martinson; a paper on "School Safety" by Mr. A. V. Rohweder, supervisor of safety for the Duluth, Missabe & Northern Railway; a discussion led by Mr. Joseph Wilson, assistant mine superintendent of the Oliver Iron Mining Company's Spruce Mine.

Programs to Interest the Community

We had a showing of several one-reel safety pictures; a paper on "Mine Lighting" by Mr. John F. Berteling, superintendent of Palms-Anvil Mines of the Pickands, Mather Company; a discussion led by Mr. Paul S. Kurtzman, superintendent of the Albany Mine in the Missabe District. We had a program of safety kinks covering 14 or 15 different kinks. We had felt for the last two or three years that we were being neglected by the executives; although they had been paying our expenses without any complaint, they weren't appearing at our meetings. So we had an executive session which was handled by Mr. John H. Harding, assistant general manager of the Oliver Mining Company and included talks from practically every manager of mines in the Lake Superior District.

We had a banquet at the Hotel Duluth with entertainment under the auspices of Mr. Francis J. Webb, manager of mines, Republic Iron & Steel Company.

On the second day we had a paper on "Electrical Installations for Metal Mines" by Daniel Harrington, chief engineer, Mine Safety Service of the U. S. Bureau of Mines. Mr. Harrington wasn't there in person but his paper was read. Discussion was led by Mr. A. C. Butterworth, chief electrical Engineer, Pickands, Mather & Company. There was a paper on "Blasting Kinks" by Mr. Thomas Michelle, service man of the Dupont Powder Company; an address on "Safety in Taxation" by Mr. L. A. Rossman, editor of the *Herald-Review* of Grand Rapids, Minnesota; an address on "Recent Work of the National Safety Council" by Mr. W. Deane Keefer, Chief Engineer, Industrial Section, National Safety Council, read by some other party; and an address on "How to Reach the Workman" by Mr. John P. Eib, supervisor of safety and labor, Illinois Steel Company of Joliet, Illinois.

We had a demonstration of new Foamite generators of the Foamite-Childs Corporation by the Marshall-Wells Company, local agents, and a trip to the plant of the Minnesota Steel Company as entertainment on the side.

Safety exhibits were put on by the American Optical Company of Chicago, the Elliot Service Company of New York City, Foamite-Childs Corporation of Utica, New York, Kindy Optical Company of St. Paul, Minnesota, Lehigh Safety Shoe Company of Allentown, Pennsylvania, the W. P. & R. S. Mars Company of Duluth, Minnesota, Mine Safety Appliances Company of Pittsburgh, Pennsylvania, the National Safety Council of Chicago, Safety Equipment Service Company of Cleveland, Ohio, Willson Goggles, Inc., and Pyrene Manufacturing Company.

CHAIRMAN POLLOCK: I would like to have Mr. Ryan say something about this conference. He was there as a visitor and he can tell us a few things about that.

JOHN T. RYAN (Mine Safety Appliances Co., Pittsburgh, Pa.): I attended this conference and it was my first offense. I had been invited in previous years but I had never gotten to it. I will say it was one of the most interesting and inspiring mine safety meetings that I ever attended. The particular feature of the program that appealed to me was that it was a managers' session. It was a splendid idea and the execution was good because the chairman had not only the managers, but in some cases the presidents of some of the companies.

The best feature of that, I think, was the fact that those men came there, the higher operating officials, and they went publicly on record before approximately 350 men, many of them their own employees, as to their attitude on safety and pledged themselves to support the safety movement.

Those conferences are a splendid thing. We have been conducting one in Pittsburgh under the auspices of the Western Pennsylvania Division of the National Safety Council for several years. I will admit that we haven't put the pep into it that you have up in the Lake Superior District, but we get a lot of good out of it in Western Pennsylvania.

We take a particular interest in that conference up in Duluth, judging from my observation of the one I attended.

There are many sections of the country where this regional conference could be held to great advantage and the men get a lot of good out of it, and I believe that it will stimulate the work of this section because we have an unusually large attendance from the Lake Superior District and I believe part of that is due to the interest that has been stimulated in their section.

CHAIRMAN POLLOCK: Is there any other district represented here that has had the regional conference in the last year?

THEODORE MARVIN (The Explosives Engineer, Wilmington, Del.): Don't they have them down in Birmingham under the auspices of the Alabama Safety Council? The National Safety Council meetings are held four or five times a year, I believe.

Various Other Meetings Were Held

R. V. AGETON (Tri State Zinc and Lead Ore Prod. Assn., Miami, Okla.): May I say a word on that? We tried to hold one this year but were unable to do so. We have a stunt that may help out. We have a weekly meeting every Wednesday of all the engineers in the Tri-State District and at those meetings we discuss everything that has happened during the previous week; all the safety engineers give their reports in detail regarding the number of shifts worked, the frequency of accidents per thousand shifts work and the severity of accidents, which is the number of days lost per thousand days work.

We have no specified program, but merely discuss the current events regarding accident prevention.

MR. BAWDEN: Mr. Chairman, that reminds me that I would like to add in our district we have monthly meetings of all safety engineers coupled with attendance by school superintendents, police heads and anyone interested in school, public or industrial safety. We have a dinner and discuss any subject that may be brought up for that purpose. We usually conduct those meetings without formality. On some occasions we have a formal meeting in order to concentrate on some particular item that we want to have taken care of.

CHAIRMAN POLLOCK: If there is nothing more on this subject, my part of the program is finished. I want to thank the men who helped me out in making the round table possible and I will turn the table back to Mr. Young, our Chairman.

(Mr. H. F. Young resumed the chair.)

CHAIRMAN YOUNG: Mr. Pollock, we certainly appreciate this very interesting part of our program which you have conducted.

D. HARRINGTON (U. S. Bureau of Mines, Washington, D. C.): I wish to call attention, gentlemen, to the monthly news letter which I am supposed to edit for the Mining Section of the National Safety Council. I understand that some of the members do not get the news letter. I am not informed as to the persons to whom the National Safety Council issues it. My handling of it is merely the getting together of the data and sending it in to Chicago and it is made up in mimeograph form and sent out from the Chicago office.

If you do not get copies of it, please correspond with the Chicago office of the National Safety Council and I imagine probably Mr. Keefer is the man to write to.

Another thing, I wish to call your attention to the desirability of your sending me items which are of a safety nature and which you think would be of value to the Council in general. If you will give them to me, I will put them into the monthly News Letter. I will appreciate very much receiving them.

Another Record of Almost Two Years

WM. T. McDONALD (Montezuma Copper Co., Sonora, Mexico): Just a moment, in line with what Mr. Harrington suggests and as a matter of getting this on record and perhaps as a matter of interest to some others, may I be pardoned for stating that in the concentrated operations of the Montezuma Copper Company, which includes their shops and a lot of work of tearing down old machinery, they ran for two consecutive years, less eight days, without a lost-time accident? During that time 86,040 manshifts were worked. That is a matter for your record, Mr. Harrington. I thought you might be interested as you were asking for such data.

CHAIRMAN YOUNG: Those are all wonderful records. I wish it were only possible that we had a longer time so that every one here could tell us what is in his heart on safety; but we haven't the time.

I hope that each of you feel that your time and money have been well spent in coming here and attending the meetings and that you will return to your respective companies better sold on safety, if it is possible, than you were before coming.

I want to take this occasion first, before presenting our new chairman, to thank the chairmen of the committees for the wholehearted cooperation and wonderful work that each of them has done during the year. Also I want to thank Jack Ryan for the time he has given to the National Safety Council work. I am sure all of you have enjoyed the entertainment that he has given and the program that we attended at the beginning of our session. He has one more number that he will give after Mr. McDowell makes his announcements, and then we will stand adjourned.

It gives me great pleasure at this time to present Mr. C. A. McDowell of the Pittsburgh Coal Company whom you have chosen as your chairman for the next year.

(Mr. C. A. McDowell took the chair.)

CHAIRMAN McDOWELL: I am very glad indeed that we don't have very much time because I won't have to talk very long. You know it is an honor to me to be chosen as chairman of this Section. I appreciate it very much, and I sincerely hope that we will all get together in some form or other either in conferences or by mail, if necessary, in order that we can keep up the good work that has been reborn, I might say, this year. I really think that this has been the best conference or the best session we have held for many years. I have had in mind for the last few years in attending these meetings, that we should get down to a basis like we had this year, that is, fewer papers and more time for discussion. The

first part of this year, early in February, I accepted a new position with the Pittsburgh Coal Company and by doing so naturally, as some of you men know, there was added responsibility and I was tied down, so to speak, on my new work. It was not possible for me to get to the executive meetings as called by Mr. Young and I am sorry for that, I only hope this year, since my work has taken on a little different attitude and we are, I think, making progress, that we can get together, and I sincerely hope that when the executive committee is called you men who have been selected for these different places will do your utmost to get to those meetings.

We desire to have a meeting this afternoon at three o'clock and I presume it can be held in this room, in order to have all the officers get together and probably formulate some plan for next year.

The Nominating Committee did not fill all the places and I desire to bring this to your attention. We would like to have all the officers mentioned on this paper report at three o'clock for this informal meeting.

It may be well to read your officers again:

First Vice-Chairman, George Martinson.

Second Vice-Chairman, A. W. Dickinson.

Third Vice-Chairman, J. P. Hodgson.

Fourth Vice-Chairman, F. C. Miller.

Secretary, Daniel Harrington.

Chairman of Poster Committee, H. C. Henrie.

Chairman of Membership Committee, H. I. Young.

Chairman of Publicity Committee, Theodore Marvin.

Chairman of the Slide Committee, H. G. Hensel.

Chairman of Program Committee, R. V. Ageton.

I am very glad indeed that this man has accepted the responsibility again for next year as we certainly have had a wonderful program this year, one that I don't think could be surpassed.

Chairman of Engineer Committee, J. M. Carmody.

Chairman of Statistics Committee, R. N. Hosler.

I notice on this paper "News Letter Editor." We have heard so many wonderful reports and all these records have been piling up in the last few years, and yet I have seen very few of them in the News Letter. I am going to ask that you kindly put that stuff down on paper in order that Mr. Harrington may print it in the News Letter and let us all get the benefit of it.

The Executive Committee will be appointed later. I missed one important committee. It is not listed on the National Safety Council form, but the same time I don't think any of us desire to miss a committee of that kind, that is the luncheon committee. We have a man that we all know is not very apt at putting across things of that kind and he was on the committee this year, and I think we ought to give him a chance again to see if he can make good, so I am going to put Mr. Ryan on that same committee for next year. It has been suggested that we should have an attendance committee. I am going to leave that open for the time being until it is decided just where the next National Safety Congress will be held, after which I think I shall appoint a chairman of what we might term an attendance committee. He can in turn appoint his assistants and see if we cannot get out more members to the National Safety Congress, at least within that vicinity.

ADJOURNMENT.

*SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL*

Cement, Quarry and Mining Joint Luncheon

Wednesday, September 28, 1927

A. J. R. CURTIS, Chairman
Assistant to General Manager, Portland Cement
Association, Chicago, Ill.

The joint luncheon session of the Cement, Quarry and Mining Sections of the National Safety Council was called to order by the chairman, Mr. A. J. R. Curtis, assistant to the general manager, Portland Cement Association, Chicago, Ill.

CHAIRMAN CURTIS: Whether your problem is to find a substitute for gasoline, cure an illness or meet the competition of a foreign competitor, the orderly procedure is the same. First of all you must diagnose the situation, find out what the problem really means; secondly, you must devise ways and means to meet the situation the diagnosis has revealed—you must prescribe a remedy.

This procedure is adopted by anyone, consciously or unconsciously, that elects to accomplish things in an orderly and logical manner.

In safety work many industries have been taking headache medicine—doping themselves with a “cure-all” supposed to be good for what ails them. They have taken the dosage without thought about the fundamentals of the problem and without an adequate diagnosis.

The reason we have made such startling progress in safety work in the cement industry is because we have diagnosed our case and then found remedies for specific illnesses. We have done this by means of a fine system of statistical records and reports. This report system, inaugurated in 1919, shows us what and where the accidents are. The records indicate what season of the year a certain type of accident is likely to occur. They enable us to measure the efficiency of this scheme or that scheme in the promotion of safety in our plants and quarries.

Ethelbert Stewart, United States Commissioner of Labor Statistics, speaking before the Cement Section of the National Safety Congress in Detroit early this year, commented favorably on our statistical system.

“I find that statistics of the Cement Section of the National Safety Council are the very best that come to my office,” Commissioner Stewart said. “You are doing a piece of work that must inevitably result in a rapid decrease in your accident rate. I do not know whether or not you are making effective use of these figures, but they are significant and you certainly should be doing so.

“In the first place you have any industry devoted to the manufacture of one definite product—cement. Your product does not go, as would be true in the chemical industry, into everything from lipsticks to laundry soap. In gathering your statistics

you have something definite to work on and you have succeeded in doing the basic thing, that is, finding the man-hour exposure in your industry and relating your accidents to that. Statistics cannot reduce accidents, but they can tell you where the accidents occur. They can and do tell you where to apply your precautionary measures and where to spend your money. They make it unnecessary to spend money along several lines when most of your accidents are occurring along one or two lines. Comprehensive accident statistics are worthwhile and I congratulate your industry and the many individual manufacturers who are cooperating to make this statistical work so effective.

"I have been able to show others that you have reduced your accidents. Statistics form the basis for a lot of standard jokes like the mother-in-law joke and everyone thinks he can take a whack at a statistician and his statistics; but, nevertheless, if you are going to improve the accident in your plant you must know where the accidents occur and that requires statistics.

"Your statistics have made it possible for me to show others that you have reduced your accidents. I hope to impress you with the importance of continuing and further perfecting your statistical work, not only for yourselves, but for the influence it is going to have on the other sections of the Safety Council on your own and other industries."

We are so well sold on the diagnosis theory because we can take our limited means and get excellent results. We don't have to guess—we can take one direct shot and make it tell. We are able to do this because our records have revealed a specific situation—the case is diagnosed and we can take steps to remedy a definite problem that confronts us.

All mining and quarrying industries can make the same sort of case study. The experience of the cement industry points to the expediency of this method because in our industry we face problems in both of these divisions.

Let me give an example of what statistics have done and will do for us. Our records show a growth in screw conveyor accidents at a certain time of the year. For the past nine years we can trace a growth in lost-time accidents of this type at a certain period.

Instead of spreading our funds to battle all sorts of accidents at this given period we can centralize our efforts to combat screw conveyor accidents when they are again in the ascendancy. So we gathered a large number of opinions of experts on how to eliminate conveyor mishaps.

This symposium will be sent to all mills when the time comes. Plans will be made well in advance to meet the situation when it arises.

I believe that a large portion of accident success is based, as I have said before, on the diagnosing of the problem in hand and then prescribing remedies for the specific illness.

Now, we are to be favored with a brief address by a man in a position to be familiar with the inside details of the accident situation. Mr. W. W. Adams is statistician for the United States Bureau of Mines, Washington, D. C., and he has kindly consented to talk to us from the point of view of the Bureau. I take pleasure in introducing to you Mr. Adams.

Safety in the Quarry Industry

W. W. Adams, Statistician, United States Bureau of Mines, Washington, D. C.

Safety in the quarry industry is a matter of direct concern to 92,000 men who are employed in the industry and it is also of almost equally direct concern to their immediate families. Thus between 300 and 400 thousand people are personally affected by the accidents that occur in connection with the

annual production of stone in the United States and in connection with the crushing and other work that immediately follows its extraction from the earth. From 120 to 150 of these men are killed by accidents each year, and 14,000 of them are non-fatally injured.

Through the cooperation of the producing companies, the United States Bureau of Mines conducts an annual canvass of accidents and employment covering the quarrying of stone, and such subsequent work as crushing, rock-dressing, and the manufacture of lime and cement. This work began in 1911 and statistics covering the past 16 years are now available. These statistics are based upon reports furnished voluntarily by the producing companies on blank forms supplied by the Bureau of Mines. Each non-fatal injury reported to the bureau involves disability of the employee for more than the remainder of the day on which the accident occurred. In other words, the Bureau's statistics are limited to what are known as "lost-time" accidents. While many of these injuries cause the employee to lose only one or two days, some of them involve the loss of several weeks or months. Taking them in the aggregate, they average about 15 days per injury. Any company whose temporary injuries average less than 15 days each has a relatively safe plant, or is lucky, or is doing effective safety work. If deaths and permanent disabilities are drawn into the picture and given their customary equivalent weights in lost days, the average accident in the quarry industry represented a loss of 104 man days in 1925 and 94 man days in 1924. In this average each fatality and permanent total disability is considered equivalent to a loss of 6,000 days and each permanent partial disability 800 days, the last-named figure being borrowed from the reports of the Industrial Accident Commission of California until sufficient reports of this class of injuries accumulates in the Bureau's records to develop a new average.

An Intensive Study of Quarry Accidents

In addition to the Bureau's annual canvass of accidents which is based on reports from all producing companies in all states, or as nearly all of them as we can obtain, a special and much more intensive inquiry into quarry accidents has been under way during the past two years. This study is based on full and complete reports—a separate and detailed report for each accident—from a limited number of companies. Each of these companies employs at least 25 men inside the quarry. They are the companies that are participating in the National Safety Competition which is being conducted by the Bureau of Mines. Two such annual contests have been completed, namely, that of 1925 and that of 1926. One of the purposes of the safety contest is to determine which quarry has the smallest loss of time from accidents in proportion to total man hours of exposure. The quarry that establishes the best record receives a bronze trophy or statue known as the Sentinels of Safety, which is the gift of the Explosives Engineer magazine. Credit for providing the trophy and for very material aid in connection with the contest, is due very largely to the enterprise of Mr. N. S. Greensfelder, the editor. The trophy is held for one year by the winning company, and is then surrendered to the winner of the next year's contest. Each year the name of the winning company is engraved on a pedestal of the trophy and each employee of the winning quarry receives an engraved certificate of honor issued by the Bureau of Mines and signed by the director of the Bureau.

The Bureau's annual canvass of quarry accidents affords a broad picture of the accident situation as it affects the whole industry or any large portion or phase thereof; it also furnishes an annual account of the volume of employ-

ment required to produce the country's annual stone supply and of the total loss of life and limb as well as the loss in Man days that went into the cost of producing the stone. The more detailed reports furnished in connection with the National Safety Competition are usually supplied as a carbon copy of the report which the company is required to send to its insurance carrier or to the state compensation commission. In this way the Bureau is furnished with valuable detailed information on accidents with a minimum of inconvenience to the company.

It will thus be seen that the Bureau of Mines statistics of quarry accidents are collected by two methods from a common source, namely, the quarry companies. It will also be observed that the statistics differ in scope, geographically, and in the degree of detail with which the information is supplied. From these two sources of information and similar information from other branches of the mineral industry, it is apparent that quarry accidents occur less frequently and cause a smaller loss of time in proportion to number of employees than do accidents at metal mines or coal mines. In other words, quarry work is not as hazardous as coal mining or metal mining, considering each of the three industries as a whole. Moreover, differences also exist between the hazard of different kinds of quarries. Perhaps the chief distinction in this respect is between quarries that produce dimension stone and those that produce non-dimension stone. Quarries that produce crushed or non-dimension stone have higher accident rates than those that produce dimension stone. For example, the fatality rate for the non-dimension group, in and about the quarry, in 1925, was 33 per cent higher and the injury rate was 7 per cent higher than the corresponding rates at dimension stone quarries; in 1924 the rates were respectively 76 per cent and 18 per cent higher. A comparison covering all years since 1916 shows that, without exception, the group rates for both fatalities and injuries, have been higher at stone quarries producing non-dimension stone, the excess ranging from 5 per cent in 1921 to 118 per cent in 1920 for fatal accidents, and from 1 per cent in 1917 to 122 per cent in 1921 for non-fatal accidents. Moreover, possible differences in length of work day at the two classes of quarries have no material effect upon this relationship. This is shown by figures which have been compiled for quarries working uniform shifts, that is, eight hours, nine hours, or ten hours.

Increased Accident Frequency Unaccounted For

In crushed-stone or non-dimension-stone quarries, where no care need be exercised to prevent breaking the stone, it might be expected that the rate from accidents from explosives would be higher than that in quarries producing dimension stone that is intended to be used for building or monumental purposes. This, in fact, has often been the case, as shown by the annual reports which the Bureau of Mines has received from the producers of stone. It does not, however, fully account for the higher frequency of accidents at crushed or non-dimension-stone quarries. A comparison of the annual figures for the two classes of quarries during the past seven years, shows that some other classes of accidents also, as a rule, occur more often at quarries that produce crushed or non-dimension stone. Crushed-stone or non-dimension-stone quarries show higher injury rates for accidents caused by handling rock at the quarry face, also for accidents from falls or slides or rock or overburden. Haulage accidents also are usually more frequent at crushed-stone quarries. Accidents caused by falling objects, which records for earlier years showed were of more frequent occurrence at crushed-stone quarries, have been materially reduced during the past four years, and in 1925 the crushed-stone rate for this

class of injuries was actually lower than at quarries producing monumental or building stone. A somewhat similar situation prevails as to accidents from flying objects; the rates for this type of accidents have been high for both kinds of quarries, but during the past three years the non-dimension quarries have established the better record. Machinery accidents also are among the major cases of injuries at both classes of quarries, but in the past few years the crushed-stone quarries have reduced their injury rates from this cause and since 1922 these rates for machinery accidents have been lower than at dimension-stone quarries. The net advantage, however, still lies with quarries that produce dimension stone; that is to say, the injury rate covering all classes of accidents combined is still lower for the dimension-stone quarries.

Quarrying Less Hazardous Than Other Mining

Accident prevention is a national as well as local problem. It is therefore appropriate that national associations, such as the Portland Cement Association, the National Crushed Stone Association, and others, should undertake or maintain some group action looking to the prevention of accidents. In 1925, more than forty states contributed to the production of stone in the United States, and in more than 34 of these states accidents were suffered by the men who produced the stone. To the extent that quarry accidents are similar regardless of location of plants, it would seem that the national associations might with advantage undertake a study of the accident-prevention problem. It has already been said that the quarry industry is less hazardous than coal and metal mines, both as regards accident frequency and accident severity. This, however, is no more than might reasonably be expected because nearly all quarry work is done in the open daylight, whereas most of the operations at coal mines and metal mines are conducted underground, where the light, which is necessarily artificial, is often not adequate for maximum safety; also in the underground work, there is the additional hazard of falling overhead material. The quarry industry should therefore not be content if it merely maintains an accident rate better than that for the mining industry, but should strive to lower its rate from its own previous levels. This has already been done to some extent so far as fatal accidents are concerned, but not to any material degree as regards injuries of a non-fatal character.

Of the 92,000 men working at quarries in 1925, the operator's returns to the Bureau of Mines showed 52,000 working in and about the quarry pits and 40,000 working at the outside plants. About three-fifths of the accidents occurred to the men working in and about the pits. These accidents accounted for 101 deaths and 8,632 lost-time injuries. The fatality rate per thousand 300-day workers was 2.28 and the injury rate was 195. The injury rate was the highest on record since 1915, when the statistics for inside and outside accidents at quarries were first segregated. On the other hand, the fatality rates previous to 1925 were, in four cases, better, and, in six cases, worse than the rate in 1925. These figures show that more progress has been made in the prevention of fatalities than in the prevention of injuries. A comparison of these figures with those for outside plants shows that more progress has been made outside than inside the quarries, and this fact has contributed favorably to the record for the industry as a whole.

The number of days a quarry is in operation is largely a matter of contracts and weather conditions. Perhaps choice plays little or no part. Yet it may be interesting to know that it is apparently safer for a quarry to work full time than part time. That is to say, the accident rate per day diminishes as the number of days the plant is in operation increases. A quarry that is in operation a full year is likely to have a lower accident rate per day than if it

worked only half a year. This conclusion is based on statistics which the Bureau has compiled for metal mines, which indicate a relationship between accident rates and continuity of operation which doubtless exists in quarries as well as mines.

These statistics (as yet unpublished) of metal-mine accidents show that accidents occur less often when operations are most continuous—that is, the accident rate declines as the number of operating days of the plant increases. This fact was indicated not only by the figures for all classes of metal mines combined, but also by the figures for individual groups. The combined rate over a four-year period (1921-1924) for fatal accidents among underground employees was 7.69 per thousand full-time (300-day) employees for mines operating less than 100 days per year, and it was 3.77 for mines operating 300 or more days per year. The non-fatal injury rate for the former group was 675 per thousand employees, while for the latter group it was 356. Considering mines of equal or similar size, the death rate for mines employing 100 or more men underground was 8.78 for 1 to 99 days of operation and 3.71 for 300 or more of operation. When the mines were classified according to principal product, it was found that iron mines operating less than 100 days had a fatality rate of 11.92 and an injury of 836, whereas those in operation 300 days or more had a fatality rate of 3.01 and an injury rate of 174. Similarly, copper mines had a death rate of 7.58 and an injury rate of 841 for less than 100 days of operation and a fatality rate of 4.09 and an injury rate of 435 for 300 or more days of operation. These figures for metal mines were for extreme groups in respect to operating time; rates for adjacent groups indicated the same tendency, but less clearly.

Similar figures for quarries have not as yet been compiled, but we hope to be able to prepare them in the near future.

An Exposure of Over Seven Million Man Hours

The experience of 44 plants in the National Safety Competition of 1926 was classified on a monthly basis to learn the seasonal variation in the amount of exposure and the seasonal variation if any in the accident frequency rates. These 44 plants had a total exposure of 7,815,377 man hours. The severity rates were also calculated on a monthly basis, but the occasional occurrence of a fatality, with its equivalent of 6,000 days, rendered the severity rates too variable for comparative purposes. The volume of exposure, as might be expected, reached its lowest level during the winter—in January; it increased steadily through June, and held this level through July, then declined slightly but steadily through August, September and October, and continued to decline more rapidly in November and December. The maximum exposure, in June, was two and one-fourth times that of January. The frequency of accidents was smallest during the four winter months of November, December, January and February; it was much higher in other months, the average rates being about 50 per cent higher for the months of greatest activity.

In order to form a mental picture of the field that lies ahead of any prospective safety program, it may be helpful to state that so far as quarry safety rests with the operators, it is necessary to reach only a small number of companies to encompass a large proportion of the employees. Less than 700 quarries employ as many as 25 men in the pit, and these 700 or less plants employ 80 per cent of all men that work at quarries in the United States. If 50 men inside the pit are considered necessary to entitle a plant to rank as a large quarry, then such plants number less than 200 and they employ nearly

60 per cent of the total quarry workers in the United States. These facts are referred to because the cooperation of the company as well as the employees must be obtained to make safety work effective. A relative small number of companies have it within their power to give a tremendous impetus to quarry safety work that will benefit 80 per cent or more of the entire industry.

The accident rates for the whole quarry industry are but slight indication of what individual companies can accomplish. For example, the industry's accident-severity rate for work inside the pits, as nearly as it can be computed from available records, was 8.202 in 1925 and 6.931 in 1924; the corresponding group rate for companies in the National Safety Competition was 7.599 in 1925 and 7.760 in 1926. Yet in the 1925 safety contest, seven quarries out of 102 and in the 1926 contest fourteen quarries out of 118 operated their plants the entire year without a lost-time accident. In 1925 sixty plants or 59 per cent of those enrolled had accident-severity rates of less than 1 and in 1926 67 plants or 57 per cent had rates of less than 1. Thus it is seen that the group average of 8.202 in 1925 and 6.931 in 1924 for the whole industry, and the National Safety Competition group averages of 7.60 and 7.76, respectively, in 1925 and 1926 are by no means the best that individual quarries can do in the elimination of accidents to their employees. In fact, the 1926 contest showed that 97 plants, or 82 per cent of the total number, had accident-severity rates that were better than the group average; 21 plants, or 18 per cent of the total number, had rates that were higher and therefore worse than the group average. This means that 18 per cent of the companies were mainly responsible for the group average being as high as it was. Had it not been for the many good companies, the rate would have been much higher. The record, in fact, showed that the companies whose rates were better than the average had a group rate among themselves of 2.314, while the rate for those whose record was worse than the average was 38.695; 2.314 for the good companies; 38.695 for the bad companies, an average of 7.760 for both combined. The bad companies had a rate that was more than 16 times that of the good companies.

Comparing Accident Experiences Is of Value

The purpose of these and similar statistics is to make it possible for individual quarries to compare their accomplishments in accident prevention with what has been done by other companies. Any individual company may be remarkably successful in the elimination of certain classes of accidents and equally unsuccessful in combatting other types. Neither the degree of success nor the degree of failure can be known without some standard of measurement. The National Safety Competition of 1926 has shown that while all of the quarries combined had a group rate of 7.760, yet 82 per cent of them had lower rates than that figure. The rates ranged from zero to more than 200. Rates for the individual companies have been published, but in such a way that the identity of each company is concealed. Each company has been advised of its own rate and of its relative standing among all companies. Copies of a circular containing these rates are available to any company upon request. Incidentally it may be stated that the circular also contains the rates of coal mines, metal mines, and non-metallic mineral mines. All of these rates have been calculated on a uniform basis and are therefore strictly comparable. The method of compilation is simple. Any company may easily prepare its own accident records in the same way. Those companies that see fit to do so will find that they are following a practice that has become standard not only in the mineral industry, but in other industries as well. Following such a prac-

tice, any company may readily learn how it ranks with other plants of the same type or with any other industrial unit.

It is hoped that the companies represented at this meeting may find it practicable to place their accident statistics on this standard and widely accepted basis. In the event that any company establishes a safety record better than those indicated in the National Safety Competition, the Bureau of Mines would appreciate it if the company making the record would inform the Bureau of the fact. The Bureau desires to learn of cases of this kind so that suitable public recognition may be given.

ADJOURNMENT.

SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Packers and Tanners Section

New Section Officers

Chairman, WILLIAM CAMPBELL, Graton and Knight Company, Worcester, Mass.
Vice-Chairman, O. C. STERN, Plankinton Packing Company, Milwaukee, Wis.
Secretary, EDWARD E. DREWS, Libby, McNeill and Libby, Chicago, Illinois.
Poster and Slide Committee Chairman, FRED SCHWARZE, Pfister and Vogel Leather Company, Milwaukee, Wis.
Membership Committee Chairman, WILLIAM C. COREY, Delaware Leather Company, Wilmington, Del.
Program Committee Chairman, F. A. HONNELL, Wilson and Company, Chicago, Ill.

JENSEN, Armour & Co., Chicago, Ill.; *Executive Committee*, THE OFFICERS and N. L. BRAINARD, Swift & Co. Chicago, Ill.; J. M. EATON, Libby, McNeill & Libby, Chicago, Ill.; LLOYD F. ALLEN, The Rath Packing Co., Waterloo, Iowa.

Tuesday, September 27, 1927

W. C. COREY, Chairman

President, Delaware Leather Company, Wilmington, Del.

The first session of the Packers and Tanners Section of the National Safety Council was called to order at nine-thirty o'clock by Past-Chairman W. F. McClellan, Armour & Co., Chicago, Ill.

Secretary of Labor Davis said before the New York State Industrial Congress:

"Every six minutes, on every day of the year, there is a fatal accident of some kind in America. Every day in the year there are 63 deaths from industrial accidents. One hundred and five thousand persons annually are permanently partially disabled. Think of the economic loss to the nation, and the sacrifice of individual happiness. And most of these accidents, if not all of them, are unnecessary, or would be unnecessary, if we were as much concerned with human welfare as we are with our property and dollars. These accidents are the penalty of our carelessness, thoughtlessness and neglect."

To hear that makes us very much depressed in spirits.

Then we read the report gotten out by the National Safety Council, compiled from reports sent in by 11 of the tanneries—with employees averaging 5,748—and we find not a single death for the whole year of 1926.

We note that the average accident frequency is increased in 1926 by 4.6 and the severity is slightly decreased.

I believe it is the frequency rate you will have to match if you are going to ward off the hidden costs of accidents.

I am going to make my talk brief because I am to be followed on this program by a man who has made an enviable record in accident prevention—Mr. Fred Schwarze, of the Pfister & Vogel Leather Co., of Milwaukee.

No-Accident Campaigns and Contests

Mr. Schwarze's company had a five year experience which produced for them last year, when they began to insure their accidents, a rate of approximately 78 cents. The basic rate is \$1.61. Perhaps Mr. Schwarze will oblige us with a history of how he did it.

As we go casting about for plans to improve our "no-accident" records it seems but natural that the no-accident campaigns should receive a great deal of our attention. The men who have conducted those campaigns are still for them. Their results have been astonishing.

Nowadays everything to be successful must be a game. I don't like to believe that we are dealing with child minds, but if the game wins, game it must be!

Perhaps you may have said at times: "Why is it I never get hurt? I'm around the plant subjected to nearly as many hazards as the others."

Isn't it a fact that most of your employees are manual workers—they work with their hands—little thinking has to be done after they are experienced—and yours is a mental job. Your mind is nimble—you always think before you act—therefore you never get hurt. You see, I've just been sneaking up on you with this "mind" business.

In 1914 there was a business depression. President Wilson said "it was mostly psychological." And he was right. All panics are psychological and they spread like wildfire.

Accidents will be found to be mostly psychological if traced to their sources. You've heard men say when an accident happens: "Well, there'll be two or three more now." And they believe it—they expect it—and, of course, they get what they expect.

If you've got any pessimistic assistants working with you, get rid of them, get them something else to do. They're in the wrong job. Surround yourself only with optimists—those who expect only the best—and then watch your records improve.

I believe, if I were managing a plant, that's the first thing I'd do—get rid of

pessimists, or tell them to change their habits of thought. You know *right now* a half dozen people in your plant who are a detriment to the place because they don't *think* right.

Do you think a pessimist wrote your slogan: "Nothing takes the place of leather?" Not on your life—he was an optimist—every inch of him.

Perhaps some of the blame for accidents might be traced to the employment department—hiring and placing left-handed people on right-handed jobs. You know what I mean—not fitted for the job. Hiring and placing is surely a job for an expert.

I believe every man takes with him wherever he goes his mental atmosphere. I cannot find a better word. I'd like to say "aura," but that doesn't quite tell it.

I believe his mental atmosphere affects everybody with whom he comes in contact and if when he goes around the plant he feels "lower than a well-digger's assistant," he'd better stay away from the employees until he feels better.

Don't you suppose that a man who goes around with spirit and plenty of optimism is going to influence a lot of people to be likewise? Surely he is. It's wonderfully contagious. No pessimist ever conducted a successful no-accident campaign.

You hear some fine things about Milwaukee once in a while—about its monster Foremen's Safety school. How does that school happen? It's because the town has a big quota of optimists and some of the best ones run that big school. Optimism is the biggest factor in cooperation.

Look at Lindbergh—the supreme optimist! Every ounce of his preparation was filled with the "I can and I will" spirit. He didn't think of the ocean below him. He kept thinking Paris, Paris, all the time. If he'd had a couple of gibbering pessimists with him you know what would have happened. They'd never have been heard from.

Now, gentlemen, I want to give you my tribute to "Safety Men." It is called "Who Are These Men?" I give it to you in all sincerity and with the hope that it may help to inspire you to greater achievements during the coming year?

Who Are These Men?

"The test of a man's worth to his community is the service he renders to it."—Roosevelt.

Before me lies a picture of the signing of the Declaration of Independence—just ordinary men doing what seemed to be their ordinary duty.

There is nothing in the picture to indicate the immediate jeopardy in which their acts placed them; nothing to show belief that theirs was a deathless deed or that foreshadowed the love and veneration in which they would be held by succeeding generations.

This picture brings to mind thousands of men whose duty today is to save the priceless gift for millions of their fellow-men—the precious gift of life.

I speak of Safety Men—men whose lives are consecrated to saving and protecting other men from the hazards of occupation—Safety Men, who, by word of mouth, by their writings, their public addresses, daily are inculcating in the minds of millions the desire to work safely, for their own benefit and for the welfare of those who work with them.

Bludgeons of discouragement and adverse circumstance have not caused these men to falter or to surrender their ideals. They have been inspired and sustained by a never-failing hope that ultimately success would be theirs. Economic values interest these men; but it is spiritual values that grip them.

They are the essence of cooperation—these men. Filled with that spirit, they erect great bulwarks against the ever-threatening tides of accident. They are the heralds of a new day, whose dawn will show a minimum waste of life and limb.

No monument is needed for these men—no marble shaft to pierce the blue of heaven. Greater is their living memorial; the millions of lives saved—the countless homes kept happy.

By their acts they give a new interpretation to civilization—a broader translation to human brotherhood.

Dedicated to the Safety Men of America.

CHAIRMAN McCLELLAN: We will now open the meeting for discussion. I will start it. I would like to ask to what you attribute the 4.61 per cent rise in frequency rate?

MR. SMITH: I just quoted that figure from this pamphlet of statistics issued by the National Safety Council. I imagine a good many of you have seen these statistics in regard to the annual number of industrial accidents.

CHAIRMAN McCLELLAN: Are there any other questions to ask Mr. Smith? Mr. Schwarze, you are a tannery man.

F. SCHWARZE (Pfister & Vogel Leather Co., Milwaukee, Wis.): Regarding the favorable experience of my company, the market rate and the credit given to our risks, I want to say that early in the safety movement, during 1911 when the workmen's compensation act went into effect, our company recognized the fact that we were dealing with labor of a rather low standard of intelligence and that mechanical safeguarding was the principal asset in lowering accidents. That factor, together with a continued administration of a safety policy by the management and subordinates, has been responsible for our favorable experience.

I might add that after one year of insurance under the experience rating plan of Wisconsin, we have been able to gain an additional 10 per cent reduction over the figures quoted by Mr. Smith.

CHAIRMAN McCLELLAN: The next speaker will be Mr. Dean Moneymaker, safety supervisor of the International Shoe Company, St. Louis.

Common Accidents in the Tanning Industry and Suggestions for Eliminating Them

**Dean Moneymaker, Safety Supervisor, International Shoe Company,
St. Louis, Mo.**

It is indeed an honor to be called upon to express our experience concerning injuries that have occurred in our tanneries, and which may help some one in preventing an accident to an employee. It would be a great deal easier for the writer to talk on accidents which occur in a shoe manufacturing plant; however, we ask that you bear with us in this discussion.

As the majority of you no doubt know there are several different classifications of tanneries. It has been my experience to deal only with tanneries manufacturing leather made from sheep skins and those manufacturing upper leather from cow hides. In a measure the general process is the same, though the time elapsing before the finished product emerges is considerably longer and goes through a great many more processes, in the case of the cow hide, than it does in the sheep skin. However, in both instances the machinery and processes are very similar.

In the tanning industry there is a great deal of heavy machinery in use, therefore necessitating a great many mechanical guards, many of these guards requiring exquisite engineering skill to develop.

Getting down to the task of pointing out the most common accidents which occur in this industry, it has been our experience that, as in all other classifications, there are only two, mechanical and non-mechanical. The former being accidents received by machine operators, and in most cases preventable.

One of the machines that has caused us much sorrow and several severe injuries has been the embossing or large hydraulic Sheridan presses, and it has been only after considerable work that we have been able to minimize this hazard to a minor degree. This machine is usually operated by two employees; one being called the feeder, who places the skin in the machine, the other the receiver, or the one who takes the skin from the machine, and each working on opposite sides of the machine. Usually it is the receiver who controls the machine, that is, tripping and causing the presses to come together. We at first tried a guard which worked on the up and down motion of the press, an iron pipe affair, so attached that when the machine was tripped it would push the operator away from the jaws far enough that their hands could not be caught in the press. This in a measure proved successful, though the possibilities of its being ineffective were too great.

A Simple Guard the Final Solution

We also tried a guard which was placed on the lower jaw of the press, and when the machine was tripped it would push the hands or arms out of the way. This proved too complicated, as it was too easy to get out of order.

The last and most effective, and the guard which we are now using on this machine, is nothing more than a strip of plate glass attached to the plates of the press, which does not obstruct the view, and is only far enough apart to slip the skin into the plates before they come together, and is not far enough apart to allow the fingers to come under the jaws of the machine. Since installing this guard we have not had a single accident on this machine, and are told by the workers that it would be impossible to get caught.

Another type of machine which has caused us considerable trouble has been the jacks. There are several types of these machines. Not being an expert in the tanning business, I cannot give you the names, but I am familiar enough with them to know that generally speaking they all operate in a very similar manner. That is, an arm moves backward and forward with a motion which is intended either to brush, knead or glaze the skin in process. The skin is usually rotated under this blade, brush or glazier on a table, of course, with instructions to the operator to keep the hands away from the point of operation. However, many times they get careless and, as the old saying goes, "play with fire," and get their hands caught under this knife or other machine part with the result, a badly lacerated or mangled hand.

We have in use at the present time a guard on the rolling jack which has proven somewhat effective, though not so effective as we would like. It is merely a skirt or curtain made of iron piping, which comes around the arm down to within a short distance from the table, so that if the operator, conscientiously or otherwise, gets his hand too close to the point of operation, he comes in contact with this guard, and, of course, is reminded of the danger, and in that way is constantly kept informed of the possibilities of being injured. We are still working to perfect a guard for these machines, though we have been told by many it was impossible to do so.

There are many more machines used by the tanneries, though our experience has been practically negative with most of the others.

The large drums in the drum room have given us some trouble, and about the only method of safeguarding we have found of any value is to have the space relative to the drums fenced off, either by movable gates or other easily manipulated protection that will keep employees away while the drums are in motion.

Most accidents in the tanneries, however, are due to falls on account of the very slippery condition of many of the floors, because of the necessity of their being wet a great part of the time. Of course, in the fleshing rooms and the vat rooms the floor is always wet, and practically all the employees wear rubber boots. The only method we have been able to devise for this condition is to keep the floors as well drained as possible, and in the aisles in some instances where trucks and other movements are required to have slightly raised platforms to travel about on. While this does not eliminate the slipping hazard entirely, it minimizes it by keeping floors as dry and well drained as possible.

Trucking By Hand Caused Many Strains

Up to a short while ago, practically all of our trucking had been done by hand. This caused a great many hernias and other strains, and only after considerable experiment with different kinds of trucks, both hand and power, it was found that practically all trucking could be done by power trucks. Therefore these electric haulers were installed, and since then, over a period of about two years, we have had only two or three reported hernias, where previously it might range as high as six or eight.

Another constant worry has been the more or less minor injuries which have developed from the tacking room by tacks flying into the employee's face and eyes, or because of the tacks falling to the floor and being stepped on, often causing quite serious infections. In our sheep skin tannery (and we see no reason why it could not be developed in all tanneries) we have a specially constructed arrangement for both the tacking boards and the manner of handling them. I do not know whether it is a new idea or not, but it has eliminated almost entirely our worry of injury to those in the tacking department. The following is about the construction:

Each board has fastened on the end and in the center a half inch or three-quarters inch iron pipe which extends about twelve inches from the board. When the board is ready for the tacking on of the skin it is placed on the track or runway, which is just a little wider than the board, and allows the board to be rotated or shoved by the two pieces of pipe resting on this track, the track, of course, being a little higher than half the width of the board. This allows handling without the necessity of lifting the weight of the board, and not only increases the output, but the physical effort is greatly reduced. To get away from the great number of tacks which are scattered about over the floor, below each truck and about the same width as the board there is a depression of about six inches, which is in the nature of a trough, and as tacks fall or are removed from the skin they fall into this trough, and are very easily gathered up, very few falling out onto the floor where they will be stepped on. The runways between these tracks are sufficiently wide for two operators to work back to back without being in each other's way.

We find also that a great many of our employees were prone to use either soft soled shoes or shoes with the soles practically worn out. This matter was given attention, and it has been found that now since the employees are

required to wear substantially soled shoes that there are very few accidents from stepping on these nails.

As to the tacks flying into the employee's face, we are requiring the employee to wear goggles and are furnishing them of a light, clear vision type, which eliminates the big majority of these accidents, though occasionally in the use of these goggles we do have an eye injury.

Regarding falls of persons other than those on slippery floors, falling objects, and so forth, about the only suggestion that we could make concerning this constant hazard is to see that the equipment is always kept in first class condition, that the plant floors, stairways, and so forth, are kept clear and free from objects, and always well lighted. We have had a considerable number of accidents due to falls of persons on stairways. Our feeling in eliminating this hazard has been that in 99 cases out of a 100 it is due not to a defect or lack of light, but is due to either running or horse play. This, as in all accidents, whether mechanical or non-mechanical, can be lessened only when the employee has acquired the safety sense; that is, acquired the habit of doing things in a safe manner and feeling their responsibility in the having or prevention of accidents.

We believe, and have successfully found that safety education is by far the greatest means of eliminating accidents in every respect. For a period of nearly a year now we have been editing monthly a very effective safety news sheet, which is nothing more than a six to ten page mimeographed booklet, giving records, statistics, articles, cartoons and other safety material, which is put up in a manner that is usually attractive to the foreman on the job. In our opinion safety work must develop and be impressed on the minds first of those in authority, such as foreman, assistant foreman, or overseer, with the constant check up of both mechanical and mental hazards which may be present, and as each problem develops it must be handled in a way that will suit the needs of that particular problem.

Mechanical and non-mechanical conditions can only reduce accidents where efficient guards are used and employees are properly trained to carry out instructions or mentally trained to sense a hazardous condition immediately and see that it is remedied.

Goggles to Avoid the Flying Tacks

CHAIRMAN McCLELLAN: The meeting is now open for discussion of this interesting paper.

H. F. WINTER (Griess Pflieger Tanning Co., Chicago): The point was brought up that to avoid tacks flying into the eyes, the workmen all wear goggles. Do these workmen wear the goggles during the entire time they are tacking or just when they are stripping?

MR. MONEYMAKER: Our experience is, that they will wear them only when they are stripping; that is, when they are knocking the tacks out. We have tried to get them to wear them all the time but we find it almost impossible, and consequently we have limited it to that period when they are knocking the tacks out of the skin, and we find that that practically takes care of it.

MR. WINTER: That has been our experience, too.

CHAIRMAN McCLELLAN: Do you use a machine called the fleshing machine in your operations?

MR. MONEYMAKER: Yes. We have it guarded and we have had very little, if any, trouble with it.

CHAIRMAN McCLELLAN: That is—where the rubber roller comes up against the top roll, you have a guard?

MR. MONEYMAKER: I say we have a guard. I don't know how to express it, but we depend more on the operator than on any guard. As to having a specific guard, we do not. We have tried out a number of little contraptions with which I am not thoroughly familiar, but they haven't been as successful as the man on the job.

CHAIRMAN McCLELLAN: In other words, you depend on the human element to operate it. You have no mechanical guard.

MR. MONEYMAKER: No. In our experience over a period of six or eight years I know of only one accident in our tanneries with that machine.

L. M. FORBES: (Editor of Hide and Leather, Chicago): On your bossing presses have you ever tried a tube-handled control on the releases? I raise that question because I wonder how the operator handles the skin, how he gets in there to handle it.

Problem on the Bossing Presses

MR. MONEYMAKER: The only method we have found of any benefit is merely a little paddle with which to reach in there and straighten it out from the other side—that is, the side from which it is taken.

MR. FORBES: The receiver releases the press?

MR. MONEYMAKER: He uses the paddle to straighten it out, then it is necessary to trip it off to straighten it out and then it is tripped again. It slows up the work but it is mighty costly if a person is hurt, and we would rather slow the work up.

CHAIRMAN McCLELLAN: We have two-handed controls on our presses.

MR. FORBES: I have seen it laid across with a stick and at the top there were two loops hanging down and if you took hold of only one loop it wouldn't release. You had to take hold of both in order to bring the plates together. I wonder if you have ever seen that or have tried it out?

MR. MONEYMAKER: No.

MR. FORBES: It seems to me to be quite an effective stunt except that occasionally the operator takes the two handles together in one hand and continues to operate with the other hand.

CHAIRMAN McCLELLAN: We have that contraption where the operator has to put up both hands to operate and we have found cases where he has tried the two together. We stopped it and have had no further trouble.

MR. FORBES: Would it be feasible on a glazing machine to work that plate glass principle and just run two pieces of plate glass above the bolster and parallel to it?

MR. MONEYMAKER: I can't say.

CHAIRMAN McCLELLAN: I would like to ask Mr. Schwarze to explain that guard which Mr. Moneymaker was speaking about.

MR. SCHWARZE: On the splitting machine Mr. Moneymaker referred to, there is a strip of metal which can be made of galvanized iron, copper or brass. It is attached to the head of the machine proper and an adjustment must be made to keep the guard strip down at a determined level. The minimum opening should be maintained between the feeding plate and the bottom of the guard strip. It affords this protection: A man feeding in there would have something to catch on to if his hand should slip. In addition, the guard has an edge turned over a rod to stiffen it and that little protection permits a finger hold.

In splitting bull hides, which are extra heavy—stock probably $\frac{5}{8}$ of an inch thick—we provide a gate guard that lays on top of the machine which simply drops down and supplements the guard behind it. You feed through it and the guard rail lays between the thumb and index finger.

CHAIRMAN McCLELLAN: He also spoke about a glazing jack.

MR. SCHWARZE: I don't know. I had in mind to ask Mr. Forbes about protection on glazing jacks. The working plane of the crank iron is right in the plane where you would have to put your plate glass.

The matter of illuminating a glazing jack is not very difficult. We tried 20 years ago to light them up but it wasn't successful. When the Mazda lamps came along we thought our difficulties were multiplied, but they were lessened. We put them on a glazing jack operating at 160 revolutions per minute and kept the jack well lighted.

In front of me is a bulletin on a guard for a glazing jack. It is a wooden strip member construction in which the jack or the agate moves back and forth. To get the light right on the leather strip we paint the inside of that gird with aluminum paint and supplement it with a half shade and get good results.

In regard to the slipping hazard which Mr. Moneymaker mentioned, I might add that only recently we have tried out putting in a granulated mixture in our cement and it is working out satisfactorily. Previously we had been furnishing our men with rubber boots equipped with leather soles and heels.

CHAIRMAN McCLELLAN: Our next topic is by Mr. Fred Schwarze, manager of the Labor Department of Pfister & Vogel Leather Company, Milwaukee, and also past chairman of this section.

Safety's Influence on Production in the Packing and Tanning Industries

Fred Schwarze, Manager, Labor Department, Pfister & Vogel Leather Company, Milwaukee, Wis.

In trying to meet the requirements of my subject I find that while our processes are very similar in a good many respects as regarding the handling of a hide after it is taken from the animal, it is equally true that they differ as widely, and this paper will therefore necessarily be confined to generalities, with the reservation that specific matters be taken care of in the discussion which may follow. As an example, I might state that live stock is an unknown quantity in the tanning industry, whereas it is a major item in the packing industry. I have never known of the presence of a "hog" in the tannery unless it be in the form of a "ham sandwich."

In presenting this paper the speaker desires to assure any reader that it can be accepted as a fact that the influence of safety on production in the packing and tanning industries is fundamentally no different than its influence in any other industry or field of endeavor, inasmuch as the principal of safety practice is basic from an economic standpoint. This statement is made with due regard for the humanitarian element which enters with the application of safety measures in any form.

While it is recognized that the packing and tanning industries have inherent conditions peculiar to the nature of these industries, yet in a major sense our problems are no different than those of any other industry inasmuch as both cause and effect will yield to efficient counter efforts, i.e., "Most problems can be solved."

In using the word "Safety" in the title of this topic it is accepted as meaning that preventive methods to conserve human life and limb are being applied, together with the necessary humanitarian interest and sincerity, and are coupled with the highest possible efficiency.

In sensing the meaning of the word "Production" it is accepted that it is to cover the complex procedure which starts with the entering of raw materials used in process and concluded with the final dispatch of the finished product to the market for the use of the ultimate purchaser or consumer.

The definition of the word "Production" is without doubt acceptable, whereas the intent and possible attainment of "Safety" efficiency in any plant is not

only subject to improvement but in a good many cases the represented standard of safety may be questioned. In the face of questions a good many explanations may be justly stated in the defense of apparent hazards.

In establishing the proper standards which control the application of labor to production, due consideration must be allowed for every facility in the physical and mental make-up of a plant, and which are necessary to carry on production in a safe and healthy manner. These factors are without doubt recognized by competent industrial engineers who may be responsible for production standards.

The conservation of health is recognized as essential, as is the necessity for safety against injury, and likewise the element of fatigue must not be overlooked.

Nevertheless, in the face of every possible effort there continue to remain in our industries hazards which to date have not yielded to the sincere endeavor of plant management to eliminate them—it being generally agreed that they are only being carried along with the expectation that the future will offer relief; and when one reviews the progress made in the safeguarding of equipment during the past 15 years he will find that numerous simple safeguards explain the elimination of hazards which for a long time appeared to be insurmountable, and it is only reasonable to expect that hazards which are permitted to exist today will yield to similar development tomorrow. Fortunately those hazards represent a minority in our industries and their seriousness is generally appreciated.

The types of hazard just mentioned are termed by the writer so-called "justifiable" hazards, and will only be tolerated when their necessity qualifies protection in the absence of a proper remedy. To guard against accidents in the face of such hazards it is essential that only the best type of labor be adapted to perform any necessary duty in connection therewith, and proper placement of employees is the best accepted protection.

The So-Called "Justifiable Hazards"

Justifiable hazards are maintained in some industries and other fields of endeavor. To eliminate such hazards without substituting an equally efficient method would, in a good many instances, hamper the process or procedure to such an extent that full efficiency would mean an aggravation of some economic factor and would possibly lead to a far greater element of distress than if the original hazard had been permitted to continue.

I quote a statement of Rear Admiral Simms, retired, U. S. Navy, in a speech delivered before the National Safety Congress at Cleveland, Ohio, wherein he stated that in connection with increasing the efficiency of U. S. Navy gun crews several hundred per cent. the hazards were also increased, thereby involving an annual loss of life which was in excess of previous experience; however, a sacrificing of efficiency in U. S. Naval gunnery would mean the lowering of the defense ability of our nation, and everyone will readily agree that maintaining efficiency, as Rear Admiral Simms quoted, was the most conservative procedure in the end.

Similar exposure in connection with police duties and the combating of conflagrations, coast guard rescue work and other similar pursuits offer an element of exposure to hazards, and it is readily seen that if these efficient institutions be set aside to avoid the hazards to which the personnel are subjected, then the result would be distressingly bad.

While the examples cited are probably more pronounced than hazards existing in industry, yet the relationship is very close, inasmuch as the men following all of these pursuits are doing so to gain a livelihood for their families and

themselves, and it is also evident that every endeavor is made to gain for the wage earner the protection to which he is entitled.

In spite of conservative allowance by management to permit a fair and safe labor policy, and a fair day's pay for a fair day's work, there will always be manifest the desire of workers to earn the highest possible wage and at a probable sacrifice of safety. The latter tendency is contingent on the wage plan in effect in a plant and is least present among the so-called day workers, and increases with the application of piece work and wage incentive plans. I refer to the chance-taker, who seems more desirous of increasing his pay check than his span of life.

The management of a plant may furnish the finest of buildings, the best of raw materials and equipment, supplementing them with a personnel qualified to produce the finished product. The management may further establish a safety policy incorporating the highest ideals. However, such good intention and policy will not administer themselves. Safety must be subscribed to by all employees of a plant, and must be maintained by the management and supervisory staff so that its standards as prescribed will not be allowed to depreciate and become an established but not a maintained institution. This is a responsibility which rests principally with the foremen.

The supervisory staff (inclusive of foremen) directly responsible for the men in any plant are the men who can best effect a favorable influence on production by reflecting efficient and safe supervision into the ranks of their workers and also insisting on an equally safe and efficient reaction; it being an accepted fact that such practice sponsors reaction down the line to the humblest worker.

Numerous measures to instill an interest in safety have been advocated, such as individual campaigns, competitive campaigns between departments, shops or other divisions; however, the final results of a good many of such campaigns may be questioned. However, any medium of education which will make a safe thinker of a worker will automatically make a better producer of him.

To eliminate a hazard before an accident occurs is without doubt the safest practice, and not to permit a hazard to continue after an accident has happened is probably the next best. Prompt investigation of every accident will in almost all instances reveal the true cause or consequent hazard.

A safely managed plant may not always be an efficient plant and vice versa. This statement is qualified by the fact that where former primitive craftsman methods have yielded to modern mechanical speed production methods, additional hazards have accompanied increased production efficiency, and likewise in a good many instances increased production methods have reduced the hazards. The latter condition being especially true in the metal industry with the introduction of automatic feed machinery replacing hand feed methods.

Exceptions can always be cited and will have to be dealt with on their merits; however, I believe that when we say, "production efficiency and safety go hand in hand," and that "without safety you cannot operate efficiently," these statements can be maintained.

Let us review the past 15 years of progress in both the safe and efficient development of our industries, and I believe that we will recognize that to go back to the former standards of safety and production would be out of the question.

Also a comparison of our industries with other diversified industries will indicate that we have developed many new ideas and products for the need of mankind, and that our institutions compare with the best as safe and sanitary places of employment and production.

ADJOURNMENT

Wednesday, September 28, 1927

The second session was called to order at nine-forty o'clock by Past Chairman W. F. McClellan.

CHAIRMAN MCCLELLAN: The first order of business this morning is the election of officers. Mr. Schwarze, have you the slate?

Report of the Nominating Committee

Chairman, William Campbell, Graton and Knight Company, Worcester, Mass.

Vice-Chairman, O. C. Stern, Plankinton Packing Company, Milwaukee, Wis.

Secretary, Edward E. Drews, Libby, McNeill and Libby, Chicago, Ill.

Poster and Slide Committee Chairman, Fred Schwartz, Pfister and Vogel Leather Company, Milwaukee, Wis.

Membership Committee Chairman, William C. Corey, Delaware Leather Company, Wilmington, Del.

Publicity Committee Chairman, Charles Boncholt, Hammond Standish and Company, Detroit, Mich.

Program Committee Chairman, F. A. Honnell, Wilson and Company, Chicago, Ill.

Engineering Committee Chairman, S. R. Jensen, Armour and Company, Chicago, Ill.

Statistics Committee Chairman, Dean Moneymaker, International Shoe Company, St. Louis, Mo.

News-Letter Editor, Lloyd F. Allen, The Rath Packing Company, Waterloo, Iowa.

Executive Committee, The Officers and—

N. L. Brainard, Swift and Company, Chicago, Ill.

J. M. Eaton, Libby, McNeill and Libby, Chicago, Ill.

W. F. McClellan, Armour and Company, Chicago, Ill.

CHAIRMAN MCCLELLAN: You have heard the report. What are your recommendations?

S. R. JENSEN (Armour & Co., Chicago): I move the slate be adopted as read. (The motion was seconded and carried.)

CHAIRMAN MCCLELLAN: Mr. Campbell, as you have been elected chairman, I will ask you to step up here and conduct the meeting.

I might say that Mr. Campbell has well earned the honor of being elected chairman. He has been a faithful attendant at all Safety Council meetings for a number of years.

(CHAIRMAN-ELECT CAMPBELL assumed the chair.)

CHAIRMAN CAMPBELL: The first subject on the program is "Keeping the Safety Committees Interested," by Mr. Louis Barr, Safety Inspector of Armour & Company, Kansas City, Mo.

MR. MCCLELLAN: Mr. Chairman, I think we will have to call on the next speaker. I understand Mr. Barr was in an automobile accident last week. A copy of his paper was forwarded to Mr. Corey and Mr. Corey hasn't shown up. Mr. Owen is trying to see if he can get a copy of it.

CHAIRMAN CAMPBELL: The next paper is by Mr. J. M. Sandel, Chicago, Ill.

Rehabilitation—An Important Factor In Accident Prevention Work

John M. Sandel, Chicago, Ill.

Many people think of rehabilitation work as supplementary to other phases or activities that are a part of the safety engineers work, but as a matter of fact, rehabilitation of the injured worker is the thing that no one should ever overlook. When you have secured the cooperation of the employees of the plant in wearing goggles, devising guards, and recommending and practicing safe methods of doing each individual job, certainly you do not want to leave to others the sole responsibility of preparing that man who is injured for gainful work again. When you take a hand in it yourself and see the possibilities that are inexhaustible for so much good to be accomplished, never again will you care to be satisfied with compliance with legal requirements alone. You are going to do all you can, and persuade your companies to "go a little further" than they "have to."

The first aim of the safety engineer is to prevent accidents. In my younger days, I remarked to the chief surgeon of one of the companies I was associated with that I was going to do my work in such a way that all the physicians would be back in private practice and be glad to be there. Our ideal is 100 per cent safety in the plant; some of us achieve it for short periods, but we still have the accidents. As soon as the accident occurs and the injured needs medical attention, the work of rehabilitation must start. It must start not only in the case of the serious accident, but the trivial accident as well.

The first step in rehabilitation work occurs when the injured man comes for the first medical or surgical treatment after the injury. A nurse or doctor should look the patient over very carefully, particularly to ascertain if there is any impairment of the function of any member of the body. A good rule is to have the patient move the injured member in all directions and execute all of the movements possible. Then you will know if there has been any injury to the tendon or to the nerves, two things which will prolong disability and which can be quickly and effectively attended to at the time of the first treatment. If any injury to or a severance of either a nerve or a tendon is discovered, a good surgeon should be secured at once.

I am going to mention many things that can be done for men who are disabled, but I want to say at this point that the most valuable thing that can be done at any time is the work that a high grade surgeon can accomplish. Prompt and effective work of a skilled man on the operating table will do more than massages, light, artificial appliances or education for anyone who has been disabled in any kind of an accident and, what is very important, surgery will accomplish all of this sooner than other methods. Any experienced industrial physician will tell you this and will be able to give you more typical examples of good results that I am going to cite. Here are a few cases that have come to my attention.

The walls of a building had been completed and the next thing was to place the roof trusses. The work had to be done with block and tackle because of structural conditions and the trusses could not be hoisted directly over the point where they were to be set. Timbers were erected to support a 15-inch I-beam which would take the trusses when they were hoisted to the required height, the idea being to transfer the load (truss) to a traveler on the bottom web of the beam after it was hoisted. The transfer was made, but some of the braces supporting the I-beam failed, and the left leg of the bricklayer foreman was pinned between the I-beam and some structural steel. When the man was picked up, any one could have taken a pair of shears and cut the lower part of the leg off as easily as any cloth could have been

cut. But instead, the whole man was taken to a hospital and operated upon that night. The bone had to be shortened a little in order to enable it to knit as the ends were badly splintered by the crushing action. But that foreman is on the job today, walking with a slight limp and a thick soled shoe, but he is every bit as good as before his injury, both as regards his earning power and his ability to serve his employer efficiently.

Here is a more wonderful case that is not yet completed, but has all the earmarks of going to be a 100 per cent success. A nurse was administering first aid when she pricked her finger on a needle. She gave it prompt treatment, but an infection set in which finally resulted in the loss of use of the entire hand. It was her right hand, and she could not have obtained other work as she was right handed. She was awarded compensation for the loss of use of her hand and the compensation board in the state was of the opinion that nothing further could be done for her. It would not allow any additional treatments. Her employer, who operates in a number of states, brought her to this city and had an operation performed. The surgeon found that the tendons and the nerves had sloughed, and he had a most difficult job ahead of him. Working with the smallest instruments, the surgeon finally secured ends of tendons that were of some use and still able to function, and transplanted tendons from the foot to the hand. The present result is partial use of the hand, with assurance of complete use in another few months with constant exercise that it should receive. Such a case is an inspiration to all safety engineers and physicians who must deal with injured employees.

Transplantation of the Nerve is Even Possible

Not only is tendon transplantation possible, but nerve transplantation is possible. If a nerve has become sloughed, it is possible to attach a transplanted nerve to another nerve outside the affected zone so that a nerve will serve a double purpose. In other words, where two nerves supplied by nature have lost their function and they lie close together, it is possible to make one transplanted nerve do the work formerly done by two.

When the surgeon has not been called in, the work of rehabilitation is long and difficult. All present from the packing industry need not be told of the men who have severed tendons and nerves in their occupations, and as a consequence have experienced impairment of function of the injured member and their entire earning power. Many a man in a packing plant has been severely cut with a knife and has lost the use of fingers and hands. Most of these men have had their disabilities so long that they cannot be helped by surgery even now. But there are enough examples of what can be done for similar disabling accidents that our present workmen need not go through life in the same way as the old timers, and need not be handicapped.

Some of the states and the national government have made some provision for the rehabilitation of men who have met with disabling injuries in industry and in war: I cannot say how many have or what states have done so. I know of the work of the Bureau of Rehabilitation of the Department of Labor and Industry of the Commonwealth of Pennsylvania, which was established by an act of legislature during the session of 1919. By this time, the Bureau has handled several thousand cases and has done very good work, and has been able to secure the cooperation of several organizations within the state as well as employers.

The Pennsylvania act is weak in that the appropriations are insufficient to permit high grade surgical work to be performed. Considering the volume of work before the bureau and the subjects that require their services, high grade surgical work would require nearly triple the amount of money now appropriated. To secure this would be almost an impossible task—but, have you had any experience with legislators?

The Pennsylvania rehabilitation act limits the application of the act to a physically

handicapped person resident of the state of Pennsylvania whose earning power is destroyed by an industrial accident occurring in that state. The Bureau of Rehabilitation is notified by the Bureau of Workmen's Compensation or by the Workmen's Compensation Board, all in the Department of Labor and Industry, whenever any person is a subject for rehabilitation, when the bureau investigates the case and takes whatever steps they can considering everything. If a man has suffered a dismemberment and artificial appliances are needed, they are provided by the state if the man cannot pay for them. Where a man can pay a part of the cost of the appliances, this is required. When a man requires an education to secure a new occupation, the act permits the bureau to pay not more than \$15 per week for 20 weeks.

Some Early Accomplishments of the Pennsylvania Bureau

Through the efforts of the bureau, the work of rehabilitation of the physically handicapped is carried on by means of vocational and trade schools and by the assistance of the Bureau of Employment of the Department of Labor and Industry in finding a new occupation for the man. In this way, some persons receive an education who otherwise wouldn't, which has its influence on the members of the injured man's family. The resources of the public school system, any vocational school, associations such as the Y. M. C. A., are utilized as much as possible. Wherever employers operate a school or will train a man in a new occupation, such available facilities are never passed by. Schools of this kind are a very valuable aid to those registered, as practically all have been injured in industry, and those schools simplify the problem in towns which have only the one industry.

Some of the early accomplishments of the Pennsylvania Bureau of Rehabilitation are the following:

Truck driver lost leg; was trained in telegraphy.

Hands lost operating a machine; received a business training.

Laborer lost an arm; was taught to operate a machine after being supplied with an artificial appliance and earns more money than before the accident.

Foreign speaking laborer lost leg; was educated and given employment as interviewer in employment department handling men of his nationality.

Agricultural laborer lost a leg; was taught to wind armatures.

Coal miner loses a leg; becomes an auto mechanic.

Maintenance machinist lost hand; trained as a calculating machine operator.

Eyes lost; trained as a stenographer using a phonograph dictating machine and touch system typewriting, or as a piano tuner.

Brakeman loses leg; becomes a locomotive engineer on a narrow gauge locomotive.

Laborer loses leg; becomes a bench assembler in an adding machine manufacturing plant.

Girl operator of a punch press loses several fingers; trained in clerical work.

Laborer lost arm at shoulder; received lump sum settlement of compensation award and established a small store to support dependents and studies telegraphy and wireless operation evenings.

Horseshoe blacksmith loses an arm and is returned to his former occupation with the aid of an artificial appliance.

All of this work is to be highly commended; the disabled men are far better off than without the training and other assistance given, but each case represents months of effort of various kinds to get the subject gainfully employed. Expert surgery will nearly always return the disabled to their former occupations within a much shorter time, and the amount the restored are handicapped in their earning power is very little. The man who must work with his hands and who has no executive ability needs all that can be done for him or he is at a disadvantage in competing for a job in the open market. When industry refits a man for his own or another

occupation after a disabling injury, the gain in loyalty and good will cannot be evaluated. So, wherever possible, get the surgeon on the job quickly, and if this is not done, look over your plant to see if there is not some place where the man can be placed, and then train the man for the place. This is not socialism or any other ism; it is good business.

I can find no better way of summarizing this whole question of accident prevention and rehabilitation than the expression of one of the best known industrial physicians of this city, which was made some years back and which is good yet. That is—

1. Hand in hand with all efforts in rehabilitation must be a greater effort in conservation; we must prevent increasing industrial casualties.
2. Medical and surgical procedures must be directed toward the maximum functional restoration as rapidly as possible so as to be useful in the future.
3. Hospitals for rehabilitation work only are needed so that convalescence will be most favorable, and because it is better to have occupational therapy, physical therapy, games, training and study under surroundings that are pleasant and harmonious, and away from the usual situations at medical and surgical hospitals.
4. Handicapped persons must be placed on the basis that physical qualifications plus occupational qualifications equals the job.
5. Medical supervision and vocational supervision are needed to make a good job of this work.

The State Stands Expense of Rehabilitation

CHAIRMAN CAMPBELL: Are there any questions to ask Mr. Sandel? I am sure he will be glad to answer them.

MR. McCLELLAN: Under your rehabilitation plan, do the employers of that state—presume it is Pennsylvania you are talking about—contribute to a fund to train the injured or do the employer themselves train them?

MR. SANDEL: Many employers do not contribute. The state stands the entire expense. The first appropriation at the time the Bureau of Rehabilitation was established was \$100,000 for two years. I can't say what additional appropriations have been made. Of course, additional ones were necessary for \$100,000 would never have carried on the work since 1919.

Of course, where the industries cooperate with the Bureau there is some expense to the industry, and often the industry is glad to share it. I think every one of you, if you were speaking for your own company as I speak for a number of others, would say that the company would be glad to do all it could for the man, and where it can get the assistance of the state which has specialists in the work to give the man suggestions, I think the industry would be glad to pay what small cost is necessary in order to do what it can for the employee.

MR. McCLELLAN: Is that carried on by the Bureau?

MR. SANDEL: It is carried on under the supervision of the labor and industry department.

MR. F. SCHWARZE (Pfister & Vogel Leather Co., Milwaukee): I would like to ask Mr. Sandel what his experience indicates is the attitude of the unfortunate employee who has been injured. Do you find generally that these men are cooperative and sincere in their endeavor to get back to some employment, or do you find that they feel the world owes them a living?

MR. SANDEL: Of course there are all kinds of people in the world, Mr. Schwarze, but I would say in the majority of cases, the adjusters of the Bureau of Rehabilitation in the Department of Labor and Industry have been able (not right at the start, but after talking to the man a while), to convince him of the advantage of taking some training, where it is needed to fit him for another job. Their hardest

work, of course; is in the mining towns and in industries like the chemical industry, where there is only one industry in the town and the man and his family have lived in that one place all their lives; and he doesn't want to go elsewhere. It is a hard task to find something for him to do, for he is not fitted to continue his old job. But in the larger centers of population there isn't a lot of difficulty and the adjusters of the Bureau have been able to get the injured man in a good frame of mind and willing to cooperate with them.

CHAIRMAN CAMPBELL: Are there any more questions?

Unfortunately, Mr. Corey couldn't be here today. We have a Round Table listed on the program next. I have a paper which I was going to read, and if Mr. McClellan will be so kind I will ask him to read it.

The Qualifications of a Safety Engineer

William Campbell, Safety Inspector, Grafton & Knight Manufacturing Company, Worcester, Mass.

Many of you gentlemen hold positions which in addition to your safety duties require you to employ the men of your shop. For that reason you should analyze yourself, as well as the applicant you interview. I am, therefore, listing the qualifications which I consider essential in a successful safety engineer.

1. *Knowledge of safe practice.* Of course, a general knowledge of what constitutes a safe machine or a safe condition is essential, but with all the diversified industries, it is impossible for any one man to be sufficiently acquainted with all the manufacturing processes to immediately pass on the safety of them. However, there are certain basic principles in safety engineering, the same as in other engineering, and if he knows these basic principles he can shortly get the details of the business.

2. *Knowledge of human nature.* Human nature being so different, every person cannot be handled the same. One man may be driven, another may be led, and still another will follow an order by simply being told. Therefore, to get men to play safe a successful safety engineer must know which method is most effective. Whether it is better to appeal to a man's reason, or to threaten him with discharge, or to picture misery and suffering in order to get him to follow safe practices, the safety engineer should be able to decide. In this he must use what is commonly known as tact, for the wrong approach will often lose a man to the safety cause. The safety engineer must have the right approach, just as much as the salesman.

3. *Personal characteristics* of a safety engineer. He must also be sympathetic. It is sometimes unpleasant to have to listen to the troubles of a workman when you have plenty of your own, but it is often worth a lot in future safety dividends.

The successful engineer must have a likeable personality and a quality of leadership, for men will follow those in whom they believe and trust, and a pleasant personality combined with a sensible mind will make for this leadership.

He must not be afraid of getting his hands dirty. Many a would-be safety engineer has been a failure because he felt his position to be very important instead of letting others feel its importance. It has been said that you can't teach safety from behind a desk, and I know of no truer maxim. The office of a safety engineer should be the whole shop, and he should spend most of his time in this office. Neither can you teach safety by writing letters. Personal salesmanship is the most successful method.

4. *The right mind* for a safety engineer. Three of the attributes necessary to successful safety engineering are judgment, initiative and vision. To these I would also add a fourth—an analytical mind.

The question of judgment often enters into safety work especially in mechanical

safeguarding for many suggestions put up to the safety engineer are foolish from a mechanical standpoint, and the safety engineer must be able to recognize the good points and cull out the bad ones. At the same time in discarding the bad or impracticable suggestions the question of tact must enter in, and the suggestor left feeling right, and not sore.

Initiative is a very important quality in any job, but in safety work it is all important for many of the old ideas in educational safety work are "done to death" and the successful safety engineer is the one who thinks up some new way of teaching safety, and puts it across.

One of the most important qualifications for a good safety engineer is to be able to get things done. I have seen more embryo safety boosters lost to the cause by the fact that their suggestions for safety were not promptly carried out than for any other reason. This is partly a management proposition, but the safety engineer should fight for the carrying out of good ideas and not let them die an early death or lose a good booster by not carrying them out promptly. If the idea is not good let the suggestor see why, but don't simply put it aside to be forgotten, for the author will not forget.

Finally, the safety engineer must have an analytical mind and be able to take the accident reports and diagnose the plant's trouble from this report, and act on the results. In fact on starting safety engineering that should be his first task. The analysis of these accidents, together with a close inspection of the plant, should at least do away with the accidents due to lack of mechanical safeguards, provided, of course, action follows by furnishing these safeguards.

The Returned Employee May Expect Preference

CHAIRMAN CAMPBELL: The meeting is open for round table discussion.

R. A. FAUST (Fred Rueping Leather Co., Fond du Lac, Wis.): Mr. Schwarze's question as to how the employee acts, whether he feels the world owes him a living or not, is interesting. How does the company treat the employee who has come back feeling that preference should be shown him?

MR. SCHWARZE: First of all, there is no choice as far as we are concerned, for the Workmen's Compensation Law of Wisconsin prescribes what our obligation is. We have to meet that obligation. Fundamentally, when we meet the obligation of the law we have met everything. But there is a moral obligation. After you have contributed to a man's hard luck in the way of compensation payments, partial or permanent disability benefits and other incidentals, they can be materially helped, as Mr. Sandel has suggested in his paper, and it is good business. It has a very beneficial reaction in building up the morale of the plant, and, as he says, it isn't an "ism," although a good many "isms" look at what the employer is doing. If the plant doesn't do just what the "ism" thinks it ought to do, you have the negative reaction of the plant. Generally under those conditions the "isms" know just what ought to be done. They are very cooperative regarding their "ism" but they are not as cooperative generally in establishing the preventive measures which will prevent the condition.

We felt under the old civil law liability, prior to the instituting of the compensation act of Wisconsin, that there was more of a moral obligation on a man-to-man basis and in a good many instances the employers of Wisconsin and other states gave the injured man a life job. Possibly you refer to the reaction that the man feels the boss owes him a life-time job.

We bumped into that question very severely and found that we had to differentiate as to what the employer's and the employee's obligation was. We take care of a man whenever possible and continue to take care of him so long as he shows loyalty, but we can't have a streak of red in the organization because there has been a

streak of hard luck. If you take an inefficient man and couple him up to some minor job when he has no loyalty, you contribute to that condition in a material way. We have held that loyalty among veterans and disability employees is a first requisite. Efficiency is purely secondary.

MR. McCLELLAN: I would like to ask some of the members what their experience has been in "No Accident" campaigns. For instance, in our plant we have carried on semi-annual and annual campaigns when we gave prizes of hams as an inducement to the employees to work toward "no accidents." They wore safety buttons continuously during the campaign and they didn't know who the winners were until the campaign was over.

I would like to know what some of the others do to stimulate safety in their plant.

I am familiar with the safety policy of Swift & Company, but I thought perhaps some of the leather companies might have some ideas which they could offer to the packers as to how they carry on this educational work.

CHAIRMAN CAMPBELL: In Worcester we have meetings which run for eight weeks. We try to get all the foremen to come to those meetings and it is quite a job. The management gives them tickets for a banquet on the last night if they continue to go to the meetings. This year we are going to give them all banquet tickets to see if we can get them all to go. I don't think you can do anything with safety committees if you don't have the foreman behind it. The foreman is the key-stone. If he wants to buck it, you might as well not have a safety engineer. They have to work together.

Safety Must Be Made a Real Part of the Job

MR. McCLELLAN: I realize that. The foreman is the key man. What I want to know is, what you do to educate your foremen in the plant. You have to help the foremen to educate the men. That is what I want to know—just what do you do to stimulate interest among the foremen?

R. A. FAUST (Fred Rueping Leather Co., Fond du Lac, Wis.): I still bear out Mr. Campbell's remark. We have a foremen's club which meets once a month to discuss the best methods of instructing the men. That is our system. We broadcast to the men direct.

MR. McCLELLAN: I know that. We have foremen's meetings, too, and we have a club which is composed of foremen and superintendents. But do you really think that your foremen get the message at these meetings and go back and present it in such a way that it will filter through the minds of the other employees? The foremen are too interested in production.

MR. SANDEL: Some years ago, when I was with the National Safety Council, I was asked to help one plant which had a sick safety organization. In this particular case I found that one of the reasons for the lethargy was that the superintendents and overseers of the company did not insist that the foreman make safety a part of their job. Safety to the foremen was just something incidental. The company thought the idea was good and were carrying insurance, but they thought they weren't saving as much money as they should.

One of the suggestions I made to the company was that they charge the cost of the accidents which occurred in the different departments to each particular department just as they did other costs.

They held one meeting at which the foremen were told that the safety movement was going to take a new lease on life in the plant. I believe from their attitude that most of them thought it was going to be the same old stuff because they were all just about half asleep. The superintendent said that they were going to do something now; then the vice-president got up and said, "From the first of next month all accident costs are going to be charged to you fellows right here. If an

accident occurs in your department you are going to bear the cost of it. It is not going to be charged up to overhead." You should have seen the men wake up.

NURSE (American Seating Company, Grand Rapids, Mich.): We have a cabinet and a senate and a house of representatives. I am a member of the house of representatives which is made up of the rank and file. We have one, two or three representatives from each department—men who are laborers in the department. Along with various other things that come up in the house meeting, the question of safety is pushed very, very far.

For instance, last month I gave each representative his own report of days lost due to sickness and accident. He made his own report and carried it back to his foreman and it was posted in his department.

We do various things like that. We alternate and try to have a different report each month. We have the chairman of the safety committee of the house and senate make an inspection every month.

MR. McCLELLAN: I know something of your plant and about the work you carry on in the doctor's office. Your plan is somewhat similar to ours. We have the same thing only we don't call it the house and senate.

The Physical Examination Required

NURSE (American Seating Co., Grand Rapids, Mich.): We do one other thing. No man is employed until he has had a physical examination, and, of course, that comes in the first aid work. After the man is examined and is ready to leave the first aid, we tell him what the safety movement in our plant means and that the men in his department will not welcome him unless he cooperates with them in keeping a clean safety record. It means a lot to the new man. He may smile at first, but we encourage him to come into the first aid with little things from an ordinary cut to an accident. Sometimes when he comes in with a small cut or a sliver or some minor thing we often bring them up before the crowd and say, "Here is an example of what we are trying to do. He pays attention to these things because he has learned their value, and that is what we want you to do."

MR. SCHWARZE: I am very much interested in finding out how some of the members educate their foremen who do not speak the English language. We have represented in our organization approximately 20 nationalities and the number of languages necessary to converse with those nationalities would probably approximate 12. I believe the larger packing houses in Chicago are confronted with the same thing. I would like to know how you put your campaign across.

MR. McCLELLAN: I think I can answer that question this way. In the packing industry, especially in our plant, where we have around 10,000 employed, we have almost any nationality you could ask for. For instance, we seem to be getting many Mexicans. In one department we have quite a number of Mexicans. We have a foreman there who can speak and read Spanish. Some ten years ago we did away with all foreign language signs. In other words, we compel everybody to read and write and speak the English language. We print all signs and bulletins as well as the plant newspaper in English only.

CHAIRMAN CAMPBELL: We have had the cooperation of the public schools in that matter. During each noon period, from a quarter past twelve to one o'clock, they send four or five teachers to our plant. We have mostly Italians, and it is surprising to see the headway they make in a year. Most of the teachers are women, who come equipped with a blackboard, and it is astonishing to see how those foreigners pick up English. The city of Worcester supplies the teachers and if the men are willing to devote their time they can learn the English language.

MR. McCLELLAN: We tried out the same thing. We conducted a school after working hours, only we didn't carry it under the term of education, but under the

"Americanization plan." In other words, we taught them a little history—the first president, etc.—and certain current topics, and helped them to write their papers and in that way helped them with English. Of course nearly all of our plant is Americanized now and that school has been discontinued.

MR. SANDEL: Years ago the Union Carbide Company at Niagara Falls used to take the National Safety Council posters and paste them on cardboard. They would then gather the men who spoke a foreign language into one group. One man who could speak the language of that group and who had been at the plant the longest and knew something of the safety work and what was being done, would tell the rest of the group just what the poster meant and in that way the men soon came to recognize what the word "danger" meant, and they picked up other words here and there. It enabled the safety department to get their message across a little better to the foreign workmen.

Handling Sulphuric Acid by Pipe Line

MR. SCHWARZE: I am confronted with a problem and I have come down here to present it and to probably get the remedy. It is the hazard in connection with the handling of sulphuric acid by pipe line under air pressure of approximately 40 pounds. The usual arrangements is a series of two valves so that in case one goes wrong the other is there for safety. In a good many cases both valves will go at the same time. What have you men done to combat that hazard? Do you take the air pressure off the line at night, and if you do, how do you guard against disintegration of the iron tanks on account of the moisture?

S. R. JENSEN (Armour & Co., Chicago): It seems to me that question is rather mechanical and it is pretty hard to give any advice unless one goes over the ground and sees the conditions. What pressure do you have?

MR. SCHWARZE: Forty pounds.

MR. JENSEN: You couldn't run with less?

MR. SCHWARZE: Hardly.

MR. JENSEN: Is it always at night that it lets go?

MR. SCHWARZE: At night and on Sunday.

MR. JENSEN: You evidently are building up more pressure at that time. How are your safety valves? Do you have some sort of a safety attachment?

MR. SCHWARZE: The danger is not due to air pressure. It is due to the valve letting go. By having air pressure on there the acid will continue to flow at the point of discharge of the valve. By releasing the air pressure only such acid as may be in the line will be discharged, and the contents of the tank will remain intact, whereas the air pressure on the tank will empty the tank.

MR. JENSEN: What kind of valves do you use?

MR. SCHWARZE: They are a patented, lead-lined valve.

MR. JENSEN: You may have to go to special construction.

MR. MCCLELLAN: It seems to me that that could be overcome by having a line in service with a tank which would have a relief line on it and if it did lose acid this other tank would catch whatever acid got away. Are your tanks lead lined?

MR. SCHWARZE: No.

MR. MCCLELLAN: Why wouldn't it be a good idea to lead-line your tanks instead of having the air get at them?

MR. SCHWARZE: It is a matter of practical construction.

MR. MCCLELLAN: They are closed vessels?

MR. SCHWARZE: Yes. The reason for the valve breaking is that foreign matter gets in below the seat and cuts the lead.

R. A. FAUST (Fred Rueping Leather Company, Fond du Lac, Wis.): We use a siphon pump, which pumps it up to the reserve tank above. Of course it requires

probably four or five weeks to replace it with that little pump. We don't have any leakages through corrosion.

MR. SCHWARZE: We have pumps on the high levels and the low levels.

MR. MCCLELLAN: Mr. Schwarze, I wonder if it wouldn't be a good idea to write to the Tanners' Council at New York on that question. It seems to be a tanners' proposition. I am not familiar with tannery operations. I think probably they have had some experience in that matter and they might have some pamphlet which they could forward to you.

CHAIRMAN CAMPBELL: George Keene, of Swift & Company, brought to my attention that he thinks this section is very small. He has been attending these sectionals quite regularly and he is of the opinion that the section ought to take in all the leather industries, harness and saddlery, the boot and shoe workers, tanners and the meat packers, because in that way the meat packers have something in common with the tanners. The hides come from the yards and go to the tanneries and there are quite a number of machines in the tanneries that we are quite familiar with that they have to use in the packing industry.

MR. SCHWARZE: (Pfister & Vogel Leather Co., Milwaukee): I had a thought which struck me yesterday morning after the meeting that I think I should contribute for the benefit of our members. It was in connection with the remark of Mr. Moneymaker regarding the use of a glass visor as a protecting guard on an embossing machine. That same feature has been used by us successfully in connection with the clipping machine in stamping out sole leather. I think you have a similar machine in the belting business. The visor does not permit the hand to go over the top and eliminates the hazard of getting the hand between the beam and the top of the die.

CHAIRMAN CAMPBELL: At present on that machine we have no guard at all. We have a long table and the man couldn't possibly get his hand in.

MR. FAUST: How much space do you allow between the visor and the lower beam?

MR. SCHWARZE: I want to be correctly understood. We are not using the plate glass visor on an embossing machine at this time. We use the visor on the clipping machine. On our guards we would have to afford the same clearance as we would on any other machine. We allow one inch to an inch and a quarter, depending on the nature of the stock.

MR. FAUST: All we use is a dead-line bar across the front, which is painted on the style of a barber pole, having a shelf 18 inches wide, so that the operator in grasping the skin will necessarily strike the bar.

We have had three serious accidents in the last four months on the embossing machines, which cost us possibly \$600.

MR. SCHWARZE: We have had one accident in the past two years on our embossing machine. We are using different types of guards, depending on the kind of stock. What we have done in the last year to comply with the Industrial Commission's orders on safety was to provide an interlock between the shifter lever on the operator's side and the feeder's position. The accident we had happened while the plates were being changed and the guards were removed. We made a rule that if an operator has an accident on his machine while the guards are off he no longer operates the machine for our company, and have posted that rule, in a little frame with a celluloid facing, right before the operator on his side and right before the feeder on the feeder's side. It is lettered in a size to conform with normal vision for that distance. If the man says he can't read the print his eyesight is below normal and he shouldn't work on an embossing machine.

ADJOURNMENT

SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Paper and Pulp Section

New Section Officers

- Chairman*, W. J. PEACOCK, Northern Paper Mills, Green Bay, Wis.
Secretary, N. H. BERGSTROM, Bergstrom Paper Company, Neenah, Wis.
Vice-Chairman for Canada, A. P. COSTIGANE, Ontario Pulp and Paper Makers' Safety Association, Toronto, Ont., Canada.
Vice-Chairman for South, G. W. PHILLIPS, The Champion Fibre Company, Canton, N. C.
Vice-Chairman for Middle West, M. G. HOYMAN, Kimberly-Clark Company, Neenah, Wis.
Vice-Chairman for East, W. A. GLEASON, Hammermill Paper Company, Erie, Pa.
Vice-Chairman for Paper Box Manufacturers, H. C. SACKETT, Alton Box Board and Paper Company, Alton, Ill.
Engineering Representative, R. M. ALTMAN, Marathon Paper Mills Company, Rothschild, Wis.
Poster Committee Chairman, AMEIL UMBERHAM, Fort Howard Paper Company, Green Bay, Wis.
Membership Committee Chairman, J. H. SLATER, Escanaba Paper Company, Escanaba, Mich.
Publicity Committee Chairman, D. D. THIRKIELD, Sorg-Oglesby-Smith Paper Company, Middletown, Ohio.
Statistics Committee Chairman, E. E. GRANT, The Crystal Tissue Company, Middletown, Ohio.
Contest Committee Chairman, A. SCOTT DOWD, The Paper Industry, Chicago, Ill.
Committee on Health Research Chairman, J. J. PLZAK, Consolidated Water Power and Paper Company, Wisconsin Rapids, Wis.
- Regional Directors:*
Maine—ALVIN RECORD, International Paper Company, Chisholm, Maine.
Massachusetts—N. F. BARTLETT, Hollingsworth and Vose Company, Boston, Mass.
Michigan—C. E. TORRANCE, Bryant Paper Co., Kalamazoo, Mich.
New York—C. H. O'CONNELL, International Paper Company, New York City.
Ohio—KENNETH L. FAIST, Champion Coated Paper Co., Hamilton, Ohio.
Pennsylvania—E. J. GAYNER, Scott Paper Company, Chester, Pa.
Wisconsin Valley—F. H. ROSEBUSH, Nekoosa-Edwards Paper Company, Port Edwards, Wis.
Fox River Valley—W. F. ASHE, Thilmany Pulp and Paper Company, Kaukauna, Wis.

Retiring Officers

Chairman, W. J. PEACOCK, Northern Paper Mills, Green Bay, Wis.; *Vice-Chairman*, M. G. HOYMAN, Kimberly-Clark Co., Neenah, Wis.; *Secretary and News-Letter Editor*, AMEIL UMBERHAM, Fort Howard Paper Co., Green Bay, Wis. *Committee Chairman: Program*, M. G. HOYMAN, Kimberly-Clark Co., Neenah, Wis.; *Engineering Representative*, A. P. COSTIGANE, Ontario Pulp & Paper Makers' Safety Assn., Ont., Canada; *Regional Directors of Conferences, Contests, Membership and Posters*: ALVIN RECORD, International Paper Co., Chisholm, Me.; N. F. BARTLETT, Hollingsworth & Vose Co., Boston, Mass.; W. A. GLEASON, Hammermill Paper Co., Erie, Pa.; G. W. PHILLIPS, The Champion Fibre Co., Canton, Ohio; WALTER L. MEAD, Consolidated Water Power & Paper Co., Wisconsin Rapids, Wis.; ERNEST AUGUSTUS, Mead Pulp & Paper Co., Chillicothe, Ohio.; R. S. TURNER, West Virginia Pulp & Paper Co., Mechanicsville, N. Y.; JAMES M. MURRAY, International Paper Co., Gatineau, Quebec, Canada.

Tuesday, September 27, 1927

W. J. PEACOCK, Chairman

Head, Department of Personnel, Northern Paper Mills, Green Bay, Wis.

The first session of the Paper and Pulp Section of the National Safety Council was called to order at nine-thirty o'clock by the chairman, W. J. Peacock, head, department of personnel, Northern Paper Mills, Green Bay, Wis.

Registration cards to obtain the names and company connections of all present were passed, following which the chairman called for general introductions, and suggested that all present, in order to get acquainted, take seats together by states. Divisions of the room were indicated and the delegates were soon shaking hands as new-found neighbors.

Registration List

Aetna Life Ins. Co.—E. H. Casavant, Hartford, Conn.; Alton Box Board & Paper Co.—C. G. Patterson, H. C. Sackett, Alton, Ill.; American Writing Paper Co.—James Murdock, Stanley Skypark, A. S. Wilson, Holyoke, Mass.; American Paper & Pulp Ass'n—D. C. Everest, Rothschild, Wis.; Appleton Vocational School—H. Heitig, Appleton, Wis.

Bergstrom Paper Co.—N. H. Bergstrom, Neenah, Wis.; Bird & Son, Inc.—F. H. Bird, R. W. Westcott, Chicago, Ill.; B. D. Rogers, E. Walpole, Mass.; Bogalusa Paper Co.—W. H. Jennings, Bogalusa, La.; Brown Company—J. J. Tellington, Berlin, N. H.; Bryant Paper Co.—C. E. Torrence, Kalamazoo, Mich.

The Celotex Co.—H. T. Bond, Marrero, La.; Champion Coated Paper Co.—K. L. Faist, Hamilton, O.; Chrysler Corp.—W. A. Beehill, O. F. Lehman, Detroit, Mich.; Consolidated Water Power & Paper Co.—C. R. Boyer, Appleton, Wis., Otto Erdman, J. J. Plzak, G. R. Stearns, Wisconsin Rapids, Wis.

Eastman Kodak Co.—John W. Newton, Rochester, N. Y.; Employers Mutual Benefit Co.—A. Kroes, Wausau, Wis.; Escanaba Paper Co.—R. W. Haddock, J. H. Slater, Escanaba, Mich.

Falls Mfg. Co.—Hugo Boldt, Frank Cota, Oconto Falls, Wis.; The Flint Kote

Co.—George Martin, Chicago Heights, Ill.; T. R. Bickford, Rutherford, N. J.; Fort Howard Paper Co.—Amiel Ueberham, Green Bay, Wis.; French Paper Co.—E. R. Breeher, Niles, Mich.

Robt. Gaylord, Inc.—E. Ahrenhoerster, St. Louis, Mo.; Great Western Paper Co.—E. A. Kennedy, Ladysmith, Wis.

Hammermill Paper Co.—W. A. Gleason, Erie, Pa.; Hollingsworth & Vose Co.—Nat F. Bartlett, Boston, Mass.; Hope Nat'l Gas Co.—Ralph A. Gawthorp, Clarksburg, W. Va.

Indemnity Ins. Co. of North America—M. J. Steinman, Philadelphia, Pa.; Independence Co.—I. F. Jones, B. H. Remaly, Philadelphia, Pa.; Industrial Commission of Wisconsin—P. A. Russell, Madison, R. D. Scoon, Superior, H. F. Menzel, Oshkosh; International Paper Co.—Alvin F. Record, Chisholm, Me., John Lundregan, C. H. O'Connell, New York City.

Kalamazoo Vegetable Parchment Co.—W. E. Walker, Kalamazoo, Mich.; Kimberly-Clark Co.—A. G. Briggs, Chas. H. Bujer, A. R. Ellis, M. G. Hoyman, G. Heeslaker, George McElroy, Harry Oehlke, A. W. Redlin, Edw. Zultlow, Neenah, Wis., L. W. Rhodes, J. P. Rucinski, Niagara Falls, N. Y., S. F. Shattuck, Neenah, Wis.

Lincoln Pulp & Paper Co.—John L. Leslie, Merritton, Ont., Can.

Mead Fibre Co.—Geo. Milhorn, H. R. Lady, Kingsport, Tenn.; Mead Pulp & Paper Co.—Ernest Augustus, L. O. Bonner, Chillicothe, O.; Michigan Mutual Liability Co.—E. H. Vallur, Detroit, Mich.; Mississippi Valley Structural Steel Co.—J. K. Stafford, Decatur, Ill.

National Safety Council—G. E. Burns, C. E. Pettibone, Chicago, Ill.; Nekoosa-Edwards Paper Co.—Franz H. Roscbush, Port Edwards, Wis.; Northern Paper Mills—W. J. Peacock, Green Bay, Wis.

Ontario Pulp & Paper Makers Safety Ass'n—A. P. Costigane, Toronto, Ont., Can.

The Paper Industry—A. Scott Dowd, E. B. Fritz, Betty E. Williams, Chicago, Ill.; Peoples Nat'l Gas Co.—L. M. Ayers, Pittsburgh, Pa.; Provincial Paper Ltd.—F. M. H. Cushing, Thorold, Ont., Can.

Rhineland Paper Co.—Geo. Roller, Rhineland, Wis.; River Raisin Paper Co.—J. N. Freeman, Monroe, Mich.; Riverside Fiber Co.—H. C. Kruegh, Appleton, Wis.

Sorg-Oglesby-Smith Cos.—D. D. Thirkield, Middletown, O.

Thilmany Pulp & Paper Co.—J. B. Delbridge, Kaukauna, Wis.; Thunder Bay Paper Co.—Albert Zagar, Port Arthur, Can.; Titanium Pigment Co.—F. A. Smith, Mr. Sherman, Carondelet, Mo.; Tomahawk Kraft Paper Co.—O. F. Duns, Tomahawk, Wis.

Union Bag & Paper Corp.—Stuart H. Brown, New York City.

Wausau Sulphate Fibre Co.—C. M. Green, Mosinee, Wis.; West Virginia Pulp & Paper Co.—John H. Crest, Luke, Md.; Wisconsin Vocational Schools—H. G. Noyes, Appleton, Wis.

Youngstown Sheet & Tube Co.—W. F. Siemen, Youngstown, O.

Reports of Various Committees

Brief verbal reports were then made by Secretary Ueberham, who said that his main activity was the production of news letters; M. G. Hoyman, for the program committee, suggested that the program would speak for itself. W. A. Gleason, for the poster committee, said that this service must be largely voluntary as suggestions are required directly from the mills to make posters effective. He urged members to develop their local talent and to get in touch with the Poster Editor of the National Safety Council with their ideas.

The chairman called attention to the poster exhibit around the room, the result of cooperation of mills responding to the news-letter suggestion. He followed with a story of the founding and growth of the section, covering a period of 12 years,

showing how the present size and influence of the section are due to the far-sighted leadership of former chairmen and loyal members. The first meeting in Philadelphia, 1915, was due to the efforts of S. F. Shattuck, of Kimberly-Clark Company, backed by G. E. Williamson of the Strathmore Paper Co., R. B. Robertson, of Champion Fibre Co., H. W. Taylor, of Dill & Collins Co., E. P. Gleason, of Nekoosa-Edwards, R. S. Turner, of West Virginia Pulp and Paper Co., A. G. Richardson, Laurentide Co., W. H. Williamson, Finch-Pruyn Co., Henry W. Stokes, York Haven Paper Co., F. W. Calvert, Scott Paper Co., F. P. Klund, Hammermill Paper Co., John M. Taylor, Diamond State Fibre Co., G. T. Kamps, Riverside Paper Co., and representatives of several allied industries, backed as a whole by several insurance companies. Friendly assistance was received also from the New York State Department of Labor, and other state agencies. Mr. Peacock commented that every paper company present at the organization meeting had remained in active cooperation with the section ever since, and all of them are in the 1927 cup contest.

The chairman showed how the section membership had increased from 30 individual mills, in 1916, to 201 company-members, controlling at least 300 mills. The activities of the section, from the first, led up toward the year-round program of 1927. Today the section is kept busy fulfilling the vision of its founders. Attention was directed to the session of Thursday morning, when the section, as a committee of the whole, would study the affairs that belong to the Paper and Pulp group. Reference to that session in these transactions will disclose the present program. In his final word Mr. Peacock said:

Now a Major Section of the Council

"You are now in a major section, major in size, in activities and in leadership. Let's feel the bigness of the thing, a section which is certainly on the map in the National Safety Council; but especially let us take it upon our minds as a charge and an inspiration to see possibilities as significant today as they appeared to the founders in 1915. We have reached the possibilities of success, viewing the section as a unit only, meeting once a year, but we have only begun to see what can be accomplished in the states and natural regions of our industry. Already one of these regions, the Fox River Valley, has held annual safety meetings with an attendance and mill representation numerically larger than the parent section. What can be accomplished also in New England, in Ohio, Michigan, the South and the far West simply waits for leaders with vision and initiative. One thing certain, the day is not far distant when the section will require the services of a full-time executive secretary, to assist in developing our regions.

CHAIRMAN PEACOCK: I will announce the Nominating Committee: Nat. F. Bartlett, W. A. Gleason, R. S. Turner and E. A. Kennedy. These gentlemen will please complete their report and present it tomorrow morning. Please see them meanwhile with your suggestions.

Are there other reports to be heard before we proceed to the program?

F. H. ROSEBUSH (Nekoosa-Edwards Paper Co., Port Edwards, Wis.): I would like to suggest that our Nominating Committee nominate officers with the idea that they will serve for two years. The first year they would serve actively; the second, in an advisory capacity. By that process I believe we would have a permanent organization of officers.

CHAIRMAN PEACOCK: Are there other suggestions? The presiding officer for the morning's program is Mr. W. A. Gleason, affectionately known as "Uncle Walt," former chairman of the section, safety engineer of the Hammermill Paper Company, Erie, Pa., one of the founding companies of the section.

(Mr. Gleason then took the chair.)

CHAIRMAN GLEASON: We have on our program as the first number this morning

a paper by Mr. Alvin F. Record, supervisor of safety and sanitation of the Otis Mill, International Paper Company, Chisholm, Maine. The fact that he has been selected for this important position by the International Paper Company is assurance enough that he can get results, but in addition, we know Mr. Record as competing very strongly for the cup.

Accident Analyses, Records and Costs

Alvin F. Record, Supervisor of Safety & Sanitation, International Paper Company, Otis Division, Chisholm, Maine

In an age when facts, figures and statistics are essential to the operation of any business, what modern manufacturing concern would attempt to do business without keeping a very accurate record of its costs of raw materials, labor and all other items, no matter how small, entering into the cost of manufacture, as well as an itemized cost of its various processes and departments? Suppose at the end of the year the profit and loss account of the balance sheet shows "red" or the profits are unsatisfactory as compared with previous years or with industry as a whole. The alert executive is thereby warned that there is trouble coming, that something is amiss. With the aid of his accounting and statistical departments he immediately sets out to ascertain just where the difficulty lies. If his system functions satisfactorily he will find the changes in his material and labor costs in each process and in each department as well as all other items entering into the question which will furnish him with a basis for wise changes in policy and possibly personnel.

What is true with business in general is also, in an equal measure, true with any accident prevention plan. The man on the job directly interested in the prevention of accidents cannot but be deeply impressed with the necessity for, and the importance of, accurate accident statistics, whereas, those not coming into contact with the compilation and application of such statistics sometimes are apt to undervalue their use and importance. The collection of figures which have no practical value, is, of course merely a waste of time and effort and it is quite necessary to sort out much interesting but otherwise useless materials. However, proper statistics to the man on the job are what the thermometer is to the physician and the compass to the mariner. They eliminate guess work and furnish certainty without which we cannot secure the results for which we strive.

Statistics should be compiled, first, to indicate the relative hazards and danger points in the mills where they are to be used; second, to determine and measure the results of accident prevention work being carried on; third, to stimulate interest and competitive effort in accident prevention work as between plants in the same industry and also between mill departments; fourth, to show the costs per department or per unit of production as far as the actual known expense is concerned, such as medical and compensation expense.

Facts compiled with these objectives in view and studied intelligently and applied should go a long way in assisting the safety overseer to point out causes of unsatisfactory experience and enable him to offer suggestions for overcoming them.

The accompanying charts illustrate the method used by the International Paper Company in preserving its accident history, analyzing experience and tabulating the cost in dollars and cents.

In making up and keeping any set of records it is first necessary to collect full information on each individual case from the time medical attention is rendered until the employee has been discharged from treatment and has re-

Figure 1 shows the form used for first reporting injury, giving full history of the injured and his injury. This report is the basic report, containing all the information necessary in making up subsequent reports.

Cellig - Ac 4442

[illegible]

Figure 1. Form for reporting an injury.

Lost time is figured, beginning the day following the accident, and ends with his actual return to work, excepting in case of a total and permanent injury where an arbitrary penalty of 500 days is charged in addition to one calendar year of actual lost time, and in case of a fatal accident 1,000 days.

Take, for instance, the question, "How Long Employed By Company?" When this information is tabulated from a number of accidents over a continuous period, it will be surprising to learn how many new employees and men transferred to new occupations will show up as injured. Correction of this condition will largely revolve around the question near the end of the report, "Was Employee Instructed in the Proper Method of Doing His Work?"

Such questions as, "Place Where Accident Occurred?," "Was Light Good?," "How Can Such Accidents Be Prevented?," "What Steps Have Been Taken

Figure 4. Analysis of the last time accidents.

This form is used at the mill end and serves the purpose of placing before the interested parties the story of each month's performance, as far as the number of accidents, lost time and cost is concerned. Our mills use this information in a variety of ways. It is especially handy in keeping up curve sheets on each of these items to indicate progress or the reverse. It is put into the form of monthly reports to the supervisory force and made the subject for bulletin posting. Most important of all, it keeps the mill executive posted on just what progress is being made by his safety organization.

The quarterly and yearly reports, as compiled and sent out from our general office, are especially valuable in that they point out and analyze hazards and danger points within different mills; measuring the effect of prevention campaigns and stimulating interest and competitive efforts between mills.

Figure 3 shows the first of these reports.

This gives the relative standings of all mills based on "Days Lost per 100 Employees" and also shows "Lost Time per 100 Employees." This report is issued quarterly for the first nine months of the year, the last one covering the whole year's experience in which penalties are charged for the fatal and permanent and total disability accidents. This illustration shows one of these yearly statements. The comparative summary is specially included to show the company's progress from year to year as a unit.

A Remarkable and Valuable Analysis

Figure 4 gives quite a remarkable analysis of lost time accidents over the yearly period. The upper section of this chart shows, "Causes of Accidents" in graphical form. Causes are divided under 12 headings and show how our accidents happen.

The section in the middle marked "Occupation" shows where our accidents occur and plainly indicates where preventive efforts should be centered. This classification is also divided into 12 distinct processes entering into paper manufacturing.

The last graph covers "Description of Injuries" and indicates what injuries resulted from accidents. The practical use of this information comes from such items as "Infections," which indicate on their face lack of proper first aid; "Eye Injuries," the lack of proper eye protection, etc.

Figure 5 is a more detailed edition of the preceding form. Each mill of the company is designated by a number, and it shows at a glance where each of its plants are meeting with difficulty and where extra efforts should be put forth. By comparison each mill can check its accidents with those of sister mills of equal size with respect to "How," "Where" and "What" has occurred.

Another is a Comparative Accident Experience Chart covering the past four years, namely 1923 to 1926, inclusive. This shows the individual experience of each of the larger operating units together with the average for all mills. The black columns show the actual time lost per 100 employees, while the columns in outline show the arbitrary penalties charged for Total and Permanent Disability and Fatal Accidents. This pictures quite vividly the effect and results of the company's efforts to prevent accidents in their mills.

This gives a general idea of this company's method of recording its accident costs and records, as well as the analysis of its experience which seems to be standing the test of time and which it considers of much benefit in efforts to eliminate industrial accidents.

The test of any set of reports or analyses comes with its practical application. When a period shows up unsatisfactorily and comes to the attention

Figure 5. At a glance the relative position of each plant is seen.

of the plant executive and his safety overseer is called in for explanation, it is then that his system should justify its existence. He should be able to say to the executive that the trouble lies at this or that point, that a certain number of new employees have received injuries in a certain department, which indicates the lack of proper supervision; that there has been several stumbling or slipping accidents at another point, which might indicate poor housekeeping; or that several infections have developed at another point, indicating lack of

first aid attention. The executive by confronting his department heads with this information certainly is able to place responsibility, and it is indeed interesting, when this is done, to see the little curve indicating progress tip its way downward again to the point where accidents, with the suffering they cause and the expense they make, will be a thing of the past.

CHAIRMAN GLEASON: I don't believe there is any question in our minds that the keeping of records and making analyses of them are what count now.

In traveling around to the different mills, you hear safety men say, "You know, I can't get any cooperation from the superintendent. I can't get any safeguards, I can't get any help at all in accident prevention work."

If you have a set of charts showing just what the cost of accidents per ton of paper is, you are going to get results, because any business today operates from the ledger side.

Are there any questions you want to ask?

G. S. STEARNS (Consolidated Water Power & Paper Co., Appleton, Wis.): Do you have a competitive method to create interest in establishing a basis of comparison?

MR. RECORD: No. It is a matter of pride between the different mills to excel one another. The first chart is a comparative chart, showing standing of the various mills.

Quarterly Reports Are Made to Each Mill

F. A. SMITH (Titanium Pigment Co., Carondelet, Mo.): In regard to the separate mills are they advised each month of their standing, or are they only advised at the end of the year?

MR. RECORD: They are advised quarterly. The last report is the annual report which covers everything.

JOHN W. NEWTON (Eastman Kodak Co., Rochester, N. Y.): Do you handicap mills? Some of them may be operating under more dangerous conditions than others.

MR. RECORD: We figure the lost time on one hundred employees, which takes care of that.

MR. NEWTON: There is a difference in relative hazards. The new mills are far superior to the mills that have been in operation for a long period of time.

MR. RECORD: We have no way yet of handicapping them. All the mills are operating on a mutual basis.

MR. ROSEBUSH: I would like to ask what items enter into the accident costs?

MR. RECORD: Just the compensation, medical bills and incidental expense connected directly with accidents.

J. J. TELLINGTON (Brown Company, Berlin, N. H.): I notice you penalize the mills for fatalities.

MR. RECORD: In the case of fatal accidents, an arbitrary penalty is charged at one thousand days.

A. P. COSTIGANÉ (Ontario Pulp and Paper Maker's Safety Association): I would like to ask if there is any connection between the records you keep and the insurance company?

MR. RECORD: The International Paper Company carries their own insurance.

MR. ROSEBUSH: I had that in mind when I asked the previous question. What would your idea be of figuring those costs if insurance was carried by an insurance carrier?

MR. RECORD: I should say that if any one carried insurance and wanted to show cause of accidents they could just eliminate the premium they are paying for insurance.

G. S. STEARN (Consolidated Water Power & Paper Co.): Do you keep data on "near accidents"—accidents that might result in something serious.
